In terms of instrumentation, Suat Sayın's arrangement includes Turkish instruments -clarinet, qanun, and a string section- aiming to evoke a local expressive atmosphere. However, these localization efforts do not obscure the fact that the melodic foundation of the piece was directly borrowed.

Orhan Akdeniz emerged as a prominent figure in the development of arabesque music during the 1970s, playing an active role as a musician, arranger, and producer. His influence is particularly evident in the early recordings of artists such as Müslüm Gürses, Esengül, and Mine Koşan, making him a defining contributor to the musical output of the period. Released in 1972 on his own record label, the song Ağlatan Yıllar appears on the surface to be an original Turkish composition; however, a detailed analysis reveals a strong melodic connection to Leily Nehary La Ya Habeeby, a piece composed for Umm Kulthum. The introductory (muqaddima) section of the Arabic song forms the melodic backbone of Ağlatan Yıllar, in which only the lyrics are translated into Turkish and the arrangement is simplified.

Figure 2. Transcriptions of the songs Ağlatan Yıllar and Leily Nehary La Ya Habeeby.

In the transcription-based comparative analysis, it was observed that both compositions are performed at approximately 70 bpm and in an 8/8 meter. Despite differences in tonal centers, they share a similar frequency range. The melodic contours, intervallic usage, and repetition patterns within the first eight measures of the introduction align almost identically. The orchestration also exhibits notable parallels; however, Akdeniz intensifies the dramatic effect through the inclusion of local instruments such as the electro bağlama, and employs the qanun and strings to create a two-voice harmonic texture. Compared to Sunbati's original arrangement, Akdeniz's version is more condensed and intense, although the melodic core remains unaltered.

This example does not merely represent melodic inspiration; rather, it points to a mode of production in which a direct borrowing is structurally reconfigured and released into the market. Nevertheless, Akdeniz's technical contributions to the arrangement may be interpreted as an effort to reshape the melodic material within his own aesthetic framework. Still, it is evident that such efforts cannot obscure the underlying issue of melodic originality. Ağlatan Yıllar exemplifies how melodic borrowing in the early period of arabesque music arose not only from the absence of copyright enforcement, but also from an unestablished compositional tradition.

Since the 1960s, Mustafa Sayan has been a significant figure in the early development of arabesque music, serving both as a composer and arranger (Şener, 2022). His travels to Egypt and the repertoire he performed there demonstrate that his musical orientation was directly influenced by the Arab world. In particular, the orchestral aesthetic he established through the use of string instruments strongly parallels Egyptian orchestral traditions. In this context, his composition Kullarına Kul Yaratmış is built upon a melodic structure taken from the third muqaddima section of Fi Youm We Leilah, a piece composed by Abdelwahab and performed by Warda.

Figure 3. Transcriptions of the songs Kullarına Kul Yaratmış and Fi Youm We Leilah.

According to transcription-based analysis, both pieces are in the key of B♭, with E♭ as the finalis. Their metronomic tempos are also very close (124–126 bpm), which suggests that the melodic structure was not merely inspired by, but rather directly transferred from the original. The muqaddima section of Abdelwahab's composition, which begins at 22:53, is used as the main theme from the opening of Sayan's piece and is further expanded throughout the composition. Although some short phrases were reordered, the principal melody and structural outline remain unchanged.

Sayan's arrangement features a string ensemble reflecting Egyptian orchestral performance practices, along with instruments such as ney, qanun, and double bass. This instrumentation reveals that the influence from Egyptian music is not only melodic but also formal. The melodic similarities identified in the piece thus appear to be the product of a systematic transfer practice rather than mere aesthetic affinity. Within this framework, Kullarına Kul Yaratmış exemplifies how, due to the absence of copyright regulation and an established tradition of original composition, arabesque music of the period frequently drew directly from external sources. At the same time, the piece reflects a creative reconfiguration approach characteristic of the era's music production. However, from a musicological standpoint, the direct transfer of the core melody may fall within the bounds of plagiarism.

Conclusion

Through the comparative analysis of three early arabesque compositions, this study demonstrates that the use of melodic material from the Arab music repertoire -particularly from composers like Mohamed Abdelwahab and Riyad Al-Sunbati -was not merely the result of individual artistic decisions, but a structural component of the production practices in Turkey during the 1960s and 1970s. These borrowings often extend beyond inspiration, showing striking similarities in pitch, rhythm, and melodic contour. While these parallels may be interpreted as plagiarism from a strictly musicological perspective, they should also be understood within the broader context of the period's underdeveloped compositional institutions, lack of copyright enforcement, and the music industry's demand for emotionally resonant, familiar material.

In this light, the reworking of Egyptian melodies with Turkish lyrics and instrumental textures was not always an act of creative transformation but often a direct transfer with minimal alteration. Although arabesque music eventually evolved into a more localized and stylistically distinct form, its early stages were marked by a dependence on external sources. This reveals that the relationship between Arab and Turkish music was neither wholly imitative nor entirely original, but complex, layered, and historically contingent. Therefore, these examples

should be seen not simply as technical duplications, but as practices shaped by the cultural economy, aesthetic values, and industrial conditions of their time.

It's Corn!: From Everyday Life's 'Sound' to Viral Musical Meme

Cevher Sarıgül[a]

[a] Istanbul Technical University, Department of Musicology and Music Theory, Turkey
sarigulcevher@gmail.com

Keywords: TikTok, Music Meme, Users, Digital Culture.

Aim

This study aims to explore how everyday sounds evolve into viral musical memes within the participatory culture of the digital age, with a specific focus on the short-form video platform TikTok. These viral transformations are not merely products of spontaneous creativity but are shaped by algorithmic flows, platform affordances, and user engagement. Musical memes, as a distinctive category of multimodal content, reflect not only user participation but also the logic of viral circulation that underpins digital media ecologies.

Taking *It's Corn!* as a central case study, this research investigates how a sound fragment from everyday life, specifically a child's spontaneous expression of joy, was remixed into a musical meme and disseminated globally. This process reflects a transition from a soundscape, rooted in the textures of ordinary lived experience, to a mediascape. In this context, sound becomes a unit of exchange, performance, and commodification within digital platforms. The study examines how such transformations construct viral culture and also engages with issues such as authorship of creative acts in digital spaces, personal expression, and commodification. Particular attention is given to questions of consent and ethical representation, especially when individuals featured in viral content, like children, may not fully comprehend or control their participation in such processes.

Material and Method

This research adopts a qualitative case study approach, focusing on *It's Corn!* as a representative example of a musical meme that emerged from a spontaneous moment in everyday life. Throughout the research process, netnography was employed as the primary method, supported by content analysis and case study techniques. The study involved the observation of how musical memes are produced, circulated, and reconfigured within TikTok's participatory environment. User engagement, comment sections, and the creative reuse of original sounds were tracked, while a multimodal analysis considered the integration of audio, visuals, and platform-specific features such as "Duet" and "Stitch." These technical affordances were essential in understanding how users interact with sound and how these interactions contribute to memetic transformations.

To provide a broader cultural context, additional viral musical memes such as *Bing Bong*, *Harlem Shake*, and *Savage Love* were briefly referenced. These cases illustrate how everyday utterances or spontaneous audio fragments evolve into digital cultural artifacts through user participation and remix culture. The analysis is grounded in a theoretical framework informed by memetic theory, participatory media studies, sound studies, and musicology. Rather than aiming for statistical generalization, the study adopts an interpretive approach to understand how digital sound objects acquire memetic status, circulate across digital platforms, and reflect broader aesthetic, cultural, and industrial patterns in music and media ecosystems.

Findings

The viral spread of *It's Corn!* on TikTok illustrates how a casual street interview evolved into a musical meme and eventually into a globally circulated cultural product. Originating from a child named Tariq expressing his excitement about corn, the video was musically remixed by the Gregory Brothers, a TikTok-based music creator duo. It then gained traction through TikTok's features such as "Use This Sound," triggering widespread user engagement.

This transformation can be meaningfully examined through Murray Schafer's concept of the soundscape. Schafer (1994) defines soundscapes as the acoustic environments created by the totality of sounds in a given space. These sonic environments are not passive backdrops but active cultural terrains that shape and reflect human behavior and social contexts. In this sense, *It's Corn!* exemplifies how a simple expression from a child, originally part of a

routine and unspectacular moment, was reinterpreted as a culturally resonant sound event and quickly disseminated through TikTok's sound-driven infrastructure.

This memetic evolution also aligns with Arjun Appadurai's concept of the mediascape, which refers to the flow of media content across borders that reshapes cultural perception and global narratives (Appadurai, 1996). Mediascapes are not merely channels of information but mechanisms through which cultural meanings are continuously constructed and distributed. In the case of *It's Corn!* the sound transcended its original physical and social context and entered a digital mediascape where it became subject to algorithmic amplification, remix culture, and performative reinterpretation by users. This shift from a local, lived experience to a digitally constructed cultural phenomenon illustrates how everyday sound can be reconstituted as a unit of digital capital and collective creativity.

The centrality of sound on TikTok further supports what Abidin and Kaye (2021) have described as an "auditory turn." This marks a platform-wide transition from visual primacy to sonic engagement. It is particularly evident in how users reimagined the expressive potential of *It's Corn!* through thousands of participatory videos, remixes, duets, and lip-syncs. These examples showcase the meme's affective and humorous qualities in diverse contexts.

While this study primarily focuses on how a sound fragment from everyday life is transformed into a musical meme through user creativity, platform affordances, and algorithmic curation, it is important to acknowledge that such content can also be interpreted through other cultural lenses. For instance, the phrase "I can tell you all about it," voiced by the child, may unintentionally evoke deeper resonances when viewed in relation to African American history, where corn has been symbolically tied to land, survival, and identity. Although the meme's viral spread is not analyzed here through that historical frame, the possibility of ironic echoes, especially considering the racialized history of labor and agriculture in the United States, opens up further lines of inquiry beyond the scope of this research.

This transformation also invites critical ethical considerations. The child at the center of the original video becomes part of a larger media spectacle, often without sustained consent or control. One of the most pressing concerns involves the issue of consent, particularly in the case of minors. Tariq, the child whose joyful remarks sparked the meme, may not have fully understood the scale and implications of his sudden digital fame. This raises important questions about the ethics of using a child's likeness in viral content, especially when the consequences and reach of that exposure are not made clear to them or their guardians. Moreover, the social dynamics of virality contribute to a power imbalance. While remixers and secondary content creators often gain visibility, audience engagement, and even monetization opportunities, the original subjects, especially those without agency such as children, tend to be marginalized or rendered secondary. Their creative input or presence may be celebrated in form but overlooked in recognition and reward. These ethical tensions are further shaped by the design and incentives of digital platforms themselves. TikTok, like many short-form video platforms, facilitates rapid content creation, remixing, and dissemination. Although these features promote creativity and participatory culture, they frequently neglect to address creator rights, consent protocols, and long-term accountability. In the context of memes like *It's Corn!* this becomes particularly visible. While derivative content thrives and circulates widely, the originators of the viral moment,those who appear in or contribute to the foundational media; are often excluded from formal credit or financial gain.

This reveals a paradox in which viral fame on such platforms brings immense visibility but little recognition, increased cultural impact but limited control. For vulnerable individuals such as children, this gap between participation and protection underscores the urgent need for clearer ethical frameworks in platform governance and digital content circulation.

Conclusion

This study examined how everyday sounds are transformed into musical memes on platforms like TikTok, focusing on their cultural, aesthetic, and ethical dimensions. Through the case of *It's Corn!* it revealed how a spontaneous moment of speech can be remixed, circulated, and collectively reshaped into a global cultural product via the platform's algorithmic structure and user creativity. This transformation shows that digital sound objects are no longer just sonic experiences but are embedded within participatory, interactive, and manipulative practices. Musical memes are not merely humorous content; they are deeply entangled with platform economies, creative

production, and user visibility. They raise critical questions about who is considered a "creator," how visibility is distributed, and who benefits from digital cultural production. These dynamics map new forms of inequality within participatory culture, especially when vulnerable subjects, such as children, are at the center of viral content and where ethical boundaries become blurred.

The reproducibility and brevity of musical memes created by users can be seen as signaling a fault line or a pipeline that extends into the music industry. Circulating within TikTok's flow, these short, repeatable formats offer not only new modes of engagement but also inspiration for creative strategies and content ideas that may inform music production itself. As a result, we may be witnessing the TikTokification of the music industry. This reflects a gradual adaptation to the platform's aesthetic logic. Users' creative interventions encourage new musical forms optimized for virality (such as short songs), and yet this creativity is often folded into the logic of platform capitalism, leaving users with limited recognition or compensation.

Ultimately, this study suggests that musical memes transform sound into more than something to be heard. They become something to play with, remix, and circulate. This signals a shift in both musical aesthetics and digital economies, proposing an expanded space of inquiry between musicology and media studies in the context of contemporary digital culture.

Polymer and Nano Composites

Radiation Attenuation of MWCNT and Magnetic Nanoparticle Reinforced PMMA Comparative Analysis of Coefficient

Deniz Hande Aydın[a], Nilgun Baydogan[a]

[a] Istanbul Technical University, Energy Institute, Turkey

Keywords: PMMA , MWCNT , Radiation shielding, Gamma Transmission, Neutrons.

Poly(methyl methacrylate) (PMMA) is a thermoplastic material used in various industrial applications due to its lightweight and durable structure. Multi-walled carbon nanotubes (MWCNT) and magnetic nanoparticles are widely used to improve the mechanical, electrical and radiation attenuation properties of composite materials. It is important to comparatively investigate the ionizing radiation attenuation performance of polymer composites reinforced with MWCNT and cobalt-containing magnetic nanoparticles.
In the experiments, measurements were carried out by gamma transmission method using Co-60 and Cs-137 sources. By analyzing the linear attenuation coefficient (μ) and half-value thickness (HVL), the effects of magnetic reinforcement particles and nanoparticle (MWCNT) additives containing cobalt on the radiation absorption capacity of polymer samples were evaluated. By examining the radiation permeability properties of the polymer composite structure, HVL values were determined and comparatively, the gamma radiation absorption capacity was investigated. This study includes results for the development of lightweight and effective radiation shielding materials.

Aim

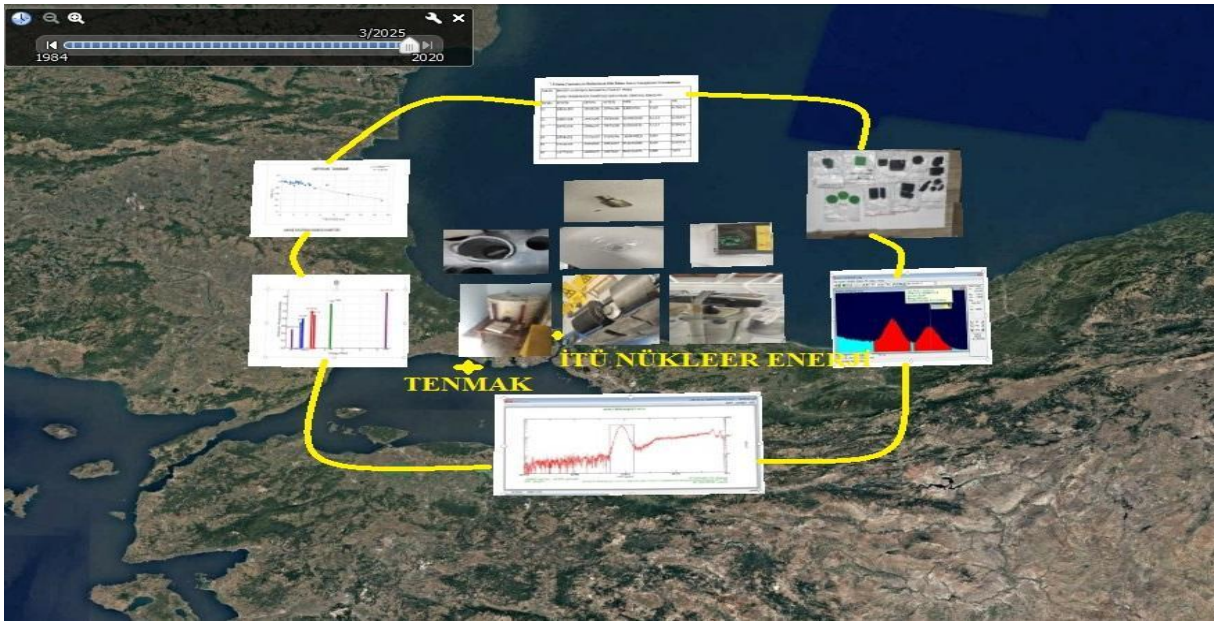

Figure 1.Graphical representation of the study.

Poly(methyl methacrylate) (PMMA) is a thermoplastic material widely used in various industrial applications due to its lightweight and durable structure. Multi-walled carbon nanotubes (MWCNTs) and magnetic nanoparticles are widely used to improve the mechanical, electrical and radiation shielding properties of composite materials. A comparative study of the ionizing radiation attenuation performance of polymer composites reinforced with MWCNTs and cobalt-containing magnetic nanoparticles is of great importance. In the experiments, gamma, beta and neutron transmission measurements were carried out using Co-60, Cs-137, Sr-90, Am-241 sources. The linear attenuation coefficient (μ) and half-value layer (HVL) were analyzed to evaluate the effects of cobalt-containing magnetic reinforcement particles and MWCNT additives on the radiation absorption capacity of polymer samples.

The gamma, beta and neutron radiation shielding properties of polymer composite structures were evaluated by determining the HVL values and comparing their radiation absorption capacities. This work provides insights into the development of lightweight and effective radiation shielding materials.

Method

In the experiments, gamma transmission method was applied using Co-60 and Cs-137 sources to determine the gamma radiation attenuation performances. Gamma transmission, which was carried out in ITU Energy Institute Radiation Detection and Measurement Laboratory, was performed using NaI Scintillation detector. Scintillation detectors are systems that detect ionizing radiation by converting it into visible light. NaI(Tl) crystal produces light (scintillation) when interacting with gamma rays.Gamma ray interaction : Gamma rays lose energy by interacting with the NaI(Tl) crystal through the photoelectric effect, Compton scattering, or pair production mechanisms. Light production : This loss of energy results in the production of visible light photons within the NaI(Tl) crystal. Photomultiplier tube (PMT) is activated : The light emitted by the crystal is detected by a photomultiplier tube (PMT). The PMT generates a signal by converting the light photons into electrons. Electronic signal processing : The signal from the PMT is amplified, converted into digital data, and analyzed. Collimator working mechanism; Collimator selects the rays coming from a certain angle or direction and allows them to reach the detector. Collimators used in scintillation detectors are usually made of lead and are used for the following purposes: Directing the rays : Blocking the rays coming from different angles and allowing only those coming from a certain direction to pass. Reducing background noise increases the sensitivity of the measurements by blocking gamma rays coming from unwanted directions.

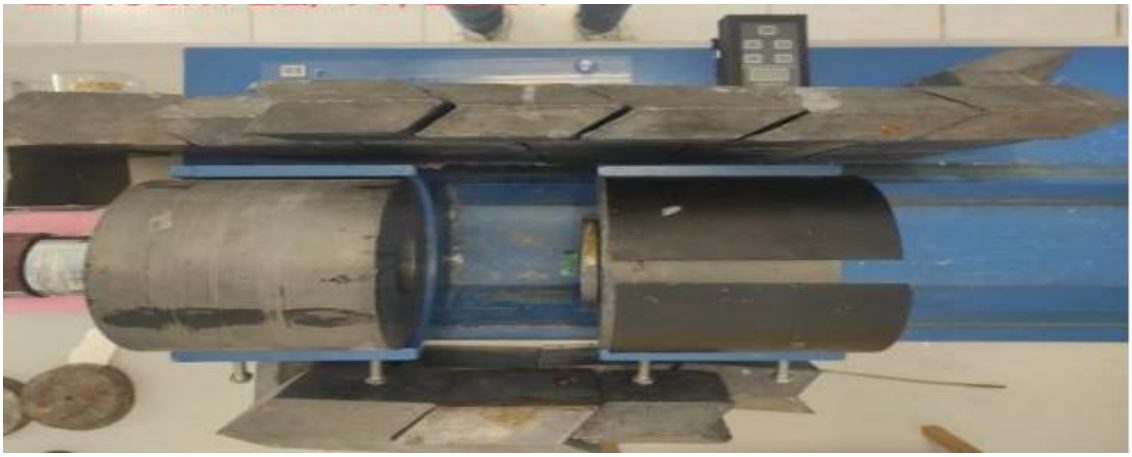

Figure 2. Gamma spectroscopy with NaI scintillation device.

Beta measuring device: The beta filter in front of the detector is in the closed position .Since beta particles cannot pass through the filter, only gamma rays are measured. The measurement obtained showed the background gamma radiation (gamma dose rate) . The detector's beta filter was in the open position , Beta particles can also reach the detector and are included in the measurement. In this case, the measurement obtained gives the sum of (Beta + Gamma). To find the beta number, pure beta is found by subtracting the gammas from the total count. Then, a graph is created showing the count amount depending on the thickness.

Figure 3. Beta spectroscopy and survey meter.

It is based on the principle that gamma rays interact with atoms of matter as they pass through the material. As a result of these interactions, gamma rays lose some or all of their energy. The gamma radioisotope source and detector are placed on both sides of the material on the same axis and the radiation intensity coming from the source and passing through the material is measured. The count values obtained using different thickness values of the material are compared to the count value obtained without using the material, and relative count values are obtained for each thickness value of the material. Thickness-relative count graphs are drawn for each material, gamma attenuation curves of the material are created, compared with each other and evaluated in line with the purpose. The gamma radiation attenuation capacity of the materials was analyzed by measuring the linear attenuation coefficient (μ) and half-value thickness (HVL). Radiation measurements were performed using a NaI(Tl) sodium iodide scintillation detector. This detector detected gamma photons with high sensitivity, allowing accurate determination of radiation attenuation coefficients.

Figure 4. Neutron measuring device.

Howitzer and Neutron hand detector Neutron measurement; The measurement is repeated 3 times using the Howitzer neutron detector , AM241 as the material and source.Since the source being worked on is active, a protective container and rope services are used inside the welding howitzer to minimize radiation exposure and similar measurements are obtained by maintaining the distance between the source materials. It is supported by protective methods such as paraffin, wooden barriers and cadmium to minimize scattering. 3 measurements were made and the material observes by keeping the experiment time the same.

Findings

During the experiment, firstly the radiation of the laboratory environment was measured. Then, the measurement was made while the source was present, then the measurements were made while the source and the material were together, and the i and ı values of the samples with increased thickness were obtained.

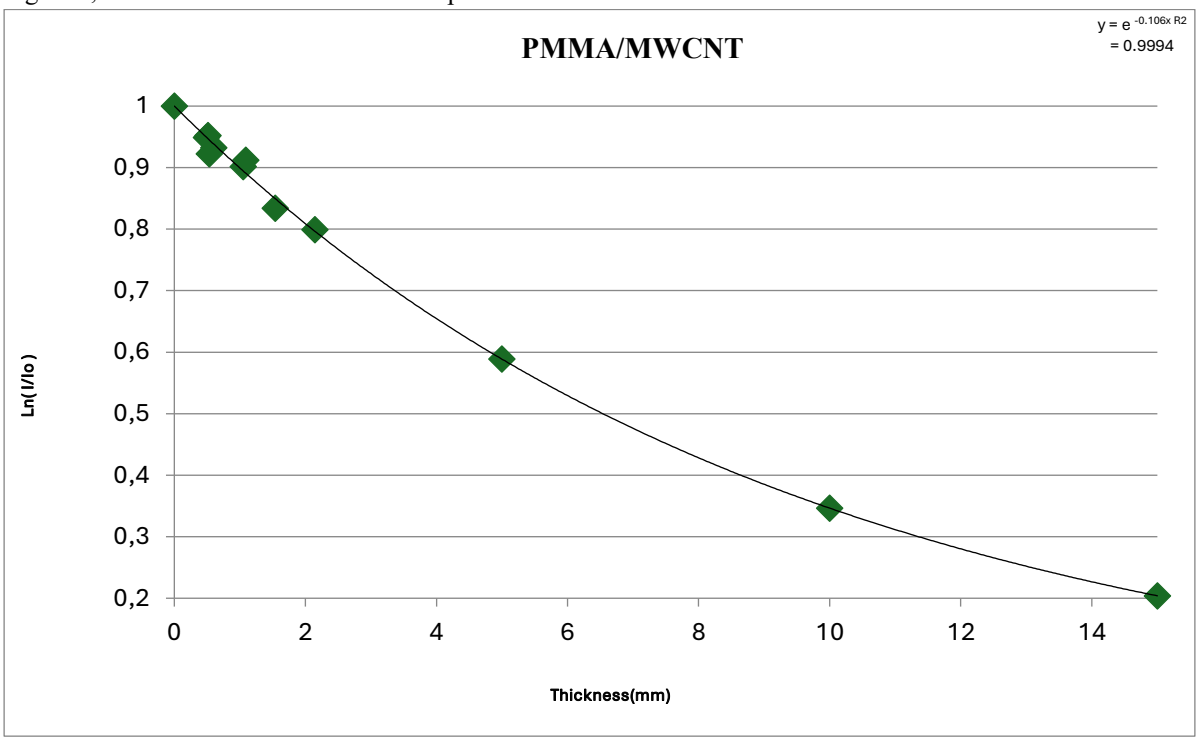

Figure 5. Gamma transmission relationship between the linear attenuation coefficient and the thickness of materials containing and nanoparticle doped PMMA/Mwcnt.

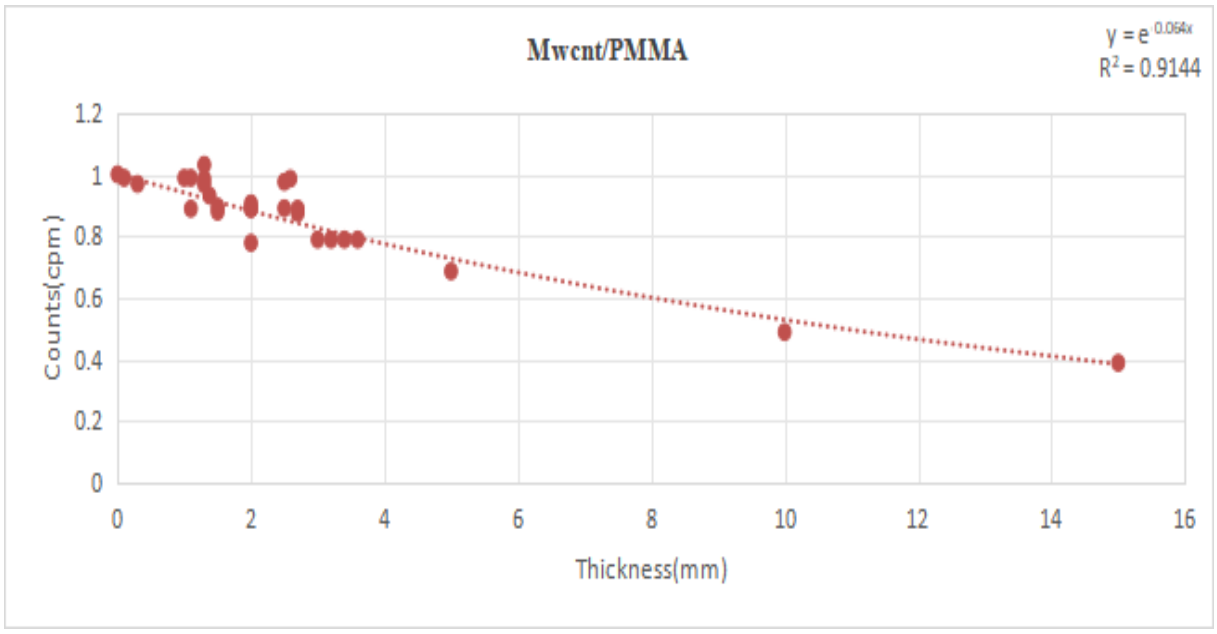

Figure 6. Beta counting graph of nanoparticle doped PMMA/Mwcnt.

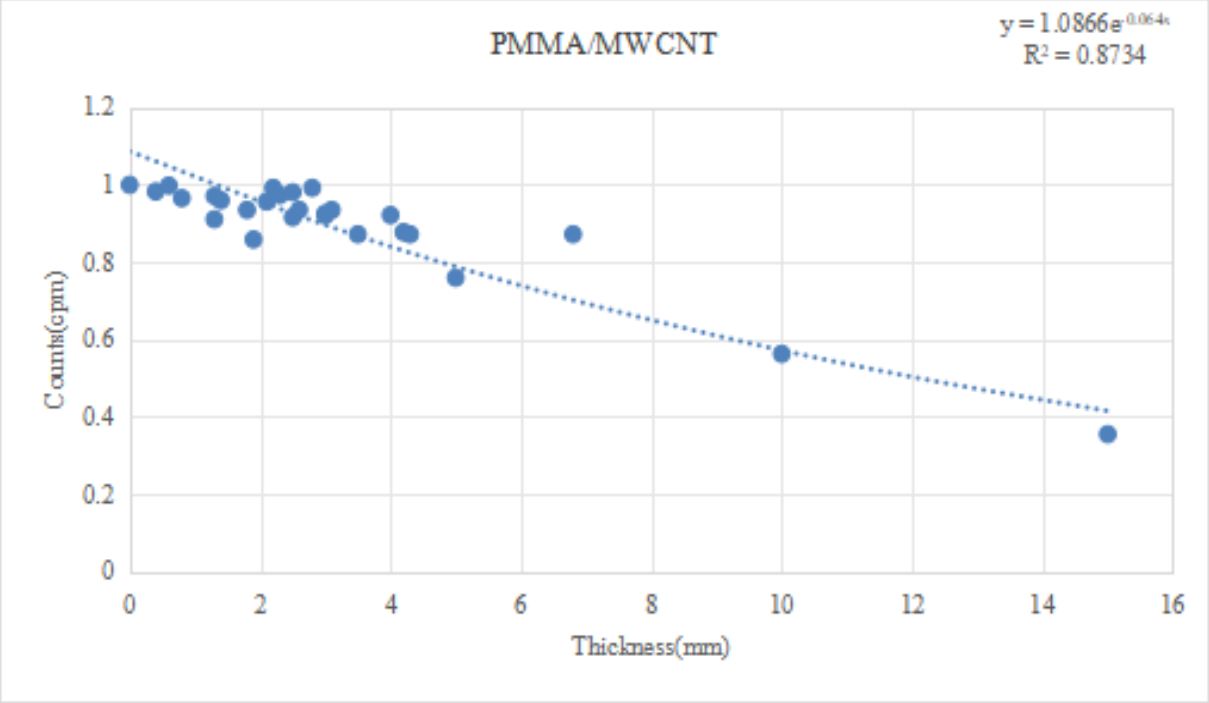

Figure 7. Neutron counting graph of nanoparticle doped PMMA/Mwcnt.

The rpe and attenuation coefficient values were found in accordance with the values obtained. As a result of the values found, the variance parts and the percentage distributions of the thickness permeabilities were calculated. According to the channel range selected in the Maestro program and the energy of the source, the highest discrimination was obtained with the material pairs

Table 1. Thickness dependent beta comparison percentile values.

Isotope	Decay Type	Main Energy Levels (MeV)
Cesium-137 (Cs-137)	Beta (-) and Gamma	0.662 MeV (Gamma)
Cobalt-60 (Co-60)	Beta (-) and Gamma	1.17 MeV, 1.33 MeV (Gamma)
Strontium-90 (Sr-90)	Beta (-)	0.546 MeV (Beta), 2.28 MeV (Yttrium-90 decay)
Americium-241 (Am-241)	Alpha and Gamma	5.486 MeV (Alpha), 0.059 MeV (Gamma)

Relative percentage error (rpe), linear attenuation coefficient (μ) percentages and Ln(ı/ıo) used to analyze the radiation absorption or permeability of the material. Peak heights gave a more discrimination result compared to the energy ranges of the peaks. If special results are selected and compared to increase discrimination in each method, discrimination increases.
This allows us to distinguish the differences between our samples, even if they are small. MWCNT and magnetic nanoparticle doped PMMA composites increase the radiation attenuation performance by gamma transmission technique . It proves that MWCNT doped composites supported with magnetic nanoparticles are more effective in absorbing gamma radiation compared to samples containing only MWCNT.

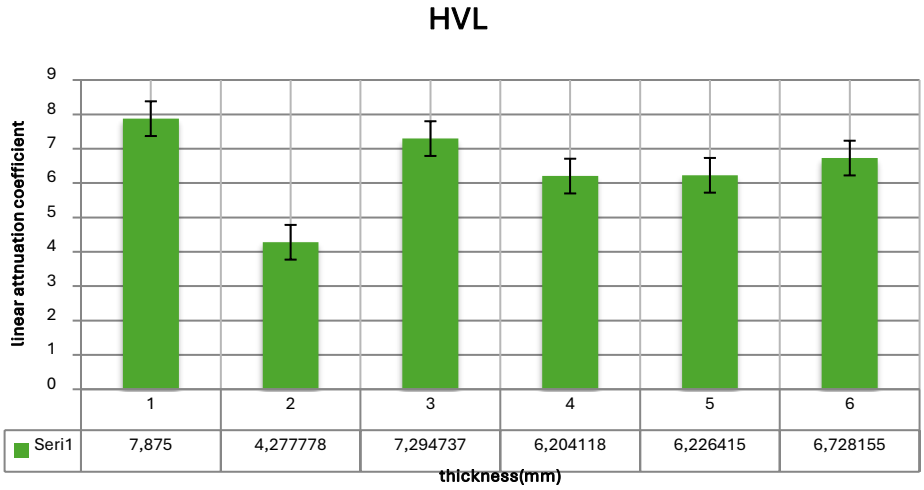

Figure 8. Linear attenuation coefficient ratio of half-value layer numbers and nanoparticle source PMMA/MWCNT containing materials.

It has also been observed that Co- 60 absorbs high energy gamma photons better, while Cs137 has a significant effect on the absorption of medium energy gamma rays.In the study, the coefficients of MWCNT and magnetic nanoparticle reinforced PMMA composites against gamma, beta and neutron radiation are clearly evident in detail. In the experiments:For gamma radiation, the coefficients of the distribution of Cesium-137 and Cobalt-60 sources were calculated. When the materials were distributed homogeneously and spread out, a significant improvement was observed.In the experiments conducted with Strontium-90 source for beta radiation, it was observed that PMMA-based materials absorb beta radiation at a high rate. Comparison of HVL (Half Value Thickness) values showed that the coupling capacity was increased with higher MWCNT content.In terms of neutron radiation, MWCNT reinforced PMMA samples were examined and it was determined that the neutron absorption capacity increased due to the high neutron capture cross section of MWCNT reinforced PMMA.

Conclusion

MWCNT and magnetic nanoparticle doped PMMA composites can be considered as lightweight and effective radiation shielding materials.

Such materials offer potential applications in nuclear power plants, medical imaging devices and aerospace applications. They can also have a wide range of applications such as space technologies, defense industry and industrial radiation shields. In the aviation and space industry, MWCNT and magnetic nanoparticle reinforced polymer composites may have various advantages in terms of electromagnetic environment repellency.

Keywords: Collagen , Hydrogel , PNIPAAm Polymer.

Aim

Hydrogels, recognized as soft and moisture-rich materials with a three-dimensional network structure capable of holding a substantial amount of water, have found extensive applications in areas such as controlled drug delivery carriers, tissue engineering scaffolds, and biosensors. Their widespread use is attributed to their distinctive characteristics, including biocompatibility, biodegradability, water retention, and adhesive properties. It is well established that stimulus-responsive polymer hydrogels serve as adaptable drug delivery platforms, enabling drug release to be regulated by various external factors. Among them, thermoresponsive hydrogels have gained significant attention due to their ease of temperature control and applicability in both in vitro and in vivo environments. Poly(N-isopropylacrylamide) (PNIPAAM), one of the most extensively studied thermoresponsive synthetic polymers, is particularly valuable in the development of materials for biomedical applications. PNIPAAM exhibits a phase transition around its lower critical solution temperature (LCST), which is approximately 32°C. Above this threshold, the polymer undergoes a rapid transformation from a hydrophilic to a hydrophobic state, resulting in the expulsion of water. Due to this unique characteristic, PNIPAAM hydrogels have been widely utilized in diverse fields, including drug release, self-healing materials, and tissue engineering. Recently, increasing research has focused on the synthesis of copolymers incorporating PNIPAAM with biodegradable components to construct polymeric networks with enhanced properties. Collagen hydrogels are three-dimensional network structures composed of collagen protein and have high water retention capacity. These hydrogels have a wide range of uses in biomedical applications such as tissue engineering and drug delivery systems due to their biocompatibility and biodegradability. Collagen hydrogels provide a suitable microenvironment for cell adhesion, growth and differentiation with their structures that mimic the natural extracellular matrix (ECM). However, the mechanical strength of natural collagen hydrogels is generally low. Therefore, methods such as chemical cross-linking or modification with synthetic polymers are used to improve their mechanical properties. Another important area of use of collagen hydrogels in medical applications is to support wound healing. Thanks to their high water content and biocompatibility, these hydrogels can accelerate the healing process by providing a moist healing environment when used as a wound dressing. Clays are natural inorganic additives widely used to improve both structural and functional properties in hydrogel systems. These substances, especially clay minerals with layered silicate structures such as montmorillonite, bentonite and kaolin, are integrated into hydrogel matrices and improve important properties of these structures such as mechanical, thermal and swelling behaviors. Clay particles in the hydrogel create physical cross-links between polymer chains, making the network structure more robust and stable. This is of great importance in terms of achieving the desired mechanical strength, especially in biomedical applications. In addition, the presence of clays in the hydrogel directly affects the swelling behavior. For example, the addition of clays such as montmorillonite limits the water absorption capacity of the hydrogel, providing a more controlled and slow swelling process. This feature is particularly advantageous in drug delivery systems. In controlled release applications, it is desired to release the drug slowly over a certain period of time, and the clay additive plays a regulatory role in this process. In our study, we synthesized an injectable hydrogel by combining pnipam and collagen. We also aimed to add additives such as

clay to provide mechanical support for use in tissue engineering, rapid drug screening systems, and drug delivery, etc.

Material and Method

2.1 Material

Collagen(Type 1), N-isopropylacrylamide(NIPAAM), Azobisisobutyronitrile(AIBN), Methanol (99% purity), *1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide* (EDC), N-Hydroxysuccinimide (NHS), Acetone (99% purity), Mercaptoundecanoic acid (MUA), diethylether.

2.2 Method

Synthesis of PNIPAAM

PNIPAAM was synthesized by radical polymerization. AIBN was used as radical initiator and MUA was used as functionalizer. NIPAAM, AIBN and MUA was dissolved in methanol. Then, vacuum and nitrogen were applied to remove the air from the volumetric flask containing the mixture. Finally, it was mixed with a magnetic stirrer in an oil bath at 70 degrees for 24 hours. The next day the mixture was evaporated at 50-60 degrees. Acetone is used to dissolve the formed PNIPAAM polymer. After dissolving it with acetone, it was precipitated by adding it dropwise to cold diethylether. The precipitated polymer was decanted and left in a vacuum oven overnight to dry completely. The fully cured polymer is ready to be used for hydrogel formation.

Synthesis of Pnipaam-Collagen Hydrogel

MES solution was prepared to dissolve collagen and PNIPAAM polymer. The pH of the solution was adjusted to 5. Then, collagen was dissolved in MES solution. At the same time, PNIPAAM was dissolved in a separate beaker of mes solution. EDC and NHS were used as activator. They were also dissolved separately in MES solution. Once all were completely dissolved, they were combined and left on a magnetic stirrer overnight at room temperature. The mixture was placed on a dialysis membrane to remove impurities. The membrane was kept in distilled water at 4 degrees for 4 days. Then, the mixture was precipitated in distilled water adjusted to 50 degrees and after waiting for a while, gel formation was observed.

Findings

The temperature-sensitive PNIPAAM polymer was successfully synthesized. Then, it was mixed with the required amount of type 1 collagen under appropriate conditions for hydrogel formation. PNIPAAM-collagen hydrogel was formed. It was observed that the formed hydrogel was in liquid form at 25 degrees and in solid form at 37 degrees. The necessary characterization studies for the synthesized PNIPAAM polymer and PNIPAAM-collagen hydrogel are continuing. Additionally, research continues on clay, which will be used to provide mechanical support.

Conclusion

As a result of this study, a thermosensitive PNIPAAM-collagen hydrogel was successfully synthesized, exhibiting desirable physical and chemical properties at physiologically relevant temperatures. The hydrogel responded effectively to temperature changes, particularly around body temperature, making it a promising candidate for biomedical applications where thermoresponsiveness is critical. Characterization analyses, including morphological, rheological, and swelling behavior assessments, revealed that while the synthesized hydrogel meets fundamental performance criteria, its mechanical strength can be further improved. To enhance these mechanical properties without compromising the biocompatibility or natural structure of the collagen network, incorporation of suitable additives has been proposed. Among these, naturally occurring nanoclays, such as montmorillonite or bentonite, are particularly promising due to their layered structure, high surface area, and ability to interact with polymer chains to reinforce the hydrogel matrix. By integrating such reinforcing agents, it is anticipated that the hydrogel will gain enhanced durability and structural integrity, thereby expanding its potential applications. In this context, the developed PNIPAAM-collagen hydrogel is envisioned for use in advanced biomedical fields such as tissue engineering, wound healing, and controlled drug delivery systems, where both

biocompatibility and functional performance are crucial. Future studies will focus on optimizing the formulation by testing various additive concentrations and evaluating their effects on long-term stability, degradation behavior, and in vivo performance.

Utilization of Carbon Dioxide Gas (CO_2) for Gas Lift Systems In Geothermal Wells

Force Lugembe Ndege [a], Ömer Inanç Türeyen [a]

[a] Istanbul Technical University, Petroleum and Natural Gas Engineering, Petroleum and Natural Gas Engineering, Turkey
ndege21@itu.edu.tr

Keywords: Flash Point Pressure, Gas Lift Systems, Geothermal Energy, Solubility of Carbon Dioxide Gas in Water, Well Head Pressure.

Aim

Geothermal wells experience a decline in pressure between the bottomhole pressure and the wellhead pressure (during both static and dynamic conditions) due to friction, gravity, and kinetic energy loss encountered during fluid flow from the reservoir to the surface. In some cases this decline could be large, leading to reduced production rates. High wellhead pressures are necessary for maintaining high production rates and keeping the geothermal power plants operational. To address the pressure loss during fluid flow in geothermal wells, artificial lift techniques are employed, such as line shaft pumps and electrical submersible pumps (ESPs), which are widely used in Türkiye and globally.

This study investigates the feasibility and potential benefits of using carbon dioxide (CO2) gas lift systems in geothermal wells as an innovative artificial lift technique. The utilization of CO2 gas for gas lift in geothermal wells, though not widely researched and adopted, presents a promising approach to enhancing the productivity and efficiency of geothermal energy extraction. By integrating CO2 gas lift systems, operators can improve flow rates, increase overall system efficiency, and reduce operational costs.

The study involves several stages, including the analysis of the thermodynamic behavior and solubility of CO2 in water at various pressures and temperatures encountered during geothermal fluid flow. Using Duan's solubility data, the solubility of CO2 in water was predicted with high accuracy through linear interpolation coding techniques, covering pressures up to 2000 bar and temperatures of 533K. Additionally, geothermal pressure profiles, partial pressures of steam and CO2, and flash point pressures were simulated by coding and validated, to understand the effects of varying CO2 mass fractions. It was discovered that increasing CO2 mass fractions reduced pressure losses, leading to higher wellhead pressures.

This study's findings indicate that CO2 has a profound effect on the wellhead pressure. Therefore, CO2 gas lift systems may serve as a viable alternative to conventional artificial lift techniques. By addressing challenges such as declining productivity and operational inefficiencies, the integration of CO2 gas lift systems contributes to improved energy production and lower operational costs. This research provides a comprehensive understanding of the effects of CO2 on the production performance for geothermal wells.

Material and Method

To be able to link the wellhead pressure to the bottomhole pressure in wells containing geothermal water with CO_2, the solubility of CO_2 with pressure and temperature must be known. For this study, the solubility of CO_2 in water is modelled with the model provided by the following Duan and Sun,(2003). A python code that determines the CO_2 solubility in water at any temperature and pressure up to 533.15K and 2000bar with high accuracy has been developed. The results of CO_2 solubility in water values were compared with the existing Duan's concentration of CO2 in water as indicated in Duan's 2003 to check the validity of the coding. The results were also compared with the experimental data obtained from Wiebbe and Gaddy ((1935); (1940)) in the same temperature and pressure range. Figure 1 gives the behaviour of solubility with temperatures for various pressures.

$$ln m_{CO_2} = ln y_{CO_2} \varphi_{CO_2} P - {\mu^{I(0)}}_{CO_2}/RT - 2\,\lambda_{CO_2-Na}(m_{Na}+m_K+2m_{Ca}+2m_{Mg}) - \zeta_{CO_2-Na-Cl}\, m_{Cl}(\quad m_{Na} + m_K + m_{Ca} + m_{Mg}) + 0.07 m_{SO_4}$$

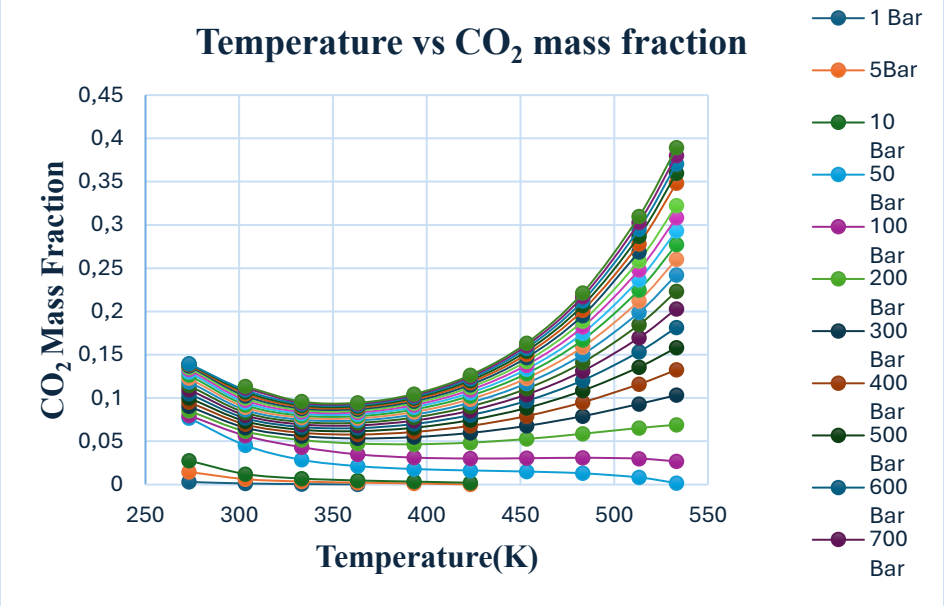

Figure 1: The plot of Temperature vs code calculated CO2 mass fraction data.

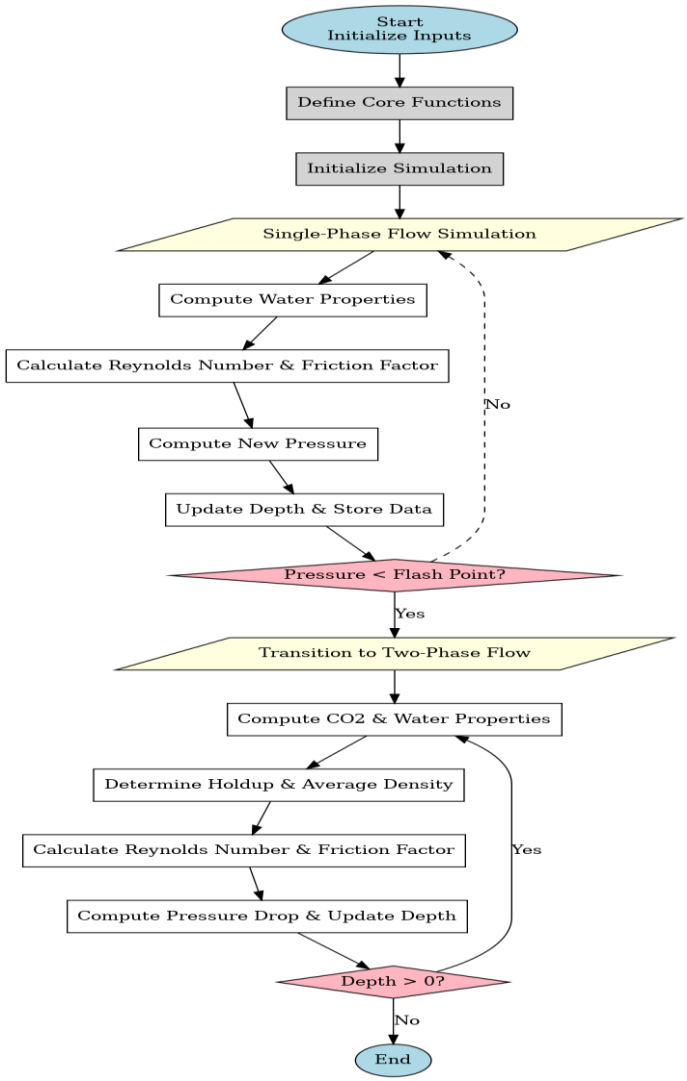

Figure 2: Flowchart for computing the wellbore pressure profile.

Findings

Numerical Modelling Methodology for Geothermal Well Pressure Profile

In this study, a computational model was developed to analyze the pressure profile along a geothermal wellbore, accounting for different pressure losses, including frictional, gravitational, and kinetic energy losses. The model is implemented as a stepwise numerical algorithm, computing wellhead pressure at various CO_2 mass fractions. The core structure of the model follows a systematic approach, integrating thermodynamic property calculations and iterative pressure drop computations.

Flowchart for Geothermal Well Pressure Profile Code Structure

A python code was written in the Visual code studio to simulate the flow in geothermal wells containing CO2. The flow chart of the code is given in Figure 1 outlines the key computational stages, including input initialization, function definitions, single-phase and two-phase flow simulations, and finalizing the computation.

Development of The Well Pressure Profile Model

During production, a typical pressure profile is given in Figure-3. As it is clear, at the lower sections of the well, there is single phase flow. At a certain depth, flashing occurs, and the two-phase region begins. The two-phase region consists of gas and water flow. In geothermal wells that produce water with CO2, the gas phase will be composed of both CO2 and steam. The flashing point occurs in the region where the deviation from the straight line begins. Furthermore, the slope of the pressure profile changes significantly because of the formation of the two phases. Figure 5 below serves as a visualization model, to help with visualization of the necessary parameters. The model developed in this study is capable of generating the pressure profile for wells that produce water with dissolved CO2.

To ensure the reliability and accuracy of the developed geothermal well pressure profile code, a validation process was carried out using real field data from two geothermal wells: AF-21 from Afyon (Cinar et al., 2006) and OB-16 from Germencik (Tureyen et al., 2014). These wells were chosen due to the availability of well-documented pressure profiles, making them ideal for testing the performance of the numerical model.

Figure 4 gives the results of the comparison of the model developed in this study to the AF-21 well. As it is clear, the model developed in this study provides a good match to the actual field data. Figure 5 gives the match to the OB-16 well pressure profile. Again, a fairly good match is obtained.

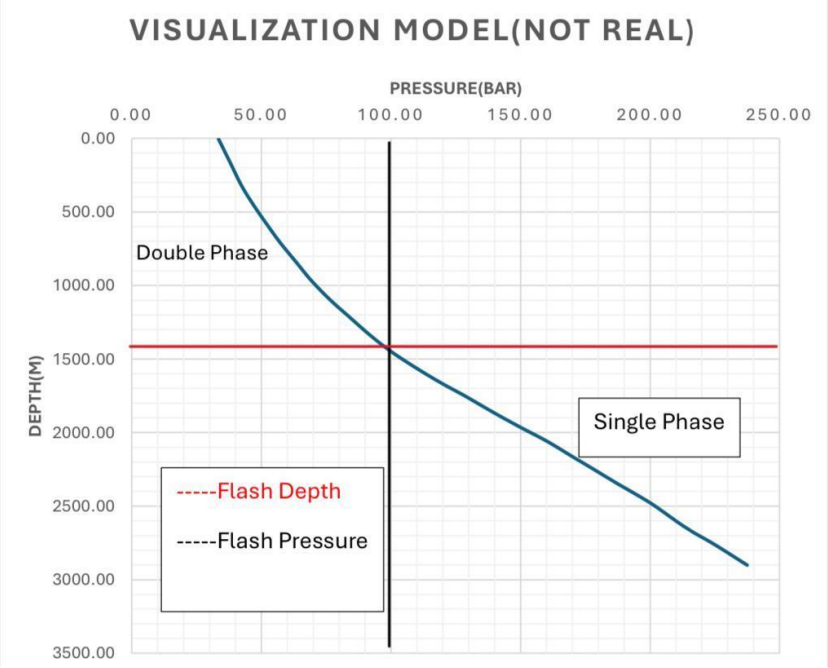

Figure 3: visualization model.

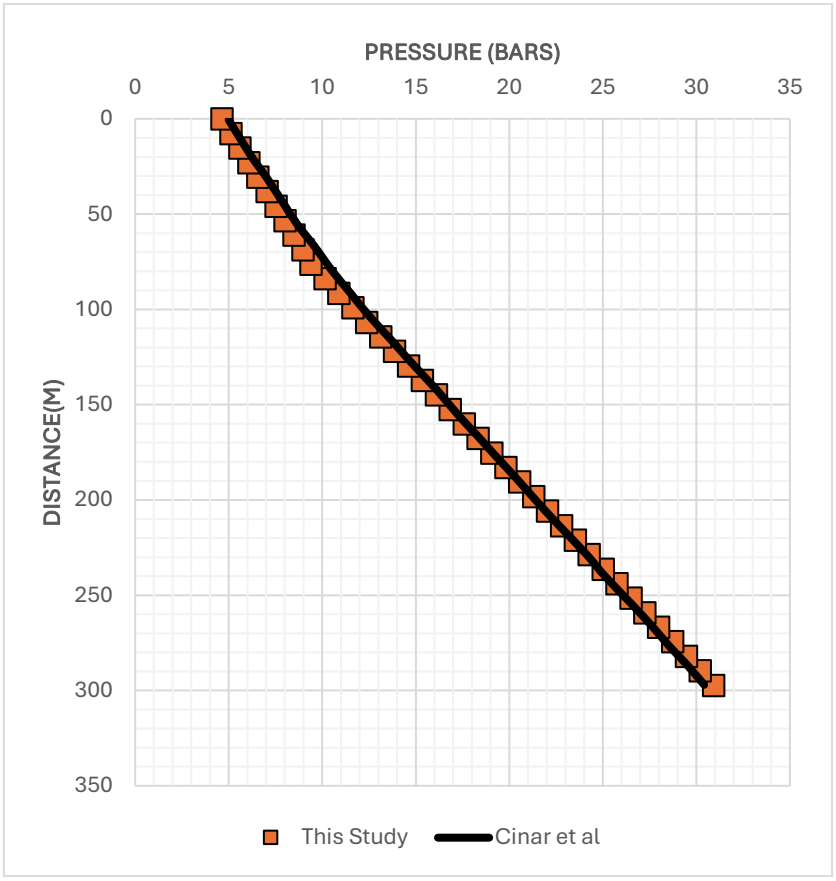

Figure 5: The pressure profile of the AF- 21 well and the model, where the mass fraction of the dissolve CO2 is at 0.9%.

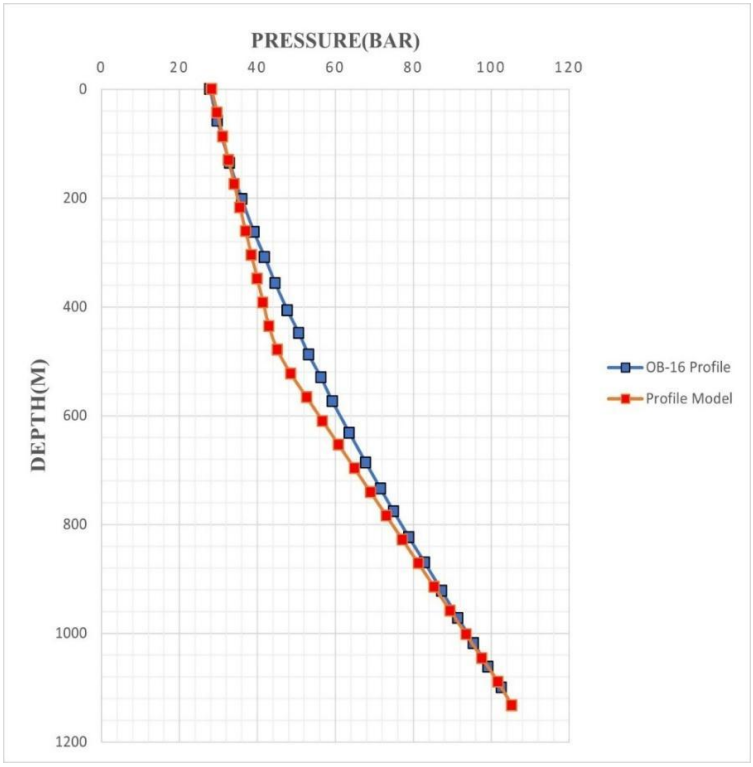

Figure 5: The pressure profile of the OB- 16 well and the model, where the mass fraction of the dissolved CO2 is at 2.1%.

Conclusion

A CO_2 solubility code was developed based on Duan's 2003 equation of state. The results obtained from the model demonstrated high accuracy when compared with experimental and modeling data, maintaining an error margin within 0.04% in the temperature range of 273 to 533 K and pressures up to 2000 bar. The model effectively predicts CO_2 solubility in water under geothermal conditions, making it a reliable tool for designing CO_2-based gas lift systems. The model can also be used to predict the flash point pressure and CO_2 mass fraction retained in liquid phase during the double phase flow in geothermal wells.

Furthermore, a geothermal well pressure profile code was designed to simulate the pressure behavior of geothermal wells under different CO_2 mass fractions. This numerical model accounted for pressure losses due to friction, gravity, and kinetic energy effects along the wellbore. The simulation results indicated that increasing CO_2 mass fractions effectively reduced pressure losses and contributed to higher wellhead pressures, thereby enhancing well productivity. The stepwise computational approach incorporated thermodynamic property calculations, phase transition modeling, and iterative pressure drop calculations to accurately represent real-world well conditions.

The findings of this study suggest that CO_2 gas lift systems could serve as an efficient and cost-effective alternative to conventional artificial lift methods in geothermal wells. By improving flow rates and increasing energy production efficiency, the integration of CO_2 gas lift can lead to significant operational advantages, including lower maintenance costs and reduced energy consumption.

In conclusion, this research successfully validates the potential of CO_2 gas lift systems for geothermal wells through both theoretical modeling and numerical simulations. The developed solubility model and well pressure profile code offer valuable computational tools for optimizing gas lift design in geothermal energy production. Future work should focus on experimental validation, field-scale implementation, and further exploration of CO_2 phase behavior under varying geothermal conditions. By advancing the understanding and application of CO_2 gas lift, this study paves the way for the adoption of innovative and sustainable solutions in geothermal energy production.

Natural Gas Engineering

Reservoir Engineering

Natural Gas Hydrate Modelling

Devrim Başar Han[a] , Murat Çınar[a]

[a] Istanbul Technical University, Petroleum and Natural Gas Engineering, Master Program, Türkiye
han22@itu.edu.tr

Keywords: Gas Hydrates, Hydrate Formation, Hydrate Mitigation, Natural Gas Distribution, Natural Gas Pipelines.

Aim

Gas hydrates are clathrate inclusion compounds in which water molecules form hydrogen-bonded cages in a lattice structure stabilized by encapsulating a small guest molecule such as methane or ethane [1]. A gas hydrate is an ice-like solid that can exist at temperatures up to 25˚C in systems with moderate pressure at 7 MPa. Water in natural gas may condense and alter the physical state to an unwanted two-phase flow [2]. The pipelines used in the production of oil and gas can experience serious safety and flow assurance problems because of plugging by solid deposits of gas hydrates, waxes, asphaltenes, and scale [3]. These conditions are commonly encountered in oil and gas offshore process facilities [4]. In this study we focus on the hydrate formation conditions that could be encountered in natural gas urban distribution systems. Based on data from a gas distribution company, the effects of various conditions on gas hydrate formation were investigated.

Within the conditions of a natural gas system, besides pressure and temperature, it is concluded that the primary factor influencing hydrate formation is the water content for such systems. According to average composition we plotted the average gas composition at various water contents and observed the behavior. Hydrate formation estimations are based on complex thermodynamic relations. In this work we provide a simple relation that would estimate hydrate formation temperature at a given pressure and water content for a typical natural gas composition encountered in urban distribution lines, on the fact that the composition in natural gas distribution lines is relatively constant. The relation proposed is compared with the generalized thermodynamic relations. The results are consistent. The equation works for a pressure range of 100-1 bar within engineering accuracy.

Material and Method

Using the data provided, aqueous phase calculations were performed, and the necessary conversions were made based on NIST Webbook [5] data. The base water content calculated as 2.09x10-5 $\frac{mol\ H_2O}{mol\ Gas}$, indicating that one mole of natural gas is flowing by 2.09×10^{-5} moles of water. The hydrate forming curve behavior of the different gas composition was analyzed at different water ratios to develop a more detailed model. The gas compositions for each month over a period of four years are given, the samples with the maximum and minimum methane content were evaluated, and presented in Table 1 and Table 2, respectively. The sample with the maximum methane content named as "Max gas composition" and the sample with the minimum methane content named as "Min gas composition". Max and min gas compositions at different water mole fractions and hydrate formation curves are presented in Figure 1.

This study was conducted for specific water ranges. The cases for different water fractions are defined as follows:
Case 1: 6.96×10^{-4} mol water
Case 2: 1.04×10^{-3} mol water
Case 3: 2.09×10^{-3} mol water
Case 4: 4.19×10^{-3} mol water
Case 5: 6.27×10^{-3} mol water

Table 1. The gas composition sample with the lowest methane content. Named as min gas composition.

Methane	Ethane	Propane	n-butane	I-butane	n-pentane	I-pentane	Hexane	Nitrogen	CO2
93.1820	3.6987	1.1252	0.2292	0.1936	0.0414	0.0539	0.0147	1.1345	0.3268

Table 2. The gas composition sample with the highest methane content. Named as max gas composition.

Methane	Ethane	Propane	n-butane	I-butane	n-pentane	I-pentane	Hexane	Nitrogen	CO2
95.8254	2.3966	0.7072	0.1022	0.1032	0.0131	0.0185	0.0102	0.6448	0.1786

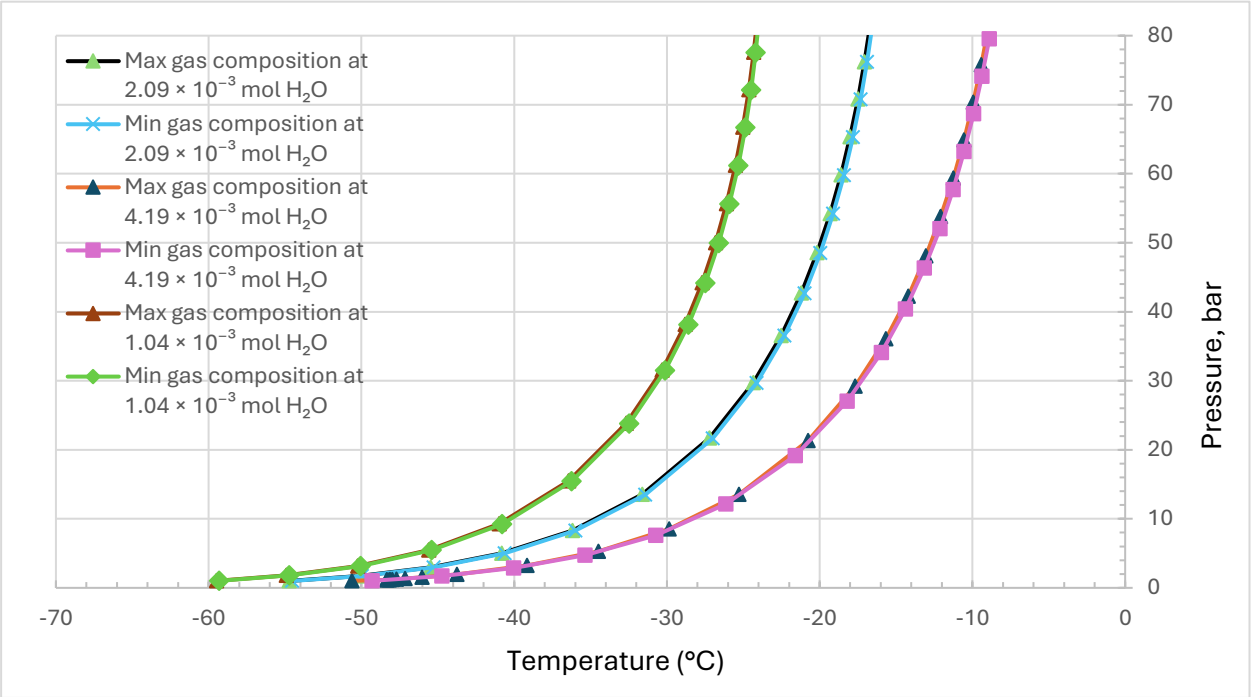

Figure 1. Effect of max and min gas compositions on hydrate formation process for case 2, case 3 and case 4.

When an average gas composition was generated and the hydrate formation curves were plotted, a similar behavior to the curves in Figure 1 was observed. The hydrate formation curves of the average gas composition are plotted.

Table 3. Average gas composition.

Methane	Ethane	Propane	n-butane	I-butane	n-pentane	I-pentane	Hexane	Nitrogen	CO2
94.5077	3.7169	0.7667	0.1220	0.1158	0.01426	0.02013	0.01616	0.5804	0.14033

Since the hydrate formation curves of the average gas composition and the hydrate formation curves of the max and min gas compositions exhibit the same behavior, all hydrate forming curve for average gas composition, max gas composition and min gas composition shown in Figure 2. Thus, subsequent calculations and analyses will be conducted based on the average gas composition.

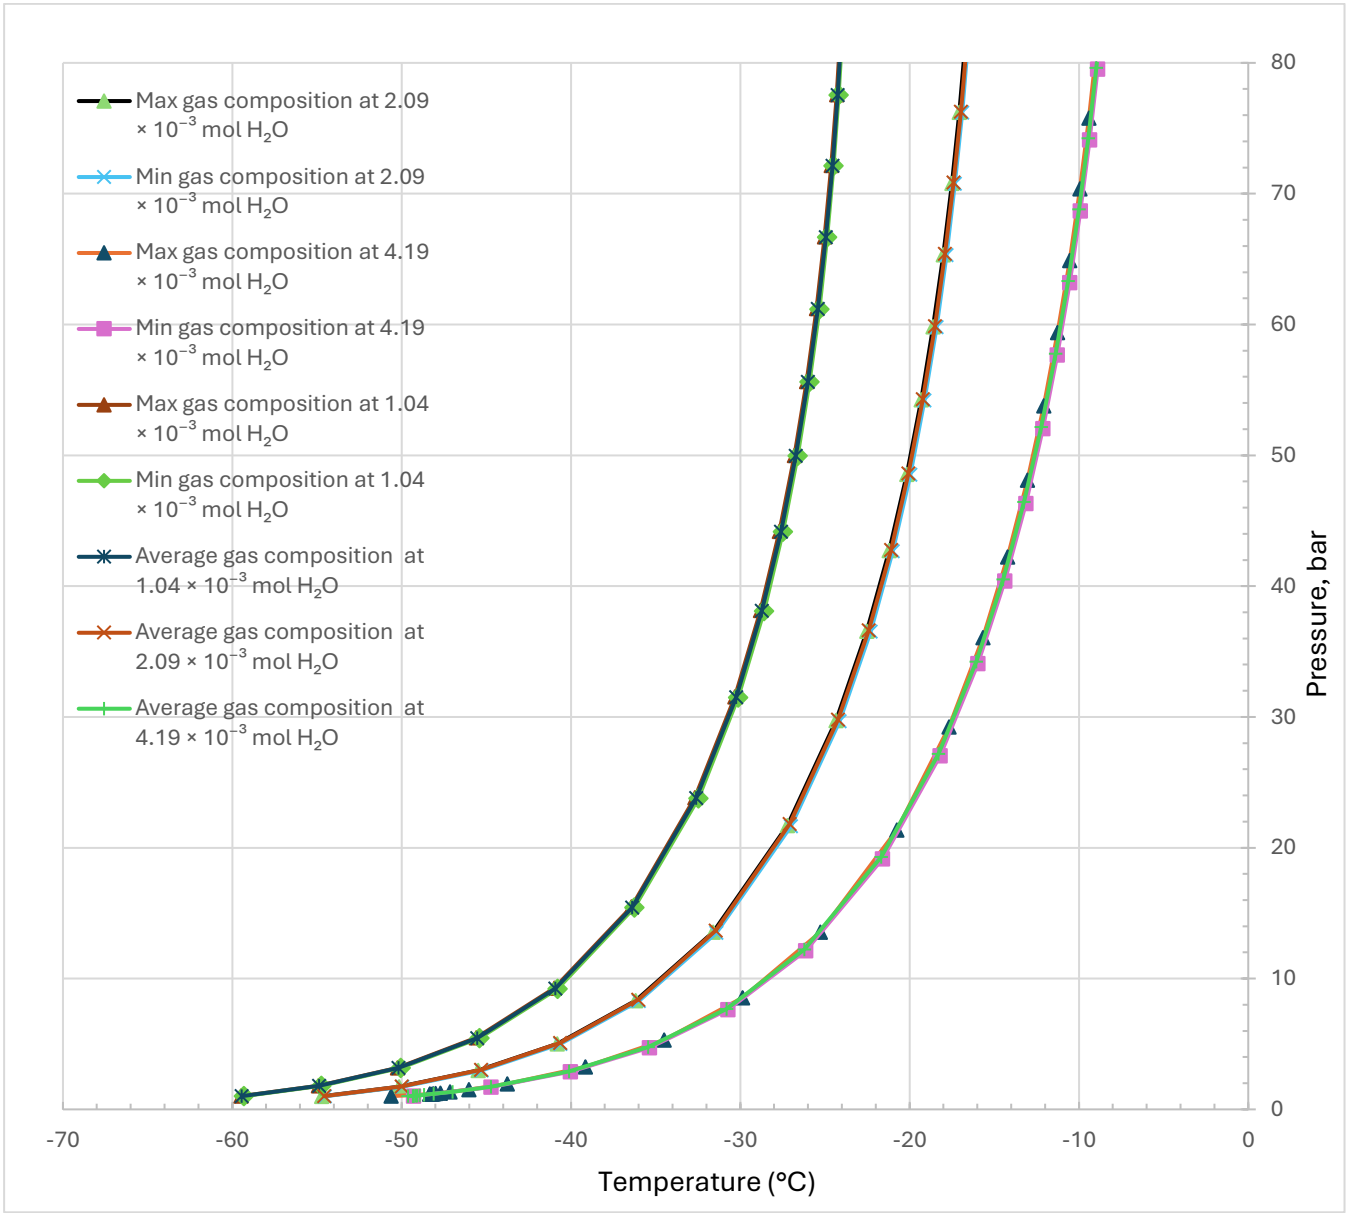

Figure 2. Comparison of max gas composition, min gas composition and average gas composition on hydrate forming curves for case 2, case 3 and case 4.

Average gas composition approach facilitates a more precise assessment of the effect of water content on hydrate formation. According to hydrate forming behavior of average gas composition at each water contents, curve parameters are determined. These curves were fitted on logarithmic trend lines so the equations were logarithmic. The curves given in Figure 3. Equations and R^2 values given in Table 1.

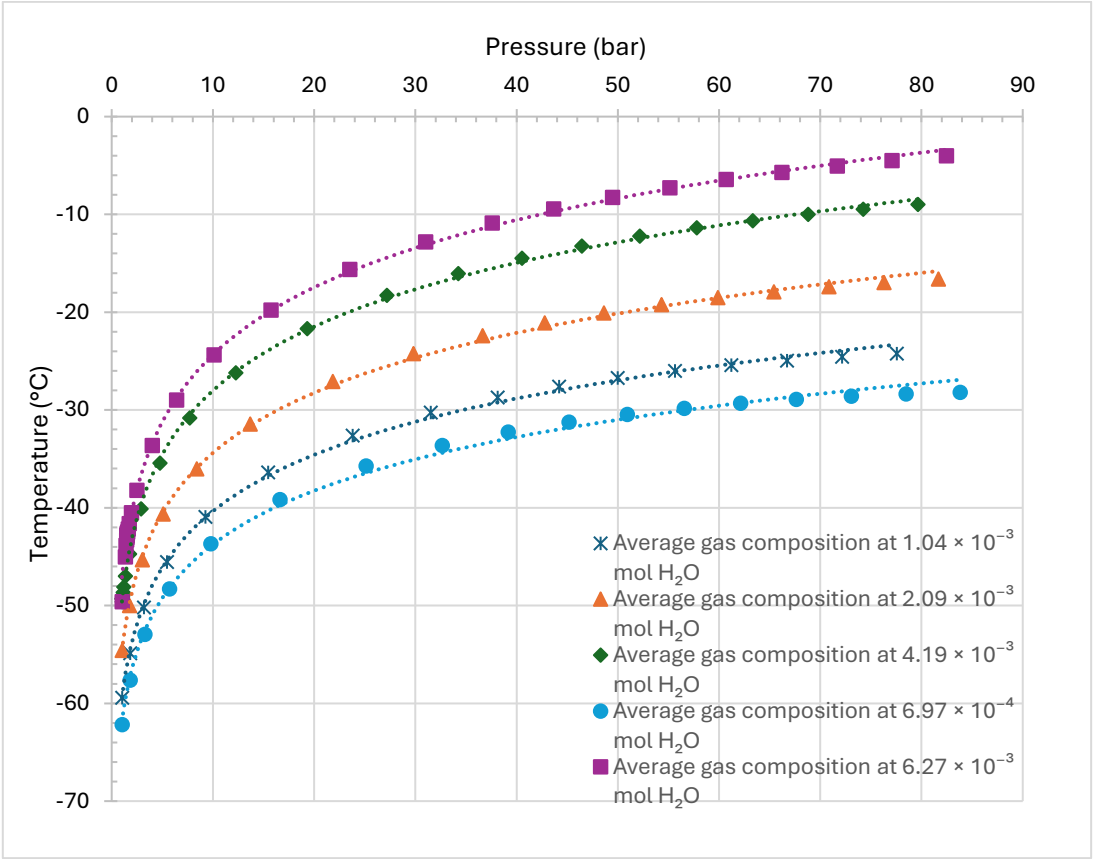

Figure 3. Hydrate forming curves of average gas composition for each case.

General equation for hydrate forming curves;

$y = a\ ln\ ln\ (x\ ) - b$ …… (1.1)

Since the general equation is $y = a\ ln\ ln\ (x\ ) - b$, the behavior of the parameters needs to be analyzed. To understand how the coefficients of equations in Table 1 behave, the parameter values were recorded as shown in Table 2.

Table 4. Equations and R^2 values of hydrate formation curves for the average gas composition at each case.

Water Content, mol	Equation	R^2 Value
6.97×10^{-4} mol H_2O	y = 7.9219ln(x) - 61.9947	0.9971
1.04×10^{-3} mol H_2O	y = 8.3144ln(x) - 59.4947	0.9986
2.09×10^{-3} mol H_2O	y = 8.8530ln(x) - 54.7768	0.999
4.19×10^{-3} mol H_2O	y = 9.4247ln(x) - 49.7153	0.9997
6.27×10^{-3} mol H_2O	y = 9.9374ln(x) - 47.2376	0.9988

Table 5. Parameters of the equations with the average gas composition for each case.

	Coefficients	
Water contents, mol	***a***	***b***
0.000697	7.9219	61.9947
0.00104	8.3144	59.4947
0.00209	8.8530	54.7768
0.00419	9.4247	49.7153
0.00627	9.9374	47.2376

To generalize the behavior of the coefficients, the graph of water content versus coefficients was plotted, which shows that both the "a" and "b" parameters follow logarithmic trendlines. Since the general equation for hydrate forming curve for average gas composition (equation 1.1) given as $y = a\ ln\ ln\ (x\ ) - b$ the equation for the "a" parameter will be substituted into the general equation in place of "a". In this equation, the x-axis represents water content; therefore, "x" corresponds to the water content."
Similarly, the equation of "b" parameters will be put instead of "*b"* in equation 1, again the "x" variable represents water content.

According to the behavior of parameter "a", the equation of parameter "a" is obtained as:

$y = 0.8844\ ln\ ln\ (x\ ) + 14.347$ …… (1.2)

Similarly, according to the behavior of parameter "b", the equation for parameter "b" is derived as follows:

$y = -6.814\ ln\ ln\ (x\ ) + 12.603$ …… (1.3)

If equations 1.2 and 1.3 are substituted into the equation 1.1 in place of the corresponding terms, then equation 1.1 becomes:

$(x) + 14.347)P\ - (x) + 12.603)$ …… (1.4)

Where "y" represents temperature, "x" denotes water content, and "P" stands for pressure. Using this equation, the temperature can be determined when the pressure and water content are known.
Similarly, the equation can be rearranged to express pressure as follows:

$P = e^{\frac{(x)\ +12.603))}{(0.8844 ln ln\ (x)\ +14.347)x}}$ …… (1.5)

Findings

These equations for pressure and temperature were derived based on the average gas composition in each case. To develop the model, the water content was varied in small increments, and the calculated pressure-temperature values were compared between calculated pressure - temperature and received or automatically calculated values with CSMGem [6] computer programming which uses complex thermodynamic relation (CPA infochem model). Since the results include a large number of graphs, only two representative cases are presented: the case 5 in Figure 4 and the case 1 in Figure 5.
As can be observed from Figures 4 and 5, the program outputs and the experimental results are in strong agreement. This suggests that Equation 1.4 provides reliable and accurate results.

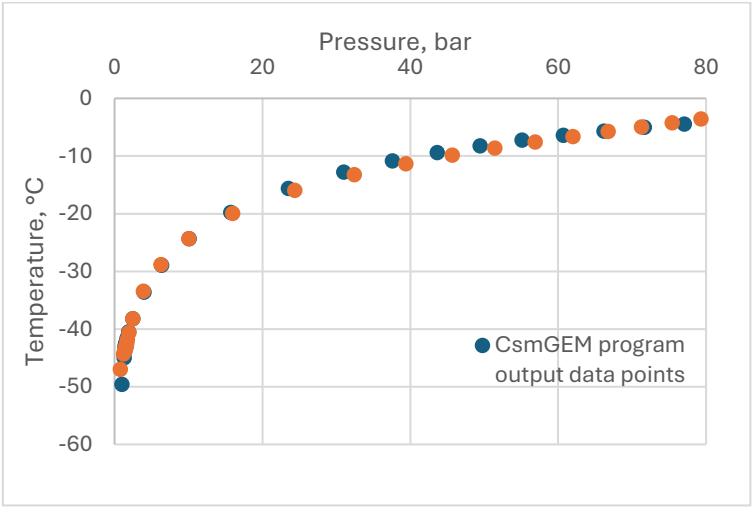

Figure 4. Comparison of simulation data and calculated data from derived equation (1.4). Comparison for case 5.

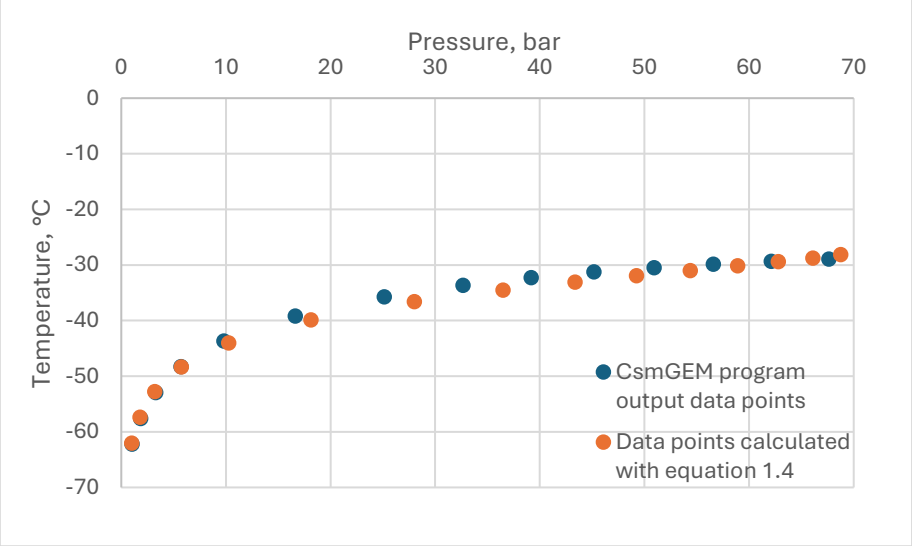

Figure 5. Comparison of simulation data and calculated data from derived equation (1.4) for case 1.

The results show better consistency with the program output at higher water contents. When it comes to low water ratios at low temperature the outcomes are consistent because of the hydrate forming process occurring naturally, but as the temperature gets high, the process is affected by another parameter. If the water content is high, the gas hydrate forming process merges at low temperature and increases in parallel with program output data.

Conclusion

This study, analyzed the formation of gas hydrates in urban natural gas flow lines, and a generalized equation was derived to predict temperature and pressure conditions for hydrate formation. The results showed that water content plays a crucial role in the formation process, with higher water percentages leading to more consistent hydrate formation patterns at lower temperatures. The developed logarithmic model effectively correlates water content with temperature and pressure parameters, and the derived equations were validated using EOS(equation of state) models. The comparison between proposed equation and EOS results demonstrated a high level of agreement, particularly at higher water contents. Additionally, the model was further verified through machine learning predictions (random forest model), achieving a remarkable accuracy of 99.4%. These findings provide a valuable tool for optimizing heating strategies in natural gas pipelines, mitigating hydrate-related flow assurance issues. Future work may focus on refining the model by incorporating additional influencing factors such as gas composition variations and external environmental conditions to enhance its predictive capabilities.

Keywords: Compressibility Factor, Density, Viscosity, Critical Properties, Reservoir Volume.

Aim

Underground storage of natural gas has been an important topic over the decades. The underground storage of hydrogen on the other hand is attracting considerable attention. Finally, the sequestration of carbon dioxide has been an important topic over the two decades. These three gases have been the center point of research for many researchers. In all applications the physical properties of these gases must be computed. Many of the gas's physical properties are essential for safe, effective, and cost-effective underground storage. These characteristics have an impact on overall safety, operational effectiveness, and storage location selection. Understanding how these gases behave under different reservoir conditions has become increasingly important due to rising energy demands and the need for carbon capture and storage (CCS) technology to reduce greenhouse gas emissions (Guo & Ghalambor, 2005). Because of its potential for use in renewable energy applications, hydrogen is becoming a prominent contender for energy storage in the future. Its storage characteristics, however, are very different from those of traditional natural gas. Likewise, sequestration of carbon dioxide is essential for lowering atmospheric emissions, necessitating a thorough examination of its storage behaviour (Li et al., 2023).

Thus, this study compares the physical characteristics of three commonly used gases and examines how they behave at various pressures and temperatures. The viability and effectiveness of storing these gases underground will be better understood thanks to this comparative study, which is essential for improving storage plans and guaranteeing the security and integrity of storage reservoirs.

Material and Method

The main thermophysical gas properties applied for the comparison of the mentioned gases are:

- compressibility factor (also known as z-factor)
- pressure over compressibility factor (p/z)
- density
- viscosity
- gas compressibility
- gas formation volume factor
- reservoir volume

For the calculation of these parameters the critical properties of the gases and reference reservoir pressure and temperature range are needed. The pressure and temperature range applied for the calculation of the gas properties are for typical reservoir conditions. The critical properties of hydrogen (H_2), carbon dioxide (CO_2), and methane (CH_4) are tabulated in table 1.

Table 1. The critical properties of gases.

Gas name	Critical pressure (bar)	Critical temperature (K)
Hydrogen	13	33.2
Carbon dioxide	73.8	304.2
Methane	46.4	190.6

With the help of critical properties and equations applied from the handbook, the main thermophysical properties are calculated and compared (Craft et al., 1991). The key gas parameter for the calculation of all properties is compressibility factor. By obtaining z-factor other properties can be computed. The gas deviation factor (z) is calculated using the "Dranchuk and Abou Kassem" method. The density, compressibility, formation volume factor and reservoir volume are given by Equations 1, 2, 3 and 4 respectively:

$$\rho = \frac{pM}{zRT} \quad \textbf{1}$$

$$c = \frac{1}{\rho}\left(\frac{\partial \rho}{\partial p}\right)_T = \frac{1}{p} - \frac{1}{z}\left(\frac{\partial z}{\partial p}\right) \quad \textbf{2}$$

$$B = \frac{p_{sc}}{T_{sc}}\frac{zT}{p} \quad \textbf{3}$$

$$V = \frac{p_{sc}}{T_{sc}}\frac{zT}{p}G \quad \textbf{4}$$

Here ρ (kg/m^3) is the density, p (bar) is pressure, M (kg/kg.mole) is the molecular weight, z is the gas deviation factor, R is the Universal gas constant, 8.314×10^{-2} bar.m^3/(K.kgmole), T is temperature (K), G (sm^3) is the volume of gas at standard conditions, and V (m^3) is the volume of gas at reservoir conditions (Craft et al., 1991). For calculating viscosity, the Coolprop software has been used (Yang et al., 2017).

Findings

From the results obtained for all gas properties, all three gases behave differently from each other at same pressure and temperature. The main reason why these gases act differently from each other is that their molecular and critical properties are very distinct. Figure-1 gives the results of the comparison of the gas deviation factors. From the results of the gas deviation factor (z-factor) hydrogen gas has shown to have the higher gas deviation factors for each pressure and temperature. This is followed by methane and carbon dioxide. This is primarily due to the fact that hydrogen has the lowest molar mass, critical pressure and critical temperature compared to other gases. The comparison of density is given in Figure-3. When comparing gases with density values, carbon dioxide has the highest density, because this gas has higher molecular weight and lowest gas deviation factor. In fact, there is a significant difference between the density of carbon dioxide and the other two gases at high pressures. Figure-4 gives the comparison of viscosity with pressure for different temperatures. Once again, we see that carbon dioxide has a much higher viscosity when compared with other gases. The compressibility behavior of carbon dioxide, methane and hydrogen are given in Figure-5. As expected, methane and hydrogen display a typical behavior of compressibility, where the compressibility decreases with pressure. The change of compressibility with temperature for methane and hydrogen is very small. The compressibility behavior of carbon dioxide, on the other

hand, is somewhat counterintuitive. Especially at low temperatures, with increasing pressure, compressibility initially decreases, then increases, and finally decreases afterwards. This behavior of decreasing, increasing and then decreasing again becomes less dominant at higher temperatures. This behavior can be explained via the density behavior. Let's consider the compressibility of carbon dioxide at 313.15 K (40 °C). Between pressures of 56 bar and 85 bar, the compressibility of carbon dioxide displays an increasing behavior. This corresponds to the region where there is a rapid increase in density (as can be seen in Figure 3). Once the rapid increase of density diminishes the compressibility starts to decline. When we compare the compressibility of carbon dioxide, methane and hydrogen, for a specific temperature, at lower pressures, the compressibility of carbon dioxide is higher than that of methane and hydrogen. At higher pressures, the compressibility of carbon dioxide becomes less than that of methane and hydrogen.

Figures 6 and 7 give the comparison of the formation volume factor and the reservoir volumes of the gases respectively. The reservoir volumes have been compared for the case where the volume of the gases at standard conditions have been taken the same. The formation volume factor and reservoir volume have shown similar results, where methane and hydrogen showed higher values at each temperature and pressure compared to carbon dioxide. The reason is that the carbon dioxide has higher compressibility.

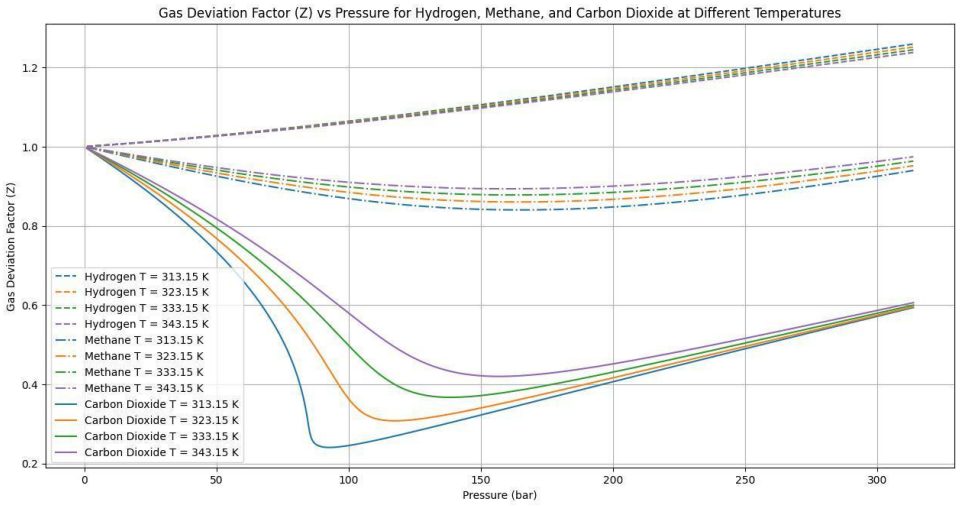

Figure 1. Compressibility factor (Z) vs Pressure for Hydrogen, Methane, and Carbon Dioxide.

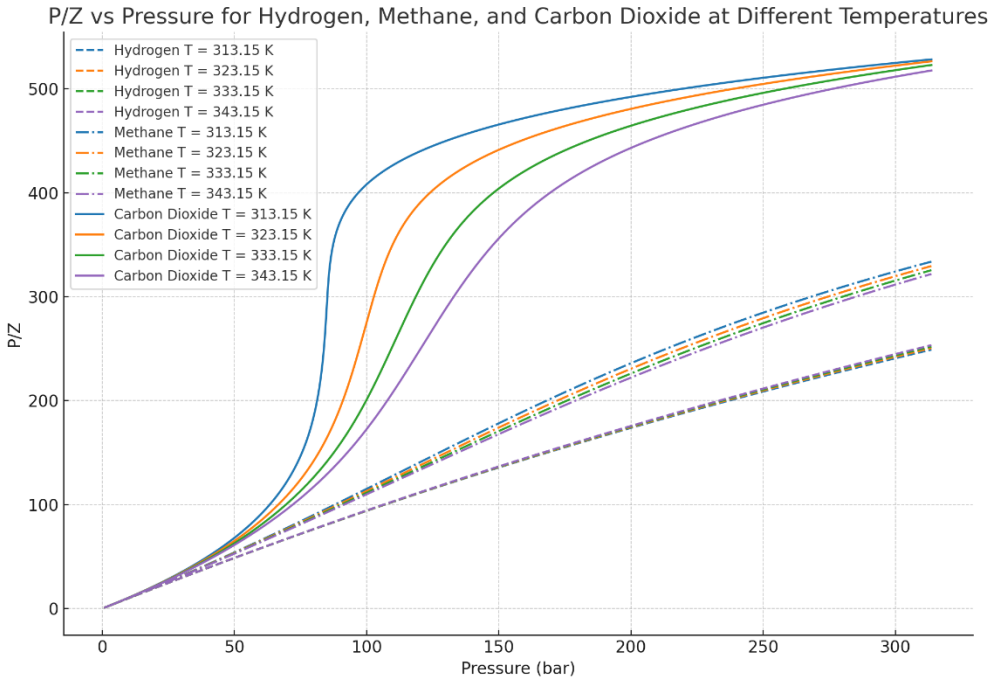

Figure 2. P/Z vs Pressure for Hydrogen, Methane, and Carbon Dioxide.

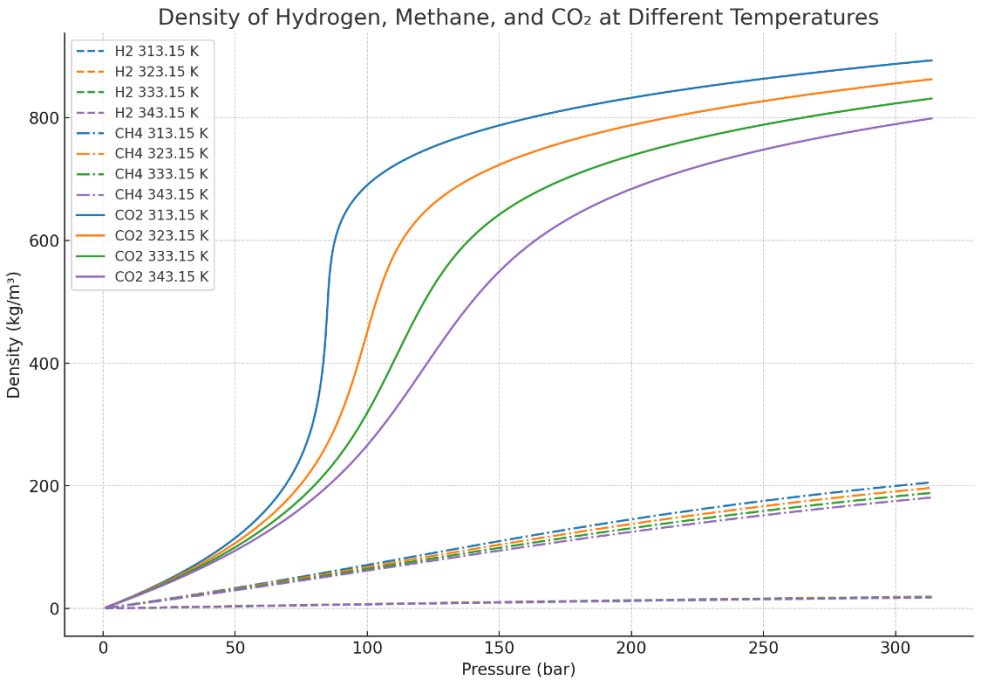

Figure 3. Density vs Pressure for Hydrogen, Methane, and Carbon Dioxide.

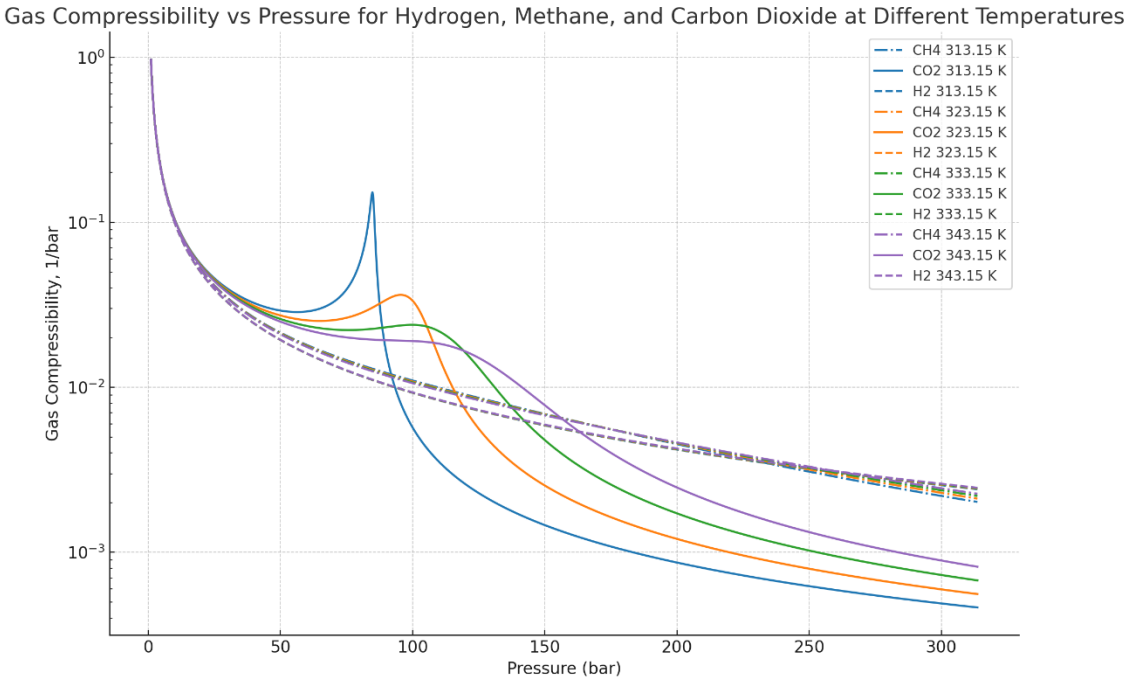

Figure 4. Gas Compressibility vs Pressure for Hydrogen, Methane, and Carbon Dioxide.

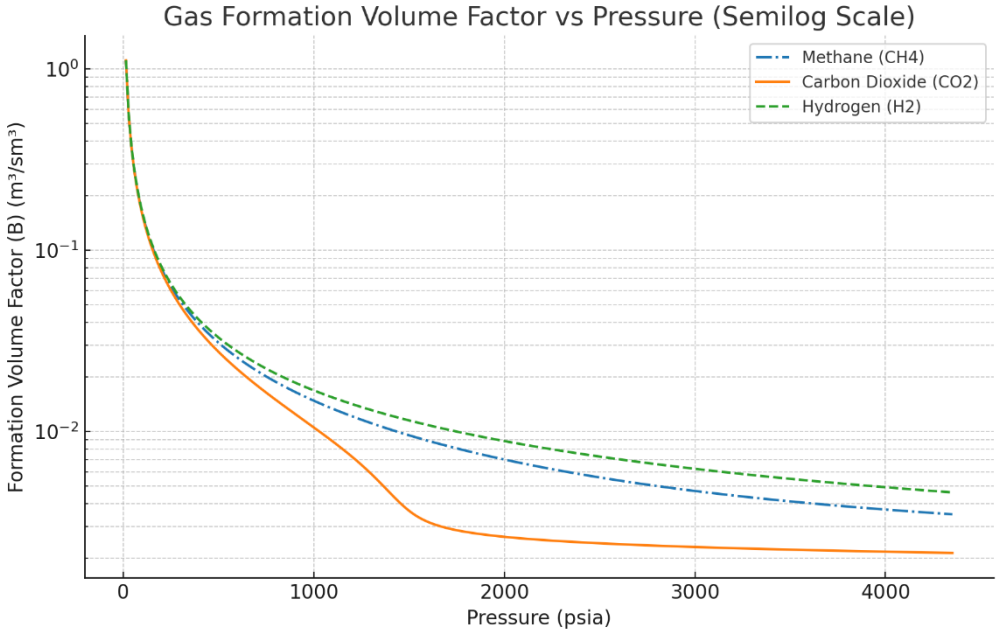

Figure 5. Gas Formation Volume Factor vs Pressure for Hydrogen, Methane, and Carbon Dioxide.

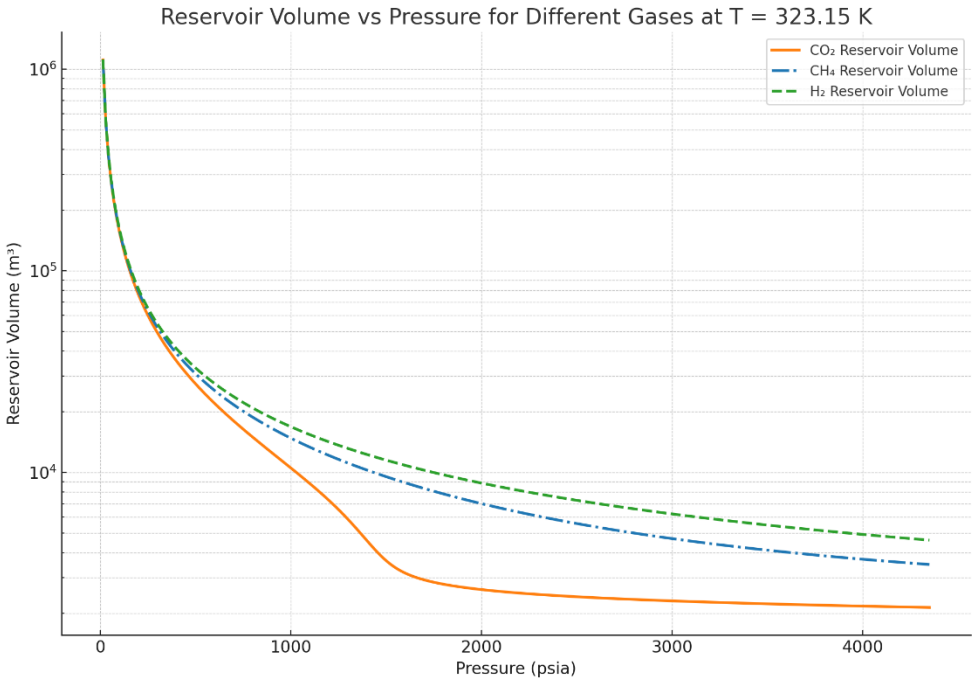

Figure 6. Reservoir Volume vs Pressure for Hydrogen, Methane, and Carbon Dioxide.

Conclusion

To conclude, in this study the comparison of three gases was calculated and analyzed under reservoir conditions. From the results obtained, it was found that all three gases showed distinct behavior due to their variations in critical properties and molecular weights. The results indicate that carbon dioxide has a much different behavior when compared with methane and hydrogen. Especially the compressibility behavior of carbon dioxide is quite counterintuitive.

The results of this investigation shed important light on how these gasses behave when stored in subterranean formations. When planning and running subterranean gas storage facilities, these variations in physical behaviour must be carefully considered. Optimizing injection and withdrawal procedures, reducing energy losses, and guaranteeing storage site stability are all made possible by an understanding of the basic gas properties under reservoir conditions. This study also emphasizes how crucial it is to choose the right storage conditions depending on the characteristics of the gas to avoid unanticipated reservoir reactions that could compromise operational effectiveness and safety.

Overall, the comparison of carbon dioxide, hydrogen, and methane under reservoir conditions offers vital data for applications involving subterranean storage, enhancing energy security and advancing more environmentally friendly energy sources.

A Machine Learning Approach to Forecast Production Performance of Hydraulically Fractured Horizontal Wells in Tight Oil Sandstone Reservoirs

Ferhat Yurttagül[a], Burak Kulga[a]

[a] Istanbul Technical University, Petroleum and Natural Gas Engineering, Reservoir Engineering, Turkey
yurttagul16@itu.edu.tr

Keywords: Artificial Neural Network (ANN), Hydraulic Fracturing, Tight Oil Sandstone Reservoirs, Production Forecasting, Numerical Reservoir Simulation.

Aim

This study targets tight oil sandstone reservoirs with hydraulically fractured horizontal wells, where permeability can be as low as 0.001 mD (Boak & Kleinberg, 2020) and porosity can be around 4% (Yao, et al., 2013), causing some difficulties in production. Hydraulic fracturing and horizontal well technologies complement each other and are generally employed together to increase hydrocarbon production in tight formations. However, the efficiency rate of these approaches varies depending on the reservoir characteristics and it needs to be investigated in detail. The main objective of this study is to develop an artificial neural network (ANN) model that can predict the production performance of a hydraulically fractured horizontal well in a tight oil sands reservoir with near-accuracy and rapidity. In developing our final machine learning (ML) tool, a large-scale simulation dataset needs to be created using a commercial software program and necessary information such as oil production rate, total production time, and cumulative production data needs to be obtained. This will enable the construction and training of a well-designed ANN model. Since traditional numerical simulation methods are labor-intensive, time-consuming, involve extensive numerical calculations, and are prone to convergence problems, this study provides a solution to reduce computation time to a fraction of a second by using a well-developed ML tool. The final ML tool is considered to be a practical and rapid decision support tool that helps reservoir engineers predict the production performance of hydraulically fractured horizontal wells in tight oil sandstone reservoirs with an error rate of less than 8%.

Material and Method

Reservoir data (porosity, permeability, number of fractures, etc.) to be used in commercial simulation software (CMG, 2015) were found from the literature and minimum-maximum limits were determined for random assignment in MATLAB. First, the parameters of 5000 different scenarios were randomly generated in MATLAB within specified ranges. An example 5-fractured reservoir drawing, along with fracture and well location layout, is shown in Figure 1. In the next step, simulation files were created in a suitable format for simulator with these parameters. Then, 5000 simulations were run and production data were extracted. Some data is needed to be cleaned due to convergence errors of the commercial simulator; thus, the number of available datasets is reduced to 3369. As a result of the code written to collect the data and organize it for the ANN model, input and output data were compiled. Input data are the parameters collected to be used in the simulation and are listed in Table 1. The data were generated based on literature. For instance; fracture length (400-1200 ft) is based on (Ostojic, Rezaee, & Bahrami, 2012), permeability (0.001-0.1 mD) is based on (Boak & Kleinberg, 2020), oil saturation (60-85%) and porosity (4-16%) are based on (Yao, et al., 2013). Output data (15) was created by dividing the time from the end of production at a fixed production rate until the minimum production rate was reached into twelve equal parts. The first and last of the time data and all of the rate data (13) were taken. A large number of randomly generated parameters, combined with many extreme conditions, led to high error rates in some data sets. These data sets were identified and cleaned, and the final data set number was reduced to 3369. Finally, the ANN model was trained and tested using MATLAB, and performance analyses were performed. The structure of the model is a neural network consisting of three hidden layers in the form of 40-35-30. The schematic view of the model is shown in Figure 2, and the symbolic representation of the outputs is shown on a sample production-time chart in Figure 3.

While creating the model, the data was divided into three as training (70%), validation (15%) and test (15%). Early stopping and dropout methods were applied to prevent overfitting during the training phase. The accuracy of the model was measured by examining the mean percentage errors and compared with traditional simulation methods.

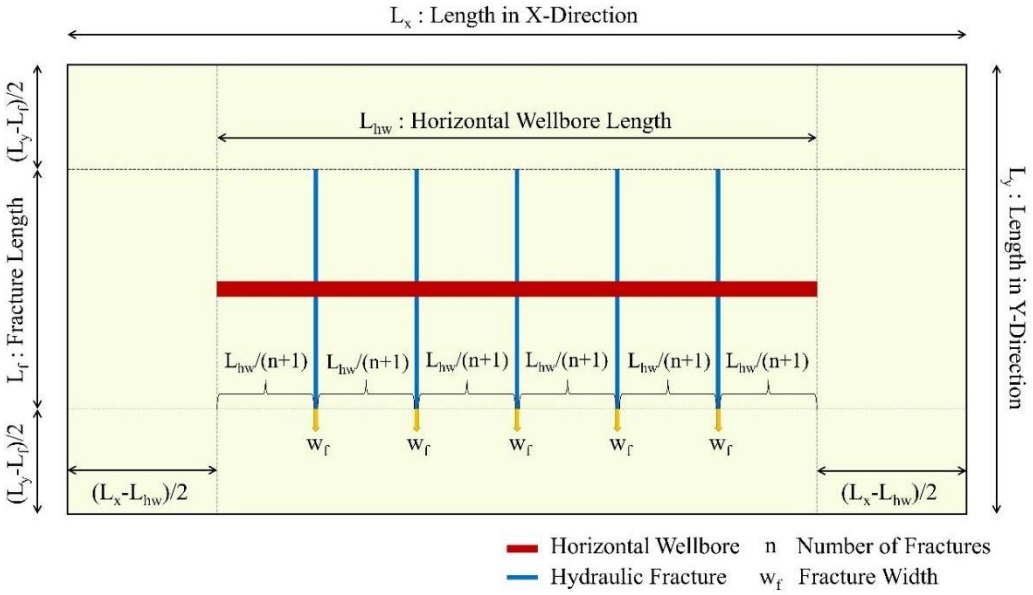

Figure 1. Top view of a sample numerical reservoir model with 5 transverse hydraulic fractures.

Table 1. Ranges of input parameters used in generating training data.

Parameters	Minimum Value	Maximum Value	Unit
Number of Fractures	5	30	-
Horizontal Wellbore Length	1000	5000	ft
Length of Fracture	400	1200	ft
Thickness	100	350	ft
Permeability	0.001	0.1	mD
Porosity	4	16	%
Initial Temperature	150	250	°F
Initial Pressure	3500	7500	psi

Permeability of Fracture	2000	15000	mD
Specific Gravity of Gas	0.65	0.9	-
API	40	50	-
Solution Gas/Oil Ratio	200	2000	scf/STB
Flowrate Specified	400	1200	STB/D
Minimum Oil Rate	50	100	STB/D
Oil Saturation	60	85	%
Water Saturation	15	30	%
Residual Oil Saturation	0.15	0.35	-
Corey Exponents	1	3	-

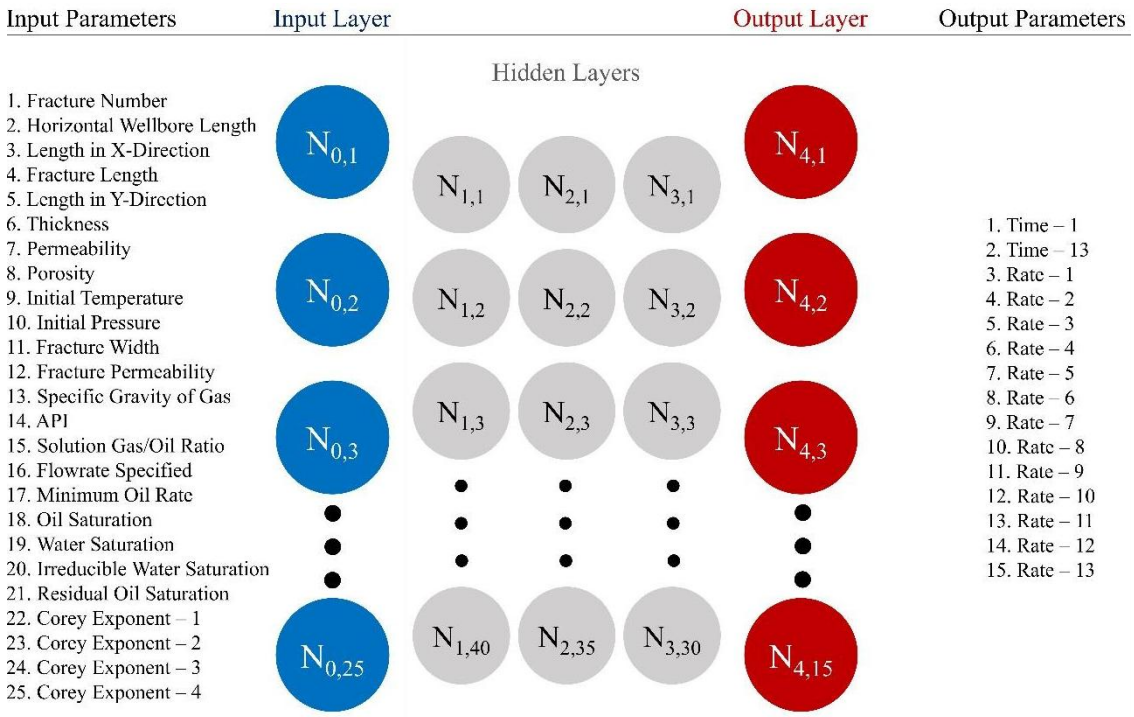

Figure 2. Schematic view of the ANN model.

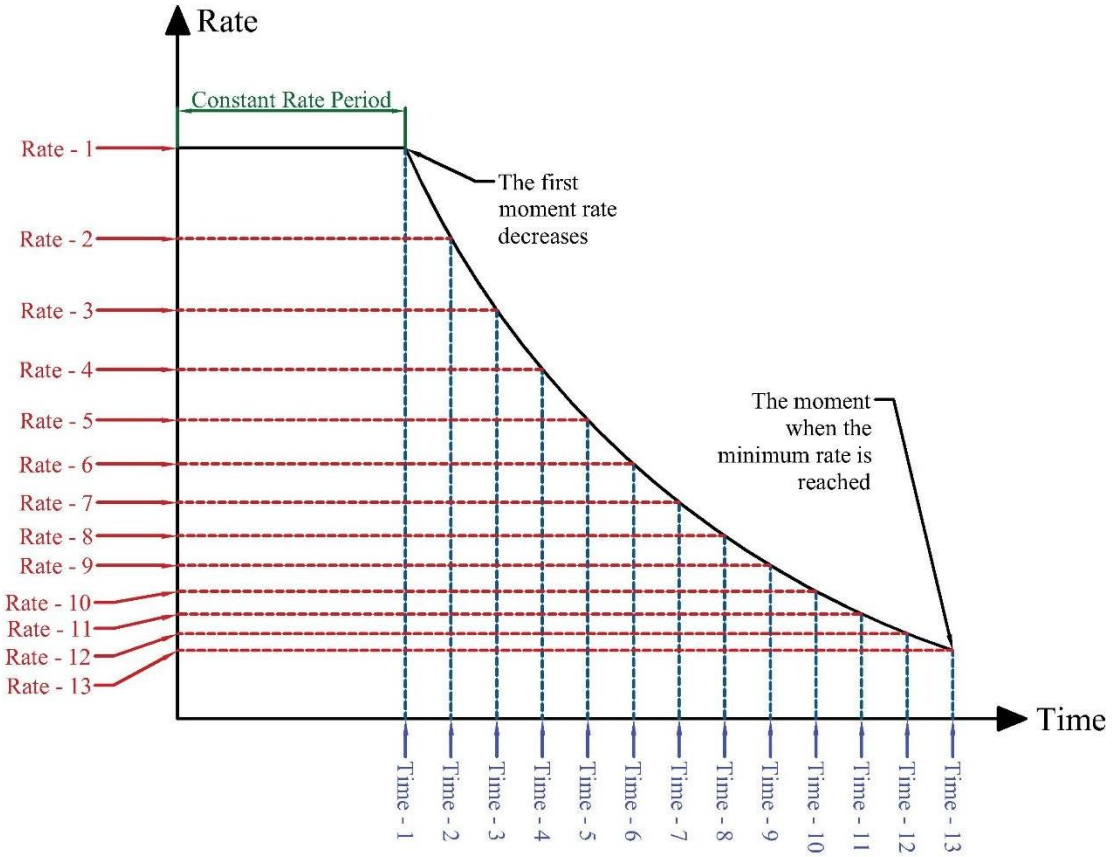

Figure 3. Display of outputs on a sample production graph.

Findings

The results obtained from the training and testing phases showed that the model was able to successfully predict production performances under different reservoir conditions. The average error rate was below 8%, which proved the high accuracy of the model. The model was particularly successful in predicting oil production rates (average error 4-5%). Moreover, error rates down to 1% towards the minimum rate levels (Figure 3) balance Time - 1 and Time - 13 errors which has the most error percentage (~%20). The average error percentages are shown in Figure 4. As can be seen, there is a higher error rate in the first- and last-time data compared to the others. This is due to the combination of some randomly generated extreme parameters. However, the success of estimating the rate data compensate the error rate of time data, and provide overall average error is 8%. The production graph of an example scenario was plotted with both ANN and simulation and compared (Figure 5). This method significantly reduced the production performance analysis time compared to traditional simulation methods and provided consistent predictions under different reservoir conditions. This model has become a useful tool for reservoir engineers in fracture design and production planning.

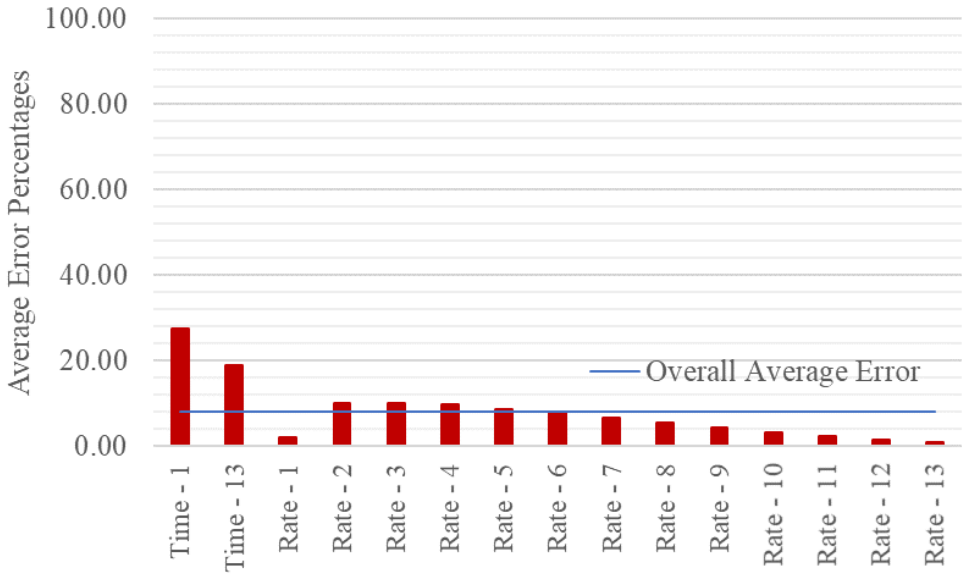

Figure 4. Average error percentages for time and rate prediction.

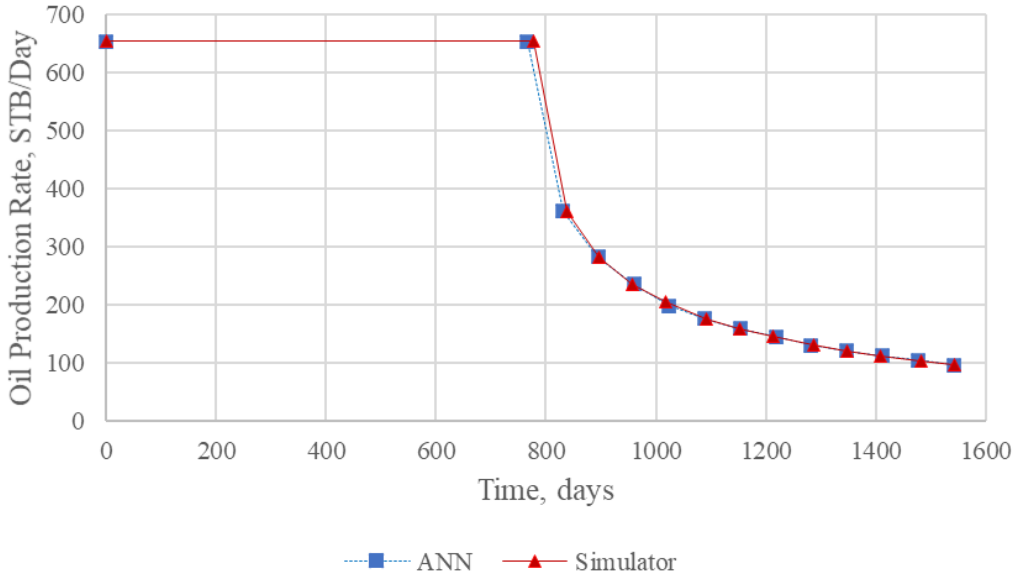

Figure 5. Comparison of production data of a sample scenario from ANN and simulator.

This example is a scenario consisting of random parameters created for ANN model. The input data of this scenario is listed in Table 2, and the error percentages of the outputs according to the simulation data are listed in Table 3. The overall average error for time data of this highly successful scenario is 1.11%, and the overall average error for rate data is 0.503%.

Table 2. Input parameters of the sample scenario.

Parameters	Value	Unit	Parameters	Value	Unit
Number of Fractures	26	-	API	46	-

Table 3. Error percentages of sample scenario data compared to the simulator.

Error Percentages				
Time - 1	**Time - 13**	**Rate - 1**	**Rate - 2**	**Rate - 3**
1.477	0.741	0.421	1.117	0.923
Rate - 4	**Rate - 5**	**Rate - 6**	**Rate - 7**	**Rate - 8**
0.882	0.895	0.673	0.554	0.329
Rate - 9	**Rate - 10**	**Rate - 11**	**Rate - 12**	**Rate - 13**
0.357	0.246	0.103	0.042	0.002
Overall Time Error: 1.11% - Overall Rate Error: 0.503%				

Conclusion

This research was focused on building an ANN model that can approximate the productivity of horizontally fractured tight oil sandstone reservoirs. Using commercial software, a set of simulations was developed for specific input constraints such as porosity, permeability, fracture characteristics, and reservoir condition. In turn, oil output parameters incorporated the oil production rate, total production time, and cumulative oil production volume. The ANN model was trained and validated using 3369 cleaned datasets and achieved an average rate of error below 8% on all datasets. It was evident that the model was able to rapidly and accurately estimate production performance which decreased computational cost when juxtaposed with brute force numerical simulations. The ANN's ability to increase the efficiency of decision-making for reservoir engineers in production forecasting and fracture optimization makes this approach compelling.

Dynamo Process in Proto-Neutron Stars

İrem Bakır[a], Kazım Yavuz Ekşi[a]

[a] Istanbul Technical University, Physics Engineering Department, Physics Engineering Program, Türkiye
bakirir@itu.edu.tr

Keywords: Dynamo, Magnetic Fields, Magnetohydrodynamics (MHD), Stars: Magnetars, Stars: Neutron.

Aim

The primary aim of this study is to address the seemingly contradictory trends in the formation of magnetars. Magnetars, a subset of young neutron stars, possess extremely strong magnetic fields. The conventional models explaining the origin of such intense magnetic fields often require very specific and extreme conditions. These conditions appear incompatible with the observed birth rates of magnetars, which are comparable to the rates of core-collapse supernovae. To reconcile this discrepancy, we propose that both pulsars and magnetars undergo a dynamo process during the proto-neutron star (PNS) stage. Central compact objects (CCOs) are presented as the exception, not participating in the dynamo process.

Material and Method

To explore this hypothesis, we employ a shear-driven dynamo model for the generation of magnetic fields in PNSs. This model is an adaptation of a one-dimensional dynamo model initially proposed by Wickramasinghe et al. (2014) for magnetic field generation in white dwarf mergers. The original model is extended to incorporate the unique parameters and evolutionary characteristics of PNSs, specifically addressing the effects of the changing radius and gravitational mass of the PNS. The dynamo model describes how kinetic energy from the motion of a conductive fluid can be converted into magnetic energy. In the context of a PNS, this involves the interaction of differential rotation (where different parts of the star rotate at different speeds) and convection (the rising and falling of hot and cold material). The model is rooted in the principles of magnetohydrodynamics (MHD), which governs the dynamics of electrically conducting fluids in the presence of magnetic fields. The fundamental equation used is the magnetic induction equation. We apply the mean-field dynamo model, where large-scale magnetic fields are generated by small-scale turbulent flow. This approach simplifies the complex MHD equations by separating the fields into mean and fluctuating components. The evolution of the toroidal (B_φ) and poloidal (B_p) magnetic field components are described using reduced dynamical equations, derived from the mean-field dynamo equations. These equations account for the generation and diffusion of the magnetic fields, as well as the effects of the shrinking radius of the PNS. The model also incorporates criteria for the stability of the magnetic fields. These criteria, based on the ratio of magnetic energy to gravitational potential energy, determine whether the fields will decay due to instabilities. The model considers the transport of angular momentum within the PNS, which affects the shear rate that drives the dynamo process. This includes the effects of viscous processes, magnetorotational instability (MRI), and convection. The model incorporates the changing radius and gravitational mass of the PNS as it evolves, using exponential decay functions based on data from Camelio et al. (2017). The evolution of the spin angular velocity is also considered, primarily focusing on the effects of the changing moment of inertia. The model equations are solved numerically using the Runge-Kutta method. The initial parameters are set to be representative of a PNS, and the implications of varying these parameters are studied.

Findings

The numerical simulations reveal several key dependencies and evolutionary paths for PNSs. Depending on the initial rotational period at the onset of its development, a PNS can transform into a magnetar, a low-B magnetar, or a normal pulsar. The dynamo process amplifies the initial magnetic fields inherited from the progenitor star. The toroidal field grows until it reaches a saturation value, while the poloidal field also increases and approaches its saturation value. The shear rate, which drives the dynamo process, reaches a maximum value during the contraction phase of the PNS and then gradually declines due to the increasing internal viscosity. The saturation values of the magnetic fields are sensitive to several parameters:

Higher initial shear rates lead to significantly enhanced saturation values of the magnetic fields.
The saturation value of the poloidal field exhibits a positive correlation with α, while the saturation value of the toroidal field increases less steeply with α.
As the buoyancy factor increases, the poloidal field experiences an increment; however, for a > 0.5, the rate of this increase becomes slower. The toroidal field increases with the buoyancy factor for a < 1.7, whereas for a > 1.7, it decreases with a.
Both fields exhibit an increasing trend with the initial mass of the PNS, but the enhancement in the saturated toroidal field strength is comparatively less pronounced than that observed in the saturated poloidal field strength.
When the PNS undergoes a dynamo mechanism with a larger initial radius, the magnetic fields reach higher intensities at the point of saturation.
The saturated fields show only a minimal dependence on Bp,0, and Bφ,0 has nearly no influence on them. In short, the initial values of the poloidal and toroidal fields are not important in setting the final values of the fields in the dynamo process.
A PNS transitions into a magnetar following the dynamo process with a rotational period of P ∼ 2−3 ms and magnetic field components up to Bp ∼ 1014 G, Bφ ∼ 1016 G. It is also observed that it has the potential to ultimately become a high-magnetic field pulsar, exhibiting a strong toroidal magnetic field ∼ 1015 G.
The saturation values of the fields increase as the average density grows, up to a certain value. However, after exceeding this threshold, the fields begin to show an inverse relationship and decrease as the average density increases.
The dynamo process is terminated smoothly by increasing the viscosity after 45 seconds, representing the cooling and crust formation of the PNS.
Central compact objects (CCOs) are suggested not to participate in the dynamo process, as their magnetic fields can be explained by flux conservation alone. Their slower initial periods (P0 ≃ 100 milliseconds) are unlikely to trigger dynamo action.

Conclusion

The study concludes that the α − Ω dynamo process during the PNS phase can explain the observed variety of neutron stars, including magnetars, low-B magnetars, normal pulsars, and high-field pulsars. The initial conditions of convective flow and rotation rate, as well as internal structural parameters, play a crucial role in determining the final magnetic field strengths. PNSs with very rapid rotation rates are more likely to become magnetars, while those with more moderate spin rates can evolve into high-magnetic field pulsars or normal pulsars. The model suggests that normal pulsars with Bp ≳ 1011 G might also exhibit Bφ ∼ 1015 G, which is supported by the existence of low-magnetic field magnetars and magnetar behavior observed from some rotationally-powered pulsars. We propose that all neutron stars may have small-scale fields, but the dynamo action organizes these fields into dipole and toroidal fields. The relatively strong small-scale fields of CCOs could be attributed to the fact that they have not undergone a dynamo process

Keywords: Neutrino Physics, Beyond Standard Model, Non-Standard Interactions.

Aim

Neutrino interactions with matter have long been considered promising avenues for uncovering new physics phenomena. Coherent Elastic Neutrino-Nucleus Scattering (CEνNS), described by Eq. (1), serves as a crucial channel for testing the Standard Model (SM) of electroweak theory at low energies and opens up numerous opportunities to expand our understanding of physics. It also provides a unique probe for exploring physics beyond the SM (BSM). Particularly, probing non-standard interactions (NSI) with neutrino-nucleus scattering has been a subject of intense interest in recent years.

$$\nu_\alpha\left(\underline{\nu}_\alpha\right) + A(Z,N) \rightarrow \nu_\alpha\left(\underline{\nu}_\alpha\right) + A(Z,N) \ , \tag{1}$$

These studies have investigated various NSI scenarios, such as those based on simplified models focusing on light mediators, model-independent approaches effective in the high mediator mass regime, and exotic neutral current interactions, along with experimental observables and implications for neutrino flavor physics and astrophysical processes.

This work aims to provide comprehensive NSI analysis for accelerator-based (COHERENT) and reactor-based (TEXONO) CEνNS experiments and to present constraints on the relevant parameters using recent TEXONO pPC-Ge (2024), TEXONO nPC-Ge (2016), and COHERENT CsI and LAr data for comparison. All possible Lorentz-invariant interaction types—vector (V), axialvector (A), scalar (S), pseudoscalar (P), and tensor (T)—are investigated within both simplified model and model-independent approaches, offering a broad and systematic exploration of new physics scenarios.

Material and Method

CEνNS, which involves neutral-current (NC) interactions between neutrinos and quarks within an atomic nucleus, is a tree-level process described within the SM. In this process, neutrinos interact coherently with a nucleus through neutral boson exchange at low energies, as illustrated in Figure 1.

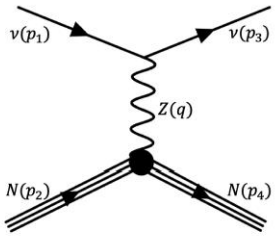

Figure 1: A tree-level Feynman-diagram of CEνNS process.

The process gives the largest cross-section compared to other neutrino interactions so far. The cross-section is enhanced by the square of the neutron number, as demonstrated in Equations (2), (3), and (4), making heavy nuclei ideal targets. Specifically, Eq. (2) defines the cross-section,

$$\left[\frac{d\sigma}{dT_N}\right]_{SM} = \frac{G_F^2 m_N}{4\pi}\left(Q_{SM_V}^2 K_V + Q_{SM_A}^2 K_A\right) \quad (2)$$

Eq. (3) describes the kinematic terms,

$$K_V = 1 - \frac{m_N T_N}{2E_\nu^2} - \frac{T_N}{E_\nu} + \frac{T_N^2}{2E_\nu^2} \quad , \quad K_A = 1 + \frac{m_N T_N}{2E_\nu^2} - \frac{T_N}{E_\nu} + \frac{T_N^2}{2E_\nu^2} \quad (3)$$

and Eq. (4) describes the vector and axialvector components of the SM weak charge,

$$Q_{SM_V} = [Z(1 - 4\theta_W) - N]\, F_V(q^2) \quad , \quad Q_{SM_A}^2 = \frac{8\pi}{2J+1}\left(\Delta_u^p - \Delta_d^p\right)^2 S_{11}^T(q^2), \quad (4)$$

where, θ_W is the Weinberg angle, J is the total angular momentum of the nucleus, $F_V(q^2)$ is the nuclear form factor, and $S_{11}^T(q^2)$ represents the spin structure functions.

Detecting such process is challenging due to the nuclear recoil energy being confined to the low keV range. This challenging objective was finally accomplished with the advancement of accelerator neutrino technology in 2017 by the COHERENT Collaboration, a few decades after its initial formulation. Since the first detection of CEνNS, numerous efforts, including those by the TEXONO Collaboration, have been made to detect the process and improve our understanding of this phenomenon.

To explore potential deviations from the Standard Model (SM), we consider new physics scenarios within the framework of simplified models involving light mediators (V, A, S, P, and T). The corresponding differential cross-sections for these new mediators are given as,

$$\begin{aligned}
\left[\frac{d\sigma}{dT_N}\right]_V &= \frac{G_F^2 m_N}{4\pi}\left(\frac{2Q_V^2}{\left(m_V^2+2m_N T_N\right)^2} + \frac{2\sqrt{2}\, Q_V Q_{SM_V}}{m_V^2+2m_N T_N}\right)|F_V(q^2)|^2\, K_V\,, \\
\left[\frac{d\sigma}{dT_N}\right]_A &= \frac{G_F^2 m_N}{4\pi}\left(\frac{2Q_A^2}{\left(m_A^2+2m_N T_N\right)^2}\right) S_{00}^T(q^2)\, K_A\,, \\
\left[\frac{d\sigma}{dT_N}\right]_S &= \frac{G_F^2 m_N}{4\pi}\frac{Q_S^2}{\left(m_S^2+2m_N T_N\right)^2}\, |F_S(q^2)|^2\, K_S\,, \\
\left[\frac{d\sigma}{dT_N}\right]_P &= \frac{G_F^2 m_N}{4\pi}\frac{Q_P^2}{\left(m_P^2+2m_N T_N\right)^2}\, |F_P(q^2)|^2\, K_P\,, \\
\left[\frac{d\sigma}{dT_N}\right]_T &= \frac{G_F^2 m_N}{4\pi}\frac{Q_T^2}{\left(m_T^2+2m_N T_N\right)^2}\left[8S_{00}^T(q^2)\, K_V + 16S_{00}^L(q^2)\left(1 - \frac{T_N}{E_\nu}\right)\right],
\end{aligned} \quad (5)$$

where $K_S = \frac{m_N T_N}{E_\nu^2} + \frac{T_N^2}{2E_\nu}$ and $K_P = \frac{T_N^2}{2E_\nu^2}$. The nuclear form factors $|F_X(q^2)|^2$ associated with each interaction type are modeled using the ***Helm form factor*** approach. The axialvector and tensor cases correspond to spin-dependent interactions, and their nuclear structure captured by ***spin structure functions,*** $S_{00}^T(q^2)$ and $S_{00}^L(q^2)$, which correspond to transverse and longitudinal spin responses,respectively. In Eq. (5), new charges are defined as $Q_X = g_{X\nu} g_{XN}/G_F$, where $g_{X\nu}$ and g_{XN} denote the couplings of new mediators to neutrino and nucleus, respectively. Here, $X = V, A, S, P, and\ T$ indicates the interaction type.

To investigate NSI in a model-independent framework, the new couplings defined in the simplified model can be converted to epsilon parameter space, usually denoted as $\varepsilon_{\alpha\beta}^{qX}$, using the relation

$$\varepsilon_{\alpha\beta}^{qX} \simeq \frac{g_{X\nu} g_{XN}}{\sqrt{2} G_F m_X^2} \quad . \quad (6)$$

This relation allows the differential cross-sections for light mediator models, given in Eq. (5), to be reformulated in terms of model-independent NSI parameters.

Our analysis uses data from both COHERENT and TEXONO experiments. The COHERENT experiment at the Spallation Neutron Source (SNS) detects neutrinos from stopped-pion decays, utilizing CsI(Na) and liquid argon (LAr) detectors. These experiments operate at higher neutrino energies and larger momentum transfer (q^2) regime

and allow interactions with multiple neutrino flavors (ν_μ, $\underline{\nu}_\mu$, ν_e). On the other hand, the TEXONO Collaboration is conducting an intensive research program on low-energy neutrino physics (< 10 MeV) at the Kuo-Sheng Nuclear Power Plant in Taiwan. In 2016, the collaboration conducted an experiment using a high-purity n-type point-contact germanium (nPC-Ge) detector cooled by liquid nitrogen with a threshold energy of 300 eV. In 2024, they upgraded experiment facilities with an advanced p-type point-contact germanium (pPC-Ge) detector, which has an improved threshold energy of 200 eV. TEXONO experiment detects low-energy electron antineutrinos ($\underline{\nu}_e$), reducing flux uncertainties associated with the presence of multiple neutrino flavors in accelerator-based experiments.

In this work, we employ a minimum$-\chi^2$ approach to derive NSI constraints from event rate predictions, considering both simplified model and model-independent frameworks. For all five interaction types (V, A, S, P, and T), we explore mass-coupling ($M_X - g_X$) parameter space in the simplified model, while in the model-independent case, we investigate the corresponding flavor-conserving (FC) and flavor-violating (FV) $\varepsilon_{\alpha\beta}^{qX}$ −parameter spaces for vector-type interaction.

Findings

Our results present the first NSI analysis of the TEXONO experiment and highlight the complementary nature of reactor and accelerator neutrino experiments in probing NSI. COHERENT experiments generally provide stronger bounds due to their higher neutrino energy range and multiple neutrino flavors, especially for FV NSI (as shown in Figure 2), while TEXONO experiment with pPC-Ge (2024) data offers competitive constraints for FC scenarios (as seen in Figure 3), and light mediator models (as seen in Figure 4) thanks to its sensitivity to low-energy neutrinos and reduced flux uncertainties.

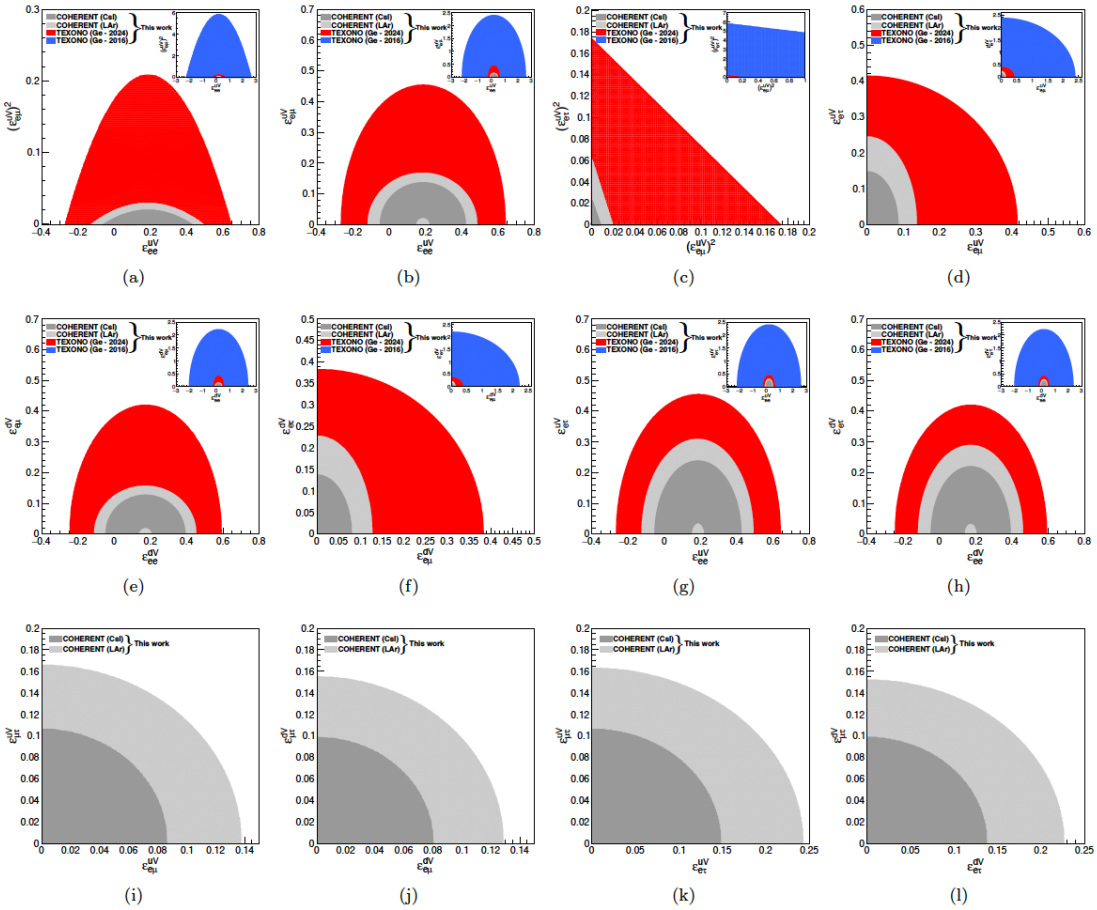

Figure 2: The 90% CL allowed region in the following parameter spaces for vector-type NSI in the FV case: $\varepsilon_{ee}^{uV} - \left(\varepsilon_{e\mu}^{uV}\right)^2$, $\varepsilon_{ee}^{uV} - \varepsilon_{e\mu}^{uV}$, $\left(\varepsilon_{e\mu}^{uV}\right)^2 - (\varepsilon_{e\tau}^{uV})^2$, $\varepsilon_{e\mu}^{uV} - \varepsilon_{e\tau}^{uV}$, $\varepsilon_{ee}^{dV} - \varepsilon_{e\mu}^{dV}$, $\varepsilon_{e\mu}^{dV} - \varepsilon_{e\tau}^{dV}$, $\varepsilon_{ee}^{uV} - \varepsilon_{e\tau}^{uV}$, $\varepsilon_{ee}^{dV} - \varepsilon_{e\tau}^{dV}$, $\varepsilon_{e\mu}^{uV} - \varepsilon_{\mu\tau}^{uV}$, $\varepsilon_{e\mu}^{dV} - \varepsilon_{\mu\tau}^{dV}$, $\varepsilon_{e\tau}^{uV} - \varepsilon_{\mu\tau}^{uV}$, and $\varepsilon_{e\tau}^{dV} - \varepsilon_{\mu\tau}^{dV}$.

TEXONO pPC-Ge (2024) data shows significant improvements over the previous TEXONO nPC-Ge (2016) data, as shown in Figures 2a-h, 3a, and 4a-e. In Figures 2i-l and 3b-d, bounds are only provided for the COHERENT experiment, which benefits from a multiple-flavor neutrino flux. In contrast, no limits can be provided for TEXONO in these scenarios due to its single-type neutrino flavor.

For light mediators in simplified model, the enhanced sensitivity of TEXONO pPC-Ge strengthens constraints in the low-momentum transfer region, and yields results competitive with those of other reactor neutrino experiments, as seen in Figures 4a and 4c. This is crucial for detecting potential new light bosons, which could mediate novel interactions beyond the SM. The new constraints from TEXONO pPC-Ge are comparable to those from COHERENT in most cases and even surpass them in scalar case in Figure 4c.

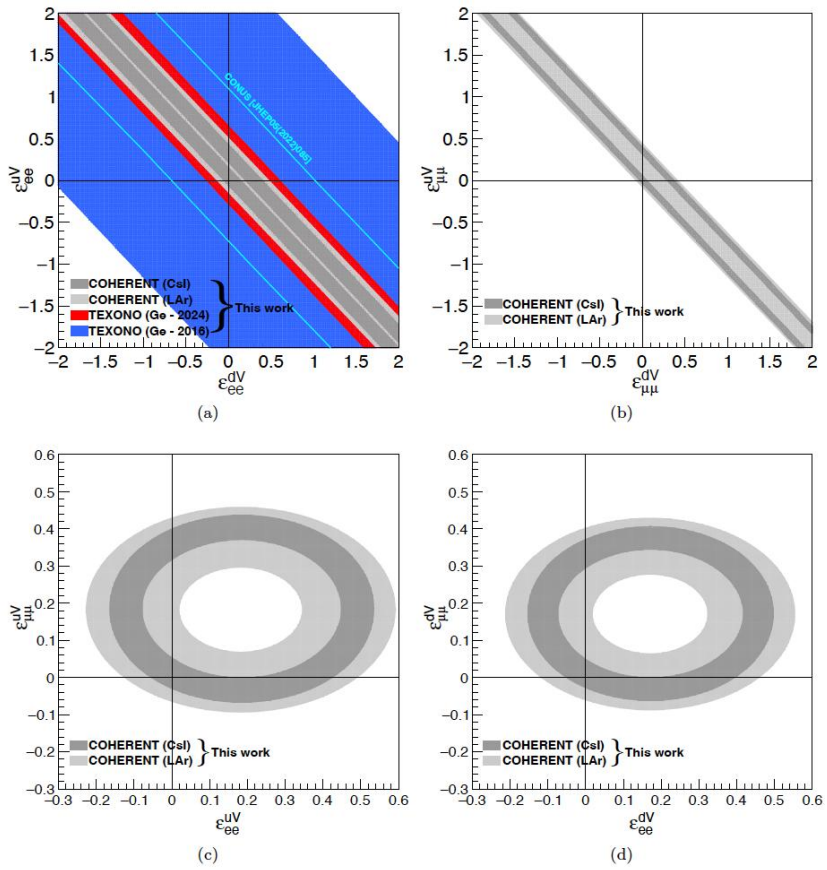

Figure 3: The 90% CL allowed region in the $\varepsilon_{ee}^{dV} - \varepsilon_{ee}^{uV}$, $\varepsilon_{\mu\mu}^{dV} - \varepsilon_{\mu\mu}^{uV}$, $\varepsilon_{ee}^{uV} - \varepsilon_{\mu\mu}^{uV}$, and $\varepsilon_{ee}^{dV} - \varepsilon_{\mu\mu}^{dV}$ parameter spaces for vector-type NSI in the FC case.

Among the five interaction types, the pseudoscalar case (Figure 4d) yields the weakest constraints due to its cross-section being heavily suppressed by nuclear recoil energy. Furthermore, axialvector and tensor interactions (Figures 4b and 4e) are also less constrained, as they are spin-dependent interactions and have contributions only from unpaired nucleons in the nucleus. In contrast vector and scalar type interactions (Figures 4a and 4c) are the most tightly constrained, with cross-sections scaling with the square of neutron number.

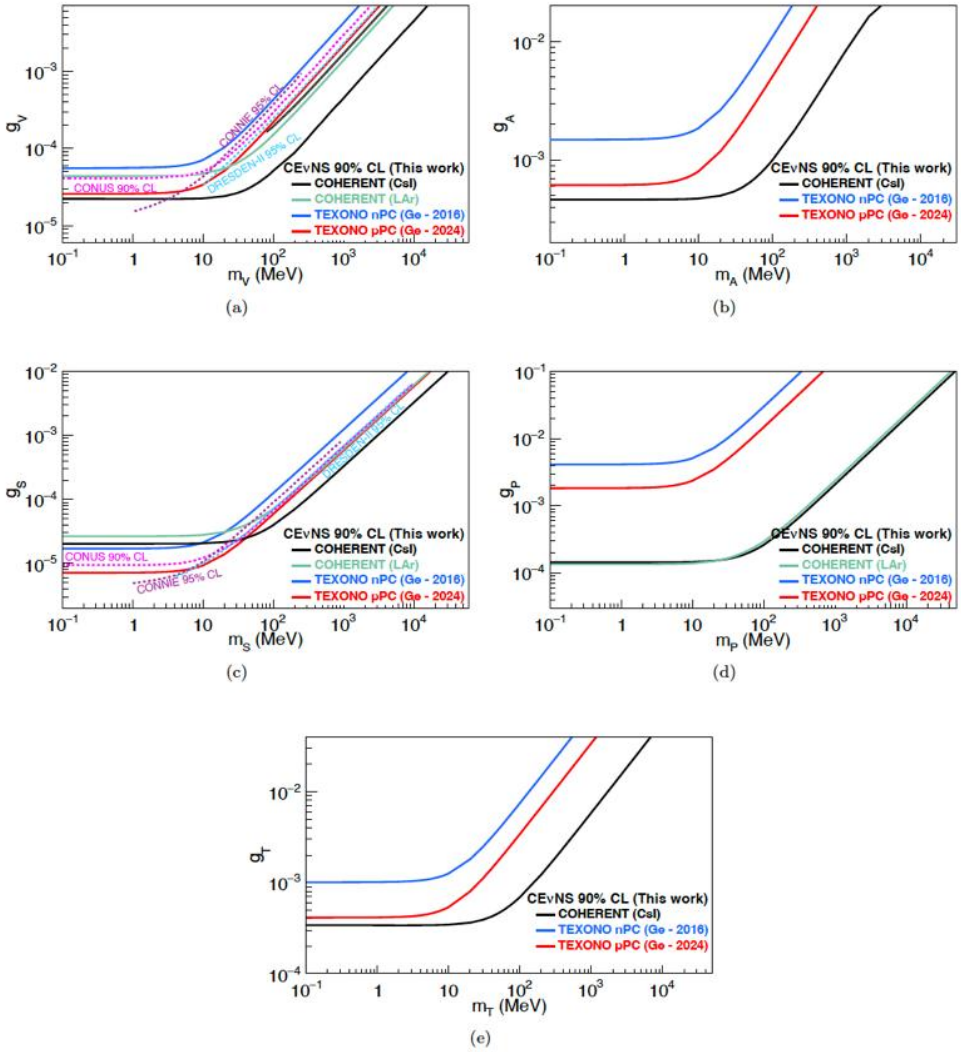

Figure 4: Bounds at 90% CL are presented for (a) vector, (b) axialvector, (c) scalar, (d) pseudoscalar, and (e) tensor mediator masses and couplings, derived from the TEXONO nPC-Ge and pPC-Ge, and COHERENT CsI(Na) and LAr experiments.

These findings confirm that both experimental approaches contribute uniquely to probing different NSI parameter spaces, reinforcing the need for complementary experimental strategies.

Conclusion

CEvNS has progressed from a theoretical concept to a measurable phenomenon, and its observation has opened a broad research program exploring neutrino properties, dark matter detection, nuclear structure, astrophysics, and physics beyond the Standard Model (BSM). In this context, our work provide valuable insights into the interplay between different NSI interaction types and experimental conditions. These findings highlight the critical role of future CEνNS experiments in refining NSI constraints and advancing our understanding of neutrino interactions. Advancements in detector technology, lower energy thresholds, and increased event statistics will further improve sensitivity to NSI effects. Future experiments with enhanced capabilities, including next-generation neutrino detectors and dark matter experiments, will provide additional opportunities to test BSM physics. As part of a global effort, TEXONO is emerging as a competitive player in the CEvNS landscape, with strong potential to lead future constraints, especially in the reactor neutrino sector. Our study contributes to these efforts by establishing a robust framework for NSI analysis using both simplified model and model-independent approaches.

Investigation of Structural and Optoelectronic Properties of metal/ZnS Junction under Density Functional Theory (DFT)

Haris Kulosmanovic[a], Murat Çalışkan[b]

[a] Yildiz Technical University, Graduate School of Science and Engineering, Physics MSc Program, Türkiye

haris.kulosmanovic@std.yildiz.edu.tr

Keywords: Density Functional Theory (DFT), Metal/ZnS Junction, Schottky Diodes, Optimization.

The combination of metal and semiconductor (metal/semiconductor junction) is one of the fundamental methods for creating active electronic components known as Schottky diodes. These diodes are renowned for their fast-switching speed and significantly lower forward voltage drop compared to conventional silicon diodes. Although it was developed quite early, even in the very beginnings of semiconductor technology, not enough material can be found in the available literature that explains what exactly happens during the formation of this junction at the quantum level. In order to better understand how the charges within the materials used in this work behave, we approached the investigation of individual properties of the materials and heterostructures composed of them under Density Functional Theory.

Aim

The aim of this thesis is to attempt to fill the gap that exists in the literature and theoretically explain the quantum nature of semiconductor devices formed using zinc sulfide. Also in this connection, certain physical properties of materials, metals and semiconductors, such as lattice constant, band structure, work function, etc., have been individually investigated. Finally, after all the research has been done, which will provide a better insight into the physical and optical properties of the combination of these materials, the possibility of using them in devices and for what purposes they could be useful will be discussed.

Material and Method

The materials studied in this work include metals (gold, silver, copper), while zinc sulfide (ZnS) served as the semiconductor.

Gold

Gold is a dense, soft, and malleable metal with a distinctive yellow luster, making it highly prized for both decorative and industrial applications. It has excellent conductivity of electricity and heat, and is highly resistant to corrosion and oxidation, contributing to its durability and widespread use in electronics and jewelry.

Silver

Silver is a lustrous, ductile, and highly conductive metal, known for having the highest electrical and thermal conductivity of any element. It is also relatively soft and malleable, with a brilliant white metallic appearance, making it valuable for use in jewelry, electronics, and as a reflective coating.

Copper (Cu)

Copper is a reddish-brown metal known for its excellent electrical and thermal conductivity, second only to silver among pure metals. It is highly malleable, ductile, and resistant to corrosion, making it widely used in electrical wiring, plumbing, and industrial applications.

Zinc sulfide (ZnS)

Zinc sulfide (ZnS) is a crystalline solid known for its wide bandgap, making it a valuable semiconductor material in optoelectronics. It exhibits luminescent properties and can appear in two primary crystal structures, zincblende and wurtzite, contributing to its use in applications like LEDs, infrared optics, and glow-in-the-dark materials.

Method

In this ongoing study, all calculations will be conducted using Density Functional Theory (DFT) with the GGA-PBE functional. The initial phase will involve optimizing the materials by determining the lattice constants, k-points grid, and cutoff energy (ENCUT) to ensure convergence and accuracy. Subsequently, a supercell will be constructed to model the metal/semiconductor junction. To analyze the electronic properties of the junction, planar average potential, charge density difference, and Bader charge analysis will be performed. Additionally, band structure calculations will be carried out for all materials to investigate their electronic behavior. These comprehensive calculations are expected to provide detailed insights into the structural and electronic properties of the materials and the metal/semiconductor interface.

Findings

Before starting any calculation, it is important to optimize the materials. Optimizations are done by performing the same calculation for different values of the same quantity for which we want to find the optimum. The goal of optimization is to find the ideal parameters for carrying out all further calculations and thus reduce their computational cost. The first optimization that needs to be done is the cutoff energy optimization. Cutoff energy, often denoted as ENCUT, is the maximum kinetic energy of the plane waves used in DFT calculations, determining the accuracy of the basis set for representing electronic wave functions (Fiolhais et al., 2003).

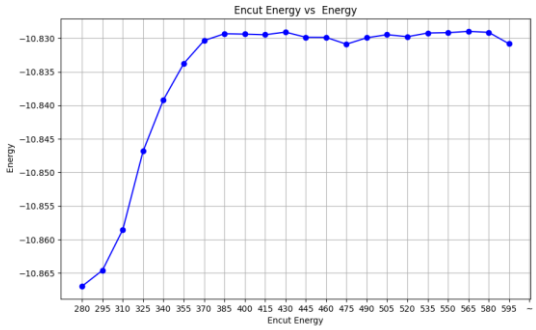

Figure 1. ENCUT optimization for silver.

As can be seen from the Figure 1, the cutoff energy values begin to converge after 400 eV, therefore we can freely use this cutoff energy value for further calculations. A similar thing was done for k-points optimization. In this optimization we determine the optimal grid of k-points in the Brillouin zone for numerical calculations, ensuring accurate sampling of electronic states while balancing computational efficiency (Lee, 2016).

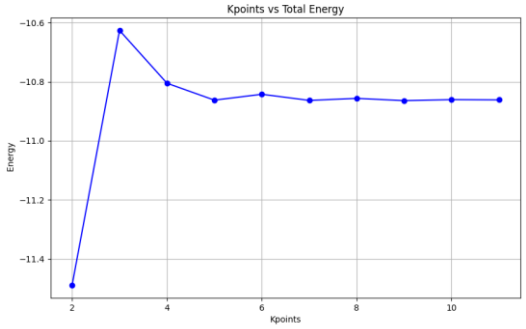

Figure 2. K-POINTS optimization for silver.

As shown in Figure 2, the total energy values begin to converge near a k-points value of 4. Finally, the crystal lattice optimization was performed and the lattice constant for which the crystal has minimal energy was found. The results obtained are quite similar to the results obtained in the experimental study of these crystals.

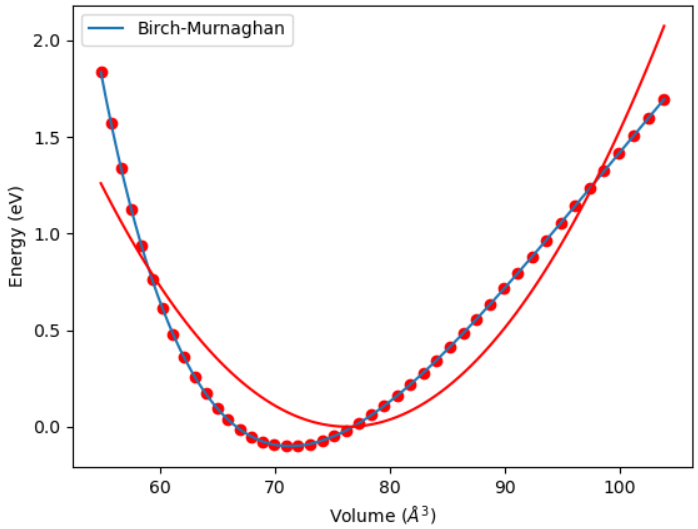

Figure 3. Lattice constant optimization for silver.

For example, the lattice constant of silver obtained in this work is 4.14 Å, which is in close agreement with the experimental value of 4.079 Å (Davey, 1925). Birch-Murnaghan equation of state fit was applied to the obtained data. The Birch-Murnaghan equation of state is widely used to fit the energy-volume relationship of materials, providing an accurate determination of the equilibrium lattice constant, bulk modulus, and its pressure derivative. This method is particularly effective for studying the structural properties of solids under compression or expansion, making it a standard tool in computational materials science (Birch, 1947).

$$P(V) = \frac{3B_0}{2}\left[\left(\frac{V_0}{V}\right)^{\frac{7}{3}} - \left(\frac{V_0}{V}\right)^{\frac{5}{3}}\right]\left\{1 + \frac{3}{4}(B_0' - 4)\left[\left(\frac{V_0}{V}\right)^{\frac{2}{3}} - 1\right]\right\}$$

Equation 1. Birch-Murnaghan equation of state.

Birch-Murnaghan equation of state is given in equation 1. Where:

- $P(V)$: Pressure as a function of volume
- V_0: Equilibrium volume (volume at zero pressure)
- B_0: Bulk modulus at zero pressure
- B'_0: Pressure derivative of the bulk modulus at zero pressure

The parameters from the Birch-Murnaghan equation of state for the silver crystal were found to be:

- $P(V)$ = -10.813086 GPa
- V_0 = 90.870389 Å^3
- B_0 = 5.771012 GPa
- B'_0 = 71.303748

After all elements were optimized, the formation of supercells was started, on which the behavior of the Schottky junction would be studied. First, by checking the mismatch ratios, it was determined that it was most favorable to work with the (111) plane in the case of each material. When the supercells (Au/ZnS, Ag/ZnS and Cu/ZnS) were formed, the ideal distances between the materials were found in a similar way as was done in the optimization of the material properties at the beginning. That is, the same calculation was performed for different values of the distance and the one with the lowest energy was found. It was also determined that the energy graph of the distance between the materials follows the Buckingham potential function (Fang et al., 2022). The optimal value for the Ag/ZnS junction is 3.246 Å. After this, Planar Average Potential, Charge density difference and Bader charge analysis calculations will be performed and after that the exact nature of these junctions will be determined.

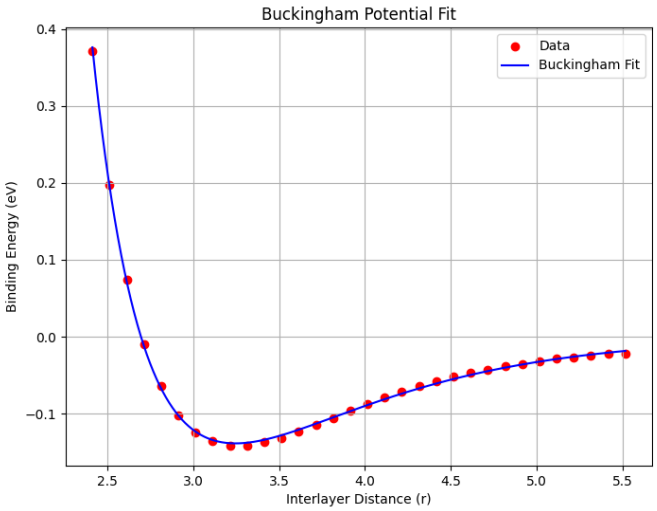

Figure 4. Optimal distance between Ag and ZnS slabs.

Conclusion

In this study, the structural and optoelectronic properties of metal/ZnS junctions were investigated using Density Functional Theory (DFT) with the GGA-PBE functional. The optimization of material properties, including lattice constants, k-points, and cutoff energy, provided a solid foundation for further calculations. The results showed close agreement with experimental values, particularly in the case of lattice constants, where the calculated value of 4.14 Å for silver closely matched the experimental value of 4.079 Å. The application of the Birch-Murnaghan equation of state further validated the accuracy of the structural optimizations. The formation of supercells for the metal/ZnS junctions, particularly focusing on the (111) plane, revealed that interlayer distances vs binding energy graph followed the Buckingham potential function. For instance, the optimal distance for the Ag/ZnS junction was determined to be 3.246 Å. These findings provide valuable insights into the electronic and structural properties of metal/ZnS interfaces, which are crucial for the development of efficient Schottky diodes and other optoelectronic devices. Future work will involve detailed analyses of planar average potential, charge density difference, and Bader charge to further elucidate the nature of these junctions. The results obtained in this study not only enhance our understanding of the quantum-level interactions in metal/semiconductor junctions but also pave the way for the design and optimization of advanced electronic and optoelectronic devices.

Imaging Ellipsometry for Material Characterization and Defect Analysis

Furkan Yıldız[a], Esra Zayim[b], Muharrem Aşar[c]

Keywords: Classical Spectroscopic Ellipsometry, CUDA, Defect Analysis, Imaging Ellipsometry, Power Electronics.

Aim

This study focuses specifically on the detection and assessment of material imperfections, as well as on the quantification of the corresponding optical constants by utilizing imaging ellipsometry—a very modern and advanced analytical tool. Traditional methods in spectroscopic ellipsometry are faced with numerous complications in characterizing the freestanding behavior of materials in certain applications, such as in defect evaluation. As illustrated in Figure 1, the major hindrance is the relatively large beam spot size, which restricts the achievable spatial resolution, combined with model-dependent analyses that tend to oversimplify the complex nature of materials by disregarding local heterogeneities. As such, the aim of this study is the creation of a high-resolution Imaging Ellipsometer capable of substantially overcoming the limitations of traditional methods. While traditional methods continue to exhibit significant success in areas such as power electronics, semiconductor manufacturing, and advanced material sciences, this research aims to offer more sensitive and versatile equipment for material analysis. The aim section should be written in Times New Roman font, justified-alignment and in 10-point size.

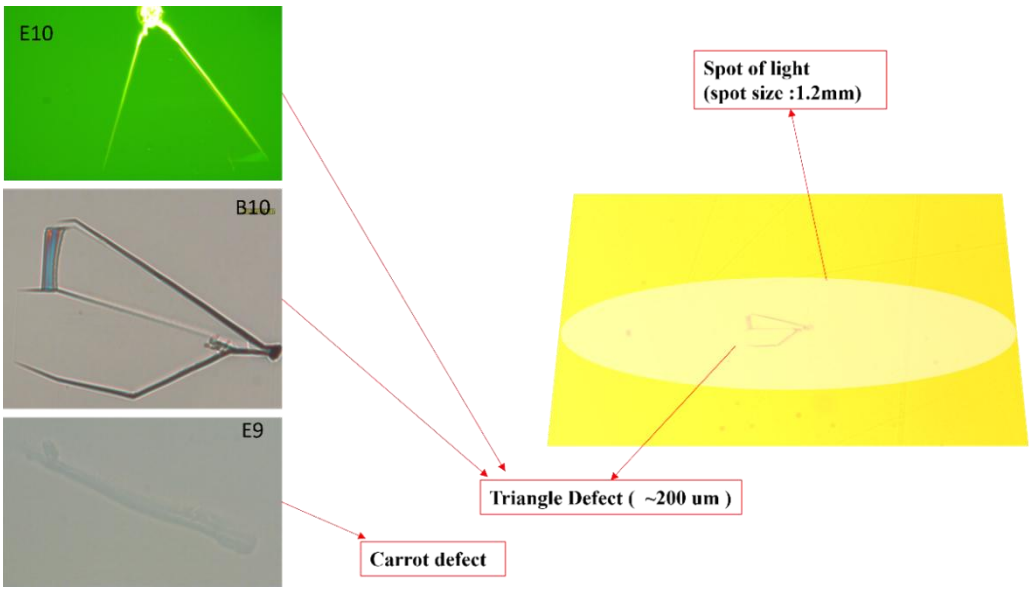

Figure 1. llustrate of the Defect size/shapes.

The impetus for such developments largely lies with the growing need for precision within material analysis that enables the evolution of nanotechnology and complex devices for different industries. Surface irregularities, structural defects, and subsurface inconsistencies largely impact the efficiency and reliability of materials that are utilized within complex technological systems. Even though conventional ellipsometry is well known for the ability of measurement of different optical properties such as refractive index and material thickness, it falls short of the precision needed for detection of these characteristics at the nanolevel. The Imaging Ellipsometer overcomes the shortcoming by combining the precision of imaging with state of the art algorithms and thereby optimizing the conventional procedures within the environments of academia and industry [1].

Material and Method

The Imaging Ellipsometry device, as shown in Figure 2, significantly differentiates itself from traditional systems by combining hundreds of complex components with highly complex computer techniques for the purpose of carrying out its goals. The core of the device lies with the tunable laser source that emits at fixed wavelength but with the capability of functioning at multiple discrete wavelengths of 633 nm, 612 nm, 604 nm, 594 nm, and 543 nm. The ability of the device to be tunable imbues it with the ability of analyzing materials under different conditions of optics and making it highly flexible and enabling complete wavelength-dependent material characterizations. The optics include the components of the motorized compensator and the analyzer that allow for precise control of the state of the transmitted light that it crucially needed for ellipsometry measurements. The device includes the complement of a highly numerical aperture of 0.75 Nikon Plan Fluorite objective that enables excellent transmitted light collecting capability and resolving of minute details on the surface of materials.

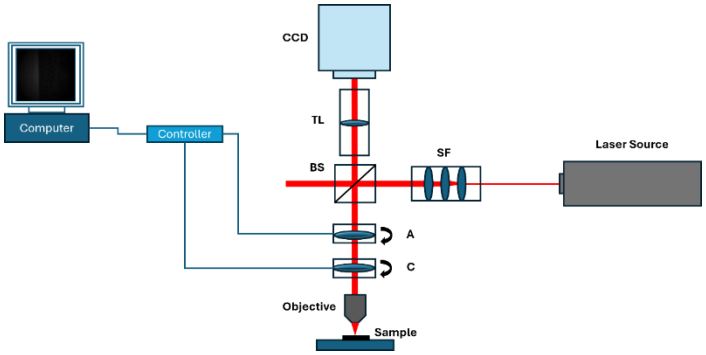

Figure 2. Schematic of a Imaging-ellipsometry optical configuration with rotary compensator and analyzer.

A beam splitter is used to precisely direct the light in the system, and a Retiga-R6 CCD camera successfully captures resulting optical information with high fidelity. The choice of the Retiga-R6 is important because of its sensitivity and pixel density, allowing the system to handle large datasets generated by imaging ellipsometry. Unlike traditional ellipsometry, which would measure a single point or a small area, this system analyzes information from over 5 million pixels, matching the high-resolution images it produces. This large increase in data volume required a new way of processing, leading to the development of CUDA-based software written in C++. By leveraging the parallel processing potential of GPU-based CUDA cores, the software skillfully manages the corresponding computational complexity, performing real-time optical signal analyses and reconstructing detailed maps of material properties.

A distinguishing feature of this Imaging Ellipsometer is the use of the unique single-arm geometric design over the more widespread dual-arm geometries of conventional systems. The dual-arm design splits the incident and reflection pathways of the light apart while the single-arm design converges these pathways into a more compact and efficient framework. Even with the introduction of difficulties by increased computational requirements, the use of a GPU counteracts these by making it easy for it to rapidly process lengthy data sets while making the feasible performance of operations within it more of a reality. The combination of these innovations at the hardware and the software levels produces a device that increases the resolution while it maintains efficiency of operation making it appropriate for industrial quality assurance processes and for the laboratory environments.

Findings

The findings of this study confirm the capability of the newly invented Imaging Ellipsometer system for overcoming the deficiencies of conventional spectroscopic ellipsometry. A thorough experimental study involving gallium nitride (GaN), silicon carbide (SiC), and several alternative substrates utilized for the purpose of power electronics and optoelectronic devices was conducted. The materials were chosen for study due to the prominence of their technological importance and the difficulties of characterizing the materials due mainly to the presence of the kind of defects that can compromise device performance. The Imaging Ellipsometer proved the ability of the equipment to find and study such types of defects with unmatched precision by identifying such characteristics of

the material such as the presence of microcracks, inclusions, and roughness of the surface that are often ignored or underassessed by conventional techniques.

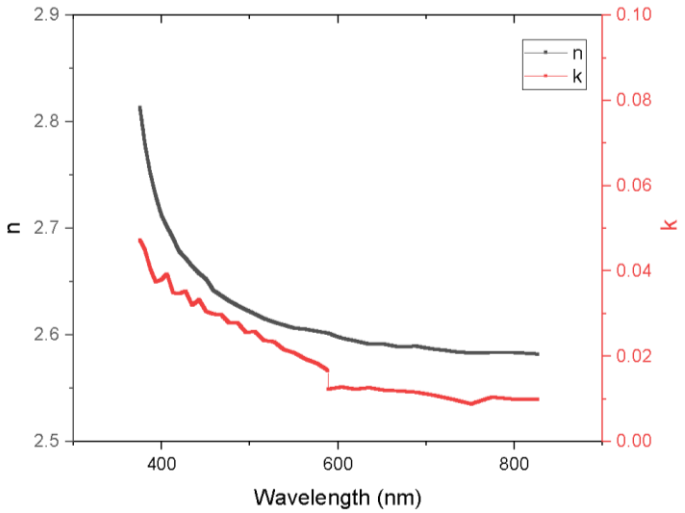

Figure 3. Optical constants of GaN:C determined from the fit.

Concurrently with the analysis of the defects, as shown in Figure 3, the system showed a remarkable capability to determine the optical constants of the material, namely the refractive index and the extinction coefficient. The measured values were compared with those obtained from standard spectroscopic ellipsometry, showing improved accuracy and spatial resolution. For example, in the case of GaN samples, the Imaging Ellipsometer produced highly detailed mappings of the optical properties that corresponded with the known positions of the defects, thus providing information on how these defects affect light interactions at the nanometer scale. Similarly, in the case of SiC samples, the system detected changes in the optical constants over the sample surface, leading to a wider understanding of material quality and homogeneity. The enhanced resolution of the Imaging Ellipsometer can be attributed to the high numerical aperture objective and pixel-level precision provided by the CCD camera; however, the latter's exceptional accuracy is mainly attributed to the powerful computational platform that supports the system. The software, which employs CUDA for parallel processing of millions of data points, ensures that fine details in material properties are retained—an element that is not present in conventional ellipsometry techniques. This ability is of particular importance for the analysis of thin films and multilayer structures, where even slight imperfections can have a dramatic impact on performance. As such, the results validate the hypothesis that the Imaging Ellipsometer outperforms previous models, placing the device at the leading edge of research in materials science and industrial applications.

Conclusion

This study presents the new Imaging Ellipsometer system that highly improves the functionality of ellipsometry equipment [3]. With the combination of high-resolution imaging with complex computer algorithms, the resultant system overcomes the limitation of conventional spectroscopic ellipsometry with the ability of thorough defect analysis and the measurement of the optical constants. The combination of the use of the tunable laser source, optics with the capability of high numerical apertures, and processing using GPUs represents the complete solution for increasing the sensitivity and the practicality of ellipsometry measurements further. Experimental results show that the improvement enables accurate material characterizations of GaN and SiC materials that give researchers and engineers more insight into material quality and performance.

The implications of this development extend beyond the laboratory, with potential applications in industries such as semiconductor manufacturing, renewable energy, and advanced electronics. In power electronics, for example, the ability to detect and mitigate defects in wide-bandgap materials like SiC and GaN could lead to more efficient and reliable devices, supporting the transition to sustainable energy systems. Similarly, in material science, the Imaging Ellipsometer offers a versatile platform for exploring new substrates and thin-film technologies, accelerating the pace of discovery and innovation [2].

This investigation adds substantially to the science of ellipsometry and represents a valuable asset for the wide spectrum of scientists wishing to extend the frontiers of material science, industry professionals aiming at enhancing the quality and efficiency of products, and researchers exploring new frontiers of materials science and nanosciences. The combination of enhanced resolution, precision, and computing efficiency within this context represents the core basis for subsequent material characterizations that are necessary for the development of more meaningful and accurate developments of science and technology.

State Construction of the "Othering" Mechanisms Leading to Stigmatization and Discrimination

Ela Gülboy

Istanbul Technical University, Graduate School, Political Studies, Turkey
gulboy23@itu.edu.tr

Keywords: Othering, Stigmatization, Coloniality.

Aim

In this presentation I will discuss how modern states construct the categories of the "other" to achieve domination and control in power relations, also how these othering practices may both symbolically and relationally lead to the stigmatization and then discimination of ethnic, racial, cultural, and ideological groups. Furthermore, I will also talk about how similar stigmatization processes take place in the inter-state relations. I will aim at drawing attention to how these othering processes can be internalized by the stigmatized groups bearing the fact that state stigmatization can be avoided and othering processes may be balanced with this fundamental awareness.

Material and Method

My method is the critical examination of othering as a process which leads to stigmatization and discrimination at national and international levels. It includes examining and discussing the major existing theories on othering, and analyzes different approaches developed by social thinkers such as Edward Said, Erving Goffman, Bruce G. Link and Jo C. Phelan, Ayşe Zarakol, Pierre Bourdieu and Michel Foucault.

Findings

Othering initially correlates to an ontological question. Human beings treat everything and everyone around themselves as the other even from the time they start the first speak, and be able to say "I." The realization and separation of self from the other, advances over time by socially and politically constructed complex mechanisms of otherization. Othering processes create binary relations. It emphasizes difference. In that sense, it dictates what or who is normal and who is not, by defining the condition and boundaries of a belonging. It defines the categories of "us" versus "them" or "I" versus "You."

The othering is a process enforced by dominant groups through a specific use of discourse; symbols, culture, social norms, and laws. These power groups or dominant nations set the norms of normality, the factors that decide who will be deemed valuable or expandable. Political construction of the "other" is an effective tool which enables states to activate a criterion that causes humanity to be divided into two asymmetrical and unequal groups; one, whose identity is valued, versus whose identity is devalued. The latter group is susceptible to discrimination whereas the former group embodies the society's or nation's norms and determines the boundaries of normativity by marking the difference of the "other".

While othering emphasizes difference, the concept of stigmatization -initially introduced by Erving Goffman- emphasizes the other's inferiority in various sorts. Being stigmatized can cause a reaction of resistance to the power groups and to its everyday restraints but it may also result in the internalization or ingraining of this alleged inferiority. One of the consequences of internalizing a stigma is that it causes the individual or the group to look at oneself from the value system of the advantageous groups as explored by Edward Said, in his works on post colonial era. This effect can also manifest itself as self-stigmatization, a by-product of the states continuous othering practices.

As Link and Phelan explore, both othering and stigmatization are socially constructed. Groups and communities are subjected to othering processes formed under these comparative judgments. In a positive reading, awareness of othering may serve the purpose of plurality and progress in a society under the varying advantages and dynamics of such different groups, however this presentation will concentrate on the negativity and deterioriating effects of

political othering when it becomes severely disruptive under political dominance, economic ambitions, and power relations.

Within a nation state, othering practices include labeling of particular groups because of ethnic, cultural, ideological differences, gender identities, religious/sectarian belongings among others. Constant othering practices result in stigmatization which in turn negatively affects the status of the stigmatized, causing inequality within a nation. In order to understand the symbolic power of the state over its citizens, Pierre Bourdieu examines the role of the state in the formation of particular cognitive structures, which in turn affects the perception of social reality. The state has the capacity to impose certain principles which can create the conditions of constructing the other. Bourdieu explains how the state produces ideologies to justify its position, how it continually constructs and reconstructs the state thinking and the mode of public thinking that corresponds with the stat's particular interest. His analysis shows how symbols, practices, and cultural forms reinforce social hierarchies and legitimize state power and perpetuate symbolic capital.

Michel Foucault's works furthermore emphasize how power, language, and knowledge serve the state's authority by manipulating meaning and reality. We experience the consent building capacity of the state, not only through security forces and courts but also through cultural hegemony. The othering mechanisms which are constructed by the state become embodied in institutions, its bureaucracy and furthermore in the everyday life. The state is the creator of the categories and hierarchies that dispenses the symbolic values and this allows individuals and groups to become stigmatized and devalorized. State's construction and degrading of the "other" leads to downward mobility of the "other" towards the periphery because of immigration, inequality in labor, and social cultural rights policies, unequal allocation of resources to other communities, even the gentrification projects within cities. Discriminated groups are heavily repressed for their votes in the hope of better financial standards. The fractured and hierarchized "other" is excluded from decision making processes and is hindered by having full access to resources and opportunities. Hence the state function to distribute material and non-material resources with a balancing intent is violated by the exclusion of the "other." This exclusion creates an institutionalized stigma affecting the institutions and bureaucracy of the government. These separatist and discriminative policies decompose the unity of nations. These can be based upon several attributes such as identity, economic conditions, religion, ideology. Furthermore, consistent exposure to othering leads to social and psychological problems, such as alienation from the society and to be perceived as a threat and a burden. Simultaneously othering paves the way for the successful "Divide and Rule" politics for the ruling parties and autocratic leaders. Stigmatized groups also serve as scapegoats for governments especially during economic recessions and high inflation periods. Creating an internal enemy or the "other" simplifies the accountability and offers an alibi.

The dischotomy established betwen a Eurocentric North American superiority of whiteness versus the inferiority of the rest of the world, Global South or Non-West has been one of the most prominent forms of othering. In this International level, dominant states impose their own categories. The othering and the eventual stigmatization is usually justified by attributing an inferiority to another nation's economic or political development or cultural values.

From the pre-state era to colonial period othering have been practiced by the ruling groups. Categories such as barbarians, savages, non-believers or people of color, the discourse of superiority versus inferiority or civilized West and uncivilized Non-West strengthened this dichotomy in a course of time. During the European colonizations between 16th to 20th century, the stigmatization of certain nations or groups helped the colonizing countries to easily exert power, extract natural resources and turn the stigmatized groups into free or cheap labor. Edward Said investigated these sharp epistemological bifurcations of the Orient and the Occident in the postcolonial times which enabled the ongoing asymmetrical power relations today. Said names the Orient as "imaginative geography" which is a constructed place devised for political apprehension. The process of othering sustains Western hegemony and coloniality. In this regard, Ayse Zarakol who analyzes the global hierarchies of otherization draws attention to how the externally imposed categories of difference or backwardness operates as a process of stigmatization. Economically, industrially, and culturally advanced nations progressively became the parties to decide on these norms and categorizations. These categorizations of "developing" and "underdeveloped"

countries, or the "core" versus "periphery;" these ongoing bifurcations affect also the state representatives in their international dealings. They shape the state leaders' understanding of their own nation's place in international relations. These ingrained stigmas, biasses and factionalized prejudices construct the "us against them" understanding upon engineered fears and insecurities. This allows the legitimation of violence and the right to intervene in the acts possessions and the culture of the "other." The epitome of 9/11 attack created another phase in global security. The threat of the other is further reduced to a mere risk factor, thereby allowing for oppressive and sometimes illegal measures without concrete evidence, to wage wars, to occupy territories, claim resources, and perpetuate systemic oppression.

Conclusion

This discussion of the literature on the othering practices and political divisions are aimed at forming a conceptual basis for further studies to increase consciousness against the stigmatization processes. These deeply rooted stigmatizations circumvent effective resistance to the political and social construction and reconstruction of othering, engineered by the states. The crucial factor for stigmatization is that the labelled individual or group is usually permanently marked with this stigma. In the end, there will always be othering but the negativity loaded on stigma might be overcome by recognizing the differences through laws and social practices which ensure equal rights. For this purpose, works related to theoretical and sociological problems of present political systems, comprehensive studies on political consequences of othering processes, the analysis of real life examples, the effective resistance methods and practices carry the utmost importance to initiate a reform for balanced political systems and relations.

Political Philosophy

An Evaluation of Socrates, Plato and Aristotle Regarding Their Conceptualizations of Political Legitimacy

Giray Çavdar[a]

[a]Istanbul Technical University, Department of Sociology, Political Studies Masters Program, Turkey
cavdar22@itu.edu.tr

Keywords: Aristotle, Plato, Political Legitimacy, Socrates.

Aim

The aim of this paper is to analyze the thoughts of three crucial Ancient political thinkers, Socrates, Plato, and Aristotle on political legitimacy of a given authority in a society.

This will contribute to the discussions of political legitimacy which are especially crucial if one were to make evaluations of the populist regimes that are in the rise in the recent years. Although these thinkers may not provide a full road-map for evaluation of political legitimacy in the modern era, they can still help with putting forward some principles which are utilized by more contemporary thinkers. Their thoughts are important because they lay down the foundation for the discussions that could come later.

Material and Method

The main methodology that will be utilized in this paper is content analysis. Socrates' Crito and Euthyphro, Plato's Republic, and Aristotle's Nicomechean Ethics and Politics will be utilized to underline their ideas on political legitimacy. This will be followed by a comparative analysis of these different thinkers and their conceptions of political legitimacy. Each different thinker's contribution will be summarized in a sentence, and different criticisms will be put forward in the same way. It will also underline how these different thinkers could contribute to one another for putting forward a more complete definition of political legitimacy.

These thinkers are picked because they constitute the foundation of political philosophy in their discussions with all three thinkers reflecting a perspective on understanding political legitimacy with Socrates focusing on individual obligations, Plato focusing on collective legitimization and Aristotle dealing with the moral implications of political legitimacy. They are not the whole of ancient philosophy, but it could be argued that they are the most crucial part of it.

Findings

One of the main arguments Socrates puts forward, as could be seen in Crito, is that a legitimate authority obligates individuals from a moral perspective. Socrates puts this forward as an essential condition for political legitimacy, meaning that a political authority cannot be considered legitimate without having the capacity to imply moral obligations (Plato,*Crito*, 50a–51c). This definition is limited in the sense that although it provides a condition for the existence of political legitimacy, it does not expand on the requirements that need to be fulfilled on the part of the state, meaning this can't be the whole of political legitimacy. It only states a quality of legitimacy, not what needs to be done to attain it. This means that this principle is only useful for defining the responsibilities of a state that is already legitimate and not what an authority can do to attain legitimacy (*Crito*, 50b–51b)

Plato brings a solution to this short-coming by suggesting that a legitimate government promotes the common good and cohesion among the different parts of the populace. Compared to the earlier definition put forward by Socrates, this definition is more expansive on the grounds that it proposes a common good as a condition that must be fulfilled on the part of the state for it to be legitimate. If a state does not fulfill the obligation of promoting common good, it is no longer legitimate and can not entail moral obligations, as put forth by Socrates (Plato, *Republic*, 427d–434c).

However, this definition also has its limitations since Plato's characterization of legitimacy is not based on individuals but rather on the community as a collective good. This is problematic because it allows the instrumentalization of individuals for the sake of what is considered to be the common good, which could be considered a violation of moral laws.

This emphasis on collective understanding of political legitimacy also paves the way for an understanding of political legitimacy akin to "might makes right" which is more of a descriptive statement rather than a philosophical one (Plato, *Republic*, 420b, 473c–474a).

Aristotle's conception of political legitimacy proposes an alternative to this collective reading of the issue of political legitimacy which completely disregards the well-being of the individual. Aristotle suggests in Nicomachean Ethics that eudaimonia is something central to people's fulfillment in life and that this is only achievable if and only if people live according to virtues that are in accordance with their lives which necessitates the existence of individual eudaimonia within a collective body concerned with the common goods. Aristotle even goes far enough to define humans as "Political Animals" whose self-realization relies in the participation regarding the issues of political body (Aristotle, *Nicomachean Ethics*, 1097a15–20; *Politics*, 1253a1–20).

Therefore, Aristotle argues that political authority is legitimate so far as it promotes the virtues of individuals within a society which is in accordance with the collective identity. Although Aristotle still puts the good of the collective body before the that of individual, he also incorporates individual good as something that is positively affected by the good of the collective, striking a balance between the two. However, this definition is also problematic on the grounds that it does not quite explain how such an authority, even if it is legitimate, could have the legitimacy to apply its power on individuals under its domain. Aristotle's definition of political authority is problematic in the sense that it necessitates an original reason regarding why people would be obligated by a specific authority at the first place therefore creating a different problem when it comes to the evaluation of political legitimacy (Aristotle, *Nicomachean Ethics*, 1098a)

As a combination of these three different thinkers, it could be concluded that an authority is legitimate so far as it promotes the common and individual good of the individuals and this results in this authority's commands entailing moral obligation.

This definition, however, also has its short-comings. One of these, as mentioned with Aristotle, it requires an original position from which political legitimacy could be derived but none of the thinkers mentioned here have no mention of such a thing. Moreover, although in this definition virtues are put forward as a fact that connects the individual to the collective body, this definition is lacking regarding where the individual will matters. Another problem that is faced in this text is also defining what common good is since Plato's definition relies on highly hierarchical picture of what society should be like which accepts injustices such as slavery as normal institutions. For a more complete definition of political legitimacy, these problems are needed to be addressed.

Although outside the scope of this text, these short-comings could be addressed through future thinkers such as Hobbes, who puts forward state of nature as an original point through which political legitimacy could be judged, and John Locke who argues that consent is essential in understanding how a political authority is legitimate. Plato's definition of political legitimacy could be grounded better if one were to utilize Rousseau and his definition of "General Will" to define what common good is without reinforcing hierarchical structures as normal as put forward by Plato.

Conclusion

In this abstract, multiple attitudes to political legitimacy belonging to the Ancient Greek philosophers were mentioned. At first Socrates' definition of political legitimacy was explained with him suggesting that political legitimacy is something that entails moral obligation on the part of those that are subject to political authority.

Later, Plato was evaluated, and it was suggested that he defined political legitimacy as tied to the authority promoting the common good and protecting cohesion within society. This was criticized on the grounds that it failed to take into consideration the importance of individuals when evaluating what is the common good.

This was followed by Aristotle and his theory of political legitimacy based on individual virtue was put forward where his suggestion of political legitimacy was that a political authority was legitimate so far as it promoted the individual virtues of people within a society.

Combining all these thinkers, it was suggested that political authority was legitimate so far as it promoted common and individual good and, therefore, entailed political obligation on the part of those who are governed.

At the end of the findings section, this definition was criticized on the grounds that although it put forward a definition of political legitimacy, it was not sufficient in itself since it did not explain why one would happen to be obligated by a political authority in the first place and it was also suggested that this problem could be solved by referencing Thomas Hobbes' state of nature regarding original political obligation. Moreover, it was also suggested that one could reference Locke to clarify how individuals could come into play regarding the issue of political legitimacy and Rousseau regarding how to conceptualize common good as a concept independent of existing conservative power structures. However, these three thinkers are outside the scope of this paper and therefore were not analyzed under the scope of this text.

Keywords: Proton Exchange Membrane, Proton Exchange Membrane Fuel Cells, Proton Conductivity, Sulfonated Polysulfone, Evaporation-Induced Phase Separation, Electrospinning.

Aim

Fuel cells operate by converting chemical energy into electrical energy through an electrochemical reaction, typically involving hydrogen and oxygen. One of the most promising types of fuel cells is the Polymer Electrolyte Membrane Fuel Cell (PEMFC), also referred to as the Proton Exchange Membrane Fuel Cell. This fuel cell type utilizes a polymeric membrane as an electrolyte, positioned between the anode and cathode, to facilitate the selective conduction of protons while acting as an electronic insulator. Hydrogen gas is supplied to the anode, where it undergoes oxidation, generating protons and electrons. The protons migrate through the membrane to the cathode, where they combine with oxygen to form water. This reaction not only produces electrical energy but also results in water vapor as a by-product, making PEMFCs an environmentally sustainable power generation technology.

Despite its advantages, the commercialization of PEMFCs remains hindered by the high cost of key materials, particularly the polymer electrolyte membrane (PEM). Currently, Nafion, a perfluoro sulfonic acid-based polymer, is the industry standard for PEMs due to its high proton conductivity, chemical stability, and mechanical robustness. However, its prohibitive cost and performance limitations at elevated temperatures necessitate the development of alternative polymeric materials with comparable or superior properties. In this study, we focus on the fabrication and characterization of sulfonated polysulfone (SPSU) composite membranes as a cost-effective and efficient alternative for PEMFC applications. A proton conductivity of 615.46 mS/cm, which is quite high compared to literature values, was obtained from the membrane produced with Aquivion. In contrast, conductivity values of 1.3 mS/cm and 1.08 mS/cm were recorded for sulfonated polysulfone (SPSU) and PES polymers mixed in different ratios.

In this study, the target was to synthesize polysulfones and their sulfonated versions, and then to prepared membranes by them. We have also developed a sulfonated polysulphone for membrane technology such as fuel cells. All polysulfones which are characterized by Fourier transform infrared (FTIR), nuclear magnetic resonance (NMR), differential scanning calorimetry (DSC) and gel permeation chromatography (GPC). We had two kind of NMR analysis for these polysulfones as ^{1}H NMR and ^{13}C NMR to characterize polysulfone backbone. Polysulfones glass transition (Tg) are determined by differantial scanning calorimetry (DSC). Characteristics of membranes were investigated by measuring the contact angle, pore sizes, and using scanning electron microscopy (SEM) images.

Material and Method

Reagent-grade chemicals with the highest purity were used in this study. Sulfuric acid (Merck MW = 98.08 g/mol, 99.999%), Dichloromethane (MW = 84.93 g/mol, ≥99.5%), Chlorosulfonic acid (MW = 116.52 g/mol, 99%).

Polysulfone (PS, Mw 30,000) was previously synthesized and directly used at Resin Pol. Lab. L108 ITU. Polysulfone were used for the synthesis and membrane preparation, were purchased and dried at 100 ºC under vacuum before use.

Synthesize of the sulfonated polysulfone (SPSU)

To enhance the proton conductivity of polysulfone, sulfonation was performed using two different methods. The degree of sulfonation (DS) is a critical parameter influencing the membrane's ionic conductivity, mechanical strength, and water uptake capacity.

• Method 1

In the first sulfonation method, polysulfone (PSU) was dissolved in sulfuric acid (H_2SO_4) with 96% purity. The solution was allowed to react for five hours, followed by a drying process. Subsequently, 0.5 mL of chlorosulfonic acid ($ClSO_3H$) was added to 50 g of dried PSU and subjected to continuous stirring for 48 hours, as illustrated in Figure 1. Upon completion of the reaction, the sulfonated polymer was precipitated by carefully pouring the solution onto ice to dissipate excess heat and prevent unwanted side reactions. The resulting solidified polymer underwent multiple washings with deionized water to neutralize residual acid, ensuring complete removal of reaction by products [1].

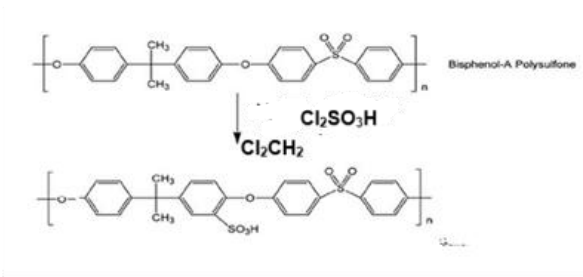

Figure. 1. Formation reaction of SPSU (Method 1).

• Method 2

The second sulfonation method employed chlorosulfonic acid in dichloromethane (DCM) as the sulfonating agent, as illustrated in Figure 2. Finally, the SPES underwent several washes in an ice-water bath and subsequently subjected to extensive washing to eliminate excess reagents followed by a 24 h drying period in a vacuum oven set at 60 ◦C [2].

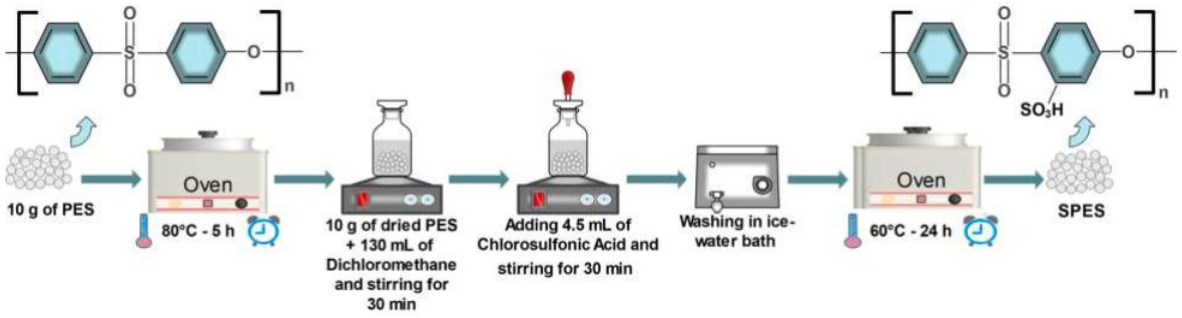

Figure 2. Sulfonation reaction process of polysulfone (Method 2) [3].

Determination of Sulfonation Degree

The sulfonation degree (DS) was quantified through a titration-based analytical approach. In this method, 0.1 g of sulfonated polymer was dissolved in 10 mL of dimethylformamide (DMF). The proton concentration was determined by titrating the solution with 0.1 M NaOH, using phenolphthalein as an indicator. The DS was found to be 16% for the first method and 35.2% for the second method, demonstrating that the latter method resulted in

a higher degree of sulfonation. The following equation was used to calculate DS. Where M is the NaOH concentration (M), V is the volume of NaOH added at the equivalence point (mL), and W is the SPSU weight (g).

$$PSU' DS\% = (0.442M \times V \times 100)/(W - 0.08 \times V)$$

Membrane Fabrication Techniques

The sulfonated polymers were processed into thin membranes using three distinct fabrication techniques:

1. Electrospinning
2. Doctor Blade Coating
3. Evaporation-Induced Phase Separation (EIPS)

Electrospinning

Electrospinning is a widely used technique for fabricating porous membranes, offering high surface area and tunable morphology. It has applications in fuel cells, lithium-ion battery separators, sensor materials, and biomedical engineering. The electrospinning apparatus used in this study consisted of a high-voltage power supply, a polymer solution feeding system, and a rotating collector drum.

The sulfonated polymer solution was loaded into a syringe and subjected to a high electric field, which overcame the surface tension and ejected fine polymer jets toward the collector. As the solvent evaporated during flight, dry nanofibers accumulated, forming a nonwoven electrospun membrane. The process duration was approximately seven hours, with real-time monitoring to prevent nozzle clogging. Any interruptions due to clogging were promptly addressed to ensure uniform membrane formation.

Doctor Blade Coating

Doctor blade coating, also known as blade coating, is a common method for producing thin polymer films. In this technique, the sulfonated polymer solution was evenly spread over a glass substrate using a reciprocating blade with a precisely controlled gap. Following uniform deposition, the coated substrate was immersed in deionized water to induce phase separation, leading to the formation of a solid membrane.

Evaporation-Induced Phase Separation (EIPS)

EIPS is a membrane fabrication technique that relies on controlled solvent evaporation to achieve phase separation. The polymer solution, containing a volatile solvent and a less volatile nonsolvent, was cast onto a flat substrate and placed in a temperature-controlled environment for 24 hours. As solvent evaporation progressed, polymer demixing occurred, resulting in the formation of a porous membrane structure. The drying process was carefully managed to prevent defects such as partial accumulation or surface irregularities.

Characterization of Membranes

To evaluate the suitability of the fabricated membranes for PEMFC applications, various characterization techniques were employed, including:

FT-IR spectra were measured using Bruker Alpha FTIR spectrophotometer (ATR sampling accessory), directly from the sample.

All ^{1}H-NMR, and ^{13}C-NMR data were obtained from a Varian spectrometer (AC 500 MHz) at room temperature. DMSO-d_6 was used as solvent. Chemical shifts (in ppm) were reported downfield from Si $(CH_3)_4$.

Morphology of products was examined by scanning electron microscope, ESEM XL30 ESEM-FEG Philips and the samples for the SEM measurement are prepared by gold coating. SEM imaging was conducted to examine the morphological characteristics of the membranes, particularly pore distribution, fiber alignment (for electrospun samples), and overall surface uniformity.

Findings

The ATR-FTIR spectra from the unsulfonated PSUmembrane (M1) was given in Figure 2. The main difference in the spectrum was the presence of two absorbances at about 1029 cm^{-1} and 1072 cm^{-1} in the SPES, which could be related to the symmetrical S-O stretch of the sulf onated groups(Figure 3).

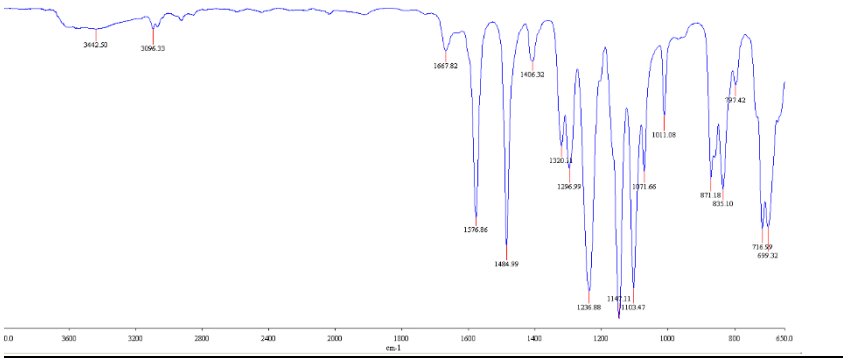

Figure 2. FTIR spectrum of PSU-M1.

The intensity of this peak in SPES spectra was increased towards the unsulfonated PSU[4]. The peak of 629 cm^{-1} is related to the S-O bending vibration and 830 cm^{-1} is related to the S-O-C stretching vibration of sulfonated groups. FT-IR analysis was performed to confirm the presence of sulfonate groups in the polymer backbone. Characteristic absorption peaks were observed in the range of 1030 cm^{-1} to 1098 cm^{-1}, corresponding to symmetric and asymmetric vibrations of sulfonate functional groups. The intensity of these peaks increased with sulfonation degree, corroborating findings from the literature.

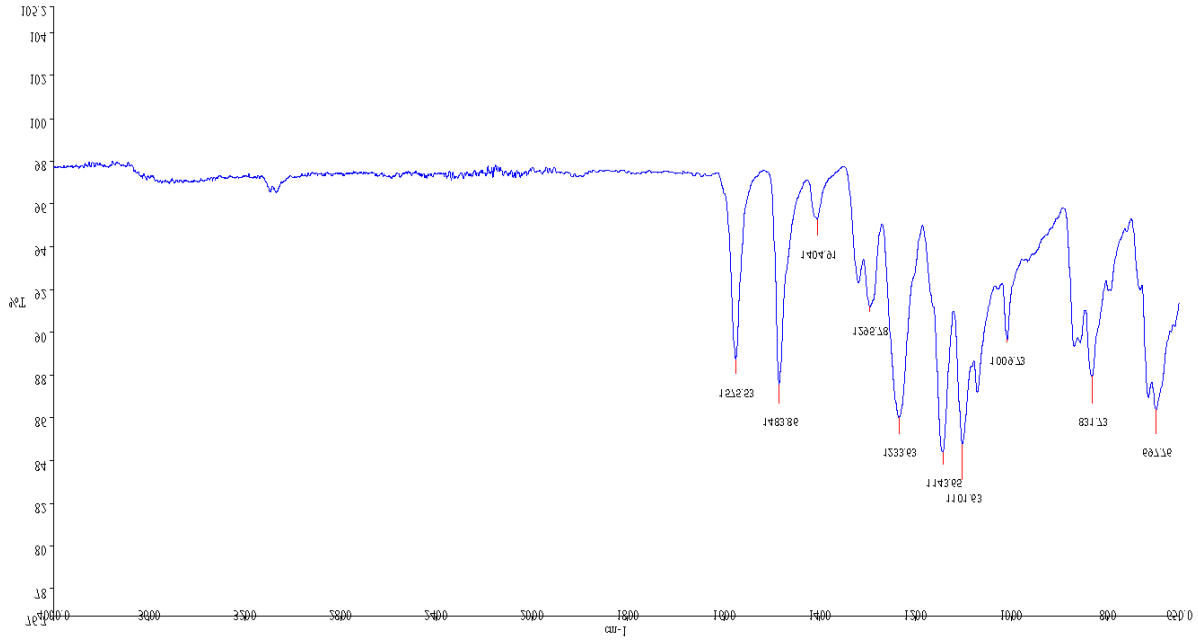

Figure 3. FTIR spectrum of SPSU (%35.2 DS).

•Membrane Performance Testing:

The fabricated membranes were subjected to contact angle measurements to assess hydrophilicity, gas permeation tests to evaluate selectivity, and proton conductivity measurements to determine ionic transport properties.

Conclusion

This study successfully synthesized and characterized sulfonated polysulfone membranes using two different sulfonation methods and three distinct membrane fabrication techniques. The results demonstrated that the degree of sulfonation significantly influences membrane properties, with higher sulfonation leading to enhanced proton conductivity. The findings of this study contribute to the ongoing development of cost-effective, high-performance PEMs, facilitating the broader adoption of fuel cell technology for sustainable energy applications. Future work will focus on optimizing fabrication conditions to further enhance membrane efficiency and durability.

Fiber Bragg Grating Sensor: Princibles, Applications, and Emerging Trends

Serhat Boynukalın[a], Kemal Atakan Kırca[b]

[a]Istanbul Technical University, Graduate Education Institute, Department of Railway Systems Engineering, Türkiye
[b]Istanbul Technical University, Faculty of Electrical and Electronics, Department of Electronics and Communication Engineering, Türkiye
boynukalin@itu.edu.tr

Keywords: Fiber Bragg Gratings (FBG), Fiber Optic Sensors, Railway Safety, Optical Sensing, Structural Health Monitoring.

Aim

Fiber Bragg Grating (FBG) sensors operate based on the principle of light reflection at specific wavelengths, determined by periodic variations in the refractive index within the fiber core. These reflected wavelengths, known as Bragg wavelengths, shift in response to external stimuli such as temperature and strain, making FBG sensors exceptionally well-suited for detecting changes in physical and environmental conditions with high sensitivity and resolution.

This study aims to analyze how thermal and mechanical influences affect the performance of FBG sensors, particularly focusing on temperature-induced expansion and strain-related elasticity. By quantifying the Bragg wavelength shift through analytical models and simulation tools, the research seeks to offer a deeper understanding of the FBG sensing mechanism under real-world conditions. This knowledge is crucial for optimizing sensor performance in critical monitoring applications.

In parallel, the study investigates the practical use of FBG sensors across various engineering fields, such as railway safety, aviation, structural health monitoring, and border security. Application scenarios include the use of FBG-equipped clearance trains for detecting rail track deformations, aircraft wing deformation tracking during flight conditions, and real-time vibration monitoring for perimeter security. The research incorporates both laboratory simulations and field tests to assess sensor reliability, robustness, and response time in each of these domains.

Moreover, the study evaluates different grating structures—uniform, chirped, and apodized—based on their wavelength reflection behavior and susceptibility to interference. It also explores the integration of digital modulation and coding techniques (e.g., PN-coding) to enhance signal clarity, extend sensing range, and support multiplexed measurements. Ultimately, the research highlights the transformative potential of FBG sensors in developing smart, proactive, and sustainable monitoring systems capable of improving safety and operational efficiency in diverse industrial contexts.

Material and Method

This study employed a multi-stage methodology to evaluate the performance of Fiber Bragg Grating (FBG) sensors in environmental sensing applications. The approach involved theoretical modeling, simulation using specialized software, and practical validation through prototype testing in real-world scenarios.

Initially, the optical behavior of FBG sensors was modeled based on Bragg's law, which defines the relationship between the grating period, refractive index, and reflected wavelength. The impact of external factors such as temperature and strain on the Bragg wavelength was quantified using standard equations incorporating thermal expansion and photoelastic coefficients (Karaman & Ünverdi, n.d.).

Simulation experiments were conducted using OptiSystem software to optimize the optical link design and modulation schemes. The system setup included a laser source, Mach-Zehnder and Direct Modulators, and photodetectors. Performance was evaluated under varying environmental parameters and signal conditions, with

particular focus on signal stability, wavelength shift accuracy, and the influence of coding techniques such as pseudorandom noise (PN) codes (Boynukalın et al., 2023).

For practical assessment, a prototype "clearance train" equipped with FBG sensors was deployed on railway tracks. The sensors continuously recorded strain and temperature data while in motion, allowing for real-time identification of track irregularities. Data was collected, processed, and interpreted to validate the sensors' reliability and responsiveness.

Furthermore, different FBG configurations were analyzed to determine their suitability for diverse application requirements. Performance metrics such as sensitivity, response time, multiplexing capacity, and resistance to electromagnetic interference were evaluated.

Overall, the combined use of analytical modeling, simulation tools, and field testing ensured a comprehensive assessment of FBG sensor effectiveness in industrial monitoring contexts.

Findings

The research demonstrated that Fiber Bragg Grating (FBG) sensors offer high sensitivity and reliability in monitoring physical parameters across a wide range of applications. Key findings from simulation studies and prototype testing are as follows:

Railway Infrastructure Monitoring:

FBG sensors installed along railway tracks successfully detected minute variations in strain and temperature, signaling potential infrastructure degradation or deformation. The use of advanced modulation schemes, particularly the Dual-Drive Mach-Zehnder Modulator, significantly improved signal resolution and accuracy in identifying local defects or stress concentrations. The clearance train application verified the practicality of using mobile FBG sensor platforms for real-time railway diagnostics (Boynukalın et al., 2023).

Aircraft Wing Structural Health Monitoring:

The application of FBG sensors in aircraft wings enabled continuous, real-time tracking of structural deformation and temperature fluctuations during simulated flight conditions. Sensor data effectively indicated load distributions and stress accumulation, which are critical for early fatigue detection (Ma and Chen, 2019). When combined with structural health monitoring software and inverse finite element methods, FBG data enabled the creation of accurate digital twins, improving predictive maintenance and operational safety (Kefal, 2020).

Security and Border Intrusion Detection:

FBG cables embedded underground or along perimeters reliably detected vibrations and movement associated with unauthorized intrusion. These systems exhibited strong resistance to electromagnetic interference and provided low false alarm rates. The technology demonstrated significant potential in enhancing security for borders and critical infrastructure (Fermann, 2016).

Building Structural Health Monitoring

FBG sensors embedded in structural elements such as columns and beams accurately captured micro-strain and displacement caused by environmental and operational loads. Real-time alerts enabled preventive maintenance strategies in bridges, towers, and high-rise buildings, reducing inspection costs and ensuring safety (Webb, 2007).

Seismic Monitoring and Early Warning Systems:

The sensors proved capable of detecting low-amplitude seismic waves, which precede major earthquake events. Their deployment near fault zones enabled early warnings by monitoring stress build-up and micro-displacements. The precision and responsiveness of FBG sensors offer a promising tool for earthquake risk mitigation (Laudati et al., 2008).

In all tested scenarios, FBG sensors demonstrated excellent performance in harsh environments, high accuracy in measurement, and strong adaptability through multiplexed deployment. These findings underscore the value of FBG technology as a versatile and robust solution for advanced sensing applications.

Conclusion

The findings of this study confirm that Fiber Bragg Grating (FBG) sensors are highly effective tools for monitoring environmental and structural parameters such as strain, temperature, and vibration. Their immunity to electromagnetic interference, compact size, and capability to operate under harsh conditions make them a superior alternative to conventional electronic sensors in many critical applications.

FBG sensors demonstrated notable performance in railway infrastructure monitoring, aircraft wing stress analysis, seismic activity detection, and security systems. Their precision in capturing real-time physical changes allows for early detection of anomalies, thereby enhancing safety, enabling predictive maintenance, and reducing operational costs (Boynukalın et al., 2023).

The use of advanced coding schemes and multiplexing configurations further improved measurement accuracy and extended the applicability of FBG sensors over long distances. Despite certain limitations, such as sensitivity to extreme temperatures and higher initial costs, ongoing advancements in sensor design and signal processing continue to expand their utility and efficiency.

In conclusion, FBG-based optical sensing technology represents a transformative advancement in modern monitoring systems. Its adaptability and precision offer significant potential to reshape safety, diagnostics, and maintenance practices across transportation, aerospace, civil infrastructure, and security domains.

Energy Efficiency Optimization through Metro Scheduling: Mixed-Integer Linear Programming (MILP) and Genetic Algorithm Approaches

Mustafa Karaipek[a], Abdurrahman Yılmaz[b]

[a]Istanbul Technical University, Mechatronics Engineering Master of Science Program, Türkiye
[b] Istanbul Technical University, Department of Control and Automation Engineering, Türkiye
karaipek@itu.edu.tr

Keywords: Energy Efficiency Optimization, Genetic Algorithm, Mixed-Integer Linear Programming (MILP), Railway, Time Table.

Aim

The use of urban rail systems is steadily increasing, bridging a significant gap in transportation and serving the public. According to the "Distribution of Public Transport Journeys by Main Transportation Modes" report published in June 2022, the share of rail systems in public transport in Istanbul is 26% and continues to rise[1]. The expansion of rail systems in urban areas has reduced road traffic, especially in densely populated cities, thereby decreasing urban carbon emissions and contributing positively to the environment. The goal is to expand the rail network to reduce individual car use and make it a cost-effective transportation method. To achieve this, efficiency must be increased and energy consumption reduced. Numerous studies have been conducted to improve energy efficiency in existing rail systems. These have focused on different parameters, such as energy recovery through regenerative braking[2], simultaneous optimization of train schedules and maintenance planning to increase infrastructure capacity usage[3], shared corridors for freight and passenger trains[4], and the use of deep reinforcement learning (DRL) for rescheduling high-speed trains under disruptions[5]. These approaches underline the multidisciplinary nature of the challenge, requiring integration of operations research, artificial intelligence, and civil engineering techniques to effectively address energy efficiency in complex rail systems.
In this study, metro schedules have been optimized to improve energy efficiency in urban rail systems. The goal was to optimize train services based on passenger demand, reduce unnecessary services, and lower overall energy consumption. The core strategy was to reschedule frequencies based on station-level passenger density, increase dwell times during off-peak hours or at low-demand stations, and transport the same passenger volume with fewer trips. While doing so, certain constraints were considered: meeting minimum service levels for passenger demand, not exceeding specific waiting times, and maintaining minimum frequencies during certain times of the day. Passenger travel time was also taken into account to ensure satisfaction, ensuring that waiting times at stations did not exceed acceptable limits. Simulation studies using data from the Gayrettepe–Istanbul Airport metro line showed that energy savings could be achieved through this approach.

Material and Method

Both deterministic and heuristic methods were used and compared. Mixed Integer Linear Programming (MILP), a deterministic optimization method, and Genetic Algorithm (GA), a heuristic method, were applied. MILP is highly effective for solving optimization problems involving both continuous and integer variables, and it was used to determine the optimal timing and frequency of metro services. While theoretically providing a global optimum, MILP can be inefficient for large-scale problems, hence GA was also tested for performance comparison. Genetic Algorithms are inspired by natural evolutionary processes and are capable of effectively searching large solution spaces. They can generate numerous alternative solutions and evolve them using genetic operators to reach near-optimal results, offering advantages for transportation systems with large datasets. The objective function was defined mathematically with the aim of minimizing total energy consumption. Variables such as service timing, dwell times, and number of trips were mathematically modeled. Passenger satisfaction was also considered when defining constraints. Simulations were conducted using both methods to compare performance.In defining the constraints of the optimization model, not only operational rules (e.g., minimum headways) but also

passenger behavior patterns were considered. For example, the model penalized excessive waiting times that could potentially cause station overcrowding or lower passenger satisfaction.

Findings

Simulation studies were conducted on the Gayrettepe–Istanbul Airport metro line, and the model's real-world performance was assessed. Analyses using actual passenger density data showed that demand-based scheduling significantly reduced energy consumption without compromising passenger capacity. Trains maintained frequency during peak hours but operated more flexibly during off-peak times, avoiding unnecessary energy use. While GA delivered faster results, it had slightly lower performance in terms of energy savings compared to MILP. However, GA was deemed more suitable for large-scale systems requiring fast solutions.

The results demonstrate that dynamic control of rail systems can significantly enhance energy efficiency. Adapting schedules quickly for special days or nights increases flexibility and enables greater energy savings. Despite energy savings, there was no notable decline in service quality. The proposed schedule adhered to constraints such as minimum frequency and maximum waiting times. Simulation results showed no meaningful increase in passenger wait times, and optimized intervals helped balance passenger density.Moreover, results showed that adjusting dwell times slightly at low-density stations helped smooth out bottlenecks without creating backlogs. This situation also contributed to more stable energy draw from the electrical grid, which is beneficial for energy distribution management. Without reducing passenger satisfaction, it was observed that the current passenger demand could be met with 98 train trips instead of 110 in the existing operation, as a result of the optimization study.

Conclusion

This study shows that demand-based scheduling in urban rail systems can significantly enhance energy efficiency. Replacing fixed schedules with dynamic plans that adapt to real-time demand reduces energy consumption and improves overall system efficiency.In large metropolises like Istanbul, operating metro lines more efficiently yields major environmental and economic benefits. The developed model can also be adapted to other urban rail systems. Smart, demand-based scheduling in rail systems not only reduces operational costs but also supports environmental sustainability. Simulation results revealed proportional reductions in carbon emissions alongside energy savings. Future work can explore additional parameters and constraints to further enhance energy efficiency, such as incorporating regenerative braking or optimizing train driving dynamics.Furthermore, incorporating real-time passenger feedback mechanisms and integrating the model into central traffic control systems could enhance adaptability. An 11% reduction in the number of train trips was achieved, and energy savings were obtained while carrying the same passenger demand.

A Safety-Critical Railway Interlocking Architecture Based on SCADE and HIMA PLCs with Python-Driven Simulation and Control

Serhat Boynukalın[a], Feride Berra Köseoğlu[b], Erdem Kısaç[b]

[a] Istanbul Technical University, Graduate Education Institute, Department of Railway Systems Engineering, Türkiye
[b] Istanbul Technical University, Faculty of Electrical and Electronics, Department of Control and Automation Engineering, Türkiye
boynukalin@itu.edu.tr

Keywords: Hima Plc, Modbus Tcp, Railway Interlocking, Scade Display, Safety-Critical Systems.

Aim

This study will design a cost-effective, scalable, fail-safe railway interlocking system that adheres to international safety standards using the SCADE (Safety Critical Application Development Environment) platform. Communication between the simulation interface and a HIMA PLC is established via the Modbus protocol, enabling real-time control of field components such as railway switches. To ensure system reliability and safety, the project emphasizes compliance with standards like EN 50128, EN 50129, and EN 50716.
Integrating certified tools and protocols becomes vital considering the catastrophic consequences of operational failures in railway systems, such as the Chatsworth and Graniteville accidents (Hartong, Goel, & Wijesekera, 2011). With their redundant architecture and SafeEthernet protocol, HIMA PLCs provide the backbone of secure communication and continuous operation in safety-critical environments (HIMA, n.d.-b), (HIMA, n.d.-c).
In addition to enhancing operational safety, the project contributes to sustainable transport goals by promoting railway usage, which offers significantly lower carbon emissions compared to other modes of transportation (Küresel Amaçlar, 2020; Bollen, 2022).

Materials and Method

This project aimed to implement a fail-safe system for railway signaling by complying with safety standards and using SCADE and HIMA PLCs through Modbus TCP integration. For this purpose, an interlocking interface was intended to be designed using a model-based approach, and communication was established with PLCs via the Modbus TCP protocol. These main components are detailed below.

Graphical Interface—HMI: The goal was to design a user-friendly interface via SCADE Display. The user could see the routes and request routes clearly, read and control the status of all switches, track circuits, and signal lights, and facilitate error detection in case of any fault, and allow for intervention.
The proposed system integrates a graphical user interface developed in SCADE Display with a HIMA PLC via the Modbus TCP/IP protocol. The primary objective is to enable real-time communication between the control system and field equipment such as railway switches and signal lights (Ansys, 2021).
The development process began with designing an intuitive interface that visualizes track availability and enables route selection (Ansys, 2021).

PLC: HIMA PLCs read the data coming from the interface, process it, and transfer the data received from field devices back to the interface. Additionally, they make decisions within the framework of safety standards and play a role in making the project fail-safe.
The HIMA PLC logic was developed using the SILworX platform to meet redundancy and safety requirements. Within this architecture, each bit exchanged through Modbus represents a command or feedback signal critical to the interlocking logic. The PLC processes commands received from the interface and returns corresponding status feedback, forming a closed-loop control cycle (Ansys, 2021).

Modbus TCP: This protocol ensures communication between the interface and the PLC by operating using input and output bit lists. These lists carry out command exchange and transmit status information to the user.
The Modbus protocol, chosen for its open-source nature and widespread industrial adoption, facilitates data exchange between the interface and the PLC (Simply Modbus, n.d.).
Although Modbus lacks inherent security features such as encryption or authentication, the system architecture ensures it is used in a closed and isolated network, minimizing vulnerability (Marrone, 2024).

The interlocking interface developed in this project was designed to enable real-time data monitoring, control of field devices, and communication with them. The HMI was designed with SCADE Display. At this stage, SCADE Display provided ease through its model-based design environment and generated code compliant with safety standards (Ansys, 2021).
However, during the project's compilation phase, additional code was written for Modbus TCP integration, and all code files were compiled manually.
Python and C programming were employed to implement the communication layer—initial development efforts involved using SCADE's Python API to access and manipulate interface variables. However, due to limitations, an alternative approach using C was adopted. By directly modifying the auto-generated header files, real-time variable control and interface responsiveness were achieved (Ansys, 2021).
In addition to C-based implementation, Python was also integrated into the system to extend its functionality. Using the SCADE Python API, dynamic variable control mechanisms were developed, enabling more flexible interaction with the interface and improving development efficiency (Ansys, 2021).
The process starts by receiving user commands via the interface prepared using SCADE Display, and then transmitting these commands to the PLC via Modbus TCP. The commands reaching the PLC are applied to the field devices within the critical safety limits provided by HIMA. The user can see the results of their commands and the status of the field equipment via the interface.
During the design process, the aim was to obtain a system suitable for a fail-safe structure. HIMA PLCs with SIL 3–4 levels were used as controllers. Modbus Slave Simulator was used, and tests were conducted in these simulation environments.
Communication reliability was ensured through iterative testing using Modbus slave simulators, and synchronization between the interface and PLC was validated through integration testing (Ansys, 2021).
The software used in the project was designed according to fail-safe principles, stopping all movements and switching field equipment to safe positions in case of errors.
All components were developed and tested according to RAMS principles (Reliability, Availability, Maintainability, and Safety), as defined by EN 50126. The methodology emphasizes fail-safe operation and scalability, ensuring the system is suitable for real-world railway applications (CENELEC, 2017).

Findings

During the testing process, it was verified whether the signal data received from the field was correctly represented in the graphical user interface. In this regard, variables controlling the visibility of a signal lamp were defined in the SCADE Display environment, and the relevant variables were mapped to specific Modbus register addresses in the C language code. By externally manipulating these registers via the Modbus Slave Simulator, different values were assigned, and it was observed that these changes were reflected instantly and accurately on the SCADE Display interface. This method confirmed that the system correctly processed the data exchanges transmitted over Modbus TCP/IP and reliably presented them on the user interface.
The implemented interlocking system successfully demonstrated reliable and fail-safe communication between the graphical user interface and the HIMA PLC using the Modbus TCP/IP protocol. All critical bits associated with turnout commands and signal indications were exchanged accurately, and their real-time reflections were confirmed through the SCADE Display interface. The interface responded dynamically to the status of the field components, enabling clear visualization of track conditions and signal states.
Thus, the system's real-time monitoring and control capability was successfully verified. During the design process, software and hardware selections followed the industry standards and fail-safe requirements specified in the project, meeting all expected criteria in terms of safety, flexibility, and integrity.
SCADE Display, certified for SIL 3–4 applications, facilitated a structured development process with integrated safety analysis and certified code generation (Ansys, 2021). The designed interface contributed to compliance with safety integrity requirements as defined in railway standards such as EN 50129:2020 for functional safety of electronic systems, and EN 50716:2023 for software development processes (CENELEC, 2023). During the testing phase, it was confirmed that changes to variables in the PLC logic were correctly and safely reflected on the graphical display and vice versa. This confirmed the robustness of the two-way communication system.
As a result, the developed system overcomes the limitations of existing traditional solutions and offers a reliable solution compatible with modern industrial automation needs.
HIMA PLCs proved highly reliable under simulation, maintaining continuous operation even in failure scenarios. Their built-in redundancy features ensured that safety logic could still be processed in the event of component faults, meeting the project's functional safety goals (HIMA, n.d.-b). Moreover, communication through SafeEthernet, developed to meet SIL 3–4 requirements, added an extra layer of security to data transfer operations (HIMA, n.d.-c).

The key findings obtained within this study's scope show that using modular architecture and open-source communication protocols in industrial automation systems significantly increases system flexibility and reliability. The data communication provided using the Modbus protocol enabled uninterrupted and reliable data flow between different components; changes on the interface could be observed consistently and in real time. The system's ability to respond quickly in tests conducted via the slave simulator confirmed the robustness of the communication structure. It revealed that the integrity between the user interface and field data could be maintained.

Furthermore, using scalable and open-source technologies like Modbus and commercial off-the-shelf PLC components, the project offers a cost-effective solution for broader deployment in large-scale transportation infrastructure.

Regarding sustainability, the project aligns with the goals of reducing environmental impact by promoting railway transportation. Compared to road or air transport, rail systems are significantly more energy-efficient and produce fewer emissions (Bollen, 2022; Selipa, 2024; Küfeoğlu, 2024).

The designed system also contributes to social sustainability by supporting the development of accessible and safe public transport networks. Aligning with the United Nations' 2030 Agenda for Sustainable Development, the system addresses the need for safe, inclusive, low-emission transport solutions, especially for vulnerable populations (Küresel Amaçlar, 2020).

Conclusion

As a result, the developed system overcomes the limitations of existing traditional solutions and offers a reliable solution suitable for modern industrial automation needs.

This study demonstrates the feasibility of designing a fail-safe, scalable, cost-effective railway interlocking system that complies with internationally accepted safety standards. Integrating SCADE Display with HIMA PLCs using the Modbus protocol successfully achieved a secure and reliable communication loop between the user interface and field elements.

The results reveal that the method can be easily adapted to different systems and yield successful outcomes in various application areas.

The graphical interface allowed real-time monitoring and control of track availability, switch states, and signal indications while operating within a safety-certified environment.

Based on simulation outputs, the developed graphical interface meets current standards and has established a foundation to accommodate future expansion and scaling needs.

Open communication protocols and commercial off-the-shelf hardware contributed to the system's economic viability and scalability for larger rail infrastructure projects.

During the design process, software and hardware selections followed the industry standards and fail-safe requirements specified in the project, meeting all expected criteria in terms of safety, flexibility, and integrity.

The adoption of standardized and certified tools, such as SCADE Display (compliant with EN 50716), the SILworX platform, and the SafeEthernet protocol, ensured that the system achieved high safety integrity while minimizing development and certification costs (HIMA, n.d.-a), (HIMA, n.d.-b), (HIMA, n.d.-c), (Ansys, 2021).

The method proposed within the scope of this study has proven its success theoretically and practically through the tests and integration processes conducted.

The system's architecture and behavior were also evaluated concerning EN 50129:2020, which outlines the requirements for the functional safety of safety-related electronic systems in railway applications. Compliance with this standard reinforces the system's robustness for deployment in real-world signalling environments (CENELEC, 2018).

The designed system's compatibility with existing structures demonstrates that the method can be effectively used in real-world applications.

From an environmental standpoint, the project aligns with the European Green Deal and global sustainability targets by promoting railway transport as a low-emission, energy-efficient mode of travel (European Commission, 2021). Furthermore, the system's contribution to public safety and infrastructure reliability positions it as a strong candidate for future deployment in innovative and sustainable cities.

In summary, the project validates the potential of combining model-based design, functional safety standards, and industrial communication protocols to create modern, safe, and efficient railway control systems. It meets the technical requirements of fail-safe operation and real-time performance and supports broader economic, environmental, and social sustainability goals.

REAL ESTATE DEVELOPMENT

Real Estate Development

An Event-Driven Architecture in Real Estate Development

Özlem Sertbaş[a], Hakan Yaman[b]

[a] Istanbul Technical University, Graduate Program in Real Estate Development, Turkey
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Turkey
sertbas23@itu.edu.tr

Keywords: EDA, Project Management, RED.

Aim

Real estate development (RED) is a long-term process that covers everything from the initial idea of a project to its final operation. It starts with an idea and is subsequently evaluated through feasibility studies to determine its financial viability, compliance with regulations, and market demand. Then, it moves to the pre-construction phase, which includes the tender process, selecting contractors, finalizing the project, and setting the budget. Then the construction phase and continues through the sale or leasing of the property. Finally, it includes managing and maintaining the building once it's up and running. Basically, RED is a continuous cycle that integrates financial, technical, and operational considerations to create usable and valuable spaces. RED projects are dynamic and typically involve long durations. RED projects also require coordination among multiple parties who may have both common and conflicting goals, making time management a critical factor for success (Eppinger et al., 2013). External factors, including the involvement of stakeholders, can significantly impact the planning and development process. These factors may result in unexpected additional expenses and delays, making it essential to have a comprehensive understanding of the process in order to accurately estimate total costs (Atkin & Borgbrant, 2010). RED has traditionally relied on the experience and intuition of developers and investors. This approach, based on experiences and instinct, involves leveraging past experiences to make informed decisions about future projects (Ruddock, 2008; Turner, 2017). Although traditional approaches used in these processes are generally based on experience and market conditions, emerging technologies have the potential to revolutionize this field. Implementing RED processes through an automated system has the potential to lower error rates, address the shortcomings of conventional approaches, and establish a scientific framework. Considering these aspects, one of the newly adopted methodologies, Event-Driven Architecture (EDA), could serve the development of this system.

Material and Method

This study introduces the result of a literature review and the potential of EDA methods to explore their application in RED processes. Literature review is carried out to understand how EDA has been used in previous studies and to identify its potential in the context of RED. This analysis will establish a basis for understanding the integration of EDA into these processes and the advantages it may offer.

Event-Driven Architecture (EDA) is a software architectural pattern that facilitates communication between distributed systems through the production, detection, consumption, and reaction to events. It enables systems to be adaptable, flexible, and robust, ultimately achieving agility in managing business processes (Sookoo et al., 2016; Vargas et al., 2008). Asynchronous Communication, loose coupling, real-time, scalability and flexibility offered by EDA can meet the needs of RED processes and provide the infrastructure for an agile approach to real estate processes.

Conducting a key search using the terms ("event-driven architecture" OR "event-driven" OR "EDA" OR "reactive architecture") AND ("real estate" OR "property" OR "realty" OR "land development") AND ("development" OR "construction" OR "project management" OR "urban planning") AND ("integration" OR "system" OR "platform" OR "application") AND ("data" OR "information" OR "analytics" OR "insight") reveals findings from a literature review and analysis of existing studies on Scopus. However, none of the papers reviewed specifically address the use of EDA within the realm of RED. For this reason, the literature review focuses on how EDA has been applied in other sectors and if EDA is feasible for RE. To achieve this, a second search was conducted using the keywords ("event-driven" OR "event-based" OR "event-oriented" OR "asynchronous") AND ("system" OR "architecture" OR "framework" OR "model") AND ("application" OR "use" OR "implementation" OR "deployment") AND

("sector" OR "industry" OR "field" OR "domain") AND ("healthcare" OR "finance" OR "transportation" OR "manufacturing" OR "retail" OR "telecommunications" OR "education"). The results of this extensive investigation offer valuable insights into the successful application of EDA in various fields.
This study revealed valuable insights into the successful implementation of EDA in various sectors. The results from both studies may guide the creation of an EDA framework for real-time data processing in RED. However, the practical application of this framework is beyond the focus of this paper.

Findings

The literature review and analysis reveal that none of the papers explicitly address the use of EDA in RED. However, there are notable research works that could offer valuable insights into the potential application of EDA within this field. Adaptability and Flexibility, Proactive Event-Driven Computing, Modularity and Loose Coupling are general principles and benefits of EDA. EDA empowers organizations to be versatile, responsive, and resilient in their management of business processes, ultimately leading to enhanced agility (Sookoo et al., 2016). The flexibility and scalability of EDA can support the dynamic nature of real estate projects, which often involve multiple stakeholders and changing requirements. Proactive event-driven computing can build upon EDA by anticipating and addressing potential negative events or capitalizing on future opportunities through the use of automated decision-making technologies (Engel & Etzion, 2011). Proactive event-driven computing could help in predicting and mitigating risks in real estate projects, such as delays or cost overruns. EDA exhibits similarities with service-oriented architecture (SOA), including modularity and loose coupling. Additionally, it is capable of processing events asynchronously, which enhances its responsiveness to real-time changes (Jieming & Yu, 2009). EDA could be used to integrate real-time data from various sources (e.g. market trends, construction progress, environmental conditions) to make informed decisions. Several industries utilize EDA systems. In the telecommunications industry, event-driven systems play a crucial role in managing and optimizing communication networks. They facilitate efficient data transmission and effectively handle substantial amounts of real-time events (Sachs et al., 2013). Also, in transportation, these systems are crucial for traffic management, enabling real-time monitoring and decision-making based on continuous data from sensors (Dunkel et al., 2008, 2011). EDA helps in managing congestion and improving the efficiency of transportation networks. In supply chain management sector, Event-driven systems enhance the responsiveness and flexibility of supply chains by processing events related to inventory levels, shipment tracking, and demand fluctuations (Chandy et al., 2007; Sachs et al., 2013). In the context of Industry 4.0, event-driven systems are used for real-time data integration and decision-making on the shop floor, improving production efficiency and flexibility (Ferrer et al., 2015; Roset et al., 2005; Rossit et al., 2019; Umer et al., 2018) for the manufactoring sector. In financial sector, event-driven systems are employed in trading platforms to exploit arbitrage opportunities, manage risks, and ensure compliance with regulatory requirements (Chandy et al., 2007; Chung-Sheng Li, 2005; Selby, 2005). Also, in public health sector, Event-driven systems support disease surveillance by processing real-time health data to detect and respond to outbreaks promptly (Chung-Sheng Li, 2005). Likewise, they are used for real-time congestion management and other critical operations in power grids, ensuring stability and efficiency in power control centers (Kumar et al., 2011). EDA facilitates the integration and communication of IoT devices across various environments, such as mobile, edge, fog, and cloud, enhancing the scalability and responsiveness of IoT applications (Berjón et al., 2022). These systems also support large-scale data dissemination and autonomic computing, improving the management and operational efficiency of enterprises (Pietzuch et al., 2007). Event-driven systems are used in the oil and gas industry as well to monitor and optimize production processes in real-time (Chung-Sheng Li, 2005).

Conclusion

RED is a complex, long-term process, then using a real-time monitoring system could help manage risks more effectively. By continuously tracking key milestones, resource use, compliance with regulations, and budget performance, this system would allow teams to spot potential issues early and to react before delays become costly. EDA is a system that reacts instantly to changes or events could improve RED processes by enabling faster data analysis and smarter decisions. With EDA, stakeholders could get clearer, up-to-date information, offering a better project management.

Conventional decision-making in RED typically depends on experience and intuition; however, an EDA-based system provides a more adaptable, data-driven option. Integrating real-time data with predictive analytics can establish a more flexible framework for risk management and decision-making. However, more research is needed to see if such systems are practical for the industry and whether EDA can work alongside or even replace older methods in some cases. While EDA shows promise for RED, its real-world effectiveness and how well it can scale up for large projects still need more profound study.

A Bibliometric Analysis of Metaverse Technologies in Healthcare Services

Seckin Damar[a], Gulsah Hancerliogullari Koksalmis[a,b]

[a] Istanbul Technical University, Department of Industrial Engineering, Faculty of Management, Istanbul, Turkey
[b] University of Central Florida, Department of Industrial Engineering and Management Systems, Orlando, USA
damar17@itu.edu.tr

Keywords: Metaverse, Healthcare Services, Bibliometric Analysis, Web of Science.

Aim

The aim of this study is to provide a comprehensive bibliometric analysis of the healthcare metaverse, an interdisciplinary domain that integrates immersive technologies, such as Virtual Reality (VR), Augmented Reality (AR), Mixed Reality (MR), and Extended Reality (XR), with medical services and education. These technologies have transformed how healthcare is delivered, particularly following the COVID-19 pandemic, by enabling new modalities for clinical training, remote therapy, surgical simulation, and mental health interventions. The acceleration of digital health platforms has exposed the need for scalable, flexible, and accessible healthcare models, which immersive technologies increasingly support. Broadly defined, the metaverse refers to a shared digital space created through the convergence of physical and virtual environments. In healthcare, this digital transformation extends beyond entertainment to create interactive environments for diagnostics, education, and collaboration, challenging traditional care models and introducing new ethical and operational concerns. The growing reliance on simulation-based environments, wearable biosensors, and telepresence technologies has reinforced the healthcare metaverse's potential to fill gaps in medical infrastructure and health equity, particularly in remote or underserved areas. This research is framed within the Science, Technology, and Society (STS) perspective, which examines how innovations co-evolve with institutional structures, societal norms, and ethical frameworks. Applying this lens to the healthcare metaverse reveals critical issues of equity, access, and the changing dynamics between professionals and patients in digital contexts. In doing so, the study not only assesses the technological diffusion of the metaverse but also explores its socio-political embeddedness within healthcare systems. Despite growing academic attention, the field remains conceptually fragmented and methodologically underexplored. This study addresses that gap by applying bibliometric techniques to map the intellectual landscape, identify leading contributors, and analyze structural patterns of the literature. By uncovering thematic clusters and deviations from classical bibliometric laws, the study offers both a diagnostic overview of the field and a foundation for future STS-informed research into the sociotechnical dynamics of healthcare innovation.

Material and Method

This study employed a bibliometric approach using 3,721 publications retrieved from the Web of Science Core Collection spanning from 1994 to 2022. The dataset was generated using targeted search queries incorporating terms such as "metaverse", "virtual reality in health", "augmented reality in health", and related phrases. The analysis was conducted using VOSviewer for mapping co-authorship, keyword co-occurrence, and bibliographic coupling networks. Microsoft Excel was used for descriptive statistics and application of bibliometric laws, including Lotka's Law (author productivity), Bradford's Law (journal dispersion), and Zipf's Law (keyword distribution). Publications were categorized by country, institution, author, document type, research area, and language. These bibliometric laws are widely used to examine the structural characteristics and maturity of research fields, making them especially suitable for analyzing a fast-evolving and interdisciplinary domain like the healthcare metaverse. From an STS perspective, bibliometric methods also offer valuable insight into the institutionalization of emerging fields, the power structures embedded in knowledge production, and the epistemic communities driving innovation.

Findings

The results show that while the USA, England, and Italy lead in terms of publication volume and impact, international collaboration is strong among European, Asian, and North American countries. This pattern indicates that despite geopolitical boundaries, global interest in healthcare transformation through immersive technology is growing. Influential institutions include Università Cattolica del Sacro Cuore and Istituto Auxologico Italiano, and prominent authors include G. Riva and C. Botella. Keyword co-occurrence revealed 12 thematic clusters, such as stroke rehabilitation, simulation, mental health, pain management, wearable technologies, and VR-based education. For instance, "virtual reality" appeared in more than 35% of the documents, indicating its dominant role in this literature. Unexpectedly, the field did not conform to traditional bibliometric laws: the keyword distribution did not align with Zipf's Law, authorship frequency deviated from Lotka's Law, and journal dispersion diverged from Bradford's Law. This divergence suggests that the field is still in a dynamic, exploratory phase characterized by disciplinary overlap and rapid conceptual expansion. The co-authorship networks demonstrated low author-level collaboration despite strong institutional and national links. This may reflect barriers in interdisciplinary communication or the nascency of shared academic platforms. The bibliographic coupling analysis revealed emerging research streams across clinical and educational domains, with varying degrees of technological integration. The rise in annual publication and citation trends after 2007 reflects the growing academic and practical interest in immersive technologies for healthcare service delivery and the subsequent expansion of related scholarly communities.

Table 1. Most influential authors according to total link strength (TLS) and citation.

	According to TLS			According to citation		
Rank	Author	Documents	TLS	Author	Documents	Cites
1	G. Riva	65	2056	G. Riva	65	1768
2	P. Langhorne	35	1044	P. Langhorne	2	1585

10	A. Gasperini	1	545	A. Gasperini	1	952

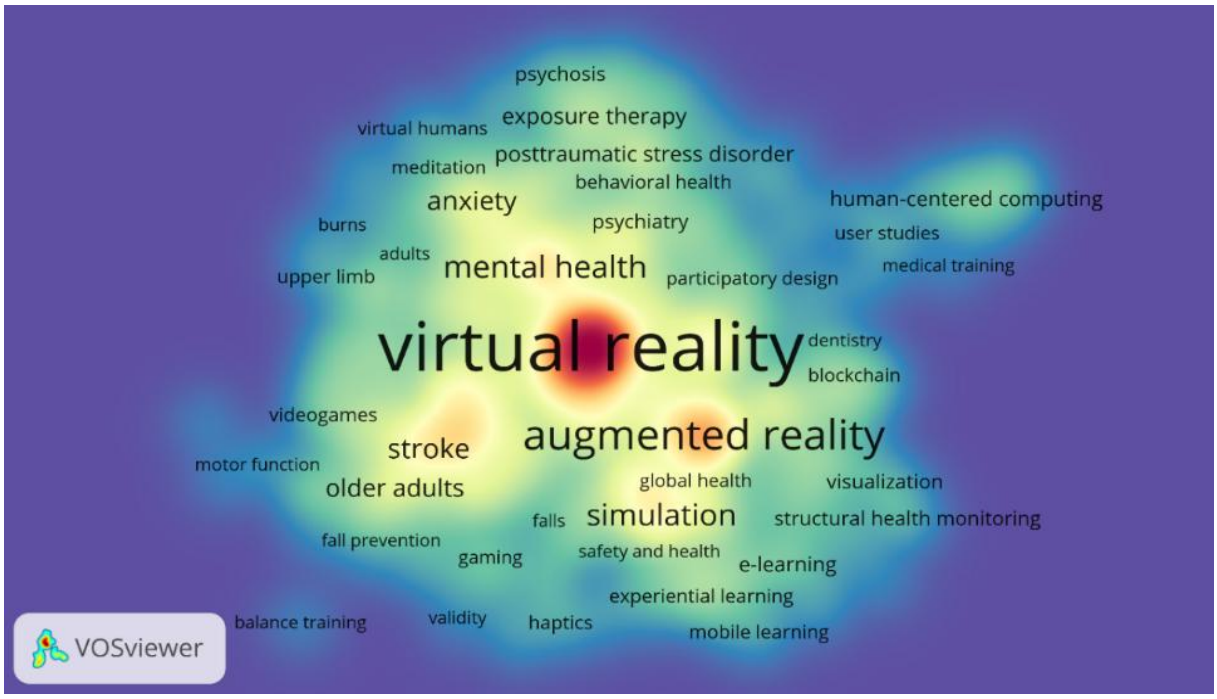

Figure 1. Co-occurrence analysis of author-keywords.

Conclusion

This study is the first comprehensive bibliometric examination of the healthcare metaverse, integrating classical bibliometric laws and network analysis. The results highlight the fragmentation and emergent nature of the field, emphasizing its relevance for interdisciplinary research and science policy. Theoretically, this study contributes to STS by elucidating the mechanisms through which technological innovations shape and are shaped by the healthcare domain. It underscores the importance of institutional actors and epistemic networks in the co-production of healthcare knowledge. Practically, the findings serve as a strategic guide for researchers, policymakers, and technology developers to navigate and contribute to this evolving field. These results may inform funding priorities, collaborative agendas, and curriculum development for medical educators seeking to integrate extended reality into training programs. As digital transformation accelerates in healthcare, understanding the knowledge structures behind metaverse applications becomes essential, particularly for designing inclusive telemedicine services and simulation-based medical education programs that address real-world challenges.

Unintended Consequences of Generative AI in Product Ideation: A Product Management Perspective

Tuğçe Gültekin Atlı[a] , Deniz Tunçalp[b]

[a] Istanbul Technical University, Department of Management Engineering, Master's Degree Program, Türkiye
[b] Istanbul Technical University, Department of Management Engineering, Faculty of Management, Türkiye
atli22@itu.edu.tr

Keywords: Decision-Making Bias, Generative AI, Innovation Management, New Product Development (NPD), Product Ideation.

Aim

The adoption of Generative Artificial Intelligence (GenAI) in product ideation has significantly transformed the new product development (NPD) process, enabling faster brainstorming, enhanced market insights, and automation-driven creativity. Unlike traditional AI systems focused primarily on analysis and classification, GenAI creates original content across multiple formats, demonstrating capabilities for divergent thinking and creative recombination particularly valuable for product innovation. In product ideation contexts, these technologies excel at generating numerous alternative concepts, creating connections between disparate domains, and developing detailed user personas based on market data.

While AI-driven ideation tools such as ChatGPT, Midjourney, Gemini, and Copilot have facilitated idea generation, they have also introduced several unintended consequences that impact creativity, originality, and decision-making. Emerging research suggests that while GenAI might increase individual productivity, it could potentially reduce the diversity of ideas across organizations through mechanisms such as training data bias and standardization of outputs.

This study explores how GenAI is reshaping product ideation in the B2B and B2C sectors, focusing on the unintended risks and challenges associated with AI-generated ideas. The research examines how product managers perceive and navigate these risks, particularly creativity fixation, decision-making bias, innovation standardization, and ethical concerns. By critically analyzing these emerging patterns, the study aims to contribute to the discourse on responsible AI adoption in product management while advancing the Science, Technology and Society (STS) literature by exploring the complex socio-technical interactions between human creativity and artificial intelligence systems in organizational settings.

Material and Method

This study employs a qualitative exploratory approach using semi-structured interviews with experienced product managers from B2B and B2C domains. Eight product managers with at least two years of experience in new product development and direct experience implementing GenAI within their ideation workflows were selected for the study. Participants were from the same sector but possessed expertise and experience in different domains, with representation across both B2B and B2C contexts to ensure comprehensive coverage of product management perspectives.

Data collection involved in-depth interviews conducted through video conferencing, with session durations ranging from 40 to 60 minutes. Each interview was recorded with participant consent and professionally transcribed. Prior to the main study, a pilot interview was conducted to refine the interview protocol and ensure question clarity and relevance. Based on this pilot, adjustments were made to terminology, question sequencing, and prompt specificity.

The research protocol followed a three-step framework: (1) exploring general understanding of GenAI and its integration into workflows, (2) in-depth exploration of experiences with GenAI in new product ideation, and (3) examination of unintended consequences and future perspectives. The interview guide consisted of 14 questions distributed across these three sections, with additional follow-up prompts developed to ensure consistent exploration of key themes. Projective techniques were incorporated into the protocol to help participants articulate

tacit knowledge and implicit assumptions, including asking them to compare ideation processes before and after GenAI adoption using metaphorical descriptions.

Data analysis employed the Gioia methodology, a rigorous qualitative approach involving a systematic three-stage analytical process: (1) coding raw data using "informant-centric" terms, (2) identifying deeper patterns and relationships to develop second-order themes, and (3) distilling these themes into aggregate theoretical dimensions. First, all interview recordings were professionally transcribed verbatim, with transcripts verified for accuracy against the original recordings. Field notes taken during interviews were integrated with transcripts to capture contextual information and non-verbal cues. Initial coding involved an open, line-by-line examination of the data to identify first-order concepts using participant-centric terms. These second-order themes were further consolidated into four aggregate theoretical dimensions: (1) GenAI's role in product ideation processes, (2) creativity fixation and cognitive dependency, (3) standardization of innovation outputs, and (4) decision-making biases and ethical concerns.

Throughout the analytical process, the research team engaged in constant comparison techniques to ensure consistency and validity in the interpretation of data. A comparative dimension was also included to examine how unintended consequences manifested differently across B2B and B2C product management contexts.

Findings

The findings highlight that while GenAI significantly enhances efficiency in product ideation, it also introduces challenges that require critical evaluation. The most significant unintended consequences identified include creativity fixation, homogenization of innovation, decision-making bias, and ethical concerns related to intellectual property and data security.

Product managers reported deep integration of GenAI tools into their daily workflows, with ChatGPT emerging as the universally preferred tool. These tools were primarily positioned as personal assistants rather than replacements for product managers. While participants consistently acknowledged efficiency benefits, their assessments varied—some reported nearly tenfold increases in efficiency for documentation tasks, while others suggested quality improvements might be offset by increased time investment in task completion.

A prevalent concern across interviews was AI's potential to constrain rather than enhance creative thinking. Seven of eight participants expressed that their creativity was being negatively affected through regular AI use. As one participant revealed, "I initially thought it helped my creative process, but now I find myself going straight to AI without thinking first, which has reduced my creativity." This indicates how tools adopted for efficiency can reshape cognitive habits in unanticipated ways. Some participants reported developing dependency patterns, with one admitting, "I've become somewhat dependent on it. I feel the need to consult it even when I know the answer, thinking it might suggest something better."

All participants unanimously observed that GenAI tends to produce standardized, predictable outputs rather than truly innovative ideas. As one participant noted, it typically presents "things that have been known in the market for a long time, compiled and collected." Another characterized AI's outputs as "outdated thoughts" that fail to capture current trends. This standardization in AI-generated content represents a significant concern for product managers whose competitive advantage depends on differentiated thinking.

Decision-making biases emerged as another critical concern. Participants described challenges in verifying AI-generated information, with one explaining, "I try to get references when AI answers, so I can actually cross-check," but often encountered difficulties because "AI often can't provide proper citations." This verification challenge created situations where, as the same participant admitted, "Sometimes I have to use it as a source even when I can't verify the information."

Ethical and intellectual property concerns were also significant. Data security emerged as a primary concern, with participants developing informal safeguards against potential information leakage. One participant revealed an unwritten organizational rule: "We have an unwritten rule not to mention our company name to AI tools." Intellectual property considerations revealed divergent viewpoints, with some participants concerned that "ideas produced by AI belong to the AI itself" and "the same idea could be given to different people, including competitors," while others offered more relaxed assessments, comparing AI-generated ideas to open-source innovation models.

Conclusion

This study illuminates the dual impact of Generative AI in product ideation processes. While GenAI provides significant efficiency gains, especially in documentation and content creation, the findings reveal a complex landscape of unintended consequences that product managers must navigate. GenAI-induced creativity fixation emerged as a particularly concerning phenomenon, with most participants reporting diminished independent thinking over time. As one participant noted, "I initially thought it helped my creative process, but now I find myself going straight to AI without thinking first," illustrating how cognitive patterns can be subtly reshaped by AI tools.

The standardization of innovation represents another significant challenge, as participants unanimously reported that GenAI produces predictable, often outdated outputs that lack truly disruptive potential. Product managers described AI-generated ideas as presenting "things that have been known in the market for a long time," raising concerns about industry-wide homogenization of product concepts if these tools become universally adopted without critical intervention.

Decision-making biases were exacerbated by verification challenges, as participants struggled to authenticate AI-generated information while sometimes feeling compelled to use it even when unverified. This creates potential propagation of misinformation through organizational decision chains. Furthermore, with no formal governance frameworks in place, product managers have developed informal practices to protect proprietary information, such as unwritten rules against mentioning company names to AI tools.

The implications for product management suggest an evolving hybrid approach. Participants demonstrated strategic task allocation, using AI primarily for structured documentation and communication tasks while maintaining human primacy for creative direction and strategic decisions. This selective application helps mitigate risks while capturing efficiency benefits. Product managers also developed adaptive strategies over time, such as thinking independently before consulting AI "to avoid bias," and creating matrix frameworks to provide structure for AI-assisted tasks.

From a theoretical perspective, this research challenges simplistic notions of AI as either purely augmentative or substitutive. The findings reveal a complex interplay where initial productivity gains can gradually shift toward dependency patterns and creative constraint if not carefully managed. The study contributes to STS literature by documenting how technological systems reshape cognitive habits and decision-making processes in professional contexts.

Practical implications include the need for organizations to develop formal governance frameworks for AI-assisted ideation, establish protocols for critical evaluation of AI-generated concepts, and implement training that helps product teams maintain creative autonomy while leveraging AI capabilities. As GenAI tools continue to evolve, finding the optimal balance between computational efficiency and human creativity remains crucial for organizations seeking sustainable innovation advantage.

Keywords: Platform Capitalism, Algorithmic Governance, Music Industry, Digital Streaming, Actor-Network Theory.

Aim

Departing from the Science, Technology and Society (STS) studies, this research explores the music industry's transformation in the era of platform capitalism with a focus on Spotify. This study specifically examines how global platform dynamics manifest in Türkiye's unique cultural and economic context, creating localized impacts on artists, production practices, and consumption patterns. The study analyzes the mediating function performed by the digital streaming platform Spotify and how it shapes the music industry via its technical infrastructure and business practices. It examines the ways in which Spotify has changed power dynamics, production methods and consumption habits. This transformation represents significant shifts in how music is produced, distributed and commodified. Rather than attempting to cover all aspects of this transformation comprehensively, this research strategically focuses on algorithmic governance and the resulting platform dependencies that have emerged in Istanbul's music ecosystem.The study aims to explore the complex relationships between human and non-human elements in the socio-technical system revolved around Spotify, including artists, listeners, producers, algorithms, and technological infrastructures. Actor-Network Theory (ANT) is particularly valuable for this research as it enables the analysis of how agency is distributed across networks rather than residing solely in human actors or technological systems. This theoretical approach uniquely positions us to understand how algorithmic systems and human actors co-produce the contemporary music ecosystem through what we identify as forms of "hybrid agency." Thus, the objective of the research is to explore how these platform dynamics are translated in a local context.

Material and Method

The research uses a mixed-method approach combining primary and secondary data collection methods. Primary data was gathered through semi-structured interviews with 12 music industry professionals in Türkiye between March-April 2025, following ethical approval from Istanbul Technical University. Participants included independent and signed musicians, sound engineers, managers, producers, music journalists, digital marketing professionals, and record label employees, providing a representative cross-section of Türkiye's music ecosystem. The interviews lasted approximately 45 minutes each and focused on understanding participants' direct experiences with Spotify, particularly regarding algorithmic bias, pressure to create algorithmically successful content, financial dependency, and practices that reinforces platform dependency. In the quantitative phase, secondary data collection was based on analysis of personal Spotify account data, including taste profiles and streaming history metrics. Descriptive statistical analysis was applied to visualize and interpret these data sets, revealing how platforms classify and commodify user preferences. Secondarydata collection method involves a systematic review of the literature on the effects of platform capitalism in the music industry, the digital music economy, and algorithmic governance of Spotify. The theoretical framework draws primarily on ANT to analyze the interaction of various actors and systems to demonstrate how they shape musical practices and experiences. This framework positions Spotify not as a neutral intermediary but as an active mediator that reconfigures power dynamics.

Findings

The research findings reveal four key dimensions of the impact of platform capitalism in the music ecosystem in Türkiye. First, Spotify's recommendation algorithms have created new forms of "hybrid agency". This creates a situation where musical preferences become entangled with machine learning. This concept helps explain how human intention and technological systems co-produce musical experiences that would not exist through either human or algorithmic action alone. These algorithms generate what might be called "taste profiles", which are digital fingerprints of listeners' musical preferences that become increasingly detailed with each interaction. While these profiles facilitate personalized experiences, they simultaneously create "filter bubbles" that limit genuine musical discovery and serendipity. These algorithmic enclosures represent a significant shift from previous modes of music discovery that relied more heavily on social recommendations, music criticism, and radio programming.
Second, platform dynamics have transformed production practices where artists increasingly design their music to perform well within algorithmic systems. This includes changing the duration and shortening songs, and placing hooks at the beginning to prevent skipping. Our interviews with Turkish music professionals revealed that the question "How will this sound on Spotify?" has become more important than artistic decisions. This is a shift where choices made are increasingly influenced by algorithmic impositions rather than artistic considerations.
Third, the thesis also reveals the effects of platform dependency. While Spotify present itself as democratic space where any artist can distribute their work, this research reveals a more complex reality. The platform's claims of democratization conflict with the empirical evidence that shows increasing concentration of streaming revenue among a small percentage of top artists. In the Turkish context, this is further complicated by the privileged position of distributors with local offices who have direct relationships with Spotify's editorial team, creating new gatekeeping mechanisms that disadvantage truly independent artists. Algorithmic systems mostly benefit already popular artists, making it increasingly difficult for independent musicians to gain visibility without significant marketing budgets or placement on editorial playlists in Spotify. This dependency extends to data-centricity, as artists increasingly make creative and marketing decisions based on metrics provided through tools like Spotify for Artists.
Fourth, the research illuminates the changing financial landscape of music. The pay-per-stream model mostly benefits highly streamed artists with large catalogs, and record labels. Independent artists now must increasingly invest in advertisements on social media platforms and continuously create for the standards of algorithms. In Türkiye, these economic dynamics are intensified by lower subscription fees which makes it almost impossible for artists to sustain themselves economically through streaming revenues alone.

Conclusion

This research explores how platform capitalism transforms the music ecosystem in Türkiye by creating new power dynamics, and dependencies for artists. This study's contribution lies in its exploration of how global platform dynamics are localized within Türkiye's specific cultural and economic context, revealing both universal and localized patterns of platform capitalism. The research contributes to our understanding of how technology reshapes cultural production through subtle but pervasive mechanisms of algorithmic governance and digital mediation. Digital platforms enable broader access to music, but they also introduce new forms of control and dependency through platform capitalism. The supposedly straightforward act of streaming a song now involves complex networks of data centers, content delivery networks, and algorithmic systems that track, analyze, and monetize every interaction. Finallythe research reveals a paradox: the very features that appear to democratize music distribution actually create new gatekeepers and barriers. Rather than viewing this transformation in simplistic terms of democratization or exploitation, our ANT approach reveals a more nuanced reality where agency is distributed across human and non-human actors, creating new socio-technical arrangements that both enable and constrain artistic expression. Algorithmic curation systems replace traditional expert-based selection methods while creating new forms of inequality and dependency. Artists must now consider not only the creative aspects of music-making but also the technical and data-driven aspects.This reconfiguration of the music industry requires new theoretical approaches and policy interventions to address emergent power imbalances. This research has significant implications for exploring contemporary music production under platform capitalism. By continuing to examine the socio-technical networks that constitute the contemporarymusic ecosystem, we can

better understand how to create more equitable conditions for listeners, musicians, musical production and consumption in the age of platform capitalism.

Aim

The study presented in these extended abstract aims to lay the groundwork for an ongoing master's thesis on sustainable operations and maintenance practices in offshore oil and gas activities, with a focus on developing a framework tailored to the future of Somalia's offshore sector. It examines the Penglai 19-3 incidents—the primary catalysts of China's largest offshore oil spill in Bohai Bay in 2011—with a particular focus on the accidents at Platforms B and C. The objective is to conduct a case study analysis of these events to identify operational and regulatory shortcomings, evaluate response strategies, and assess environmental impacts. By detailing the failures—including inadequate maintenance and inspection practices, deficiencies in risk assessment and management, delayed reporting, and weak regulatory oversight—the study seeks to extract critical lessons from these incidents. These insights are intended to inform and support the development of more robust and sustainable operations and maintenance (O&M) frameworks for the offshore oil and gas industry.

Materials and Methods

The methodology adopted in this study combines a comprehensive literature review and case analysis to investigate offshore oil spill and prevention response, focusing on the Bohai Bay 2011 Oil Spill Incident. A systematic literature review was conducted to gather insights into the causes, impacts, and mitigation strategies for oil spills. Sources included peer-reviewed journals, governmental reports, and industry publications. Key focus areas included oil spill environmental impacts and reasons to draw parallels and derive lessons applicable to the Bohai Bay 2011 Oil Spill Incident. The Bohai Bay 2011 Oil Spill Incident was chosen as the primary case study due to its significance as one of the largest offshore spills in China's history. Data were collected from governmental reports, environmental studies, and independent assessments to provide a detailed account of the

incident, including the causes, response measures, and environmental consequences. Key aspects of the case study included examining operational practices, regulatory gaps, and the response strategies implemented during the spill.

Findings

Based on the author's review and independent assessment of the Penglai 19-3 incident, several operational, maintenance, and risk management weaknesses were identified. These findings, summarized below, highlight critical factors contributing to the 2011 Bohai Bay oil spill and inform risk mitigation strategies for emerging offshore fields such as those in Somalia.

The 2011 Bohai Bay Oil Spill, recognized as China's largest offshore oil spill (Yang et al., 2017), occurred as a series of oil spill incidents at the Penglai 19-3 and Suizhong 361 oil fields in the Bohai Sea. This study focuses particularly on the incidents at Platforms B and C of the Penglai 19-3 oilfield, which were the main triggers of the 2011 Bohai Bay Oil Spill and does not cover the Suizhong 361 spill in detail. The Bohai Sea is a semi-enclosed continental shelf sea in the northern region of China. It is surrounded by land on three sides and connected to the Yellow Sea through the narrow Bohai Strait (Figure 1), The first spill at Penglai 19-3 was caused by a leak in a subsurface reservoir during water injection operations, resulting in the release of oil from a natural geological fault on June 4th. The second spill occurred on Platform C on June 17 when operators encountered unexpected high pressure while drilling a water injection well, leading to a loss of well control and the subsequent release of a large volume of oil (Wang et al., 2020a).

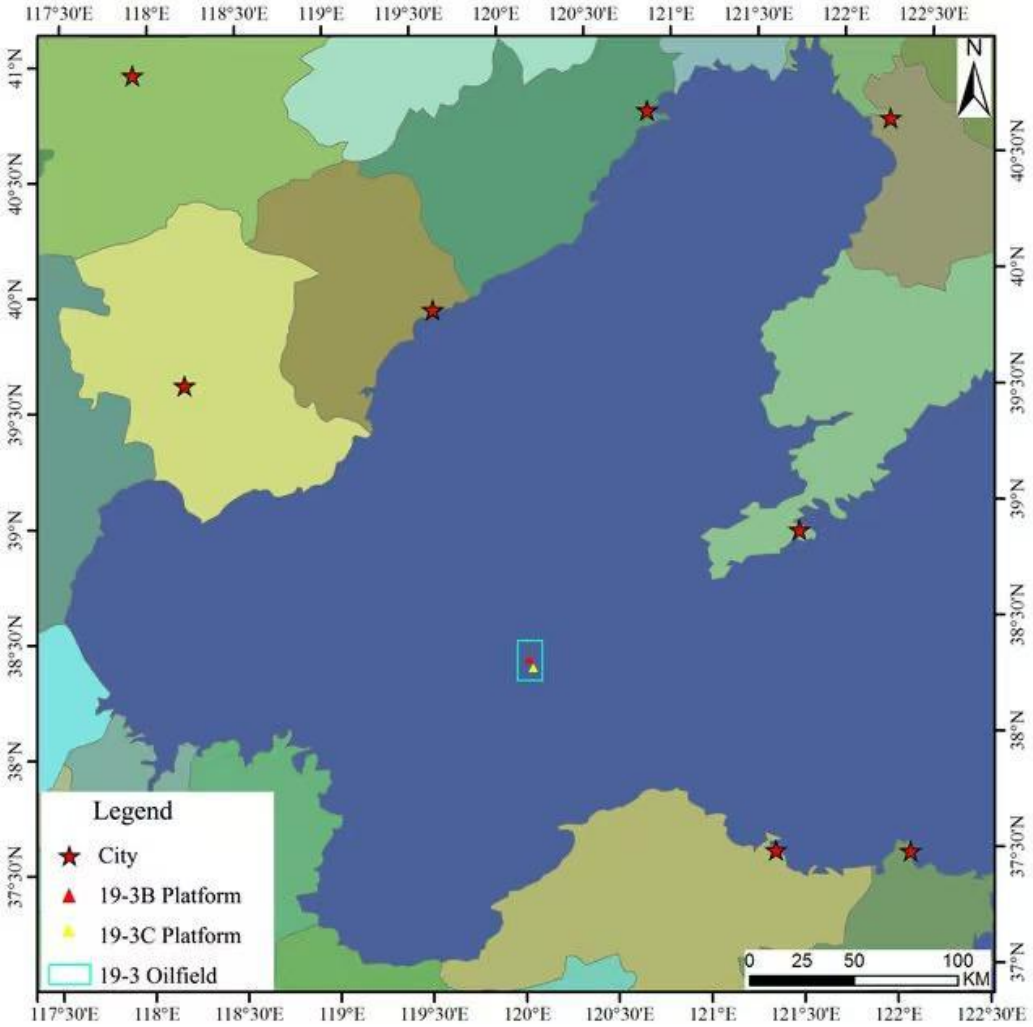

Figure 1: Location of the Bohai Sea with Penglai 19-3 oil field platforms B and C (marked by red and yellow triangles, respectively, at approximately 120°E, 38.5°N) (Yan et al., 2015).

The primary issue was poor integration between subsurface geological knowledge and operational practices, especially regarding fault compartmentalization and pressure monitoring. The field's structural complexity and compartmentalized reservoir system were not fully considered during water injection operations, increasing the risk of localized overpressure.

The oil platform was operated by ConocoPhillips China Inc. (COPC), which reported the release of 723 barrels of oil and 2620 barrels of mineral oil-based drilling muds into the sea over several days [2]. However, the spill turned out to be much larger, as shown in Table 1. Over the following months, oil continued leaking from the seafloor at a steady rate. By early July 2011, an oil slick covering 840 square kilometers had formed around the spill site (Chenglin Liu, 2014). The Chinese government eventually estimated that more than 60,000 barrels of oil and drilling mud had spilled into the Bohai Sea (Yang et al., 2017). The spill directly threatened the marine ecosystems and economies of three provinces: Shandong, Hebei, and Liaoning (Pan et al., 2015).

Table 1: Timeline and Impact of the 2011 Penglai 19-3 Oilfield Oil Spill Incident (Wang et al., 2020a)(Yang et al., 2017)(China.org.cn, 2011)(Zhang, Y. Z., 2013).

Date	Event Summary	Volume Estimate	Polluted Area	Notes
June 4, 2011	Leaking oil detected near Platform B	Not reported	Not specified	Initial detection, no immediate response reported
June 17	Second spill reported near Platform C	Not reported	Not specified	COPC delays reporting to State Oceanic Administration (SOA)
July 5	SOA briefing; NGOs demand apology	723 barrels oil, 2,620 barrels mud (COPC)	Not specified	COPC accused of concealing spill for ~1 month
July 13	SOA criticizes ineffective containment	Not updated	4,240 km²	Production halt ordered; response deemed inadequate
July 14	COPC updates estimate	1,500 barrels (COPC)	Not specified	Revised estimate still underreported
Aug 12	Company admits larger spill volume	>3,200 barrels (COPC)	Not specified	Concedes insufficient leak checks
Aug 23	SOA reports extensive pollution	Not specified	5,500 km²	870 km² severely contaminated; aligns with Zhao's >5,500 km²
Aug 31	COPC claims leaks sealed	>60,000 barrels (CG)	5,500 km²	CG estimate: cleanup deadline met
Sept 7	State Council warns of environmental issues	Zhao: tons range	>5,500 km²	Long-term ecological risks noted

The initial response efforts were criticized for their delayed and inadequate nature, with reports of the spill being downplayed or concealed by the operating company (Lustgarten, A., 2008). Eventually, the spilled oil was contained using various techniques such as skimming, dispersants, and sorbent materials (Wang et al., 2020b). The spill had significant impacts on the marine environment and local fisheries in the Bohai Sea region, as shown in Figure 2.

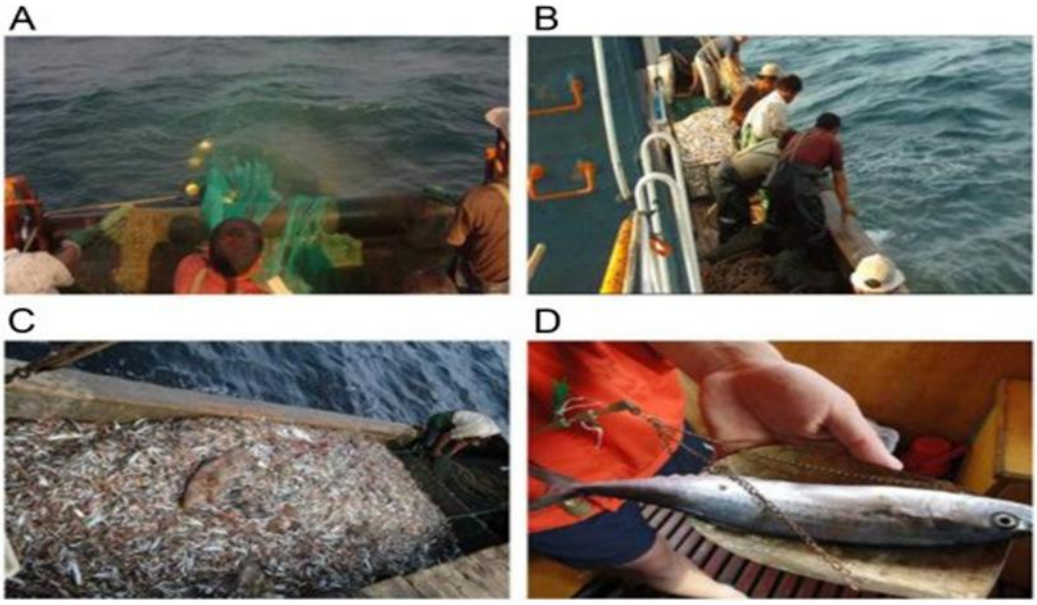

Figure 2: Illustration of the field investigations conducted: A) deploying the trawling net into the sea; B) retrieving the trawling net from the sea; C) unloading the catch onto the deck of the vessel; D) measuring the biological metrics of the primary catch (Pan et al., 2015).

One of the significant contributors to the Bohai Bay 2011 Oil Spill Incident was inadequate maintenance and inspection practices (Wang et al., 2020b). Offshore drilling operations require robust infrastructure monitoring to detect vulnerabilities in equipment and seabed stability (Guo et al., 2019). In this case, the high-pressure water injection led to cracks in the seabed, a failure that could have been prevented through regular inspections and predictive maintenance protocols (Wang et al., 2020b). The lack of advanced technologies to monitor underwater infrastructure in real time exacerbated the problem, delaying the detection of cracks and leaks (Jiang, 2022). Additionally, the absence of systematic equipment audits and insufficient training of maintenance personnel revealed serious flaws in operational readiness (Ettayib & Kara, 2025). The spill also exposed significant gaps in risk assessment and management practices (Wang et al., 2020b). Effective offshore operations depend on comprehensive risk analysis to anticipate potential hazards (S LI & Zhang, 2013). In this case, the high-pressure water injection system's operational limits were not adequately evaluated, leading to conditions that the infrastructure could not withstand (Zou & Wang, 2017). Furthermore, contingency planning was either absent or insufficient, as evidenced by the delayed response to the spill (xu & Zhao, 2014). Without a robust risk management strategy, the operators failed to prioritize early warning systems or establish rapid response mechanisms, allowing the spill to escalate (ZHOU, 2014). Regulatory oversight also played a role; weak enforcement of safety protocols and limited industry accountability prevented proactive risk mitigation efforts (Li, 2013). The challenges of addressing the spill were compounded by delayed reporting and a lack of strong regulatory frameworks (Liu et al., 2012). Operators did not report the incident promptly to Chinese authorities, which delayed emergency containment efforts (Chen, 2012). This delay indicated a failure in communication channels between the oil company and regulators, a critical component of effective risk management (Zhang & xu, 2014). At the time, although China had Environmental Protection Laws and Regulations in China as shown in Table 2, its offshore drilling regulations lacked detailed safety standards and enforcement mechanisms, leaving companies without clear accountability for operational risks (Yu & ZHOU, 2014).

Table 2: Major Environmental Protection Laws and Regulations in China (Government of China, n.d.-a),(Government of China, n.d.-b)].

Regulation	Description
The Environmental Protection Law of the PRC (September 1979)	Covers all environmental protection issues.
The Marine Environmental Protection Law of PRC (August 1982)	Aims to protect the marine environment and resources, prevent pollution damage, maintain ecological balance,safeguard hu- man health, and promote the development of marine programs.
Regulations of the PRC concerning environmental protection in offshore oil exploration and exploitation (December 1983)	Prevents pollution damage to the marine environment by off- shore oil exploration and exploitation.
Regulations of the PRC concerning the dumping of wastes at sea (March 1985)	Strictly controls the dumping of wastes at sea to prevent pollution damage to the marine environment.
Management guidelines on environmental protection at construction projects of the PRC (March 1986)	Strengthens the management of the environmental impact as- sessment of construction projects.

China implemented regulatory reforms following the Penglai 19-3 oil spill, as outlined in Table 3. These reforms included strengthened environmental regulations, enhanced oil spill response and preparedness, improved offshore safety regulations, more stringent monitoring and inspection protocols, strengthened penalties for non-compliance, international cooperation, development of an offshore oil spill response network, and promotion of cleaner energy exploration. Implementation occurred through legislative updates and administrative directives starting in 2012, such as revising environmental protection laws, mandating contingency plans and real-time monitoring systems, and aligning with IMO/IOGP standards by 2014. Enforcement is managed by the State Oceanic Administration (SOA) and other agencies via increased inspections, third-party audits, fines, and public disclosure requirements.

Table 3: Offshore Regulatory Reforms Following the Penglai 19-3 Spill (Zhang, Y. Z., 2013),(Ettayib & Kara, 2025), (Yu & ZHOU, 2014), (State Oceanic Administration, n.d.), (Ministry of Natural Resources, n.d.).

Category	Reform	Year	Notes
Strengthened Environmental Regulations	Revision of Environmental Protection Laws	2013	Mandated EIAs and spill contingency plans following Penglai spill
Strengthened Environmental Regulations	Enhanced Pollution Control and Liability	2016	MEPL updated for ecological damage compensation and coastal protection
Enhanced Oil Spill Response	Mandatory Emergency Drills and Plans	2012	Improved spill preparedness post-Penglai
Improved Offshore Safety	New Drilling Standards and Safety Audits	2012	Addressed well control failures

Monitoring/Inspections	Frequent Checks and Real-Time Data	2013	Strengthened oversight after spill
Penalties	Tougher Fines and License Revocation Risks	2013	Increased accountability
Institutional Reform	Ministry of Natural Resources Established	2018	Centralized marine oversight, replacing SOA for better coordination
International Cooperation	Alignment with IMO/IOGP Standards	2014	Adopted global best practices
Spill Response Network	National Spill Response Plan Development	2015	Unified response framework
Cleaner Energy	Sustainability Reports Mandated	2015	Promoted greener operations

Author's Contribution

This study proposes a novel synthesis of the Penglai 19-3 failures by organizing them into three categories. First, geohazard assessment and fault identification, which allowed oil leaks through natural faults during injection. The second was weak maintenance and monitoring, which made it difficult to detect leaks and cracks early. The third was poor communication with government regulators, which delayed the emergency response. This way of organizing the problems makes it easier to understand how one failure led to another. It also helps suggest simple actions like better hazard training, real-time pressure checks, and faster reporting to avoid the same problems in future offshore operations.

Conclusion

The Penglai 19-3 incidents critically underscore the need for a comprehensive and proactive approach to offshore oil spill prevention and response. This case revealed significant deficiencies in operational practices, including inadequate maintenance and gaps in risk assessment, along with shortcomings in monitoring, communication, and regulatory enforcement. These findings highlight the urgency of implementing robust safety measures and aligning offshore operations with international standards.

Building on this analysis, the study lays a foundation for identifying critical components of sustainable operations and maintenance (O&M) practices, particularly in regions with developing offshore capacities. The institutional and technical gaps observed in the Penglai case serve as a reference point for formulating context-aware policy recommendations, especially within the scope of the ongoing master's thesis on Somalia's offshore sector.

Preventive strategies—such as regular infrastructure maintenance, real-time environmental monitoring, and stronger regulatory oversight—are essential for minimizing the risk of future spills. These insights contribute to the development of practical guidelines that support both environmental protection and operational reliability in emerging offshore contexts.

Keywords: Electric Arc Furnace (EAF) Slag, Geotechnical Properties, Recycled Concrete Aggregate (RCA), Waste Utilization.

Aim

The construction industry needs to adopt new sustainable practices because of the reduction of natural resources. Additionally, to decrease the environmental challenges posed by waste generation, some new materials should be utilized in various functions. Recycled concrete aggregate (RCA) and electric arc furnace (EAF) slag are two industrial products with considerable potential for reuse in different applications in construction practices. Nonetheless, their utilization is limited due to the insufficient data for their engineering properties and their long-term performance. The other issue that has significant importance is the swelling potential that it should be ensured. This study aims to specify this gap by performing a comprehensive characterization of RCA and EAF slag, evaluating their properties as alternatives to conventional construction materials.

As the result of the tests is shown below, the data for RCA aligns with the typical range of conventional granular materials. (Das, 2015). Additionally, EAF slag in case of complication performance and density outperforms natural aggregate. As expected, the mixture exhibits intermediate properties. The primary goal of this study is to reach the physical, mechanical, and geotechnical properties of RCA, EAF, and the mixture of them at different ratios by weight. The findings of this research are expected to provide sufficient data and considerable insights into the workability of using RCA and EAF slag in construction applications and promoting the reuse of waste material. Additionally, the swelling potential of EAF slag should be decreased to be utilized in a long-term period. By indicating the determined properties of the materials, this research can reach the purposes of sustainable engineering, such as waste management, environmental protection, and natural resource conservation. Additionally, the test results will be able to present functional data for the applications that can be utilized in the construction industry.

As a result, this study aims to connect waste management and civil engineering. Moreover the findings of the study will help to develop guidelines for the use of these materials in various applications and contribute to a more sustainable construction system.

Material and Method

Materials

The materials that have been under investigation in this research are:
1-Recycled Concrete Aggregate (RCA) is sourced from demolished concrete structures. The materials are removed from impurities such as wood, metal, and plastic.
2-Electric Arc Furnace (EAF) Slag is obtained from steel manufacturing facilities. EAF slag has been collected, cooled, and processed to extract metallic residues. The slag was crushed and sieved according to standard procedures to reach the needed specifications for this study.

The mixed forms of RCA and EAF slag were prepared to evaluate the combined performance of these materials.

Figure1. EAF slag and RCA.

Methods

A comprehensive series of laboratory tests was conducted to evaluate the different properties of the materials, such as index and engineering properties. The methods used are described in detail below:
A sieve analysis was done to determine the particle size distribution of the mentioned materials. They were passed through the standard series of sieves ranging from 75 mm to 75 µm, and then the percentage of material retained on each sieve was calculated. This test was performed according to ASTM C136/C136M-14.
The specific gravity of materials is determined by using a pycnometer. The specific gravity is measured according to the volume of displaced water. The process was done based on ASTM C127-15.

To evaluate the compaction properties, the standard Proctor test was done at different moisture contents. By utilizing standard molds and a hammer that should be dropped from a specific height, the properties were assessed. The dry density and optimum moisture content of the materials and the mixture of them were determined. This test is critical for understanding the compaction behavior of the material and the maximum reachable dry unit weight, which influences their performance in the applications. The test was done based on ASTM D698.

To evaluate the bearing capacity and strength of RCA and EAF slag and their mixtures, the CBR test was performed. The test was done under both dry and water-soaked conditions:

Dry CBR: The samples were prepared with optimum moisture content and were tested without soaking.

Water-Soaked CBR: Samples were submerged in water for at least 96 hours in order to create a simulation of long-term exposure to moisture; after that, the CBR test was performed.

The strength data were obtained from both conditions and were compared to standard crushed stone aggregates. The test is relevant to assess the performance of materials in road subgrades and base layers. The test was performed according to ASTM D1883-16.
To assess the volumetric stability of materials, conducting this test is needed. Compacted soil samples are saturated with water, and the change in sample height is measured during a specified time duration. This test has significant importance in order to evaluate the material performance during a long-term time interval. Materials with low

swelling potential are more sustainable for geotechnical applications. The procedure is done based on the ASTM D4546-14.

By using a direct shear apparatus, the shear strength parameters of materials are assessed. Samples are subjected to varying normal stresses, and the shear stresses are recorded to determine the internal friction angle and cohesion. These parameters are so crucial for assessments of materials performance in case of slope stability and embarkment applications. The test is done according to ASTM D3080/D3080M-11.

All tests were performed according to international standards. Mostly including ASTM to ensure the reliability of the results. Additionally, during all the procedures, samples were prepared, tested, and data were recorded by careful attention to reduce the errors and minimize probable mistakes and guarantee the accuracy of findings. The series of data that were collected from the standard laboratory tests have been analyzed to compare the properties of the materials with conventional construction materials properties.

Findings

The experimental data from the sieve analysis, specific gravity, compaction, and California Bearing Ratio (CBR) tests provide a series of data that can show different properties of RCA, EAF slag, and the mixture (50% EAF + 50% RCA). Below is a comprehensible analysis of the results and findings.

RCA: The grain size distribution of this material shows that the gravel percentage (G) of it is 31.1%, the sand percentage (S) is 67.6%, and the percentage of fine grains (M and C) are 1.3%. Its uniformity coefficient (Cu) is 10.57, and the coefficient of gradation (Cc) is 0.772. According to the Unified Soil Classification system (USCS), RCA was classified as SP (poorly graded sand), and according to AASHTO classification, RCA is a granular material used in road subgrades that was classified under the A-1-a category.

EAF slag: The grain size distribution of EAF slag shows that 62.2% is gravel (G), 37% is sand (S), and 0.80% is fine grains (M and C). EAF slag is coarse grained, and the uniformity coefficient (Cu) is 8.64, and the coefficient of gradation (Cc) is 1.17. According to the Unified Soil Classification system (USCS), RCA was classified as GW (well-graded gravel), and according to AASHTO classification, EAF shows excellence of stability for various applications and was classified under the A-1-a category.

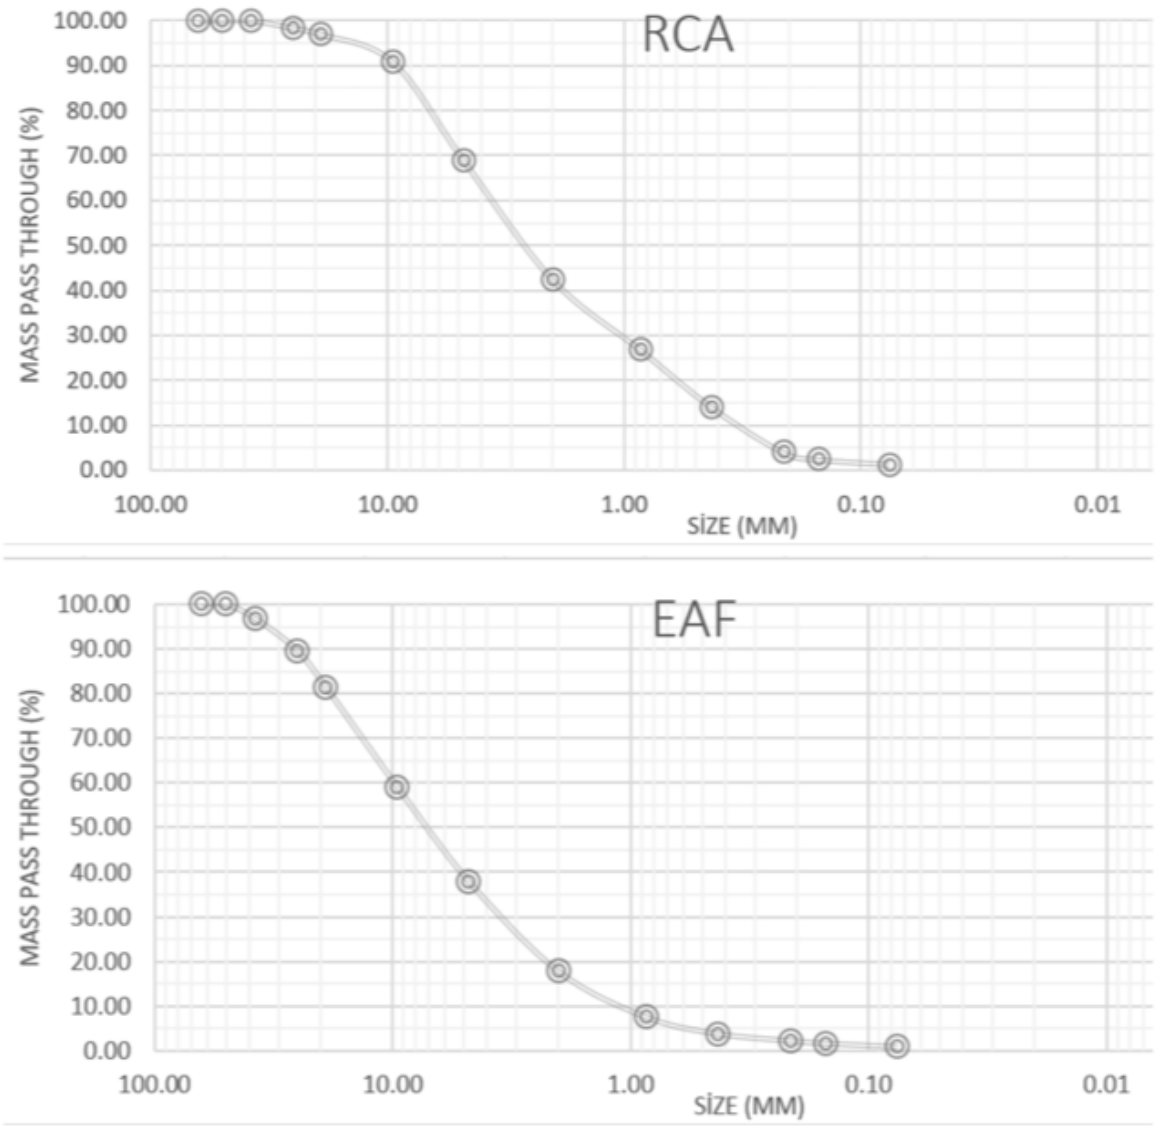

Figure2. Grain size distribution curve (EAF and RCA).

The specific gravity of RCA (2.59) is a little bit lower than the conventional natural sand soil aggregates (2.6-2.8), which is related to the existence of adhered mortar in RCA (Oikonomou, 2005).
On the other hand, EAF slag indicates a superior specific gravity (3.74) because of its metallic content. This high specific gravity increases its sustainability for road base layers and the other high-density applications.
The compaction test result indicates that, the data for RCA aligns with the typical range of conventional granular materials. (Das, 2015). Additionally, EAF slag in case of complication performance and density outperforms natural aggregate. As expected, the mixture exhibits intermediate properties.

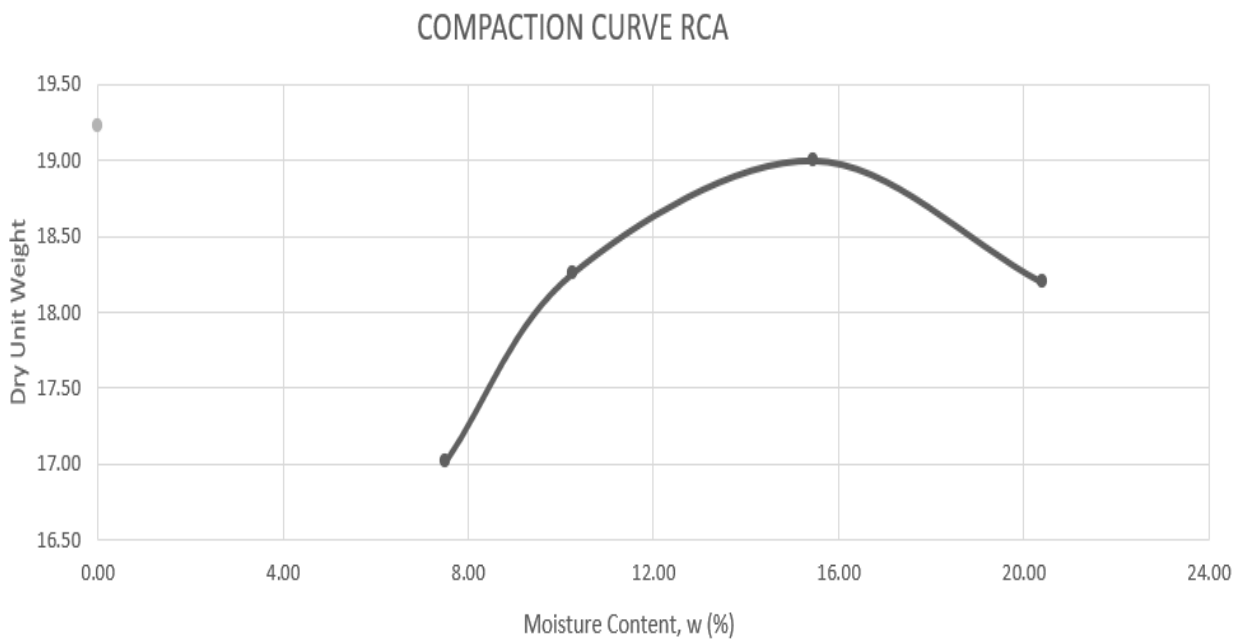

Figure3. Compaction curves of materials (RCA).

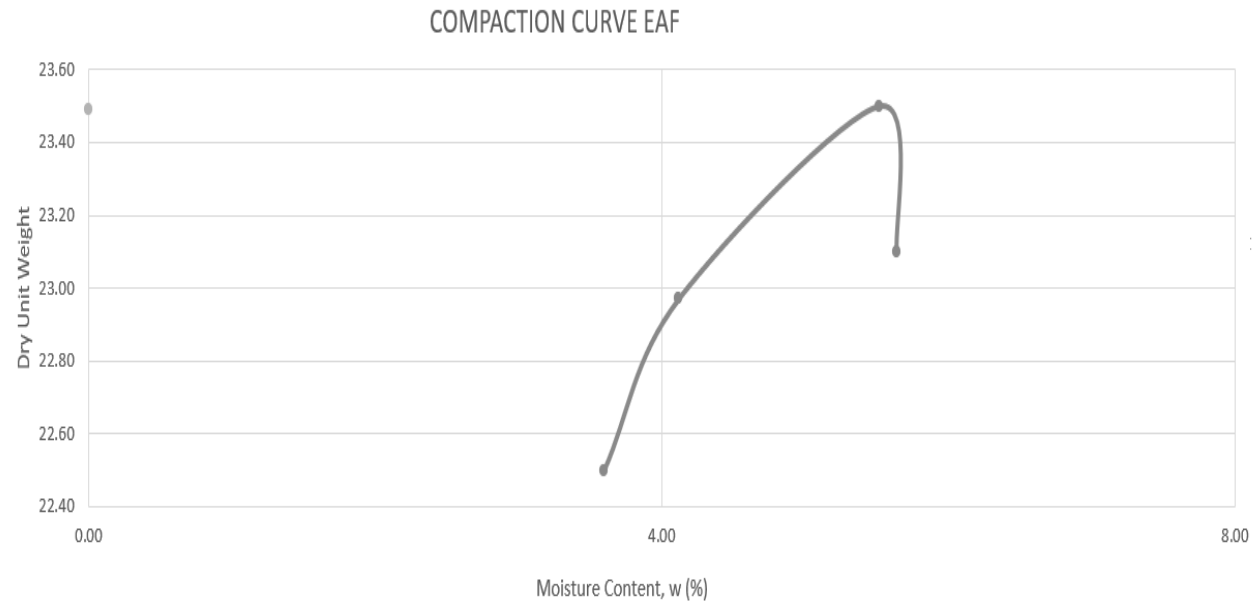

Figure4. Compaction curves of materials (EAF).

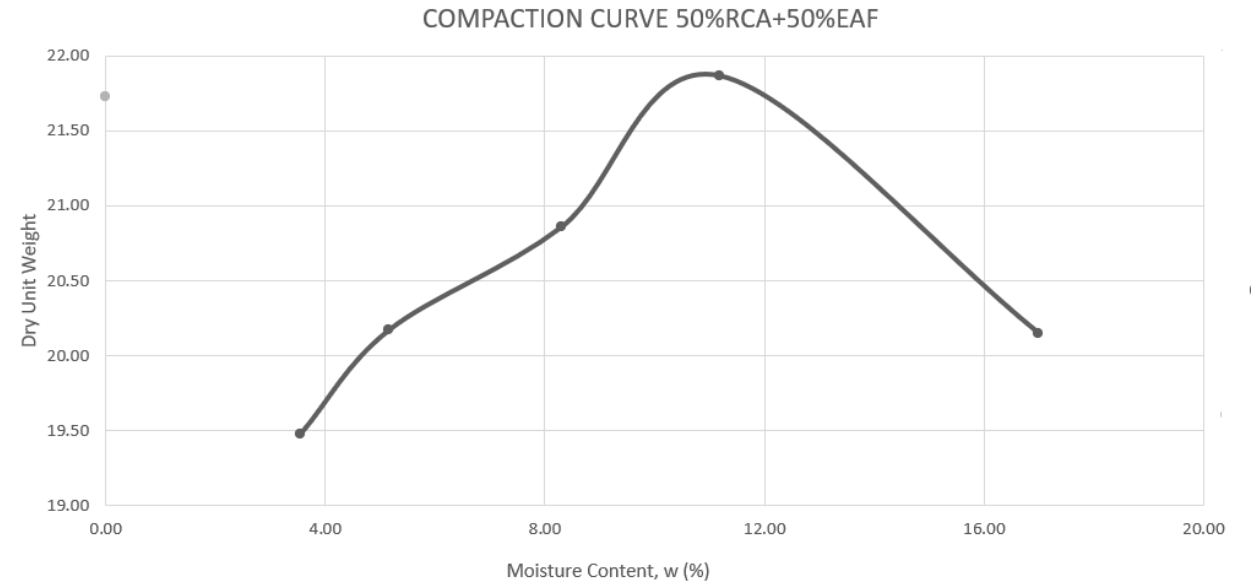

Figure5. Compaction curves of materials (50%RCA+50%EAF).

4. California Bearing Ratio (CBR)

The result, as shown below, indicates that EAF has a CBR value higher than conventional materials. As well, the mixture of the materials shows higher load-bearing capacity. The swelling percentage of RCA is almost 0%, and this property for EAF is 3.44% in the soaked CBR test result.

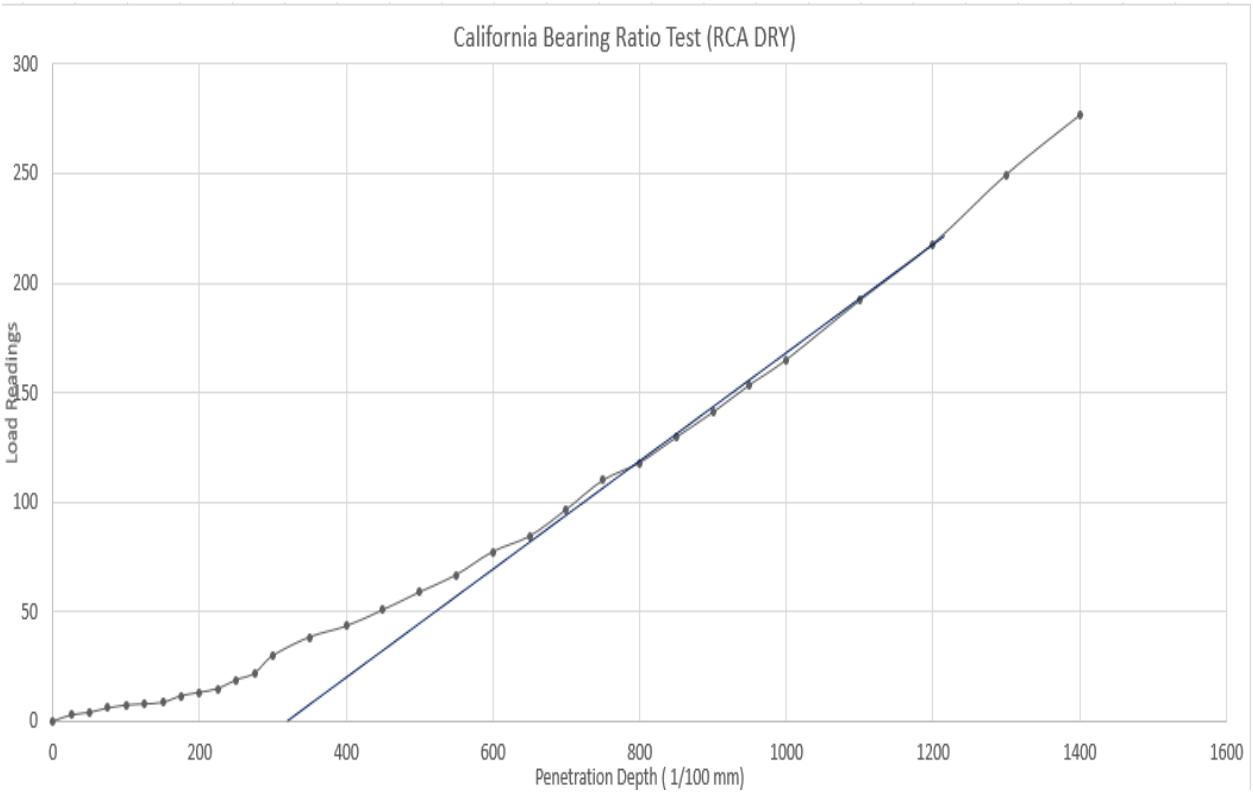

Figure6. CBR test result for RCA(Dry).

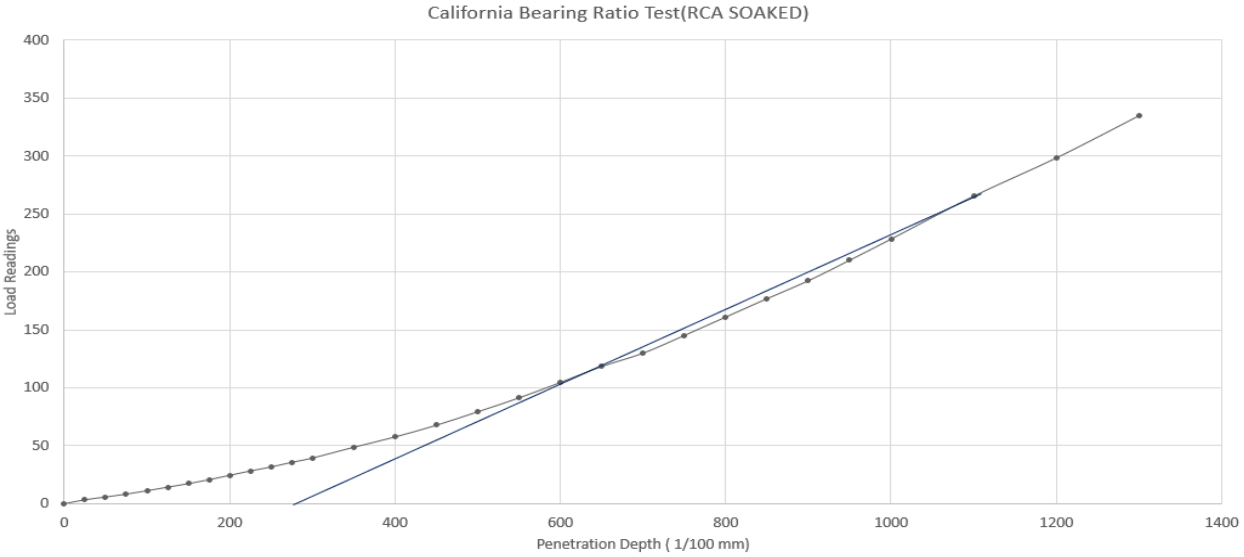

Figure7. CBR test result for RCA(Soaked).

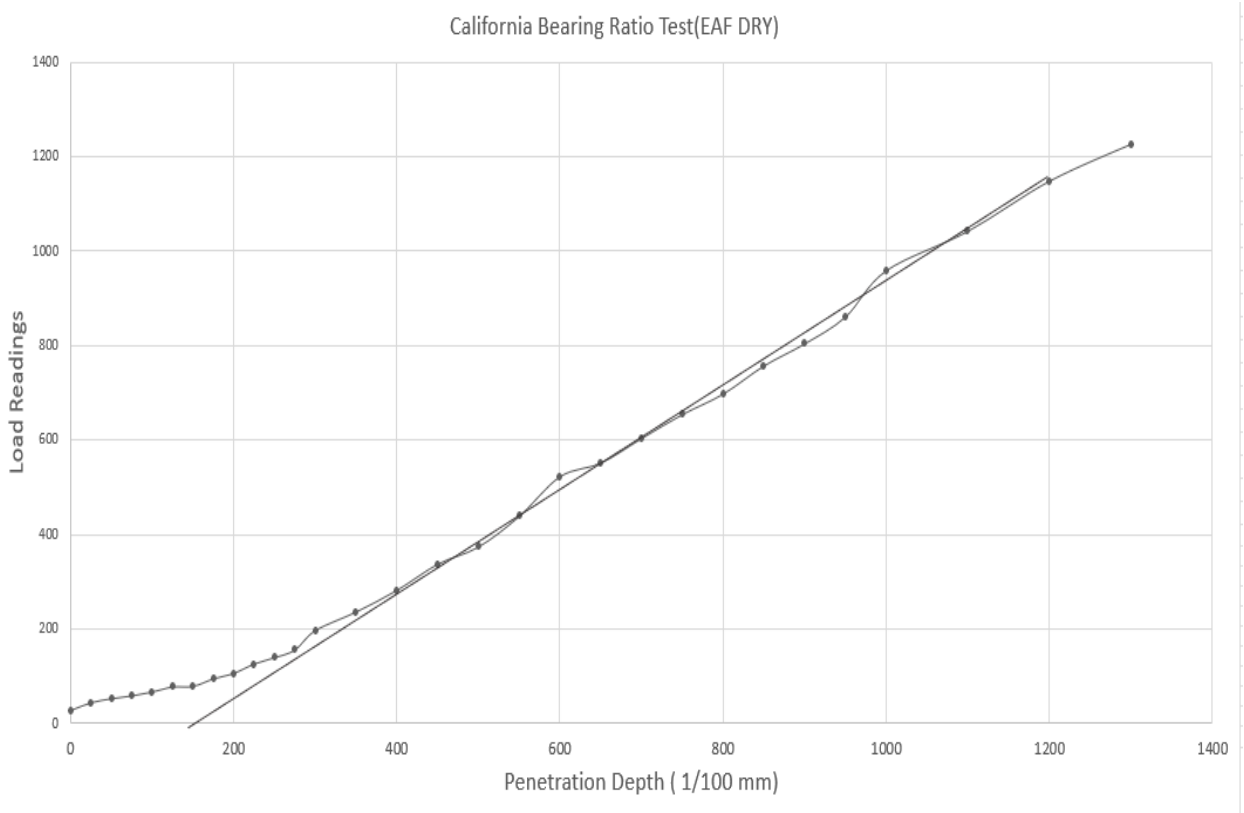

Figure8. CBR test result for EAF(Dry).

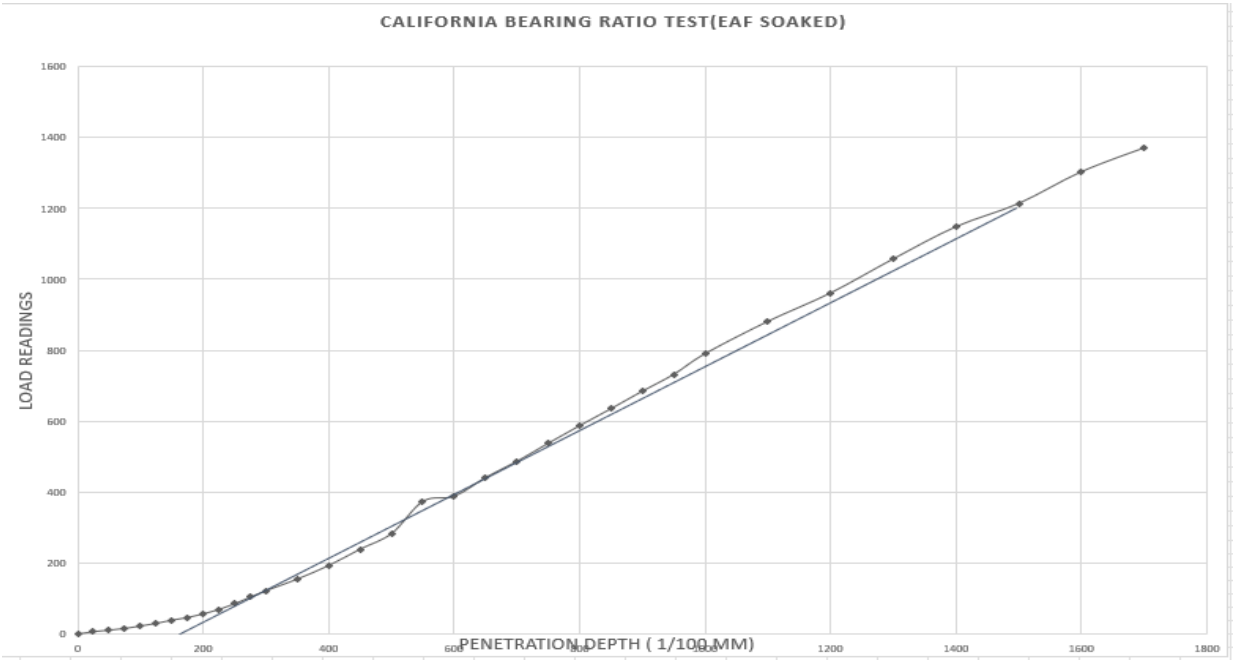

Figure9. CBR test result for EAF(Soaked).

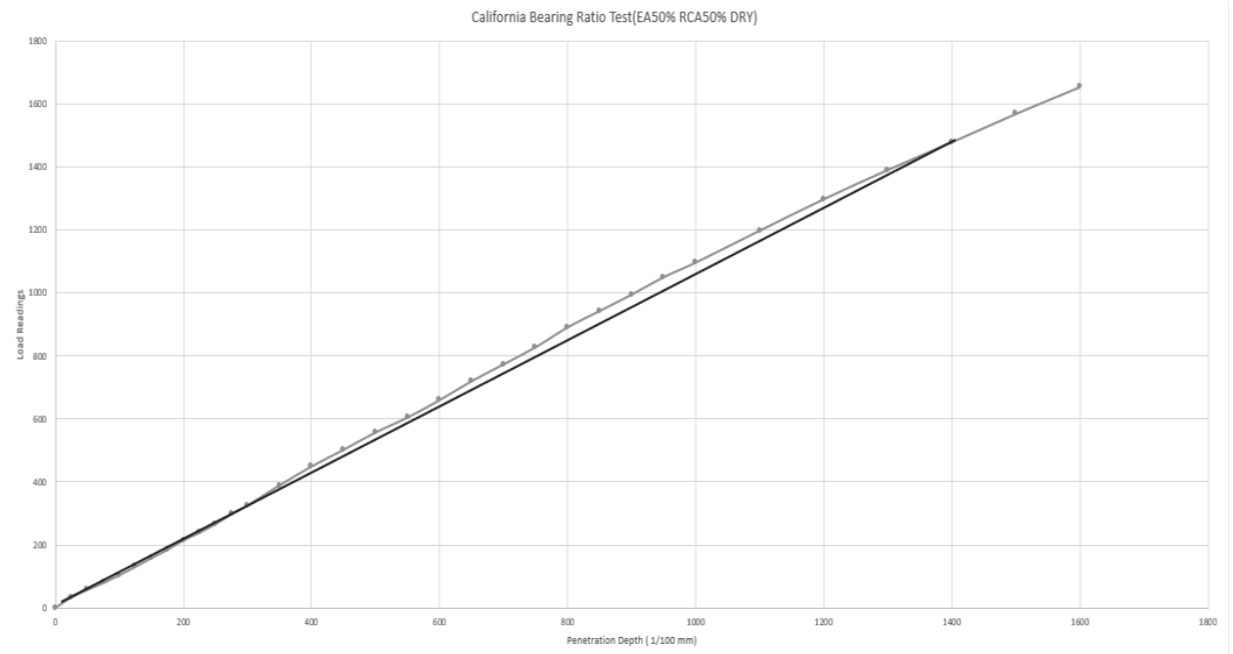

Figure10. CBR test result for the mixture (50% RCA+50% EAF).

Conclusion

The utilization of RCA and EAF slag is suitable and aligns with global needs to provide sustainable construction material and methods by decreasing the use of natural materials and managing and reducing waste generation. (Oikonomou, 2005; Pasetto & Baldo, 2012). These materials also has environmental and economic benefits. such as reducing the utilization of conventional materials and natural aggregates, using waste materials for construction applications, and reducing the cost of projects by using recycled materials.

EAF slag provides high strength, density, and stability. Its CBR value and high specific gravity of EAF slag show its significant performance compared to natural aggregates (Pasetto & Baldo, 2012; Arulrajah et al., 2013).
RCA indicates suitability for low-traffic applications as a supplementary material, especially when it is mixed with EAF slag. Additionally, as shown before, its grain distribution and compaction features align with granular materials.
Furthermore, the mixed material of EAF and RCA shows sustainability, cost-effectiveness with superior performance, and significant properties such as CBR value that is higher than conventional materials and the materials themselves.
Additionally, accelerated swelling tests and direct shear tests are currently being performed to assess more properties of these materials and provide more comprehensible data for more conditions and ensure better their sustainability and performance.

Dynamic Site Response Analyses For A Site With A Deep Cut

Yusuf Şahin[a], Gürkan Özden[b]

Keywords: Design Spectra, Dynamic Soil Response, Finite Element, Retaining System

Aim

In earthquake engineering, the seismic performance of structures is not solely dependent on the structural system but is also directly influenced by the dynamic properties of the underlying soil. In this context, site response analyses are among the fundamental engineering procedures used to understand how ground motion is altered as it propagates through soil layers and to estimate the resulting surface motion. These analyses have been mandated for certain soil classifications under the Turkish Building Earthquake Code (TBDY) since its enforcement in 2018. Local site conditions can significantly affect both the amplitude and frequency content of ground motions arriving at the surface. Neglecting these effects, especially in soft, thick, or heterogeneous soil profiles, may result in considerable deficiencies in structural design.

Among various site response analysis methods, one-dimensional (1D) site response analysis is the most commonly employed. This method is suitable for soil profiles that can be idealized as horizontally layered and laterally continuous, assuming seismic waves propagate only in the vertical direction. In such stratified media, reflections and refractions at layer boundaries with different dynamic properties alter the wave propagation characteristics, ultimately modifying surface ground motion. 1D analyses allow the computation of spectral characteristics and amplification factors based on these wave propagation mechanisms.

The use of 1D site response analyses in engineering practice dates back to the 1960s. The equivalent linear analysis method proposed by Seed and Idriss (1970) assumes that soil behaviour under small strains can be represented using linear elastic formulations. In this approach, the dynamic response of soils is characterized by the shear modulus (G) and damping ratio (ξ), which are iteratively updated during cyclic loading.

However, it has been observed that this approach is inadequate in capturing the behaviour under large strain, high-amplitude motions. This led to the development of nonlinear soil models. Reduction curves introduced by Vucetic & Dobry (1991) and Ishibashi & Zhang (1993) offered alternatives applicable to various soil types. The degradation relationships between shear modulus and damping ratio with shear strain, developed by Darendeli (2001), enabled more realistic modelling of soil behaviour by including factors such as plasticity index, effective stress, and number of loading cycles.

One of the key outputs of 1D site response analysis is the design response spectrum and associated spectral quantities. These include spectral acceleration (Sa), spectral velocity (Sv), and spectral displacement (Sd), which represent the maximum responses of single-degree-of-freedom (SDOF) systems with unit mass subjected to ground motion. Among these, Sa is particularly emphasized in structural design against horizontal seismic loads. Keeping the natural period of a structure as far as possible from the dominant periods of the soil profile is crucial for controlling structural behaviour.

The calculation of these spectral quantities is generally based on the damped free vibration response of a system. According to Kramer (2024), spectral acceleration represents the peak absolute acceleration response of a unit-mass SDOF system in dynamic analysis. The mathematical framework for obtaining spectral quantities from ground motion recordings dates back several decades. The Turkish Building Earthquake Code (TBDY 2018) defines design spectra based on spectral acceleration and velocity components for different soil classes and seismic hazard levels. These spectra are directly used in engineering design and in evaluating the results of site response analyses.

Turkey lies on active tectonic zones with significant seismic potential. As a result, most of its densely populated cities are located in earthquake-prone areas. Given the aging building stock, unplanned urbanization, and irregular migration, urban transformation projects have accelerated in recent years. During this transformation process, the use of deep excavation support systems and deep foundation elements has become common in high-rise and basement-intensive projects.

However, the influence of such systems on the dynamic behaviour of soils has not been sufficiently investigated. Site response analyses typically focus only on the natural soil profile, while the impact of engineering structures like retaining systems and foundation elements on soil-structure interaction is often overlooked. In reality, even if a soil profile appears suitable for 1D analysis, the stiffness of structural components in a retaining system or their geometric configuration can render the analysis inherently two- or even three-dimensional. Example configurations of such structural arrangements within a plot are presented in Figure 1. For this reason, the integration of foundation and shoring systems into two- or three-dimensional site response analyses is essential to accurately capture the realistic behaviour of the ground.

Figure 1. A building plot that may not be included in the scope of one-dimensional ground response analysis.

Furthermore, the elastic design spectra defined in TBDY 2018 are limited to five generic soil classes, from ZA to ZE. This classification is insufficient to capture the diversity of local soil behaviours and the impact of engineering applications. It also fails to account for the influence of foundation and retaining systems constructed within a given profile on the site response spectrum. As a result, potential spectral mismatches or amplifications may be underestimated in design. Therefore, site response analyses should be supported by more detailed modelling and multi-dimensional approaches to enhance reliability.

Material and Method

As part of this study, two-dimensional finite element analyses were conducted in the time domain. In this context, nonlinear soil behaviour was taken into account, and both one-dimensional and two-dimensional site response analyses were performed under free-field boundary conditions. Additionally, in the two-dimensional models, retaining systems representing structural effects were also modelled, and their influence on the dynamic behaviour of the soil was evaluated.

During the modelling process, lateral displacements of the retaining system components within the excavation zone (excluding the socket region) were constrained in order to limit uncontrolled horizontal deformations that may occur during excavation. This approach aimed to minimize the influence of excavation stages on the analysis. The boundary conditions were defined to realistically simulate wave propagation. Free-field boundaries were applied along the lateral edges to prevent artificial reflections of seismic waves from the model limits. At the bottom boundary, a compliant base was implemented to allow input motion transmission while preventing wave reflections.

The geometry of the numerical model is shown in Figure 2, and the parameters associated with the soil profile are presented in Table 1. The model illustrated in the figure represents a typical soil profile and a two-dimensional retaining system cross-section, representative of conditions in the İzmir city center. For improved numerical stability, velocity-time input records were preferred.

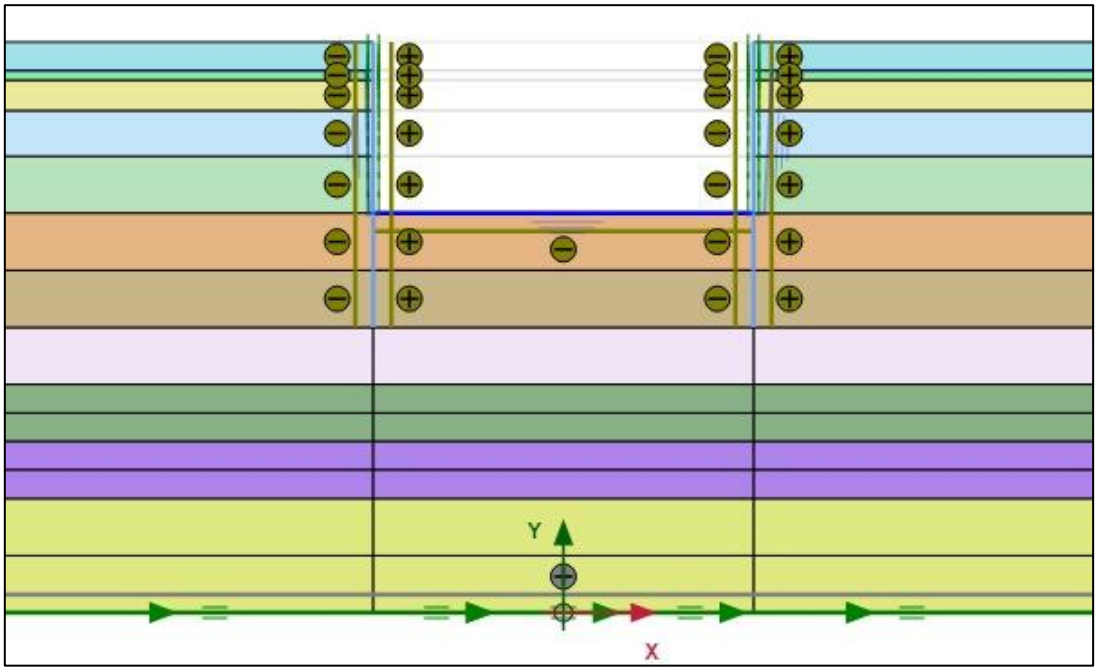

Figure 2 Geometry of finite element model.

Findings

As a preliminary phase of this ongoing research, three representative ground motion records from the DeepSoil database which widely adopted in conventional 1D analyses, were carefully selected and implemented in the numerical simulations. Selected earthquake motion properties are given in Table 2.

Table 2. Properties of selected earthquakes.

Earthquake Motion	a_{max} (g)	V_{max} (m/s)	T_0	Effective Duration (s)
Kocaeli	0.151	0.14	0.164	11
Loma Gilroy	0.357	0.28	0.399	5
Mammoth Lake	0.378	0.138	0.164	11

Table 3 presents the maximum PSA values for each ground motion record under three modelling conditions: one-dimensional (1D), two-dimensional (2D), and two-dimensional (2D) with retaining structures .

Table 3. Maximum spectral acceleration values.

Earthquake Record	PSA_{max} (g)		
	1D	2D Free Field	2D Diaphragm Wall
Kocaeli	0.47	0.52	1
Mammoth Lake	0.82	1.3	1.44
Loma Gilroy	1.06	1.1	1.4

The results obtained from this study clearly demonstrate that excavation support elements such as diaphragm walls have a significant effect on the seismic motion computed at the foundation level. In particular, in the short-period range, the inclusion of such systems in the model led to noticeable increases in spectral acceleration values. For example, during the Kocaeli earthquake, the peak spectral acceleration (PSA) under free-field conditions was approximately 0.52 g, whereas it increased to as high as 1.0 g in the model that included the retaining system. Spectral acceleration curves for foundation level for every chosen seismic record can be seen in Figure 6. Similar trends were observed in the Mammoth Lake and Loma Gilroy ground motion records. This increase suggests that the retaining system alters the horizontal constraints imposed on the soil. In order to see the differences clearly between analyses methods, in Figure 7, spectral accelerations are given in much tighter period interval.

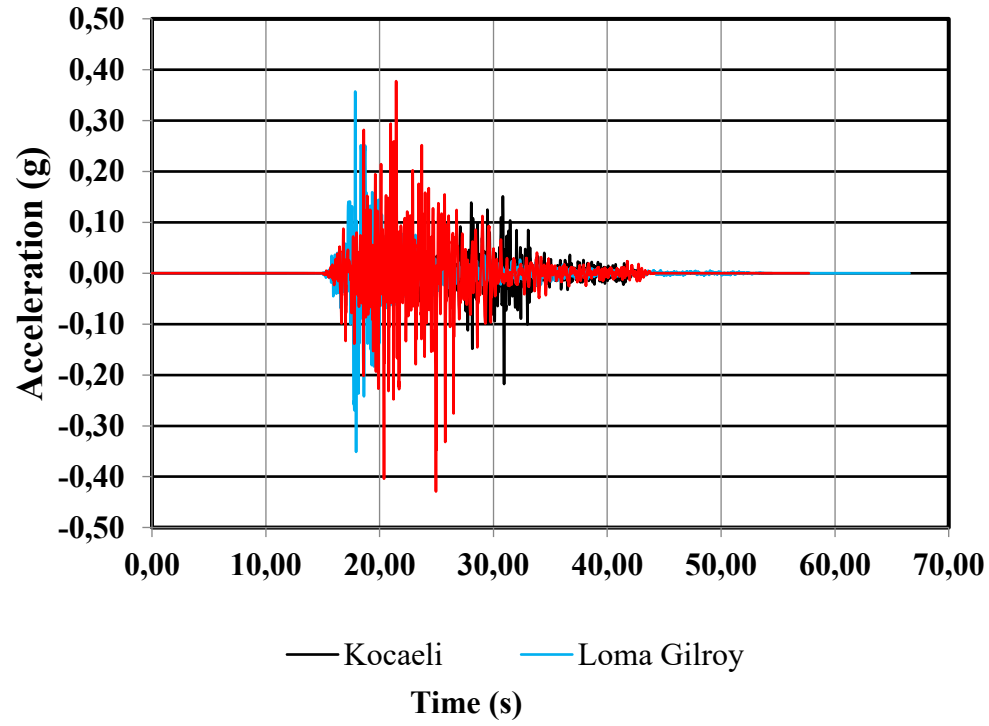

Figure 3. Acceleration-time curves of 3 earthquake records used in the analysis.

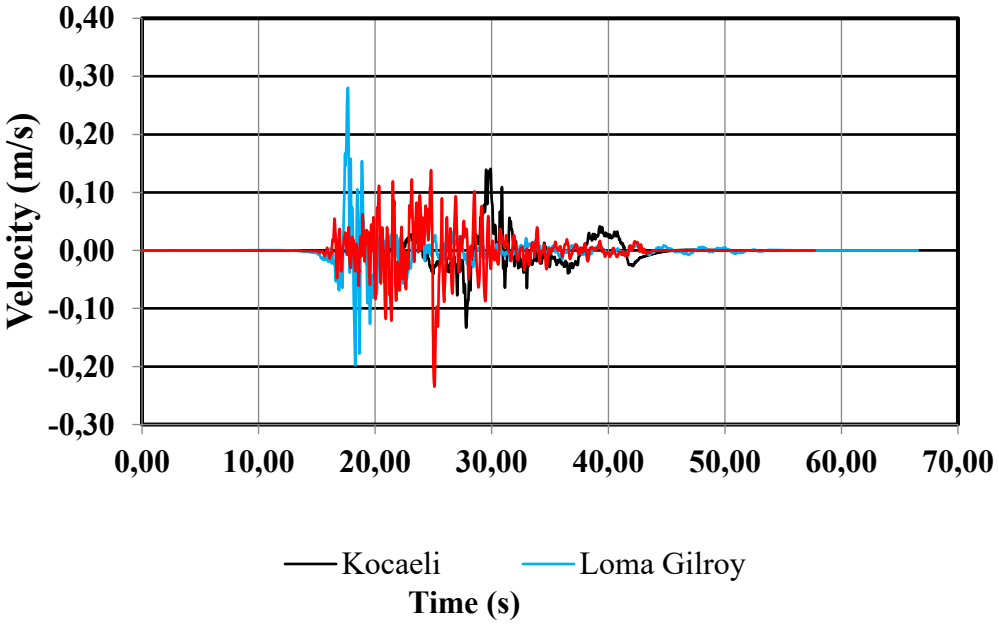

Figure 4. Velocity-time curves of 3 earthquake records used in the analysis.

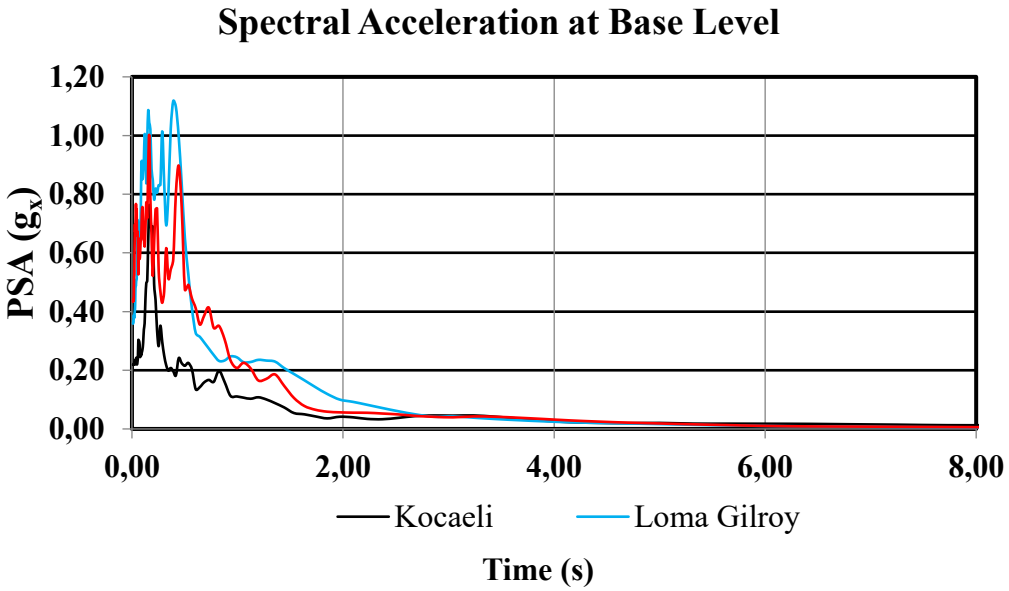

Figure 5. Acceleartion spectra of the selected earthquake record at base level of the model.

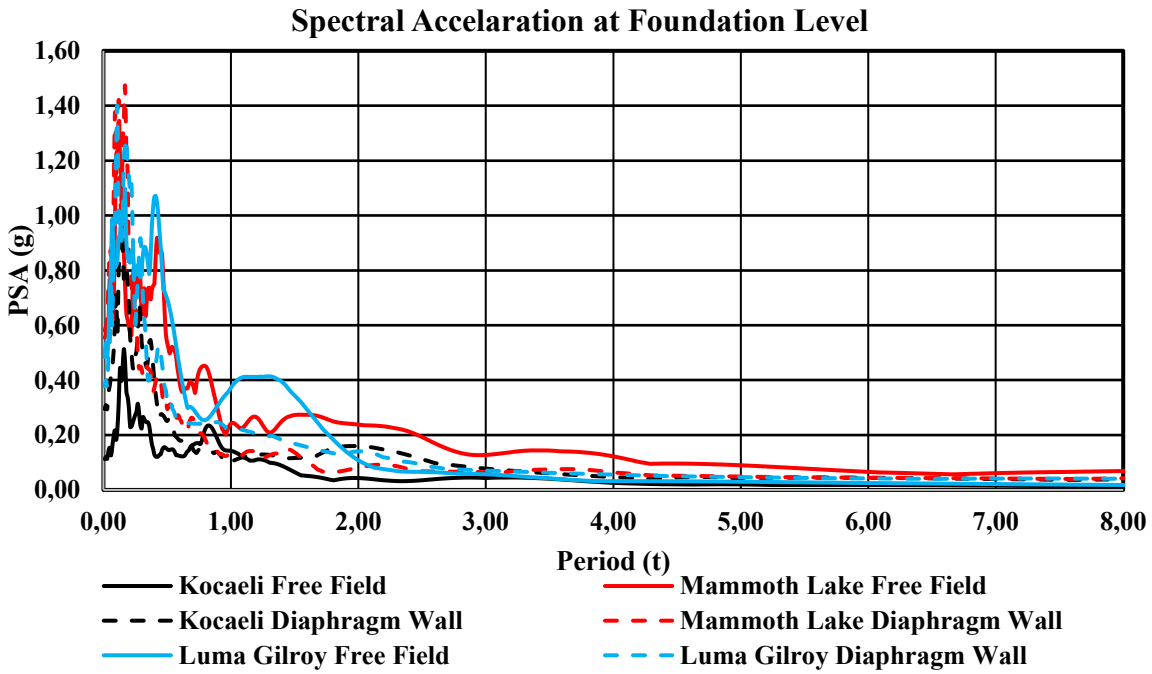

Figure 6. Spectral acceleration at the bottom of foundation (t = 0-8 s).

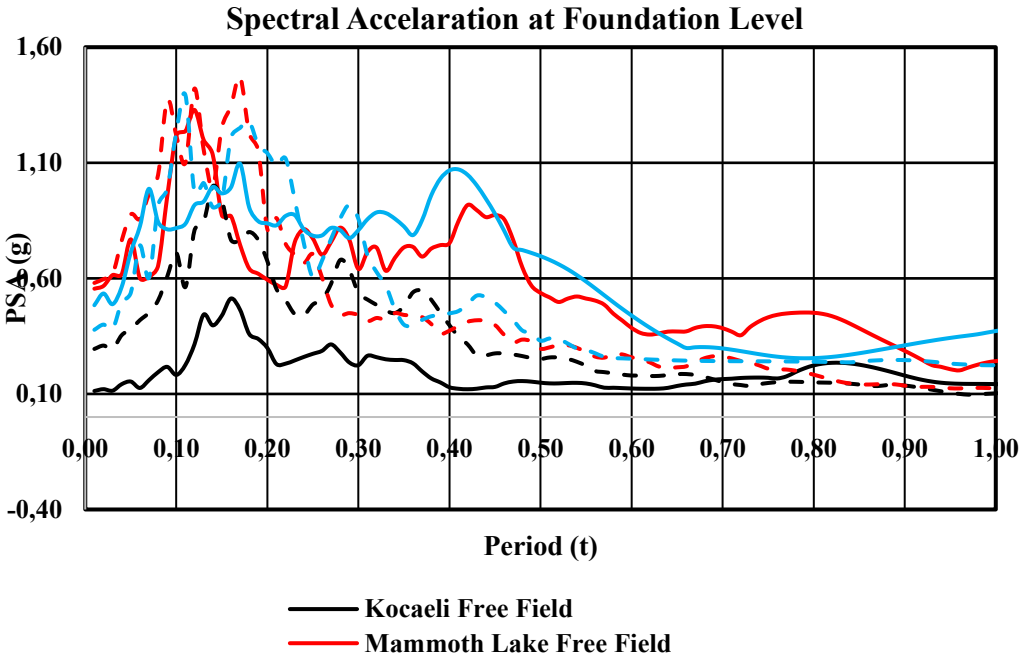

Figure 7. Spectral acceleration at the bottom of foundation (t = 0-1 s).

Conclusion

The findings indicate that idealized spectra based only on generalized soil classifications may be insufficient for cases where buildings with basements surrounded by rigid retaining systems such as diaphgram walls, and that multidimensional analyses incorporating soil-structure interaction yield more realistic results, with noticeably increased spectral acceleration values in the short-period range. Yet, the necessity of three-dimensional analyses becomes more apparent in buildings with extensive base areas, particularly in regions where geological formations vary significantly.

Modelling Lateral Spreading in a Sandy Soils

Hamed Feizollahzadeh Ardabili[a], Ayfer Erken[a]

[a]Istanbul Technical University, Civil Engineering Department, Geotechnical Engineering Program, Turkiye
feizollahzadeha@itu.edu.tr

Keywords: Liquefaction, Lateral Spreading, Sand, Opensees, PM4Sand.

Aim

The definition of liquefaction is the during earthquake under undrained conditions, effective shear resistance of saturated sandy soil would decrease radically, causing excess pore water pressure to be generated. This conditions also make effective stress to decline and make the granular soils to liquefy and behave like a viscous fluid. Additionally, loosening sand effective shear resistance results in the transformation of stress from sand particles to porewater pressure, (Toloza Barría P, 2018).

This condition causes the loss of strength and stiffness that contributes to the ground settlement. The impact of liquefaction can be observed in the nature of the movement of ground surface motion. One of the Liquefaction phenomena is lateral displacement. Gentle slopes underlain by loose sands which are prone to liquefaction-induced lateral spreading must have a shallow water table as well as slopes between 0.3 to 5%, (Idriss and Boulanger, 2008).

The scope of this study is to properly built a soil model which can simulate as well as capture a sandy soil behavior. To do this, it is paramount that the set-up of soil, constitutive soil parameters and boundary condition should be chosen as appropriate as possible. There are not many available examples to understand the Opensees platform and how to model a soil. Therefore, many attempts should be made for evaluating and understanding this platform properly. One of this research's goal is to calibrate as well as validate the PM4Sand constitutive model parameters.

Material and Method

In this study Opensees platform was utilized. Opensees is a finite element software which allows its user to simulate and analyze the seismic response of structural and geotechnical systems. Soil's dimensions are 20-meter width and 4-meter depth in the middle of the soil as a constitutive model PM4Sand was used. The reasons for utilizing PM4sand is that this model can capture post-liquefaction reconsolidation. The experimental data is driven from a coordinated program which is called LEAP, Liquefaction Experiments and Analysis Projects. It provides researches with a reliable source of data for calibration as well as validation of their numerical modeling for analysis of liquefaction phenomenon. In this program, sandy layer in the centrifuges test was setup up with 5° slope to evaluate the lateral spreading phenomenon as a result of liquefaction. Furthermore, for calibrating soil parameters, strain-controlled cyclic simple shear test was modelled and verified by different experiments for different relative densities. The first step of modelling is to in PM4Sand as suggested by, (Chen et al. 2019), is to find the best fit for cyclic stress ratio versus number of cycles. Then finding the best fit for shear stress and shear strain is the next goal. The boundary condition was selected as free-Field condition which are two columns at sides of soil model. The soil columns width is much bigger than main soil's elements. Additionally, the columns thickness was selected 1000 meter, so that, the boundary effect would be eliminated and the result in the middle of the soil model would not be affected.

Findings

In this study, the result of Cambridge university experiment was selected for validation of soil model. There are two different model were simulated and analyzed. The results of this study show that OpenSeespy platform using PM4Sand constitutive model can perfectly capture the soil behavior during liquefaction. The paramount soil parameters were found and their effects are pointed out. In Table 1, the list of important parameters for the first model with the big-column side boundary is listed.

Table 1. First soil model Calibrated PM4Sand parameters and their values.

Primary parameters	D_r	Relative density	40%	Modified
	G_0	Shear Modulus coefficient	390.0	Calibrated
	h_{po}	Contraction rate parameter	0.42	Calibrated
	$\rho_{saturated}$	Mass density of the material	1.99	(Wang et al. 2019)
Secondary parameters	e_{max}	Maximum void ratio	0.7389	(Chen et al. 2019)
	e_{min}	Minimum void ratio	0.4915	(Chen et al. 2019)
	ϕ_{cv}	Critical state effective friction angle	35.6	(Chen et al. 2019)

Although in Boulanger and Ziotopoulou (2015) have a formula for calculating G0 in this thesis it was decreased to capture the lateral displacement results.
It will be observed in the results of the simulation; the model can capture the behavior of the experiment during the consolidation phase. In this study, the excessive pore water pressure, acceleration, and lateral displacement of the model were compared with a centrifuge experiment done by Cambridge University. The simulated model in this study is perfectly aligned with the experimental study.

The first step is the calibration of the soil parameter in the PM4Sand constitutive model. As it is evident from Figure 1, the soil parameter is calibration, and the next step is to compare the acceleration at different layers.

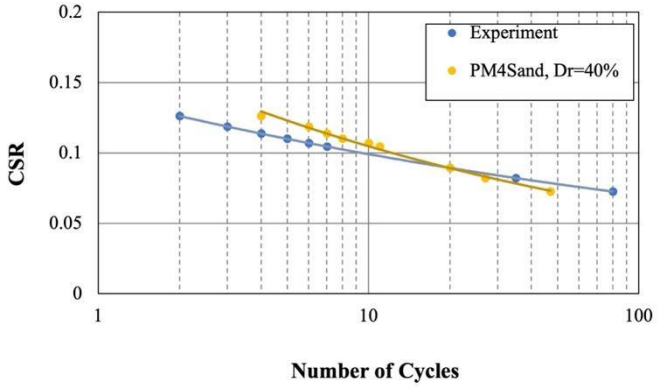

Figure 1. CSR Vs. number of cycles for the first and the second model, (Ana Maria Parra Bastidas, 2016).

The next step is to calibrate shear strain and shear stress of experimental data and simulation data. The experimental data for sand with 40 percent relative density that were utilized is from (Ana Maria Parra Bastidas, 2016). In Figure 2 the shear stress and shear strain of simulated and experiment data is compared and the results show that the simulation data is aligned with experiment.

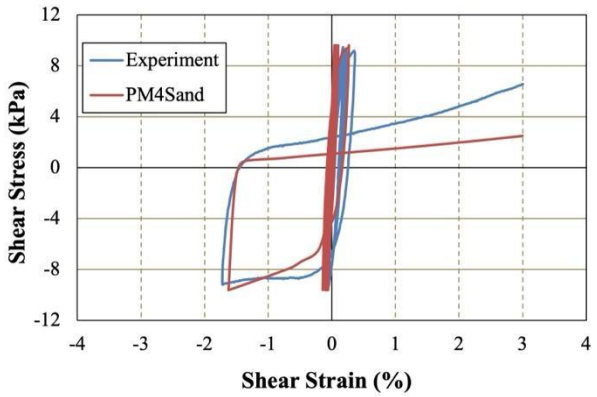

Figure 2. Shear stress vs. Shear strain of sand with Dr=40%, the cyclic stress is 95 kPa, (Ana Maria Parra Bastidas, 2016).

For next step of calibration, the Figure 3 represents another soil behaviour. In the plot the shear strain versus pore water pressure of the sandy soil with 40 percent relative density is shown. As it is evident, the behaviour of the experiment and simulation are almost the same.

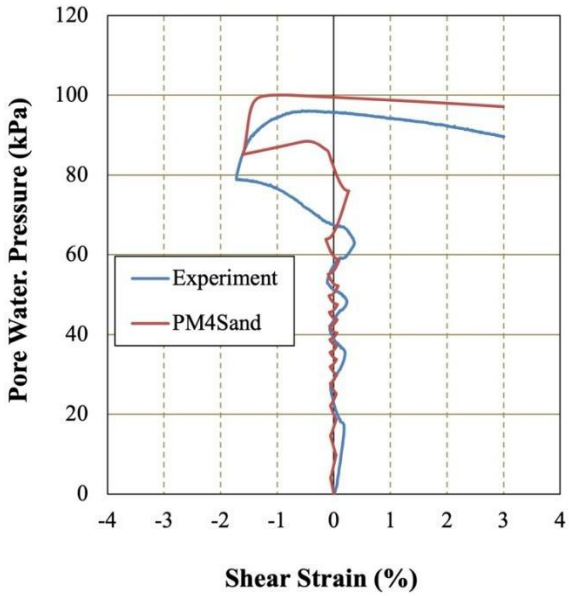

Figure 3. Pore water pressure vs. Shear strain of sand with Dr=40%, the cyclic stress is 95 kPa, (Ana Maria Parra Bastidas, 2016).

After calibrating the model's parameter, the next step is to validate the soil to evaluate whether model's setup and boundary conditions the producing prudent output. Therefore, next step is to build the model with free field boundary and validate it with centrifuge model results. The centrifuge model is Cambridge university experiment CU2 LEAP-2017 joined experiment. The first step and the most important output to make comparison is the acceleration of the input motion versus the output. In Figure 4. represents the acceleration at 1.5-meter below the surface of experiment and simulation results soil model. As it is obvious from Figure the model can capture the behavior of soil.

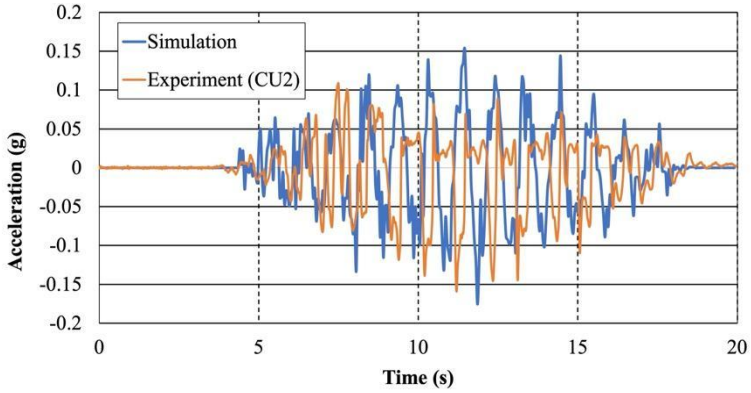

Figure 4. Acceleration Vs. Time at 1.5-meter below the surface, (Manzari, M. T, 2020).

The Figure 5. represents the acceleration versus time at surface of the soil. This figure is provided so that it will provide more about the validation of the soil simulation. As it can be seen from the Figure 5 simulated models aligned with the experiment data.

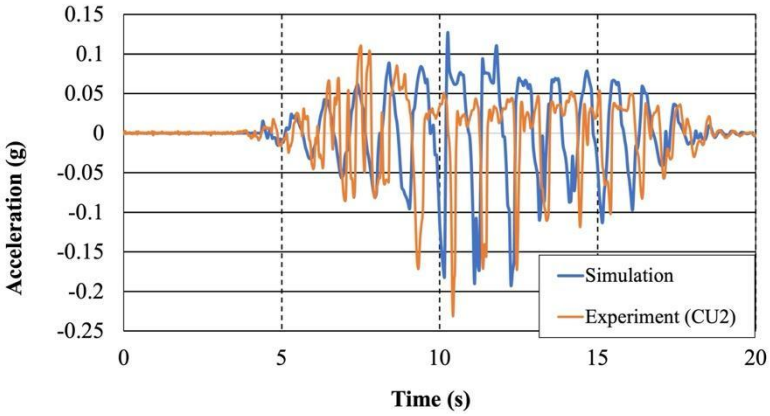

Figure 5. Acceleration Vs. Time at the surface, (Manzari, M. T, 2020).

After evaluating acceleration, the next step is evaluating pore water pressure at different depth. In Figure 6 it can be observed that at 3.5-meter below the surface model captured the maximum excessive porewater pressure and consolidation after the shake. Pore water pressure should be evaluated in different depths, therefore, in Figure 7, excess pore water pressure was evaluated at 3.5-meter below the surface. As it can be observed in both depths model can follow the experiment data. The excess pore water pressure the peak and after the shaking is over can be consolidated as same as the experiment.

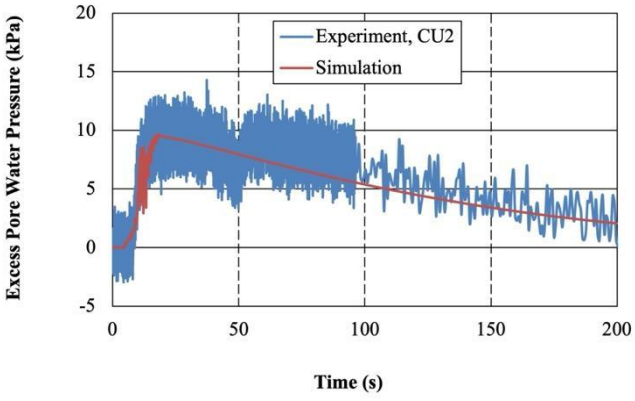

Figure 6. Excess Pore Water Pressure Vs. Time at 1-meter below the surface, (Manzari, M. T, 2020).

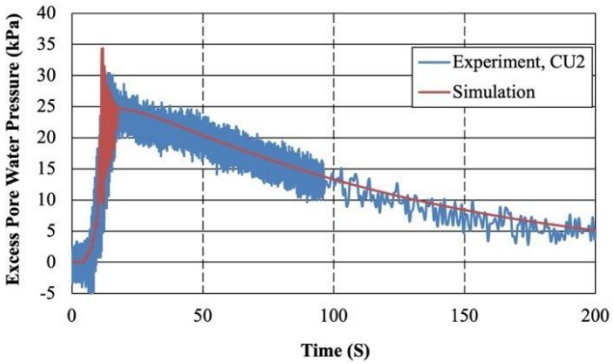

Figure 7. Excess Pore Water Pressure Vs. Time at 1-meter below the surface, (Manzari, M. T, 2020).

The next and the last step is the lateral displacement of the model at the surface. Figure 8 shows the lateral displacement at the surface. The results of the model are perfectly aligned with the experimental data. As it is evident from the Figure, model captured the behavior of soil. The lateral displacement of the model is as same as experimental data. This research's goal is to assess the lateral displacement during dynamic loading. As it can be seen from the plot the model is perfectly aligned with experimental data.

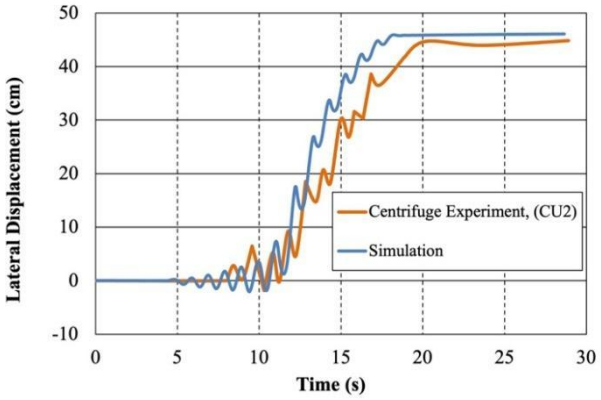

Figure 8. Lateral Spreading Vs. Time at the surface.

Figure 9 represents vertical displacement during dynamic loading. Maximum vertical displacement is 5 cm. Due to the fact that in the experiment there was not any output for vertical displacement the output of simulation solely were share.

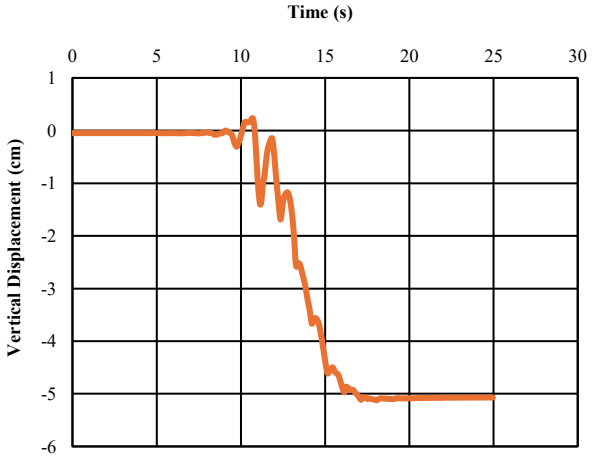

Figure 9. Vertical Displacement Vs. Time at the surface.

Conclusion

To sum-up model is calibrated. The calibration of the model was the first step. After calibration, validation of the model had to be done. In validation phase consists of three steps that should have been done. The first step was to assess the acceleration at different depths. The next step was to evaluate excess pore water pressure in different depths. At last, the lateral displacement of the soil at the surface was evaluated. Calibration as well as validation of the model was done, and compared with high accuracy. It can be observed that the model's setup and boundary, and soil parameters are calibrated and validated.

Investigation of the Effects of Vibration Dampers Positioned on Hanger Cables of an Existing Suspension Bridge

Muhammed Emin Demir[a], Kadir Ozakgul[b]

[a] Istanbul Technical University, Graduate School, Structural Engineering Master of Science, Türkiye
[b] Istanbul Technical University, Department of Civil Engineering, Civil Engineering, Türkiye
demirmuh18@itu.edu.tr

Keywords: Suspension Bridge, Hanger Cable, Vibration, Stockbridge Damper.

Aim

The objective of this scientific work was to investigate the effects of Stockbridge dampers positioned on the hanger cables, which are one of the main structural elements of an existing suspension bridge. These Stockbridge dampers have been positioned on the hanger cables because of their vibration reducing nature and they are suitable to have an effect on many structural expositions (Larsen et al., 2021). Within the framework of structural engineering, it is crucial to determine the structural behaviour and effects of the dampers in a correct manner, so that optimisation and development of new approaches would be possible. The main objective of this study is to investigate the structural behaviour of the hanger cables with Stockbridge vibration dampers installed. The evaluation of efficiency of the Stockbridge dampers and their effectiveness under different conditions were aimed. In this study, positive consequences of installing dampers in terms of vibration were focused. This study utilises the site measurements for the comparisons to understand the differences between with or without dampers installed on hanger cables. This scientific work aims to make contribution to modern suspension bridge design procedures within the scope of the structural engineering with results obtained with the site experiments, processing, and computations.

Material and Method

In a suspension bridge, hanger cables are critical structural elements that transfer the loads of the deck and the superstructure to the main cable. Since suspension cables also carry the dynamic loads of the suspension bridge, provide a connection between the structural elements of the suspension bridge and are open to many dynamic external factors such as wind, they are subject to vibrations (Chen et al., 2018). Considering the applications in different bridges in terms of structural engineering, applications of placing vibration dampers on suspension bridges by optimising them with different designs in order to take precautions against vibrations have been made in suspension bridges. The effectiveness of the vibration dampers on suspension bridges of different designs and different specifications was tested after commissioning in the field and their positive contribution to the suspension bridge dynamics was observed (Inoue et al., 2017). In order to dampen the vibrations in the hanger cables and keep them under control, Stockbridge vibration dampers were installed in the hanger cables.
Stockbridge dampers, the mass dampers positioned on the hanger cables of an existing suspension bridge, were experimented with on-site experiments. Ambient vibration records were obtained using a three-dimensional accelerometer placed on the hanger cable. Forced vibrations of the hanger cables were also recorded with a three-dimensional accelerometer placed on the hanger cable while applying force directly to the hanger cable. These field vibration records were taken for different situations. In order to take the unlike situations into consideration, different hangers with unique lengths and conditions were measured. Some of the longest cables on the bridge were recorded before and after the installation of the damper. To determine the difference due to the damper, the vibrations were measured with and without the damper for both free and forced vibration situations. A flowchart of the method illustrating the data analysis procedure is shown in Figure 1.

Figure 1. Data Analysis Procedure Flowchart.

The experimental on-site vibration measurement records were analysed using MATLAB software (The MathWorks Inc., 2024). Fast Fourier Transform was used to convert the time domain data to the frequency domain; therefore, to calculate the modes of the vibrations. Dominant frequencies of the hanger cables and Fourier Amplitude Spectra were calculated. As seen in Figure 2 and Figure 3, forced vibration acceleration measurement of a hanger cable analysed and Fourier Amplitude Spectra at after forced vibration condition conducted for both situations hanger cable equipped with damper (see Figure 2) and without damper (see Figure 3).

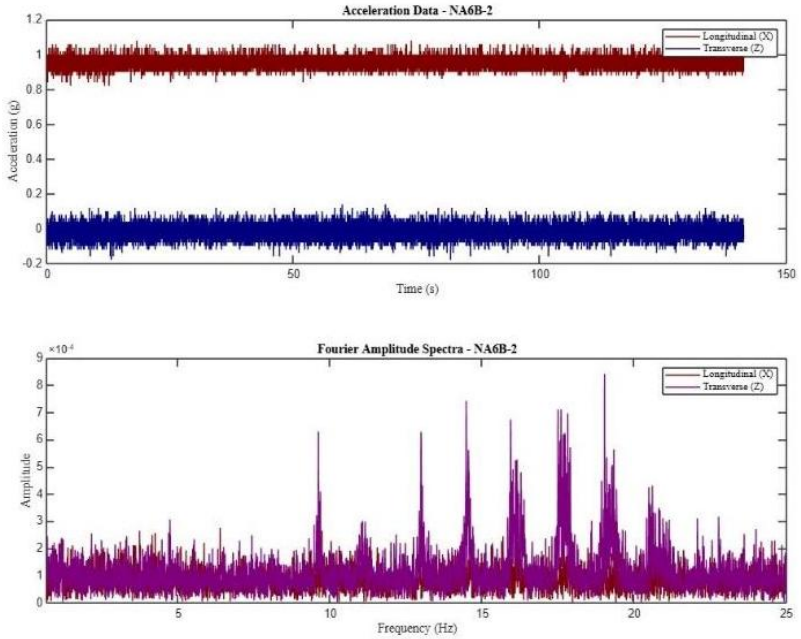

Figure 2. With Damper Acceleration Data and Fourier Amplitude Spectra (The MathWorks Inc., 2024).

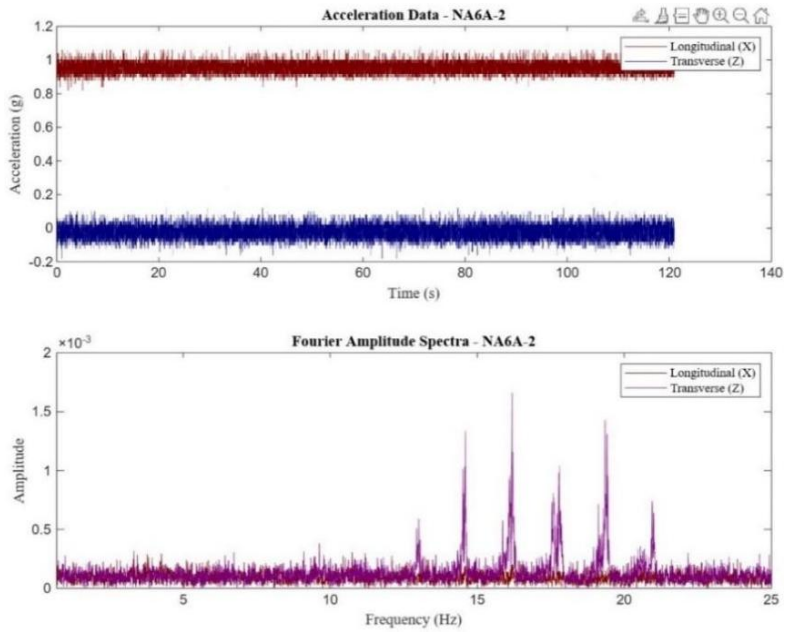

Figure 3. Without Damper Acceleration Data and Fourier Amplitude Spectra (The MathWorks Inc., 2024).

As seen in Figure 2 and Figure 3, the amplitudes of vibrations after forced vibration are reduced at the hanger cable equipped with damper condition.

Comparisons were also made between the vibrations of the hanger cables before and after the installation of the damper. Modal analyses were also performed on the processed field measurement data. Modal damping ratios obtained and changes in natural frequencies identified. For the effective damping ratios under the influence of Stockbridge dampers, the amplitude of the vibrations after the forced vibration experiment measurements would be utilised.

Findings

After the analysis of the vibration data, dynamic behaviour of hanger cables characterised. In the forced vibration cases the FFT and PSD analyses verified that the Stockbridge vibration dampers have a crucial role in reducing the amplitude of vibration and dominant frequency peaks. Modal analyses showed outputs revealing that Stockbridge dampers effectively redistribute the vibrational energy and improve damping of the hanger cable comparatively to the situation of uninstalled dampers. The vibration records with amplitude declines after forced excitation were used for the estimation the effective damping ratios, to make quantitative measure of the enhancement at dynamic performance in terms of vibration for the hanger cables provided by the Stockbridge dampers.

A comparison was made between the processed site experiment results of long hanger cables with vibration dampers and shorter hanger cables without vibration dampers. The study proven that long cables of the existing suspension bridge equipped with Stockbridge vibration dampers are having significant reductions in vibration amplitude and damping performance of long hanger cables is improved by the vibration dampers. Damping ratios of the damper equipped hanger cables have positively increased compared to the hanger cables without dampers.

Conclusion

For conclusion, this experimental research validates the efficiency of the Stockbridge vibration dampers installed on the hanger cables of an existing suspension bridge by providing analyses of the vibration records at different initial conditions. It could be stated that, after evaluating with the application of advanced signal processing techniques to the vibration records measured on site both ambient and forced vibration situations, the hanger cables equipped with Stockbridge vibration dampers have a positive impact on dynamic behaviour by means of reducing the vibration and lowers the vibration energy transferred to the suspension bridge structure. Modal analysis performed confirms that the Stockbridge vibration dampers contribute to the enhanced damping ratios.

Overall, the results of this research authenticate the effectiveness of Stockbridge vibration dampers in terms of improving the dynamic performance of suspension bridge hanger cables, and also highlight the importance of integrating comprehensive vibration analysis methods through the application and optimisation of hanger cable vibration dampers for the suspension bridge design.

Potential challenges of the proposed methodology at the measuring stage could be where using the proper equipment and work time selection is important because of the variable intensity of usage of the suspension bridge. When developing new approaches for other bridges, used methodology needs to be modified by utilising the parameters of the structure such as boundary conditions, vibration damper characteristics and modal analysis of the bridge.

The possible limitations could be considered as understanding and analysing the effects of the vortex induced vibrations on the hanger cables of the suspension bridges which needs complex analysis with laboratory and site measurements.

Artificial Intelligence Based Surrogate Models for Stiffened Plate Buckling Analysis

Hasan Kıyık[a], Metin Orhan Kaya[b]

[a] Istanbul Technical University/Faculty of Aeronautics and Astronautics, Department of Aeronautical and Astronautical Engineering, Graduate School, Türkiye
[b] Istanbul Technical University, Faculty of Aeronautics and Astronautics, Department of Aeronautical Engineering, Türkiye
kiyik16@itu.edu.tr

Keywords: Artificial Intelligence, Surrogate Modelling, Optimization, Stiffened Plate, Finite Element Analysis.

Aim

In structural engineering applications, accurately predicting the buckling behavior of stiffened plates is crucial yet computationally demanding, especially when employing traditional finite element (FE) solvers directly within iterative design optimization frameworks [1]. This study presents a novel approach that employs artificial intelligence (AI) based surrogate models [2] to efficiently evaluate critical buckling load factors and corresponding mass values of stiffened plates. Initially, a comprehensive dataset was generated using finite element analyses conducted via ANSYS software [3], encompassing diverse configurations of stiffened plates characterized by variations in stiffener height, stiffener thickness, and base plate thickness. Subsequently, the resulting dataset was systematically divided into training and test sets, facilitating the development and rigorous evaluation of several AI-driven regression models. The surrogate models developed in this work exhibit strong predictive capabilities, significantly reducing computational overhead compared to direct FE simulations. By rapidly approximating complex FE responses, the proposed methodology enables swift exploration of design spaces, markedly accelerating structural optimization processes. Ultimately, this research underscores the practicality and efficiency of AI-based surrogate modeling as a robust alternative to conventional finite element methods, particularly for iterative optimization tasks in the analysis and design of stiffened structural plates.

Material and Method

In this study, stiffened plate models [4] were designed and analyzed using ANSYS [3], a commercial finite element solver, to generate the necessary dataset for training and testing artificial intelligence based surrogate models. Various stiffened plate configurations were systematically modeled by varying geometric parameters such as stiffener height, stiffener thickness, and base plate thickness, and their corresponding critical buckling load factors and mass values were computed. The resulting dataset was partitioned into distinct training and testing subsets to rigorously evaluate model performance.

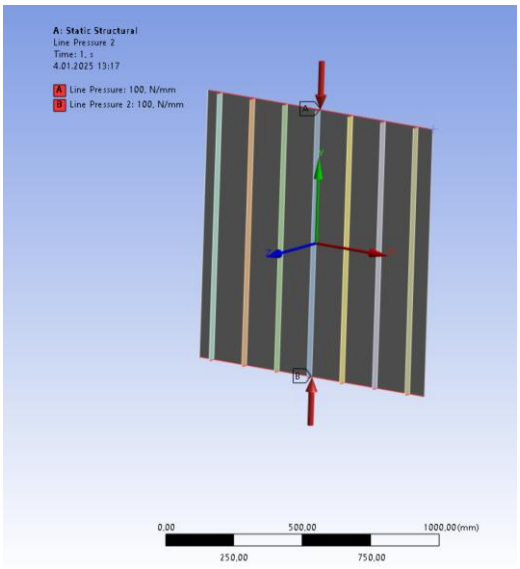

Figure 1. Loading Conditions of the Eigenvalue Buckling Analysis.

Table 1. Randomly Selected Samples from the Training Data Set.

Input			Output	
Plate Thickness [mm]	Stiffener Thickness [mm]	Stiffener Height [mm]	Load Factor	Mass [Kg]
2.5	20	30	5.372	18.56
3.5	2	45	2.87	11.44
4	4	45	5.10	14.57

For surrogate modeling, several state-of-the-art AI algorithms were implemented and evaluated in the MATLAB environment, including Artificial Neural Networks (ANN) [5-6], Support Vector Regression Machines (SVRM) [7-8], Ensemble Learning methods [9-10], and Gaussian Process (GP) [11-12] regression models. To ensure an unbiased and thorough comparison of model performance, hyperparameters for each AI model were optimized through a systematic grid search method [13]. This approach allowed for a fair assessment of predictive accuracy and generalization capabilities across different surrogate modeling techniques, thus facilitating the identification of the most effective model for accurately predicting stiffened plate buckling behavior.

For the studied stiffened plate buckling analysis, 245 number of samples are generated using ANSYS finite element solver with linear sampling method (5x7x7). The samples were generated as follow; Plate Thickness [mm]: 2-4, Stiffener Thickness [mm]: 2-20, Stiffener Height [mm]: 20-50. These generated samples will be used to train the AI models to predict the Load Factor, and Mass [Kg] characteristics by creating a mapping between inputs (Plate Thickness [mm], Stiffener Thickness [mm], Stiffener Height [mm]) and outputs (Load Factor,Mass [Kg]) of the train data samples. In order to check the generalization capabilities of the AI models and prevent models from overfitting, an additional 50 samples generated using Latin-Hyper-Cube sampling method will be used for benchmark purposes.

Findings

a) Surrogate Modelling

The following error metrics are used to benchmark the prediction performance of each AI-based surrogate model. Each model's hyperparameters are determined via grid search optimization with the validation method of K-fold (K=5) [14]. The performance results givenin Table 2 belong to each model's test samples response using Mean absolute Error (MAE, such as equation 1) and Relative Mean Error (RME, such as equation 2).

T: Targeted value, P: Predicted Value by AI model, n: total number of samples.

$$MAE = \frac{1}{n}\sum_{i=1}^{n} |T_i - P_i| \quad (1)$$

$$RME = \frac{100}{n}\sum_{i=1}^{n} \frac{|T_i - P_i|}{|T_i|} \quad (2)$$

Table 2. Regression Performance of Load Factor for Each Surrogate Model for Test Samples. All Not Mentioned HP (Hyperparameter) are Taken as Default Values in MATLAB 2023B.

Model	Optimal HP	MAE	RME [%]
Artificial Neural Networks-ANN	# hidden-layers: 3; # Neurons: 54-45-10; Activation function: sigmoid;	0.07	1.7
Support Vector Regression Machine-SVRM	Kernel Function: Polynomial; Polynomial order 2;Epsilon 0.0032; Box constraint 0.001	0.64	14.1
Ensemble Learning	Method LSBoost; # Learning Cycle 239; Learning Rate 0.105; Max # splits 171	0.42	9.6
Gaussian Process-GP	Kernel Function: ard matern 52; Sigma 0.000713; Basis Function Constant	0.1	2.2

Table 3. Regression Performance of Mass for Each Surrogate Model for Test Samples. All Not Mentioned HP are Taken as Default Values in MATLAB 2023B.

Model	Optimal HP	MAE	RME [%]
Artificial Neural Networks-ANN	# hidden-layers: 2; # Neurons: 7-151; Activation function: tanh;	0.02	0.04
Support Vector Regression Machine-SVRM	Kernel Function: Polynomial; Polynomial order 2;Epsilon 0.005945; Box constraint 575.96	0.04	0.3
Ensemble Learning	Method LSBoost; # Learning Cycle 491; Learning Rate 0.0961; Min Leaf Size 1; Max # splits 4	0.63	4.3
Gaussian Process-GP	Kernel Function: squaredexponential; Sigma 0.0001898; Basis Function none; Kernel scale 975.2	0.01	0.02

As it can be seen from the results given in Tables 2-3, ANN model is found to be the best model for prediction of Load Factor, while GP model is found to be the optimal surrogate model for prediction of Mass characteristic. In the next subsection, both of these models will be deployed to assist in an optimization process.

b) Surrogate Model Assisted Optimization

In this section, the obtained ANN and GP models will be used to assist optimization of the studied stiffened plate buckling analysis. Here it is aimed to obtain the maximum load factor of a design with a targeted mass value. The cost function (such as equation 3) that will guide the optimizer algorithm is defined as cost function. Although the selection of the optimization algorithm is an important matter for computational efficiency of the whole process, with the usage of surrogate model for creating response of cost function for candidate solution requires far more less computational budget (both memory and computation time <1 ms) compared to the traditional approach of directly using finite element solvers such as ANSYS (computational time for each evaluation >1 minutes).

$$Cost_i(PT_i, ST_i, SH_i) = Min\left[|M_T - M(PT_i, ST_i, SH_i)| + \frac{1}{LF(PT_i, ST_i, SH_i)}\right] \quad (3)$$

MT: is the targeted Mass value, $Cost_i(PT_i, ST_i, SH_i)$: is the cost value of the ith candidate solution, $M(PT_i, ST_i, SH_i)$: is the response of surrogate model for the predicted value of Mass for the ith input, $LF(PT_i, ST_i, SH_i)$: is the response of the surrogate model for predicted value of Load Factor for the ith input.

Herein three different optimization algorithms (Random Search [15], PSO [16], GA [17]) are deployed for finding the optimal values of for a targeted Mass value of 11.44 kg with maximized Load Factor. For a fair benchmark between algorithms, the function evaluation of each method is limited to 2000. This corresponds to the following Hyper parameters for each algorithm; PSO (particle swarm optimization) & GA (genetic algorithm): 40 iterations with 50 populations, and max evaluation of 2000 for random search. The obtained optimal values of design variables, the corresponding Load factor, and Mass values are presented in Table 4 alongside the finite element result of the same design configuration from ANSYS.

Table 4. Optimal Design Variables Obtianed from Optimization Algorithms for $M_T = 11.44$, with Maximum Function Evaluation of 2000. The Obtained Surrogate Model Results are Compared with ANSYS Results.

Algorithm	Input			Surrogate/ANSYS	
	Plate Thickness [mm]	Stiffener Thickness [mm]	Stiffener Height [mm]	Mass [Kg]	Load Factor
Random Search	2.45	5.35	44.63	11.42 / 11.42	3.85 / 3.79
Genetic Algorithm	2.63	4.82	44.46	11.41 / 11.44	4.05 / 4.23
Particle Swarm	2.73	4.45	44.98	11.41 / 11.44	4.12 / 4.32
MOGA+ANSYS	2.95	3.52	47.71	11.445	3.97
	2.95	3.52	47.528	11.44	3.94
	2.96	3.52	47.35	11.45	3.94

As it can be observed from Table 4, the proposed surrogate model assisted optimization approach can achieve better simulation results compared to ANSYS optimization tool results. Here it should also be considered that, if we neglected the initialization cost of generating AI models (training and test samples), the whole optimization process is took less than a minutes for all the mentioned optimization algorithms, while a single function evaluation for MOGA (Multi-Objective Genetic Algorithm) + ANSYS is likely to take more than 2 minutes. Thus, for different optimization targets, the proposed approach can obtain more than 10 of optimized designs in the same duration for a case where the designer can only achieve a single optimization design using MOGA+ANSYS approach.

Conclusion

Total of 295 number of data samples (245 Training + 50 Test) for a stiffened plate is generated. Using these data samples a series of AI surrogate models are created and their performances are benchmarked. For prediction of Load Factor characterics Artificial Neural Network found to be the optimal AI approach where, for Mass value prediction Gaussian Regression process is found to be the better solution. The selected optimal surrogate models of Load Factor (ANN) and Mass (GP) are integrated to optimization algorithms to accelerate the whole optimization process. As a result a computationally efficient optimization approach is achieved where not only managed to find better performance metric compared to the traditional approach of directly using ANSYS and built-in optimizers, but also can obtain these results in a fraction of computational time compared to the benchmark approach. The obtained results are validated for different types of optimization algorithms (PSO, GA, RS) with simulated results from the ANSYS.

Keywords: Sandwich Plate, Gradient Elasticity, Removal of Singularities, Internal Length Scale Parameter.

Aim

Classical continuum theories which are widely used in the macro-scale analyses of laminated sandwich plates are not capable of describing the deformation phenomena accurately at the micron and nano-scale observations since microstructural effects are not accounted for. Stress and strain singularities occur under point loads, at sharp crack tips and re-entrant corners of those systems when classical elasticity is used. To eliminate the singularities, gradient elasticity can be used as an alternative to classical elasticity. In gradient elasticity, micro-structural effects are considered by using additional constitutive parameters namely internal length scale parameters which are included into the higher-order gradient terms.
The aim of this study is to remove the stress singularities occurring under point loads and at sharp crack tips of symmetrical laminated sandwich plates using gradient elasticity theory and perform stress and relative error analyses. For that purpose, a MATLAB code is developed.

Material and Method

The formulation of the sandwich plate is based on the first order shear deformation theory. Undeformed and deformed states of a plate edge section under the assumptions of this theory are shown in Figure 1.

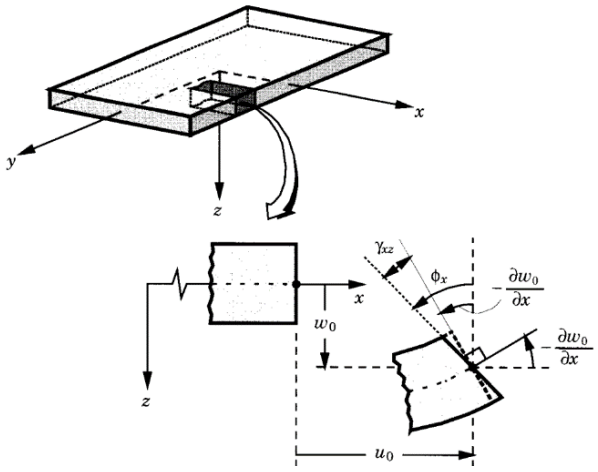

Figure 1. Undeformed and deformed states of a plate edge section (Reddy, 2004).

Displacement field according to this theory is given in Equation 1.

$$u(x,y,z) = u_0(x,y) + z\emptyset_x(x,y)$$

$$v(x,y,z) = v_0(x,y) + z\emptyset_y(x,y) \quad (1)$$

$$w(x,y,z) = w_0(x,y)$$

Cross-section of a laminated symmetrical sandwich plate is shown in Figure 2.

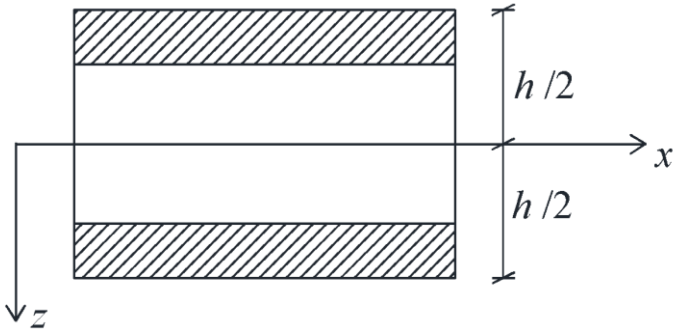

Figure 2. Laminated symmetrical sandwich plate cross-section.

The governing equations of gradient elasticity are fourth-order partial differential equations (p.d.e.) so that at least C^1 continuous shape functions are required. One of the gradient elasticity theories which is derived by Aifantis and co-workers (Ru-Aifantis gradient elasticity theory) is preferred in this study due to its straightforward finite element implementation, (Ru and Aifantis, 1993; Aifantis, 1992). The mathematical structure of Ru-Aifantis theory allows fourth-order p.d.e. to be solved as a decoupled sequence of two sets of second-order p.d.e. Thus, C^0 continuous (linear) shape functions suffice for the spatial discretization and only one internal length scale parameter is sufficient for satisfactory results, (Askes, 2011; Askes and Aifantis, 2011; Askes et al., 2008; Tenek and Aifantis, 2002; Çalık-Karaköse and Askes, 2015; Çalık-Karaköse, 2023; Bagni and Askes, 2015). The linear elastic constitutive relations are enriched with the Laplacian of the strain as shown in Equation 2,

$$\sigma_{IJ} = C_{IJKL}\left(\varepsilon_{KL} - L^2\varepsilon_{KL,MM}\right) \tag{2}$$

where σ, C and ε are the stress, constitutive and strain tensors, respectively and l represents the internal length scale parameter. The equilibrium equations in fourth order are defined as shown in Equation 3,

$$C_{ijkl}\left(u_{k,jl} - l^2 u_{k,jlmm}\right) + b_i = 0 \tag{3}$$

where u_k is the displacement vector and b_i are the body forces.

As shown in Equation 4, the first analysis step of Ru-Aifantis theory, classical elasticity solution is performed where displacements are obtained.

$$C_{ijkl}u^c_{k,jl} + b_i = 0 \tag{4}$$

In the second step, the obtained u^c_k classical elasticity displacements are used as input values to find the gradient-enriched stresses, as shown in Equation 5.

$$\sigma^g_{ij} - l^2\sigma^g_{ij,mm} = C_{ijkl}u^c_{k,l} \tag{5}$$

The finite element used in the implementation is a rectangular element having five degrees of freedom per node (three translations and two rotations) which can be used for sandwich plate models subjected to in-plane forces as well as out-of-plane forces, Figure 3. Since its formulation is based on the first order shear deformation theory, it can also be used for moderately thick and thick laminated sandwich plates where shear deformation effects are of importance. Linear shape functions are used for all degrees of freedom for simplicity.

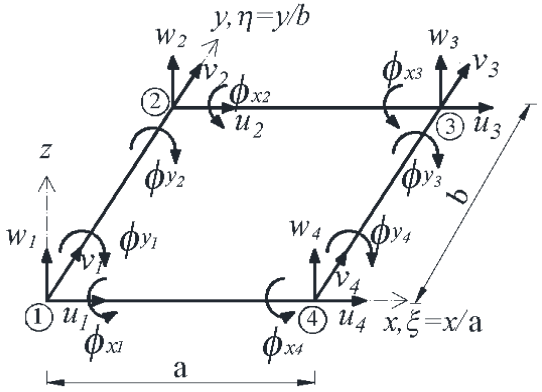

Figure 3. Laminated sandwich plate finite element.

The set of equations obtained from the finite element discretization is given in Equation 6.

$$[K_{uu}\ 0\ -K_{u\sigma}^{T}\ K_{\sigma\sigma}]\left[\underline{u^c}\ \underline{\sigma^g}\right] = \left[\underline{f}\ \underline{0}\right] \tag{6}$$

Here, K_{uu} is the first and $K_{u\sigma}\ and\ K_{\sigma\sigma}$ are the second solution step element stiffness matrices. The first set of equations gives the unknown nodal displacements $\underline{u^c}$. The gradient enriched stresses $\underline{\sigma^g}$ are obtained using the second set of equations where the nodal displacements are used as input data.

Findings

Two numerical examples are carried out to show the efficiency of the presented approach in eliminating the stress singularities occurring under point forces and at sharp crack tips. The first example is a clamped square plate subjected to a central point load and the second example is an axially loaded sandwich plate with sharp cracks (Mode I fracture problem), Figure 4.

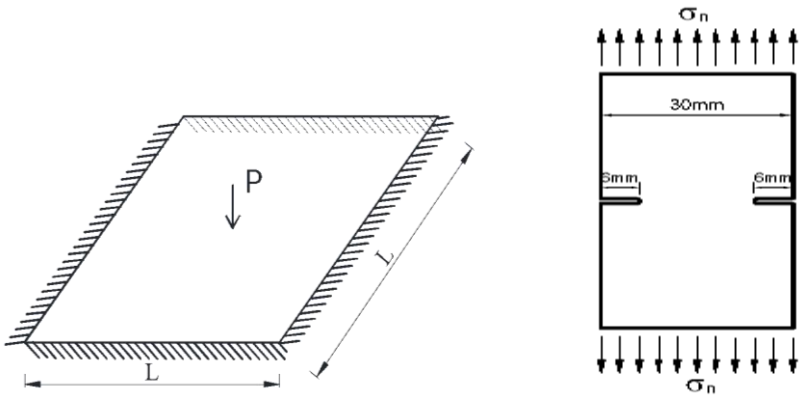

Figure 4. Clamped sandwich plate under central point load and Mode I fracture problem.

Both examples have the same cross-sectional properties, the face sheet thickness is 0.01m and core thickness is 0.08 m. Elastic moduli of the face sheets and the core are E_1=200 GPa and E_2=8 GPa, respectively. In Figure 5, σ_X stress components at the top surface of the clamped plate which is discretized using a 32x32 mesh are plotted for the classical elasticity and gradient elasticity solutions. It is observed that singularity occurring under the point load is removed with the usage of gradient elasticity.

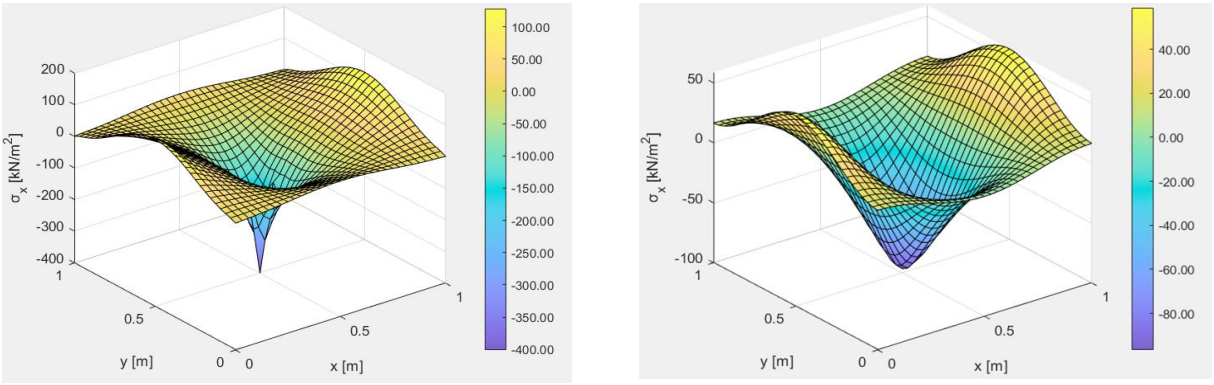

Figure 5. Clamped plate under central point load - Surface plots of σ_x stresses (left - classical elasticity solution), (right - gradient elasticity solution (l=0.125m)).

The σ_x stresses under the point load and at the top points of the face sheet and the core are given in Table 1. It is seen that in classical elasticity solution, the stress values diverge with mesh refinement for both laminates. The stresses converge to finite values with the usage of gradient elasticity indicating the removal of singularities.

Table 1. Classical elasticity and gradient enriched σ_x stresses under the point load.

mesh	σ_x (Classical)		σ_x (Gradient enriched) ℓ=0.125 m		σ_x (Gradient enriched) ℓ=0.25 m	
	Face	Core	Face	Core	Face	Core
(4x4)	-91.457	-2.927	-43.271	-1.385	-17.367	-0.556
(8x8)	-204.896	-6.557	-76.953	-2.463	-31.103	-0.995
(16x16)	-310.533	-9.937	-91.970	-2.943	-37.022	-1.185
(32x32)	-400.993	-12.832	-96.619	-3.092	-38.819	-1.242
(64x64)	-484.093	-15.491	-97.888	-3.132	-39.302	-1.258

In addition, convergence studies are carried out to show the effectiveness of the finite element implementations. For that purpose, relative error analyses in L2 norm are performed using Equation 7.

$$\|e\|_2 = \frac{\|\sigma_e - \sigma_c\|}{\|\sigma_e\|} \qquad (7)$$

Here, σ_e and σ_c are the exact and calculated stresses, respectively where the exact stresses are the stress values of the finest mesh (64x64) solution treated as the reference mesh solution.

In Figure 6, the relative stress errors in L2 norm are plotted against the number of degrees of freedom in bi-logarithmic scale for classical elasticity and gradient elasticity solutions. Relative errors decrease with increasing number of degrees of freedom. The slopes of the obtained straight lines which give the convergence rates of the numerical solution to the exact solution show that gradient elasticity solution has considerably higher convergence rate compared to the classical elasticity solution.

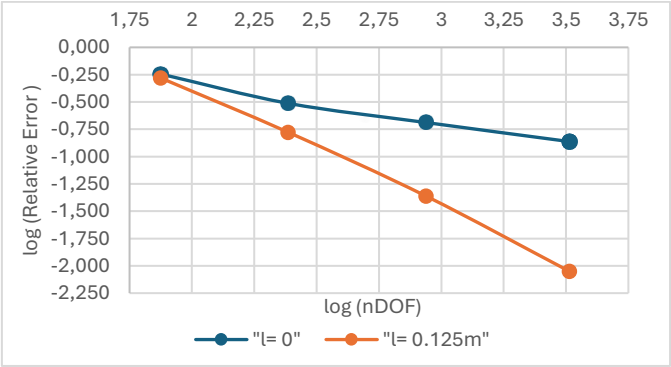

Figure 6. L2 Norm of relative stress errors for classical elasticity and gradient elasticity solutions.

In Figure 7, σ_X stress components of the Mode I fracture problem are plotted for the classical elasticity and gradient elasticity solutions. Note that due to symmetry, one fourth of the plate is used in the calculations assigning appropriate boundary conditions and it is discretized using a 32x32 mesh. Singularity occurs at the sharp crack tip with the usage of classical elasticity and it is removed when gradient elasticity is used as seen in Figure 7.

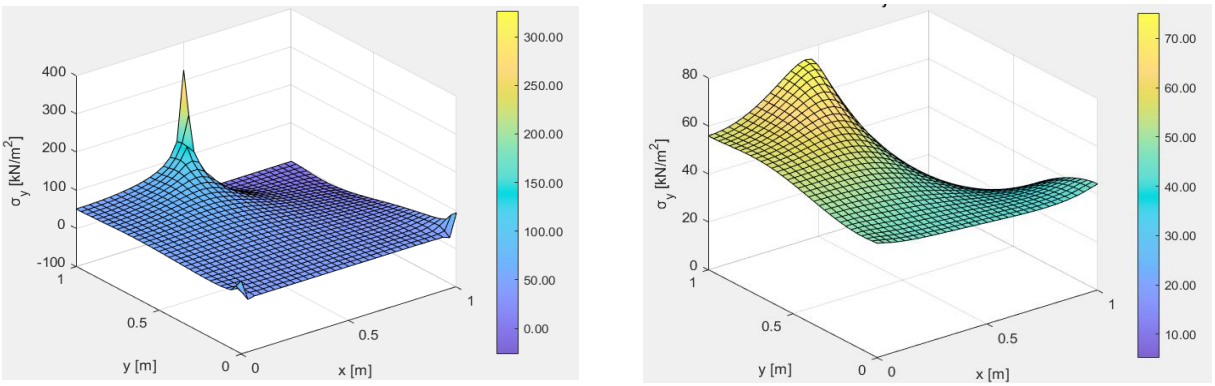

Figure 7. Mode I fracture problem - Surface plots of σ_x stresses (left - classical elasticity solution), (right - gradient elasticity solution (l=0.125m)).

In Table 2, σ_y axial stresses at the crack tip are given for the face sheet and the core. As in the first example, it is observed that the stresses increase in classical elasticity solution with mesh refinement for both laminates and they converge to finite values with the usage of gradient elasticity.

Table 2. Classical elasticity and gradient enriched σ_y stresses at sharp crack tip.

mesh	σ_y (Classical)		σ_y (Gradient enriched) ℓ=0.125 m		σ_y (Gradient enriched) ℓ=0.25 m	
	Face	Core	Face	Core	Face	Core
(4x4)	110.022	4.401	70.399	2.816	53.777	2.151
(8x8)	160.008	6.400	71.948	2.878	53.912	2.157
(16x16)	229.422	9.177	71.208	2.848	53.556	2.142
(32x32)	326.607	13.064	70.191	2.808	53.198	2.128
(64x64)	463.373	18.535	69.425	2.777	52.949	2.118

Figure 8 shows the relative stress errors in the L2 norm plotted against the number of degrees of freedom in a bi-logarithmic scale for both classical and gradient elasticity solutions with increasing internal length scale parameters. It is observed that relative errors decrease with increasing the number of degrees of freedom as well as the length scale parameter. Classical elasticity solution has lower convergence rate compared to gradient elasticity solution and the convergence rates do not change for increasing length scale parameters indicating that the smallest parameter l=0.125m is sufficient for satisfactory results.

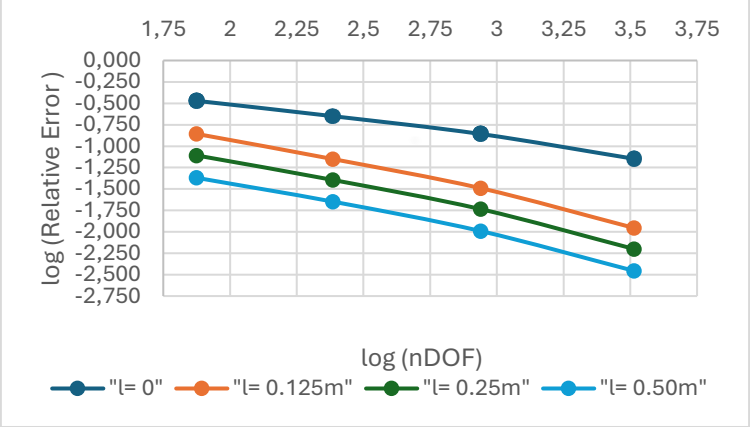

Figure 8. L2 Norm of relative stress errors for classical elasticity and gradient elasticity solutions.

Conclusion

It is demonstrated through numerical examples that stress singularities occurring under concentrated forces and at sharp crack tips are removed and smooth distributions are obtained with the usage of gradient elasticity theory. Due to the small elastic modulus of the core material, the stress values at the face sheets are considerably larger than the core values. It is observed from the classical elasticity solutions that the stress singularities occurring under the point load and at the sharp crack tip become more apparent with mesh refinement. Stress values get closer for all meshes with gradient elasticity. The relative stress errors decrease considerably with mesh refinement for both classical elasticity and gradient elasticity solutions. Convergence rates of gradient elasticity solutions are higher than the rates of classical elasticity solutions.

Effect of Strut Shape and Relative Density on the Homogenized Material Properties and Anisotropy of Octet-Truss Unit Cell

Soheil Gholibeygi[a], Hale Ergün[b], Bahar Ayhan[b]

gholibeygi19@itu.edu.tr

Keywords: Homogenization, Octet-truss, Anisotropy, Tapered Strut, Finite Element Method.

Aim

Cellular materials and lattice structures have drawn significant attention due to their exceptional mechanical properties. Truss-based lattice structures, in particular, offer advantages such as high specific strength, superior stiffness-to-weight ratio, excellent energy absorption capacity and lightweight characteristics. These properties make them highly applicable in various industries, including aerospace, defense, biomedical engineering, automotive design, and sports equipment manufacturing. Additionally, their structural behavior can be fine-tuned by adjusting factors such as topology, strut shape, cell size, and base material (Morrish et al., 2017; Qi et al., 2019).

Lattice structures generally exhibit two distinct mechanical responses: stretching-dominated and bending-dominated behavior. Those governed by stretching mechanisms tend to have a high stiffness-to-weight ratio, whereas bending-dominated structures excel in energy absorption (Habib et al., 2018).

The octet-truss lattice, a statically determinate space-filling Platonic solid, is known for its stretching-dominated meso-structural behavior. Among various lattice geometries, the octet-truss was selected due to its near-isotropic elastic response, making it a suitable choice for applications requiring uniform mechanical performance.

At the microscopic level, the basic unit cell of a lattice structure, often called the Representative Volume Element (RVE), exhibits a heterogeneous nature. However, when viewed at the macroscopic scale, it can be represented as a homogeneous anisotropic continuum. To simplify the analysis and design of lattice structures, a homogenization approach is commonly used. This method replaces the intricate geometry of the RVE with an equivalent homogeneous material at the macroscopic level, whose mechanical properties are effective material parameters. Although the base material of the lattice is isotropic, the overall mechanical response after homogenization can become fully anisotropic. This is due to the fact that the effective elastic properties are influenced by the RVE's geometry at the microscale, including its orientation (De Pasquale et al., 2018).

In this study, three different strut shapes were considered. Those are cylindrical, tapered, and dumbbell-shaped. This research explores how these different strut shapes affect the homogenized properties of an orthotropic octet-truss unit cell, all of which exhibit cubic symmetry. Additionally, the relative density is varied from 0.05 to 0.4 in increments of 0.05 to assess its influence. The study also examines the anisotropic behavior of the samples. The homogenization method is based on reaction force calculations to determine the effective material properties by using finite element software (ABAQUS, 2022).

Material and Method

The homogenization approach for RVE involves applying uniform strain conditions at the microscale, as can be seen in Figure 1, to determine the effective elastic properties. Additionally, periodic boundary conditions (PBCs) are necessary to simulate the deformation of the surrounding material, ensuring that the external surfaces of the deformed RVE remain periodic. These PBCs are implemented using EasyPBC which was developed to automate the identification and generation of necessary boundary node sets, constraint equations, displacement boundary conditions, and post-processing calculations for determining effective elastic properties (Omairey et al., 2019). It was written in the Python language utilizing ABAQUS commands. This plug-in facilitates the application of PBCs by generating node sets for each side, edge, and corner of the RVE. During this process, constraint equations are

established to link each node with its corresponding counterpart on the opposite side, ensuring periodicity in deformation. The code generates these constraint equation sets based on the required homogenized properties, adjusting applied displacements at specific reference points through boundary conditions.

$$\begin{aligned}[E_1(v_{23}v_{32}-1)/D\ -E_1(v_{21}+v_{23}v_{31})/D\ -E_1(v_{31}+v_{21}v_{32})/D\ 0\ 0\ 0\ -E_2(v_{12}\\ +v_{13}v_{32})/D\ E_2(v_{13}v_{31}-1)/D\ -E_2(v_{12}v_{31}+v_{32})/D\ 0\ 0\ 0\ -E_3(v_{13}\\ +v_{12}v_{23})/D\ -E_3(v_{13}v_{21}+v_{23})/D\ E_3(v_{12}v_{21}\\ -1)/D\ 0\ 0\ 0\ 0\ 0\ 0\ G_{23}\ 0\ 0\ 0\ 0\ 0\ 0\ G_{13}\ 0\ 0\ 0\ 0\ 0\ 0\ G_{12}\ ]\end{aligned} \tag{1}$$

$$D = v_{12}(v_{21}+v_{23}v_{31}) + v_{23}v_{32} + v_{13}(v_{31}+v_{21}v_{32}) - 1$$

$$\underline{\rho}_{co} = 6\pi\sqrt{2}\left(\frac{R}{L_{strut}}\right)^2 - \frac{32}{2-\sqrt{2}}\left(\frac{R}{L_{strut}}\right)^3 \tag{2}$$

$$\underline{\rho}_{to} = 24\pi\sqrt{2}\left(\frac{R}{L_{strut}}\right)^3 + \frac{2\pi\sqrt{2}}{5}\frac{h}{L_{strut}}\left(\frac{R}{L_{strut}}\right)^2(3+4\alpha+8\alpha^2) - \frac{16}{\sqrt{2}-1}\left(\frac{R}{L_{strut}}\right)^3 \tag{3}$$

$$\underline{\rho}_{do} = 3\pi\sqrt{2}\left(\frac{R}{L_{strut}}\right)^2 - \frac{8}{\sqrt{2}-1}\left(\frac{R}{L_{strut}}\right)^3 - 6\pi\sqrt{2}\,(1-\alpha^2)\frac{h}{L_{strut}}\left(\frac{R}{L_{strut}}\right)^2 \tag{4}$$

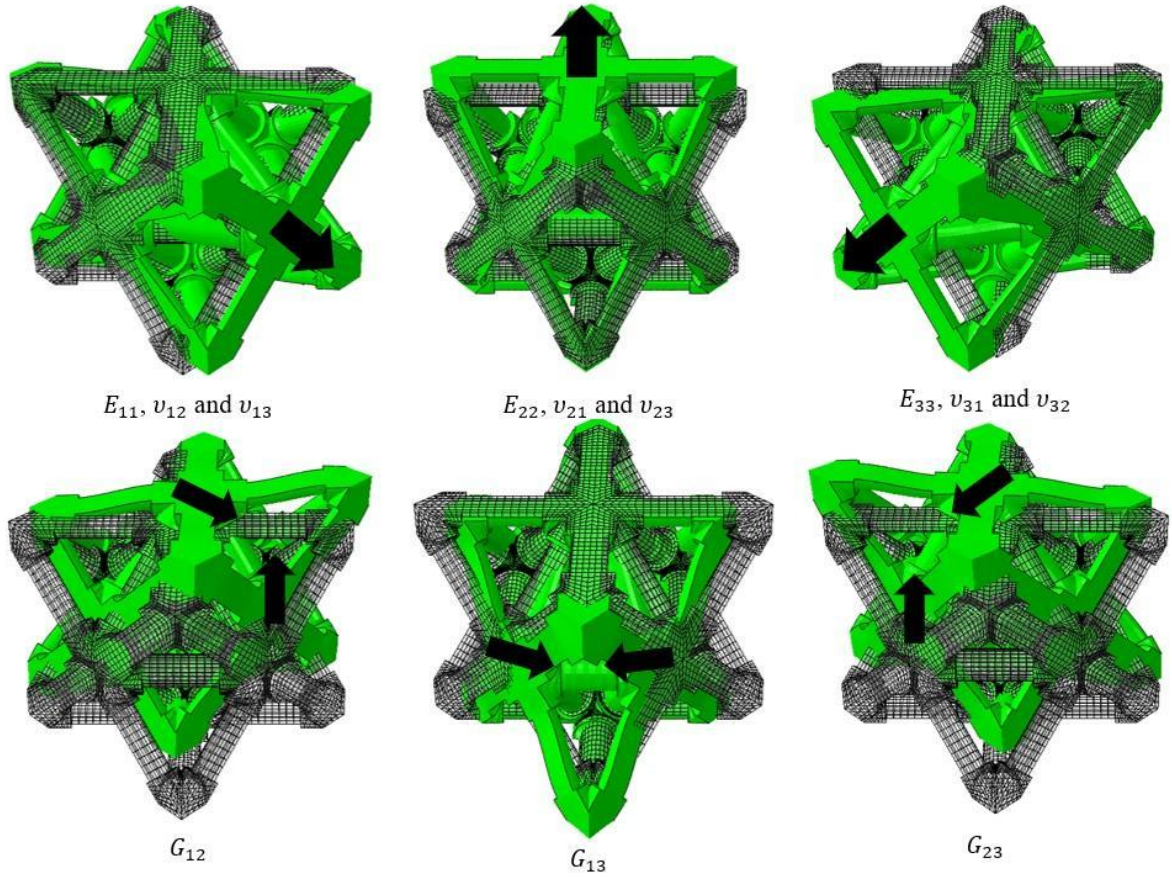

Figure 1. Required displacement type boundary condition to estimate the effective elastic properties of an RVE.

Reaction force data must be specifically requested for the reference point where displacement is applied on a given surface, depending on the required elastic modulus. To determine the corresponding stress value, this reaction force is divided by the area of the affected surface, and the resulting stress is then used to calculate Young's modulus by dividing it by the applied strain. Additionally, the output data from the same job used to compute Young's modulus is also utilized to estimate Poisson's ratios in the two transverse directions. This is done by calculating the transverse strain and dividing it by the applied axial strain. Also, Shear moduli are determined by calculating the ratio of shear stress to shear strain in the corresponding directions.
This plug-in computes all homogenized elastic moduli, shear moduli, and Poisson's ratios. Using Equation 1, a stiffness matrix is generated for each unit cell. Subsequently, ELATE, an open-source online tool for analyzing and visualizing elastic tensors, is utilized to examine the anisotropy and spatial variation of Young's modulus, shear modulus, and Poisson's ratio of the unit cells (Gaillac et al., 2016).

Cylindrical, tapered and dumbbell-shaped struts were used in this study as shown in Figure 2. They have been used to simulate Octet-Truss unit cells in order to investigate the effect of strut geometry on the mechanical properties and the anisotropy of this lattice material. All unit cells have the same cell side length of $L_{uc} = 6\,mm$ resulted with the same strut length of $L_{strut} = \frac{L_{uc}}{\sqrt{2}} = 3\sqrt{2}\,mm$. The length and the radius of the struts are denoted by L_{strut} and R, respectively. For tapered and dumbbell-shape configurations, the strut ends are of cylindrical shape over a length of strut diameter $2R$. Here, $h = L_{strut} - 4R$ is the middle part of the strut where the modification is conducted for the tapered and the dumbbell-shaped struts. In tapered one, between these two end regions, the strut radius changes gradually in a parabolic manner reaching its extreme value of αR at the strut center. However, in the dumbbell-shaped struts, between the two end regions, the strut radius changes abruptly to the value of αR. The strut shape is therefore defined through the factor α, with $\alpha < 1$ describing notched configurations and $\alpha = 1$ describing a perfectly cylindrical configuration (Tancogne-Dejean et al., 2016). The results for the values of this factor $\alpha = 0.5, 0.6, 0.7, 0.8, 0.9, 1.0$ are presented in this study.

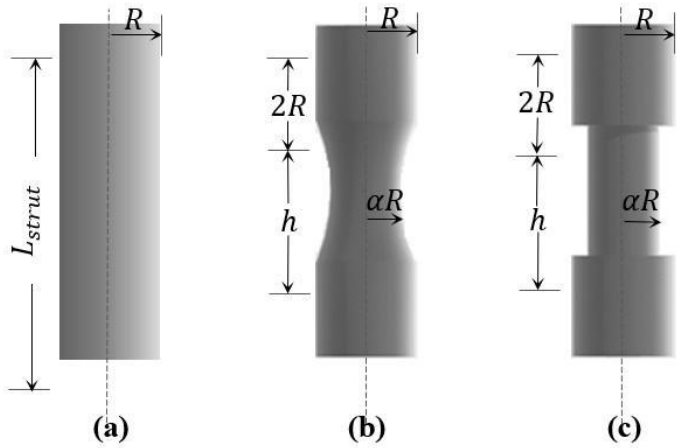

Figure 2. Geometry of **(a)** cylindrical, **(b)** tapered and **(c)** dumbbell-shaped struts.

The relative density of a lattice material $\underline{\rho}$ is defined as the ratio of the macroscopic density of the cellular material and the density of the bulk material. Relative density of octet-truss unit cell $\underline{\rho}_{co}$ is already given with Equation 2 for cylindrical struts (Tancogne-Dejean et al., 2016). The analytical expression of the relative density for tapered $\underline{\rho}_{to}$ and dumbbell-shaped $\underline{\rho}_{do}$ octet-truss are derived and presented in Equation 3 and Equation 4, respectively. In order to make a comparison between the unit cells with different shaped struts, the relative density is kept constant and the required radius values of the struts are calculated by using Equations 2, 3 and 4. The results for the relative density values of $\underline{\rho} = 0.05, 0.1, 0.15, 0.2, 0.25, 0.3, 0.35, 0.4$ are presented in this study.

Hexagonal linear element type C3D8R, that is available in ABAQUS library, is used with mesh seed size of $0.2\,mm$ in all models. The number of elements in a unit cell was approximately between 17408 and 65664, depending on their relative density value. Mesh of the cylindrical, tapered and dumbbell-shape octet truss unit

cells for the same relative density of $\underline{\rho}_{co} = \underline{\rho}_{to} = \underline{\rho}_{do} = 0.2$ are shown in Figure 3. Tapered factor α for tapered and dumbbell shaped struts in this figure are both $\alpha = 0.5$.

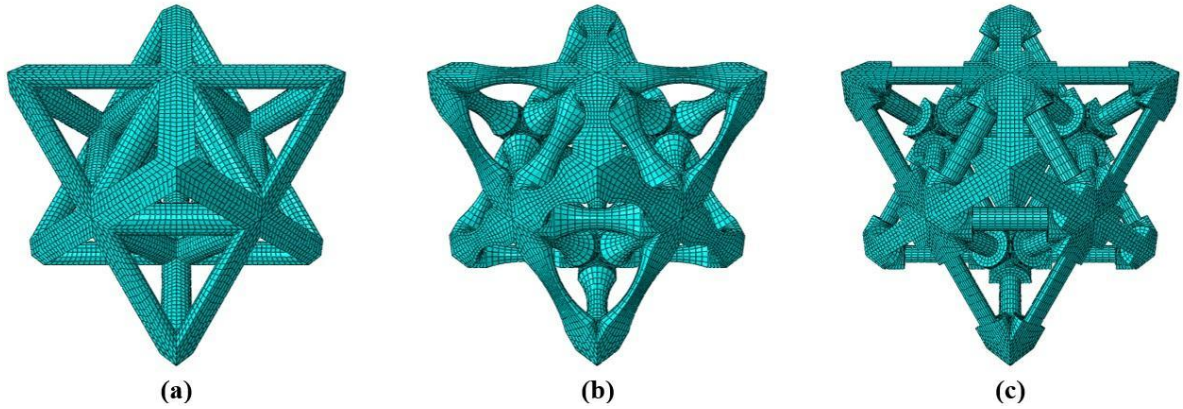

Figure 3. Mesh of octet truss unit cells for constant relative density $\underline{\rho}_{co} = \underline{\rho}_{to} = \underline{\rho}_{do} = 0.2$ with **(a)** cylindrical ($\alpha = 1$), **(b)** tapered ($\alpha = 0.5$) and **(c)** dumbbell-shaped struts($\alpha = 0.5$).

In this study, Nylon-12 is the bulk material with which octet truss lattice unit cell is additively manufactured. This isotropic linear elastic material is used in all simulations that has elastic modulus of $E = 969.52\ MPa$ and Poisson's ratio of $\upsilon = 0.33$.

Findings

The homogenized values of E_{11}^{c} and G_{12}^{c} for cylindrical octet-truss unit cell for different values of relative density are tabulated in Table 1. Also, effective material properties of tapered unit cells (E_{11}^{T}, G_{12}^{T}) and dumbbell-shaped unit cells (E_{11}^{D} and G_{12}^{D}) along with their variations relative to the cylindrical octet-truss are tabulated in Table 2. Data in this table is also plotted in Figure 4. Generally speaking, as relative density increases, the influence of strut shape becomes more pronounced. The values with which maximum improvements has obtained for each relative density are printed in bold font in Table 2. These maximum data are marked with red circles in Figure 4 . For example, it can be seen that the maximum improvement of 13.01% in Elastic modulus is obtained for relative density of $\bar{\rho} = 0.4$ by modeling the octet-truss with tapered struts for $\alpha = 0.7$. Also, in the same model, the maximum enhancement of 8.61% in shear modulus G_{12} is obtained for $\alpha = 0.8$ in comparison to the cylindrical one. The shaded cells in Table 2 and the shaded regions in Figure 4 highlight the cases when there is degradation in modulus values. In this figure, data for $\alpha = 1$ represent the homogenized modulus of cylindrical octet-truss unit cells. These values are plotted with dashed horizontal lines for each curve in order to compare with the other modified strut configurations.

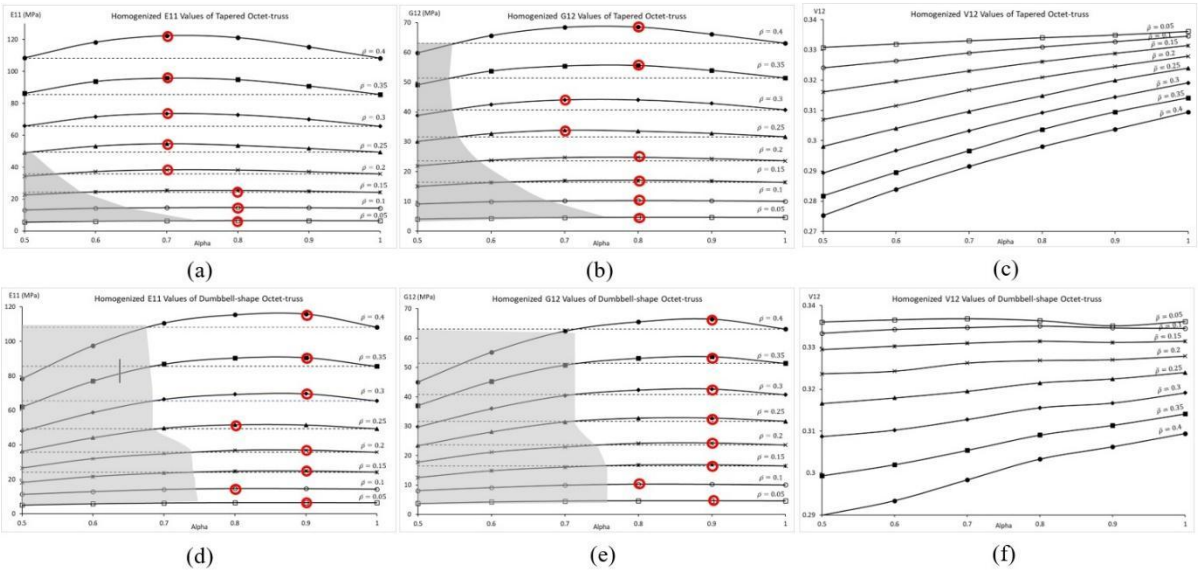

Figure 4. Homogenized value **(a)** E_{11}, **(b)** G_{12} and **(c)** υ_{12} of tapered, **(d)** E_{11}, **(e)** G_{12} and **(f)** υ_{12} of dumbbell-shaped octet-truss unit cell.

Figure 4 indicates that at low relative densities of $\bar{\rho} < 0.15$, the differences in Young's modulus and shear modulus among octet-truss unit cells with various strut shapes are negligible. However, for higher relative densities ($\bar{\rho} \geq 0.15$), tapered octet-truss unit cells exhibit the highest elastic and shear modulus at $0.7 \leq \alpha \leq 0.8$ interval, whereas in dumbbell-shaped unit cells, the highest values occur within the range of $0.8 \leq \alpha \leq 0.9$. Additionally, as α increases, the homogenized Poisson's ratio also increases. Overall, tapered struts are preferable over cylindrical and dumbbell-shaped ones for achieving improved effective material properties.

According to Figure 5, by increasing relative density $\bar{\rho}$, homogenized value of E_{11} and G_{12} increase for all models. Black line represents the cylindrical octet-truss.

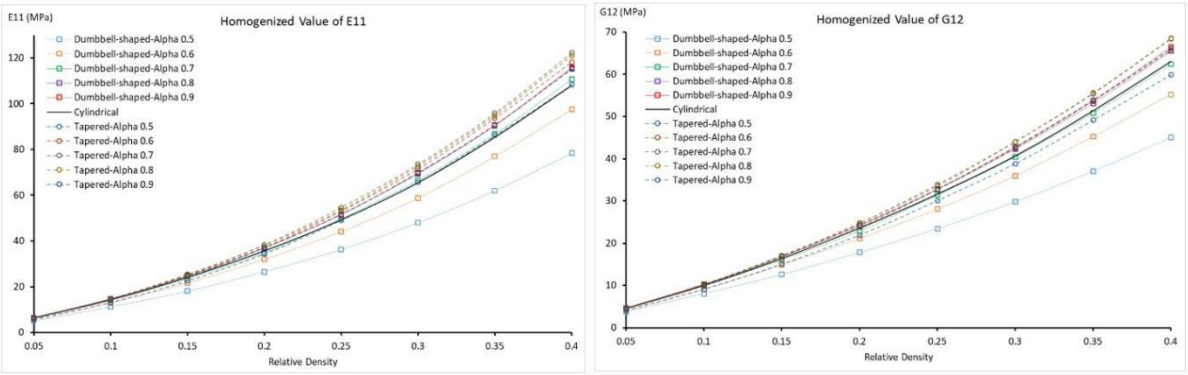

Figure 5. Homogenized value **(a)** E_{11} and **(b)** G_{12} of octet-truss unit cell.

Anisotropy is defined as the ratio of the maximum to the minimum values of the related material properties (Gaillac et al., 2016). To analyze the impact of strut shape on the anisotropy of Young's modulus, shear modulus and Poisson's ratio, stiffness matrices of three model, each with a relative density of 0.4 and tapering factor of $\alpha = 0.7$ for tapered and dumbbell-shaped unit cells, were computed and imported into the ELATE online tool (Gaillac et al., 2016). The results are presented in Table 3. This allowed for the calculation of minimum, maximum, and anisotropy values, as well as the extraction of spatial dependencies. The results indicate that the tapered octet-truss exhibits the highest minimum and maximum values for E and G. Furthermore, modeling the struts with tapered and dumbbell shapes reduces anisotropy, bringing its value closer to one which suggests that the structure becomes more isotropic.

Table 3. Minimum, maximum values of E, G, υ and anisotropy of tapered, dumbbell-shaped and cylindrical octet-truss for $\underline{\rho}$ =0.4 and $\alpha = 0.7$.

Strut shape	E	G	υ
Cylindrical	 Young's modulus in (xy) plane	 Shear modulus in (xy) plane	 Poisson's ratio in (xy) plane
	$E_{min} = 108.2\ MPa$	$G_{min} = 41.322\ MPa$	$\upsilon_{min} = 0.10791$

	$E_{max} = 154.83MPa$ $Anisotropy = 1.431$	$G_{max} = 63.085\ MPa$ $Anisotropy = 1.527$	$\upsilon_{max} = 0.39962$ $Anisotropy = 3.7034$
Tapered	 $E_{min} = 122.28\ MPa$ $E_{max} = 166.44\ MPa$ $Anisotropy = 1.361$	 $G_{min} = 47.342\ MPa$ $G_{max} = 68.426\ MPa$ $Anisotropy = 1.445$	 $\upsilon_{min} = 0.11549$ $\upsilon_{max} = 0.3639$ $Anisotropy = 3.1509$
Dumbbell	 $E_{min} = 110.67\ MPa$ $E_{max} = 152.50\ MPa$ $Anisotropy = 1.378$	 $G_{min} = 42.617\ MPa$ $G_{max} = 62.392\ MPa$ $Anisotropy = 1.464$	 $\upsilon_{min} = 0.11662$ $\upsilon_{max} = 0.37565$ $Anisotropy = 3.2211$

Conclusion

At low relative densities ($\bar{\rho} < 0.15$), the differences in Young's modulus and shear modulus among octet-truss unit cells with various strut shapes are negligible.

For higher relative densities ($\bar{\rho} \geq 0.15$), tapered octet-truss unit cells with $0.7 \leq \alpha \leq 0.8$ exhibit the highest elasticity and shear modulus, whereas in dumbbell-shaped unit cells, the highest values occur within the range of $0.8 \leq \alpha \leq 0.9$.

As α increases, the homogenized Poisson's ratio also increases.

Tapered struts with $0.7 \leq \alpha \leq 0.8$ are preferable over cylindrical and dumbbell-shaped ones for achieving improved effective material properties.

Tapered octet-truss exhibits the highest minimum and maximum values for E and G. Modeling the struts with tapered and dumbbell shapes reduces anisotropy, bringing its value closer to one.

Aim

The hyperbolic paraboloid (hypar) is a doubly curved, anticlastic, ruled surface that looks architecturally complex to construct but structurally has a relatively simple shape formed by the combination of straight lines. This unique geometry became popular in architectural design during the mid-20th century. Its doubly curved surface provides exceptional structural rigidity, allowing architects to span large distances using surprisingly thin materials. Surface structures in architecture and engineering are components whose thickness is significantly less than their other dimensions, such as plates and shells. These structures are already efficient by design, but incorporating specific structural patterns (variations in thickness or openings) can further enhance their material efficiency while also creating visually interesting architectural spaces (Rivera et al., 2020). Due to this dimensional advantage, they are more likely to be used for specific design and structural engineering problems. In light of its high rigidity, the hyperbolic paraboloid resists uniform loads through tension, compression, or shear forces within its plane. This structural behavior enables it to remain remarkably thin while covering large spans by reducing out-of-plane bending. (Sprague, 2013) In this research paper, it is aimed to find the optimum characteristic features on an example model in architectural and structural terms by establishing various parameters from the design stage of the hyperbolic paraboloid shape. Hyperbolic paraboloids are among the most fascinating warped surfaces in construction. Though they have a double curvature, their shape is defined by two intersecting sets of straight lines, making it possible to use straight timber formwork and eliminating the need for costly curved molds (Sprague, 2013). Within this study, the reinforced concrete shell structures designed by Heinz Isler, Félix Candela, Pier Luigi Nervi, Eduardo Torroja, Bernard Lafaille, Fernand Aimond, Anton Tedesko, Sergio Musmeci and other renowned architects and engineers were thoroughly examined. Before Candela's groundbreaking free-edge shell designs, most shell structures incorporated edge ribs for stability. While hypar shells generate strong forces normal to their edges, their slender cross-sections -enabled by their double curvature- offer little resistance in that direction (Burger & Billington, 2006). Candela spent a considerable portion of his career experimenting with these types of structures. The experiences led to the construction of numerous free-edge vaults in different shapes, including triangles, squares, pentagons, hexagons, and octagons. The most famous of these is the shell roof of Los Manantiales in Xochimilco, Mexico which is one of Candela's finest works, often seen as a groundbreaking design that remains difficult to surpass (Tomás & Martí, 2010). The sample model in this study was created by taking inspiration from Felix Candela's famous buildings, Los Manantiales in Xochimilco and the Bacardi Rum Factory in Mexico.

Material and Method

The example model, composed of two intersecting curved-edged reinforced concrete hypar shells, was created using four parameters; support span, edge height, center height and edge overhang. The aim was to determine the most suitable and economical form for construction by generating design alternatives through varying these parameters. A parametric model of a hyperbolic paraboloid shell, inspired by Felix Candela's designs, was created using Rhinoceros 3D with the Grasshopper plug-in. Structural analysis was then performed using Structural Analysis and Design (SAP2000) commercial software by Computers and Structures Inc. In this study, the following stages were generally followed for parametric modeling and analysis: (1) defining the parameters that

will form the 3D model; (2) generating variable models according to the parameters; (3) creating a mesh structure for these models; (4) performing analyses in the static analysis program; (5) comparing the obtained results.

Findings

This study demonstrates that the 3D representation of shell structures using parametric analysis software enables designers to effectively explore various configurations, evaluate their structural behavior, and improve both form and structural performance at the conceptual design stage. In the design process of the sample shell structure, Felix Candela's structures were mostly taken into account. Visionaries in lightweight structures, such as Frei Otto and Félix Candela, developed a remarkable range of designs by integrating form and analysis, often utilizing techniques like form-finding (Goldbach & Lázaro, 2024). In order to push the design limits of these structures, various models were produced according to the parameters as mentioned earlier (support span, edge height, center height and edge overhang) and comparisons were made between them. The thickness of the designed shell structure was also kept as a parameter; however, the shell does not have a variable thickness, unlike Candela's structures, where the thickness is kept constant in the models. Within these models, a new hyperbolic paraboloid based reinforced shell models are presented to the literature. A group of obtained hypar shell models are given in Figure 1. Support span, edge height, center height and edge overhang values for the listed shapes in Fig.1 respectively: (a) 20,15,10,5; (b) 20,20,10,5; (c) 20,15,10,10; (d) 20,20,10,10; (e) 20,20,15,5; (f) 20,20,15,10.

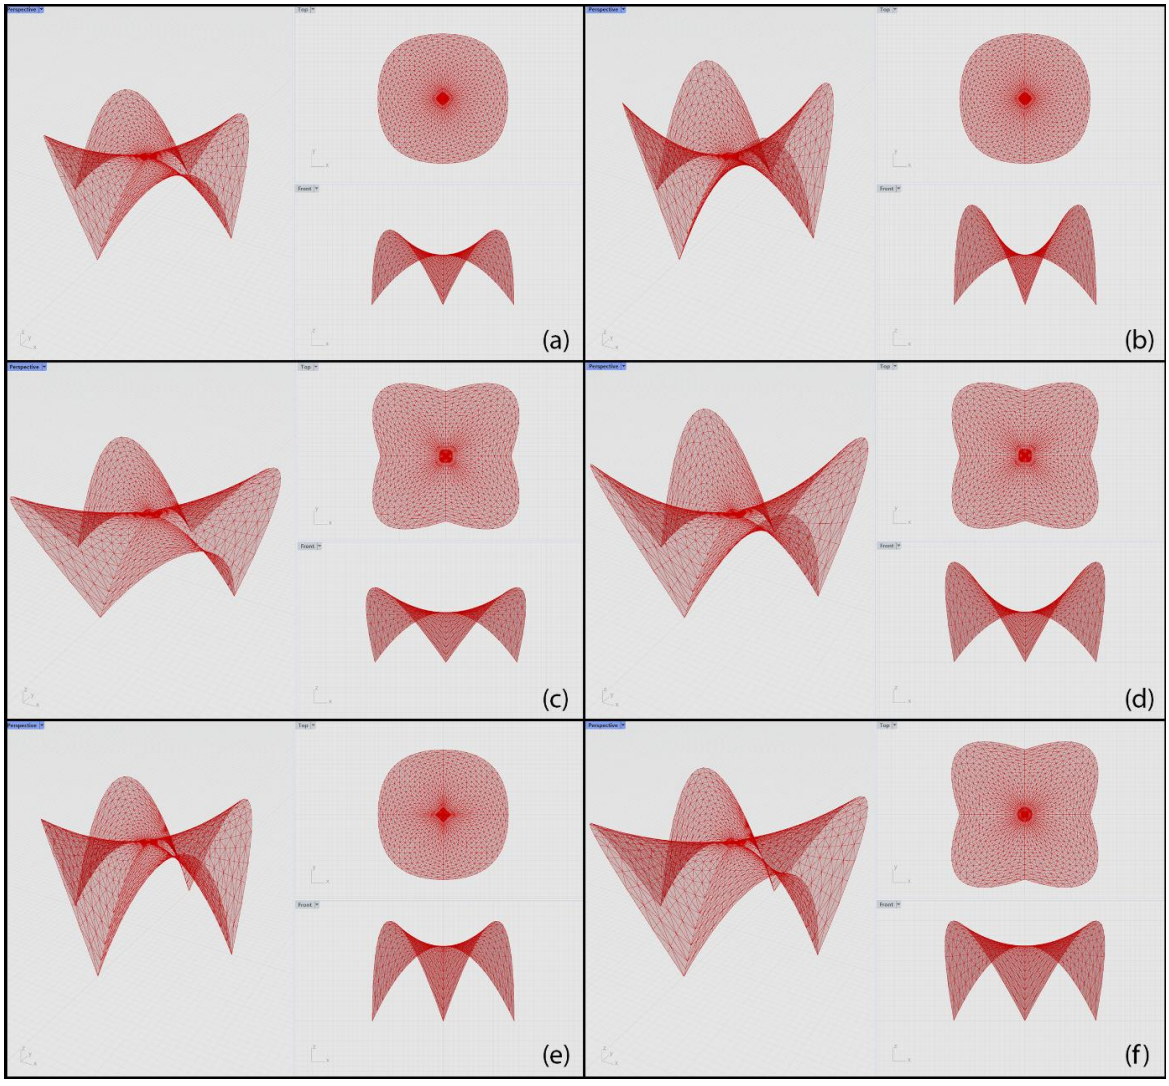

Figure 1. Support span, edge height, center height and edge overhang values for the listed shapes are respectively: (a) 20,15,10,5; (b) 20,20,10,5; (c) 20,15,10,10; (d) 20,20,10,10; (e) 20,20,15,5; (f) 20,20,15,10.

Conclusion

One challenge with hyperbolic paraboloid roofs is that they require extremely precise assembly during construction, which means workers need to have a high level of skill. This is especially true for thin concrete shell structures, as they have to be cast on-site with highly accurate formwork. On top of that, workers must carefully manage the concrete's thickness and ensure the surface stays smooth at every stage. (Wang et al., 2023) One of the biggest reasons for the move away from producing these hyperbolic paraboloid shell structures today is the increasing use of different methods to span large openings in structures and the difficulties mentioned. However, even minor enhancements to the form of these structures can lead to substantial improvements in their mechanical behavior. Various objective functions, including strain energy, overall weight, and tensile stress distribution on both shell surfaces, can be used to optimize their performance (Tomás & Martí, 2008). This study highlights the crucial role of 3D modeling and structural analysis in the design of shell structures. By utilizing parametric analysis software, designers can efficiently explore different configurations, assess their structural behavior, and refine both form and performance early in the design process, ensuring a more informed and optimized construction approach. Even though optimization can be achieved in terms of design, the development of construction techniques and construction methods for these shell structures can be developed as a future work suggestion.

Aim

In February 2023, a sequence of consecutive earthquakes struck Türkiye on the same day, a Mw 7.7 earthquake with an epicenter in Pazarcık/Kahramanmaraş and a Mw 7.6 earthquake with an epicenter in Elbistan/Kahramanmaraş. These seismic events, followed by numerous aftershocks, affected 11 provinces and more than 14 million people, resulting in over 53,000 casualties, 100,000 injuries, extensive damage to more than 90,000 reinforced concrete (RC) structures, and an economic loss exceeding US$100 billion (Narlitepe et al., 2024). Investigations identified critical structural deficiencies, including poor material quality, construction defects failing to meet ductile design requirements, and design errors in several regions. In response to the severe impact and lessons learned from these earthquakes, new regulations (communiqué) were developed, which is still a draft, to introduce additional enhanced seismic design provisions to the existing seismic design code of Türkiye, Türkiye Building Earthquake Code (TBEC, 2018). In the scope of this study, two different RC buildings were designed based on the same real architectural plan. First, the structural system of Building 1 was designed according to TBEC (2018) under a 475-year return period earthquake ground motion (DD-2). Then, the structural system of Building 1 was modified in accordance with the additional seismic design requirements of the Draft Communiqué (2025), while maintaining the same architectural plan, and named as Building 2. This study presents a comparative structural analysis of these buildings, providing insights into the impact of the proposed regulatory amendments on seismic resilience.

Material and Method

The Draft Communiqué (2025) introduces additional seismic design provisions aimed at mitigating potential construction defects by imposing obligatory use of shear walls, stricter displacement and vertical stress limits, and limitations on column dimensions and irregularities of the structural system. For buildings classified with a building height class smaller than 6 (buildings higher than 10.5m for seismic design classes 1 and 2, and 17.5 m for seismic design classes 3 and 4), the minimum cross-sectional areas of RC shear walls (Aw) and columns (Ac) must be determined based on the number of storeys (N), building plan area (A), and short-period design spectral acceleration (Sᴅs) using Equations 1. and 2. These calculated minimum cross-sectional areas shall be satisfied independently in both principal directions.

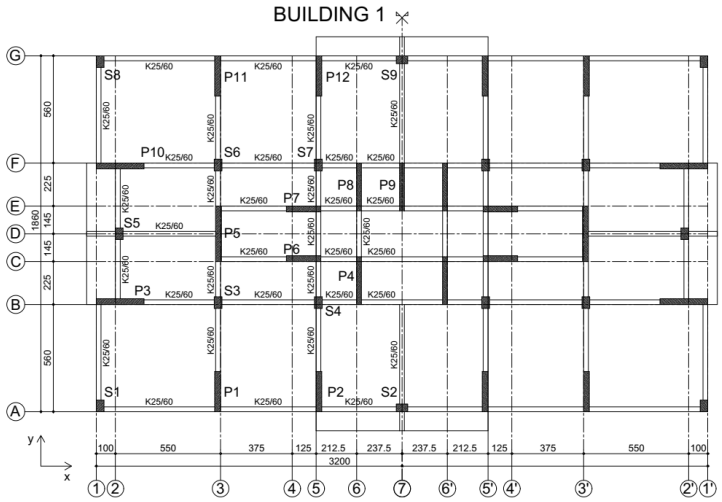
$$A_w \geq min\ (0.002N, 0.02) S_{DS} A \quad \#(\ SEQ\ Denklem\ \backslash *\ ARABIC\ 1)$$

$$A_w + A_c \geq max(0.009, min\ (0.003N, 0.03)) S_{DS} A \quad \#(2)$$

For considering the relative storey drifts as per TBEC (2018), the approximate effective relative storey drift value for the 72-year return period earthquake ground motion (DD-3) is derived from the effective relative storey drift determined through the analysis, which is conducted under the DD-2 earthquake ground motion. The calculated drift for the DD-3 earthquake ground motion must remain within the allowable limit, which is determined based on the infill wall connection type (flexible or brittle) and the structural system type (RC or steel). Instead, the draft

communiqué introduces a stricter 1% storey drift limit for DD-2 earthquake ground motion. To ensure a regular structural system and efficient load transfer during an earthquake, the communiqué mandates that at least 50% of the beam-column axes in each direction must be arranged continuously from one end to the other of the building in plan. Furthermore, the cross-sectional aspect ratios of columns are restricted to a maximum of 1.5. Another new restriction is the allowable axial load ratio for columns and shear walls. Under TBEC (2018), the axial load limit for columns is set at 40% of axial load capacity of the columns (without consideration of reinforcement), whereas the draft communiqué reduces it to 35%. Similarly, for RC shear walls, the allowable axial load ratio is lowered from 35% in TBEC (2018) to 25% in the Draft Communiqué (2025).

Yalova, a city with a high seismic risk, was selected as the design location for the buildings. To represent the general soil conditions of the region, ZD soil class was used in the analysis. Based on data from the Earthquake Hazard Map of Türkiye, the short-period design spectral acceleration (S_{DS}) was determined as 1.446 for DD-2 earthquake ground motion level (AFAD, 2018). Each building was designed as a six-storey structure (total floor area of 582 m²) with a floor height of 3 m. The materials used in the buildings are C30/37 class concrete and B420C class reinforcing steel. To ensure an accurate representation of structural behavior under seismic loads, a software, which utilizes finite element analysis, was used for the structural design of the buildings (ETABS v19). In the modelling process, columns and beams were modelled as frame elements. RC shear walls and slabs were modelled as shell elements of maximum dimensions of 50 cm. While RC shear wall elements were manually partitioned, slab elements were automatically meshed, ensuring a precise structural representation. During the dynamic analyses, as per TBEC (2018), the effective section stiffness of cracked RC structural members was considered. The eigenvalue method was utilized to determine the modal characteristics of the structure, such as mode shapes and natural vibration period. In addition to that, the mode superposition method, which accounts for each vibration mode, was employed to calculate the base shear force of the buildings.



Column Sizes (cm)						RC Shear Wall Sizes (cm)					
Element No	Building 1	Building 2	Element No	Building 1	Building 2	Element No	Building 1	Building 2	Element No	Building 1	Building 2
S1	40/60	50/75	S8	40/60	50/75	P1	30/210	30/350	P8	25/250	25/250
S2	60/40	75/50	S9	60/40	75/50	P2	30/210	30/350	P9	25/250	25/250
S3	40/60	-	-	-	-	P3	250/30	650/30	P10	250/30	650/30
S4	40/60	50/75	-	-	-	P4	25/250	25/250	P11	30/210	30/350
S5	40/60	50/75	-	-	-	P5	30/290	35/390	P12	30/210	30/350
S6	40/60	-	-	-	-	P6	180/30	150/25	P13	-	475/30
S7	40/60	50/75	-	-	-	P7	180/30	150/25	P14	-	475/30

Figure 1. Plan and Element Sizes of Buildings 1 and 2.

Building floor plans, which has a symmetry in y direction are shown in Figure 1. As per Building 1, the effective relative storey drift, which was close to the limit value (calculated as 0.0173 for DD-2 earthquake ground motion), played a crucial role in determining the dimensions of the structural elements. Since the relative storey drift at the 5th and 6th floors remains below the calculated limit, the RC shear walls P1, P2, P11, and P12 in y direction were shortened by 30 cm, while P3 and P10 in x direction were shortened by 40 cm compared to those on the lower stories. The total area of the columns of Building 1 was 3.84 m² while that of RC shear walls were 5.16 m² and 9.91 m² in x and y directions, respectively. As per Building 2, the minimum required cross-sectional areas of RC shear walls and total vertical structural members, as determined by Equations 1. and 2., were calculated as 10.1 m² and 15.15 m², respectively. To meet the minimum RC shear wall area requirement in x direction, columns S3 and S6 were removed in the structural plan of Building 1, and the lengths of RC shear walls, namely P3 and P10, were extended, resulting in a total of 12.15 m² RC shear wall area and 16.64 m² total vertical structural element area in this direction. In y direction, the relative storey drift limit (0.01 drift ratio) was the key factor in determining the required RC shear wall area. The structural design included a total of 14.26 m² of RC shear walls and 18.76 m²

of vertical structural member cross-sectional areas. To enhance structural stiffness and control storey drift, 30/80 cm beams were used along two axes, and 35/70 cm beams were arranged along two axes in y direction.

Findings

In Building 2, the total cross-sectional areas of RC shear walls increased by 136% and 44% in the x and y directions, respectively, while the total cross-sectional areas of vertical structural members (RC shear walls and columns) increased by 85% and 36% in the x and y directions, respectively, compared to Building 1.

Figure 2a. presents the effective relative storey drifts for the DD-3 earthquake ground motion in both x and y directions for the respective buildings, along with the calculated limit value, which is 0.8% for brittle infill wall connection type specified by the TBEC (2018). Notably, at the 4th storey, where relative storey drifts reached their maximum values, the effective relative storey drifts in Building 2 were reduced by 58% in x direction and 33% in y direction with respect to Building 1 due to larger dimensions of structural members, as mentioned by the Draft Communiqué (2025). Figure 2b. presents the effective relative storey drifts for the DD-2 earthquake ground motion in both x and y directions for the respective buildings, along with the %1 limit value (for brittle infill wall connection type) specified by the Draft Communiqué (2025). The effective relative storey drifts at the 4th storey in Building 2 were reduced by 64% in x direction and 41% in y direction with respect to Building 1. It should be noted that there is no torsional irregularity in these buildings.

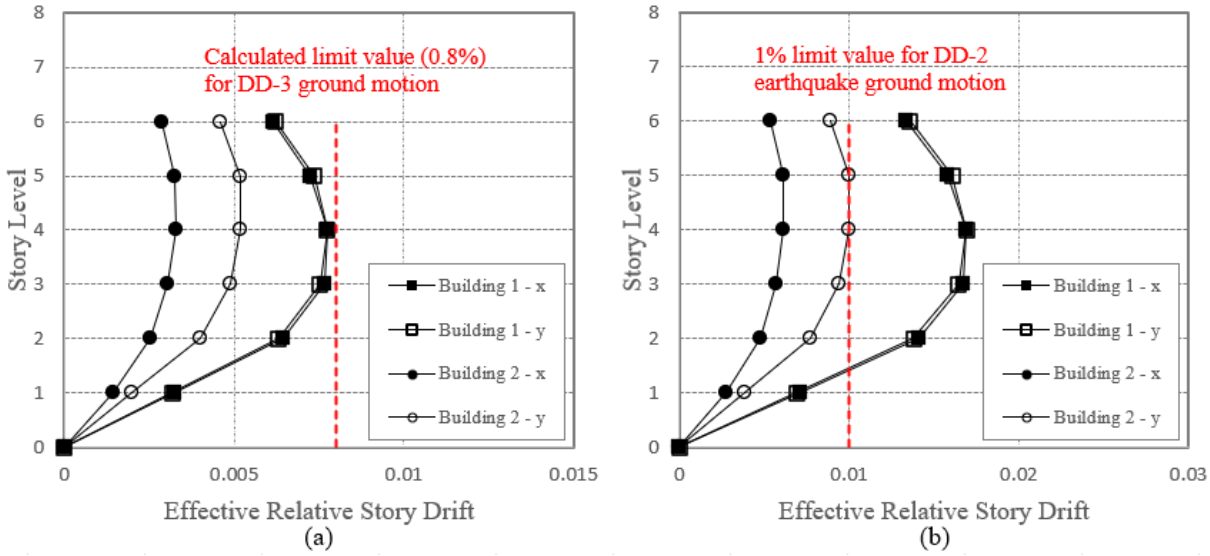


Figure 2. (a) Effective relative storey drift of the buildings for DD-3 earthquake ground motion and %0.8 limit value for TBEC (2018), **(b)** Effective relative storey drift of the buildings for DD-2 earthquake ground motion and %1 limit value for Draft Communique (2025).

Table 1. presents the vibration periods and base shear forces of the buildings along x and y directions. The decrease in the vibration periods by 61% in x direction and 30% in y direction for Building 2 is also mainly due to increased stiffness of the structural system in Building 2. For Building 2, the shortening of periods in both directions led to a significant increase in base shear force (by 111% in x direction and 33% in y direction).

Table 1. Natural vibration period and base shear force values of the buildings.

	Period (s)		Base shear force (kN)	
Buildings	*x* direction	*y* direction	*x* direction	*y* direction
Building 1	0.87	0.639	5046	6809
Building 2	0.34	0.449	10643	9066

Conclusion

The Kahramanmaraş-centred earthquakes that occurred in Türkiye in February 2023 caused destruction and casualties in a wide region covering 11 provinces. Following these earthquakes, work began on the Draft Communiqué (2025) that introduced additional seismic design requirements to the existing TBEC (2018) regulation. As part of this study, the additional requirements proposed by the Draft Communiqué (2025) were examined, and the structural systems of two buildings were designed using the architectural plan of an actual building, one based only on TBEC (2018) (Building 1) and the other incorporating both TBEC (2018) and the Draft Communiqué (2025) (Building 2). The structural analysis results of the buildings are presented comparatively below:

- The effective relative storey drifts of Building 2 are lower than those of Building 1, and its natural vibration period are shorter compared to Building 1 due to the increase in system stiffness resulting from the larger member sizes.
- In Building 1, the effective relative story drifts under the DD-2 earthquake ground motion exceed the 1% limit specified in the Draft Communiqué (2025).
- In Building 2, the 1% effective relative story drift limit (for brittle infill wall connection type) is observed to be a governing factor in the dimensioning of vertical structural members in the y direction. In case a flexible joint infill wall connection type had been selected during the design process, this limit would have increased to 1.5%, and the minimum vertical structural element area specified in the Draft Communiqué (2025) would have been sufficient for this structure.
- In Building 2, the lower relative story drifts compared to Building 1 lead to a reduction in residual deformations after the earthquake.
- The significant increase in base shear force in Building 2 compared to Building 1 in both directions is due to the shortening of the natural vibration periods.

Keywords: Heat Aging, Concrete Confinement, PET FRP.

Aim

Fiber-reinforced polymer (FRP) confinement is a widely accepted method for strengthening reinforced concrete structural members. By externally wrapping concrete elements with FRP, lateral deformation under compressive loading is effectively restricted, leading to significant improvements in compressive strength and ductility (Ilki et al., 2004). Over recent years, Polyethylene Terephthalate (PET) fiber reinforced polymers, derived mainly from recycled plastics, has attracted increasing attention as an eco-friendly and economically competitive alternative to traditional carbon and glass FRP materials (Bai et al., 2019). Researches have indicated that PET FRP confined concrete exhibits comparable improvement in compressive strength and a high improvement in ductility compared to conventional FRP materials, highlighting its potential for wider structural applications (Dai et al., 2012; Lam & Teng, 2003).

However, the durability of PET FRP confined concrete under prolonged exposure to elevated temperatures has not been thoroughly investigated. High-temperature conditions can present challenges related to the degradation of the polymer matrix and deterioration of the adhesive bond between FRP wraps and concrete substrates, potentially resulting in loss of confinement efficiency and structural stability (Benzerara et al., 2023). Understanding the effects of high-temperature on PET FRP confined concrete is crucial, particularly for structures located in hot climates or environments susceptible to thermal stresses.

To address this critical knowledge gap, the current study investigates the effects of sustained dry heating at 50°C for 6 weeks on the compressive behavior of PET-FRP-confined low-strength concrete specimens. The experimental program includes 12 low-strength concrete specimens wrapped with PET FRP, equally divided into two groups. One group was kept under normal laboratory conditions, while the other group was subjected to a continuous temperature of 50°C. Normal laboratory conditions involved ambient indoor settings with a temperature of approximately 20 ± 2°C and relative humidity ranging between 50% and 65%. Specimens were stored in a well-ventilated environment, free from direct sunlight, wind, or any form of artificial heating or cooling that could induce unintentional thermal effects.Following the thermal exposure period, axial compression tests were conducted on both groups to evaluate and compare the impact of elevated temperatures on compressive strength and overall confinement effectiveness. The findings of this research will provide novel insights into the thermal resilience of PET FRP and its suitability for structural applications under elevated temperature conditions.

Material and Method

The main test variables of the experimental study were the number of confinement layer of PET FRP (0, 2 and 3) and difference between curing conditions (laboratory and dry temperature cabinet).

A test program with 12 concrete specimens was planned. The specimens were standard cylindrical samples with a diameter of 150 mm and a height of 300 mm. These concrete specimens were produced using ready-mixed low strength concrete. The 28-day average compressive strength of the concrete used was determined to be approximately 9.02 MPa. Six of the twelve specimens were produced to be exposed to laboratory conditions, and the other six to dry heat.

Recycled PET sheets bonded to the concrete surface with epoxy resin were used as confining material. The PET sheet manufacturer reports that the density of PET sheets is 600 gr/m^2 and that PET FRP has a tensile strength of 950 MPa, a tensile strain capacity of 11.6%, and the first and second moduli of elasticity of 12 and 9.4 GPa. In order to experimentally determine the mechanical properties of PET FRP, five coupon specimens were prepared and tested in accordance with ASTM D3039M-17. The obtained properties are presented in Table 1. The values in parentheses show the relevant coefficient of variation. The wet lay-up method was used to apply the FRP sheet to the outer surface of the specimen. Initially, the surface of the specimen was cleaned. Then, a layer of epoxy resin was applied to the surface, and a continuous fiber sheet was impregnated with epoxy and bonded to the concrete surface, with fibers-oriented hoop-wise. Following the wrapping, an additional epoxy layer was applied to enhance resin impregnation. It should be noted that an overlap length of approximately 230 mm was adopted to eliminate the risk of slipping. After then, the upper and lower parts of the specimens (30 mm high) were confined with additional carbon FRP to avoid premature failure of the specimens around loading place. Lastly, the top and bottom surfaces of the specimens were capped with high strength repair mortar (4-5 mm thick) to provide a uniform distribution of the compression stresses. The confined specimens were left in the laboratory for curing.

Table 1. The mechanical properties of PET FRP obtained from the coupon tests.

Tensile strength (MPa)	Modulus of elasticity (GPa)-First	Modulus of elasticity (GPa)-Second	Tensile strain capacity (%)
493 (3.3%)	15.2 (7.7%)	5.5 (4.5%)	7.17 (5.2%)

Test program is presented in Table 2. Each specimen is denoted with symbols: "UN" indicates unconfined specimen. Confined specimens use a numerical prefix to represent the number of FRP layers, followed by "P" for PET (e.g., 1P for one layer of PET FRP). For the specimens exposed to heat aging, a "DH" is added to the end of the name. For instance, 3P-DH refers to the specimen with three layers of PET sheet subjected to dry heat at the cabin (Table 2).

Table 2. Test matrix.

Specimen	Condition	Total number of FRP layers	Total number of identical specimens
UN	Laboratory	0 (unconfined)	2
2P		2	2
3P		3	2
UN-DH	Heat aging	0 (unconfined)	2
2P-DH		2	2
3P-DH		3	2

An Instron closed-loop testing machine, with the capacity of 5000 kN, was used for conducting displacement-controlled monotonic uniaxial compression tests on all specimens. The displacement-controlled test of each specimen was conducted at a constant rate of 0.6 mm/min until the failure of the specimen. Axial deformations along the entire height of the specimen were measured using four TML CDP50 type linear variable displacement transducers (LVDT) with 50 mm capacity, fixed at each corner between the lower and upper steel loading plates. Additionally, four LVDTs with the same capacity, set at mid-height (with a gauge length of 150 mm) were used to measure the mid-height deformations. The measurements were recorded using a TML TDS-303 data logger and switch box and all obtained data were transferred to the computer for storage and processing. The setup and instrumentation of the tests are shown in Figure 1.

Figure 1. Test setup.

Findings

In order to understand the effect of test variables on the test results, the average stress-strain relationships are plotted and given in Figure 2 and the values of key points are presented in Table 3.

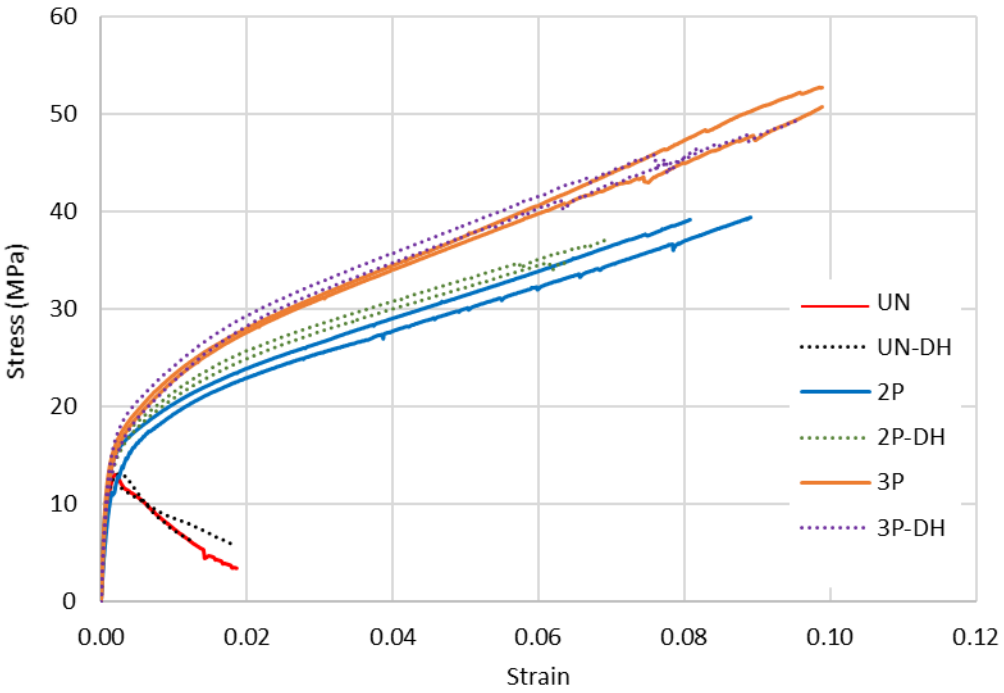

Figure 2. Stress-strain relationships.

Table 3. Test results.

Specimen	$f_{cc}(MPa)$	$\varepsilon_{cc}(\%)$	(f_{cc}/f_{co})	$\varepsilon_{cc}/\varepsilon_{co}$
UN	13.6 (f_{co})	0.00260 (ε_{co})	-	-
2P	39.3	0.07445	2.88	30.09
3P	51.1	0.09925	3.75	44.11
UN-DH	12.5	0.00252	-	-
2P-DH	36.3	0.06673	2.88	26.47
3P-DH	47.7	0.08876	3.82	35.23

The ratio of the axial strength of the specimen under the heat aging condition to the axial strength of the specimen under laboratory conditions is calculated as 0.91 for unconfined specimens, 0.92 for 2P specimens and 0.93 for 3P specimens. It is observed that there is a strength loss of around 6.6 to 8.7% due to heat aging. The ratio of the axial strain at peak stress of the specimen under the heat aging condition to the axial strain of the specimen under laboratory conditions is calculated as 0.97 for unconfined specimens, 0.90 for 2P specimens and 0.89 for 3P specimens. It is understood that there is a strain capacity loss of around 3.1% for the unconfined specimens and 10.5% for the PET FRP confined specimens due to heat aging. These ratios show that the effect of dried heat applied at 50°C for 6 weeks may be evaluated as negligible.

Conclusion

This experimental study examined the effects of sustained heat aging at 50°C for six weeks on low-strength concrete specimens confined with PET FRP. The results showed a moderate reduction in strain capacity (approximately 10.5%) under elevated temperature conditions, while the peak compressive strength was only slightly affected. Although this reduction may appear negligible at first, it raises important concerns regarding the long-term stability and reliability of PET FRP confinement systems at high temperatures. Since FRP strengthening systems are intended to maintain the long-term effectiveness of reinforced concrete members, it is imperative to investigate the potential for progressive degradation in strain capacity following extended or repeated thermal exposure. Therefore, further studies are required to examine the axial behavior of PET FRP-confined specimens under higher temperature levels and longer exposure durations to fully assess their long-term structural performance.

Keywords: Etabs, Nonlinear Time-History Analysis, Seismic Evaluation, Seismic Performance, Tscb 2018.

Aim

The seismic performance of buildings is critical for ensuring their resilience in earthquake-prone regions. This study focuses on evaluating the seismic performance of various structural systems by employing the nonlinear time-history method. The objective is to compare the seismic performance and evaluation of different structural systems at both the element and system levels, providing insights into how structural choices can impact the seismic performance of a building. More specifically, the study investigates the effects of slab systems under seismic event on the deformation of structural members, energy dissipation of building, and relative displacement of floors. Three structural systems commonly used in seismic regions were selected for this study: a beam-slab system, a flat slab system, and a flat slab system with perimeter beams

Material and Method

The study assumes a hypothetical building located in the Mahmutbey, Istanbul, a region with high seismicity. The building in the study consists of one basement and eight above-ground floors, nine floors in total. The basement is designated for car parking area and the upper floors designed to function as a hotel. Each floor has a height of 3.5 meters, including the basement, resulting in a total building height of 24.5 meters above ground level. The building has an orthogonal structural system with five spans in the X-direction and three spans in the Y-direction, each eight meters long. The total building dimensions are 40 and 24 meters in the X- and Y-directions, respectively. C35 concrete grade and B420C reinforcement steel are used. Building is designed by considering design earthquake level whose probability of exceedance in 50 years is 10% in accordance with the Turkish Seismic Code for Buildings (TSCB) 2018 [1]. The design spectral accelerations for the region obtained from Turkish earthquake hazard map [2]. The values for S_{ds} and S_{d1} are 1.112 and 0.389, respectively. ETABS [3] software is adopted for the design and nonlinear time-history analysis. Dead and live loads are determined in accordance with TS 498 [4]. The lateral load resisting system is identical in all three structural types, with the same dimensions, layouts, and configurations. Three different column sizes are utilized in the design: 80x40 cm, 40x80 cm, and 80x80 cm. Two U-shaped core shear walls with a thickness of 30 cm are located at the center. The basement is surrounded by 30 cm thick rigid shear walls. The thickness of the slab varies according to the structural system: 20 cm for the beam-slab system, and 27 cm for both the flat slab system and the flat slab system with perimeter beams. The constructive requirements for structural members specified in TS 500 [5] are satisfied. Additionally, these structural members are designed in accordance with the TSCB 2018 [1].

Modeling the behavior of the structural components is essential for performing the nonlinear analysis. Accordingly, confined and unconfined concrete models, along with reinforcement steel models, are employed in compliance with the specifications of TSCB 2018 [7]. The concrete material properties are defined according to TSCB 2018 [1], which is adopted Mander model [6]. Distributed plasticity model is used for the columns and shear walls, meanwhile lumped plasticity model is used for the beams. Therefore, Fiber P-M_2-M_3 and Fiber P-M_3 are defined for the columns and shear walls, respectively. M3 hinges are defined for the beams subjected to flexure only. The shear walls are modeled with confined boundary zones and an unconfined web. The beams are modeled by using stiffness modification factor obtained from moment-curvature relationships. Slabs and basement walls are modeled elastically by using the corresponding stiffness modification factor for flexural and shear, as per TSCB 2018 [1].

The nonlinear time-history analysis was performed using 11 pairs of earthquake records, in accordance with TSCB 2018 [1]. The records are selected based on fault type, seismicity, and the soil class of the region. Consequently,

the selected records have magnitudes ranging from 6.6 to 7.5 and shear wave velocities (Vs30) between 360 and 760 m/s, with strike-slip fault type. The records are obtained from the PEER NGA West 2 database [7]. The selected records are scaled to the **M**aximum **C**onsidered **E**arthquake (MCE) using a simple scaling method, ensuring that the mean spectrum remains above the 1.3 times of target (MCE) spectrum in the range of $0.2T_p$ to $1.5T_p$. The acceleration time history records of the selected ground motions are applied to the model in both X and Y horizontal directions. Initially, the X- and Y-components of the ground motion are applied to the corresponding directions of the building. The analysis is then repeated with the components rotated 90 degrees to assess the building's seismic response.

For the performance evaluation, deformation limits corresponding to three damage levels—Immediate Occupancy (IO), Life Safety (LS), and Collapse Prevention (CP)—are determined based on the TSCB 2018 [1]. These limits are further adjusted according to the shear force ratios in reinforced concrete elements. The mean deformations for each element are obtained through the nonlinear time-history analysis. Average deformations are compared with the predefined thresholds to evaluate the performance of each structural system under the MCE. This comparative analysis provides an in-depth understanding of the building's response to seismic forces and allowed for an evaluation of the structural systems' ability to resist seismic effects. The results show that all buildings, except for flat slab system, have satisfied the controlled damage performance target.

Findings

The results from the nonlinear dynamic analysis reveal differences in seismic performances of the three structural systems. The beam-slab system exhibits the best performance, with the smallest deformations and the most uniform energy dissipation. This system has higher stiffness resulting in improved lateral resistance and reduced interstory drifts. On the other hand, the flat slab system demonstrates the weakest performance, with larger deformations, lower stiffness and higher interstory drifts. Energy dissipation in the flat slab system is more irregular, resulting in less efficient force distribution and greater risk of local failure. The performance of the flat slab system improves when beams are configured at the perimeter of the slab. The system surrounded by the beams demonstrates reduced interstory drifts. The perimeter beams contribute to distribute the seismic forces more uniformly, which improves its ability to resist lateral forces and enhancing its seismic performance.

Conclusion

Based on the findings, beam-slab systems are highly recommended for earthquake-resistant designs, especially in seismic regions. However, for buildings where flat slab systems are required due to functional or architectural reasons, configuration of perimeter beams significantly improves seismic performance. Overall, this study highlights the importance of selecting appropriate structural systems to optimize seismic resilience and provides valuable insights into improving the seismic performance of buildings in earthquake-prone areas.

Keywords: Nonlinear Analysis, Steel Connections

Aim

This study aims to investigate the nonlinear behavior of flush end-plate beam-to-column connections and evaluate the influence of different steel frame configurations on the seismic performance of a four-story steel building featuring a special moment-resisting frame as its primary seismic force-resisting system. Specifically, three gravity frame configurations integrated with the four-story steel building are examined: (1) a reference frame employing conventional pinned beam-to-column connections, (2) a frame incorporating two-bolted flush end-plate beam-to-column connections (FEP-2B), and (3) a frame with four-bolted flush end-plate beam-to-column connections (FEP-4B). The investigation assesses the impact of these configurations on the lateral stiffness and strength of the special moment-resisting frame. Initially, finite element analyses under cyclic loading are performed to capture the detailed nonlinear behavior of the connections. Subsequently, the derived moment–rotation curves are integrated into a structural model to conduct pushover analyses, thereby providing insights into the role of flush end-plate connections in enhancing the seismic performance of steel structures supported by gravity frames.

Material and Method

Both connections, shown in Fig.1, were designed as semi-rigid and partial-strength connections, with the primary objective of achieving plasticity through the yielding of the end plate. This design approach aims to enhance energy dissipation capacity and ductile behavior while also improving both strength and stiffness. Additionally, this approach is intended to reduce the risk of brittle failure by promoting plastic deformation within the end plate, rather than permitting tensile failure of the bolt, which could result in a sudden fracture. Consequently, a thin end-plate design strategy was consistently employed throughout the design process.

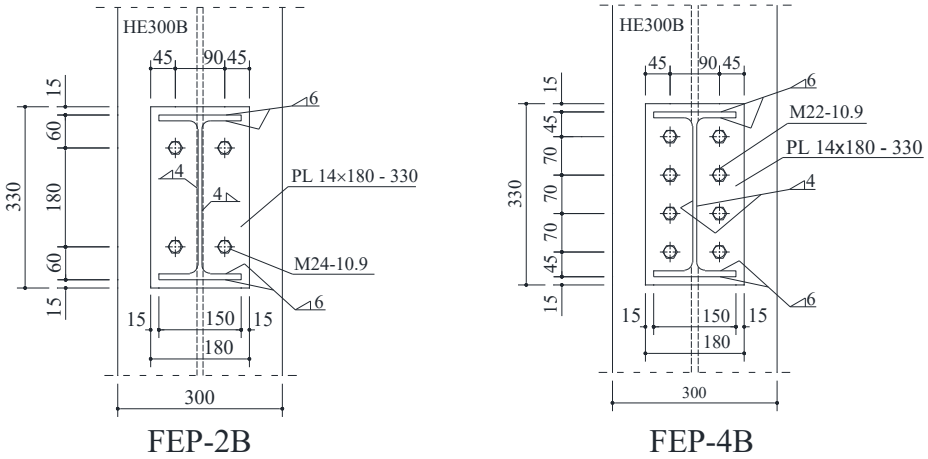

Figure 1. Flush end-plate configurations.

To investigate the influence of flush end-plate connections on frame behavior, a comprehensive finite element analysis was initially performed on two types of flush end-plate beam-to-column connections to obtain the moment-rotation curves of the connections. The finite element model was developed using ABAQUS software, incorporating material nonlinearity, geometric nonlinearity, and the cyclic nature of the applied loading. The modeling approach was validated against experimental data obtained from similar end-plate connection systems.
For the flush end-plate connections, a detailed contact model was implemented to accurately simulate the interactions among the bolts, end plates, and column surfaces. Friction coefficient was taken as 0.3 while penalty formulation and hard contact was utilized for tangential and normal behavior between interacting surfaces. All

components were discretized using C3D8R eight-node solid elements. The end-plate thickness was set at 14 mm for both the two-bolted and four-bolted configurations. While the beam and column sections and the material properties remained consistent across the models, variations were introduced in the bolt dimensions, bolt pretension loads, and spacings to investigate their effects on connection performance.

The steel material used in the analysis was modeled using a tri-linear engineering stress-strain model suggested by Baei et al. (2012) for 10.9 grade bolts and S275 steel. True stress-strain values were obtained using the material model explained by Kauffman et. al. (2001) to implement the material's post-yield behavior into the finite element analysis. The hardening rule followed the combined hardening model to include both isotropic and kinematic hardening, which is important for cyclic loading conditions. Elastic modulus and Poisson's ratio were taken as 200 GPa and 0.3, respectively.

The connections were subjected to cyclic loading in accordance with AISC 341-16, thereby simulating the nonlinear behavior typically observed during seismic events. Incremental displacements were applied at the free end of the beam, while the frame boundary conditions were modeled with fixed supports at both the base and the top of the column to replicate rigid connections. Additionally, the beam was constrained to prevent movement perpendicular to the loading direction. The loading protocol followed a displacement-controlled method, with load increments applied until a rotation of at least 0.6 radians was achieved.

Drawing upon the finite element analysis outcomes, a two-dimensional frame model representing a four-story structure was systematically derived from the three-dimensional building model depicted in Fig. 2 and 3. This model was subsequently employed to conduct a comprehensive pushover analysis. The structural elements were the same as the building designed by Karasu (2018). Three distinct frame configurations were considered for the structural analysis: a control frame featuring pinned connections for the gravity frames; a frame employing flush end-plate connections with a two-bolt configuration; and a frame utilizing flush end-plate connections with a four-bolt configuration. This approach was facilitated by an equivalent frame assumption, explained by Lignos et. al. (2000), where the moment-resisting frame is integrated alongside an equivalent one-bay gravity frame connected with rigid links, as shown in Fig. 3.

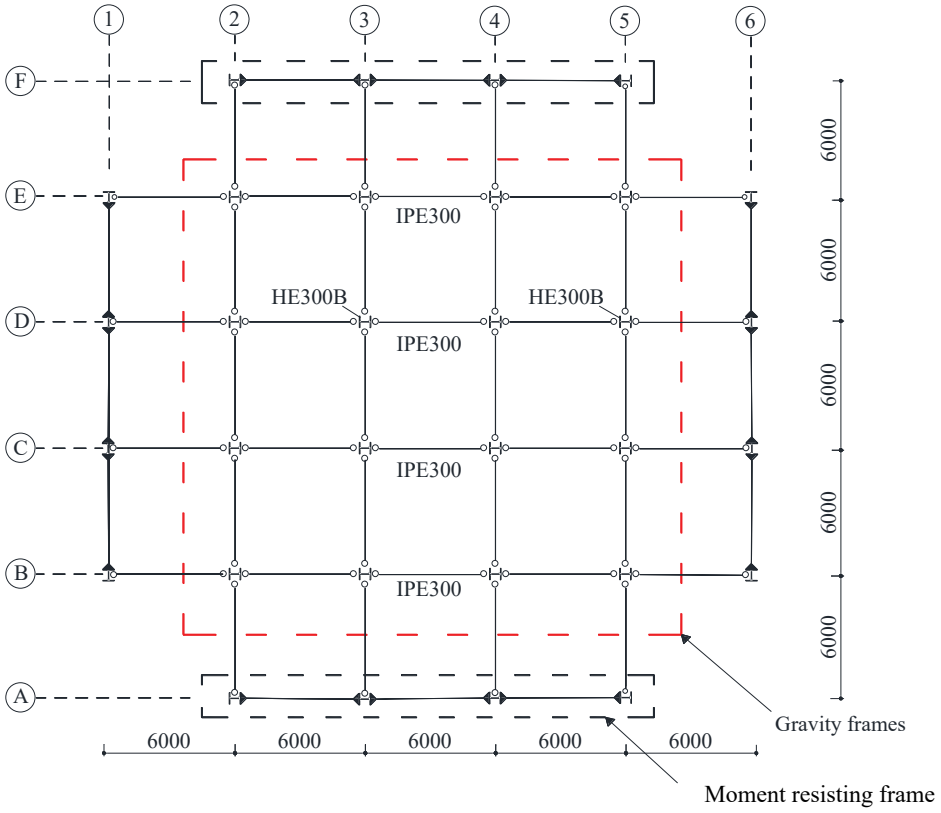

Figure 2. Plan view of the structural system

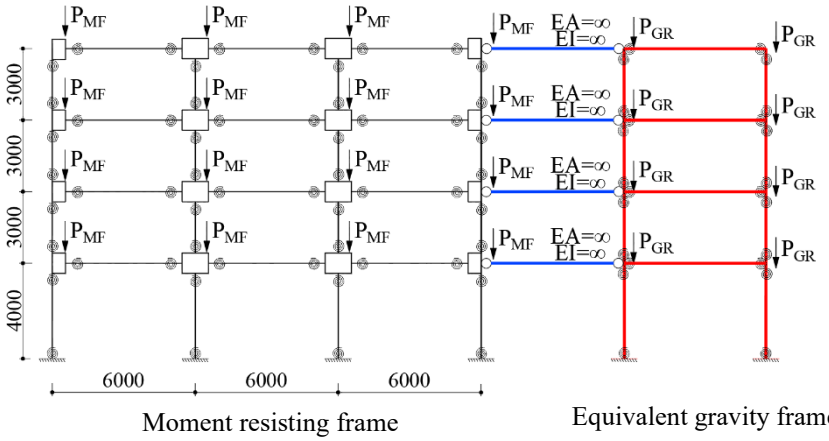

Figure 3. Equivalent frame model of the structure.

Nonlinear static pushover analysis was executed using OpenSEES structural analysis software. In this framework, the model was discretized using elastic beam–column elements, with the plastic hinge behavior represented by spring elements calibrated from the finite element analysis results. Concentrated plasticity approach was utilized for the spring elements using zero length elements. Uniaxial hysteretic material models were employed to characterize the moment–rotation behavior of the connections within the OpenSEES framework. Fig. 4 provides a graphical representation of the moment–rotation curves corresponding to these connections.

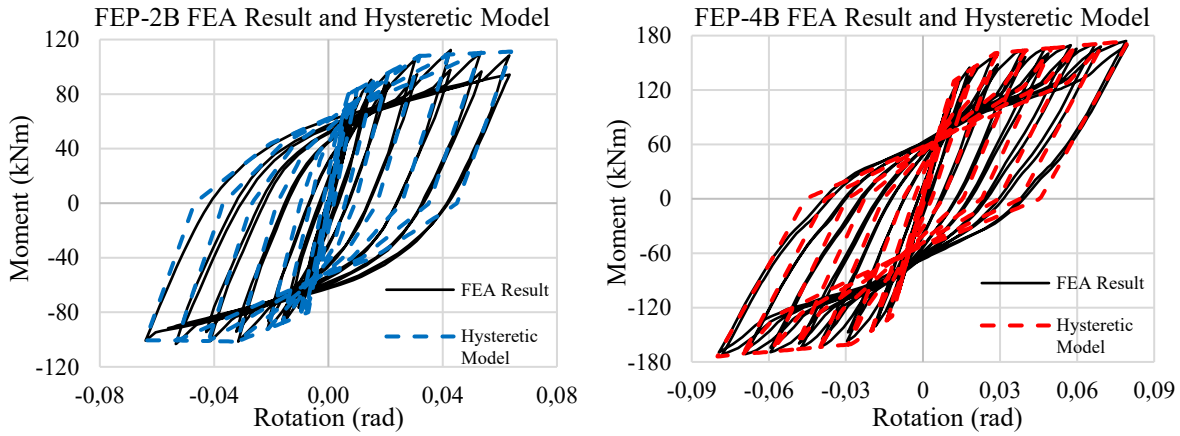

Figure 4. Moment-rotation curves obtained from FEA and hysteretic models.

The pushover response for each configuration was obtained as shown in Fig. 5 by incrementally applying lateral loads until a predefined target displacement was achieved.

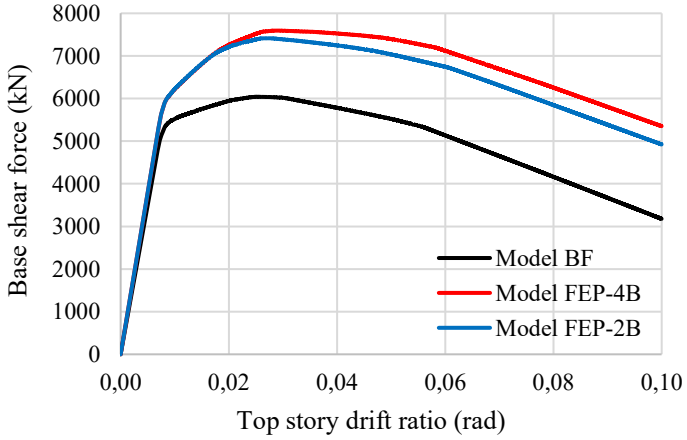

Figure 5. Pushover results .

Findings

The results from the finite element modeling and subsequent structural analyses reveal the following observation:

Finite element analyses of the connections: Both two-bolted and four-bolted connections displayed considerable strength and stiffness to be classified as semi-rigid and partial strength connections. It was observed that both connection configurations exhibited a high degree of ductility; however, the two-bolted configuration facilitated a more uniform yielding of the end plate.

Damage and Failure Mode: The failure mode indicated that the frame with the two-bolted connection showed localized yielding at the beam-to-column connections before significant displacement occurred. On the other hand, the four-bolted configuration delayed failure and showed higher initial stiffness.

Performance of the connections: Both flush end-plate connections exhibited significantly enhanced stiffness and energy dissipation compared to conventional pinned frames. Specifically, the two-bolted configuration demonstrated greater stiffness during the backloading phase, during which the end-plate underwent complete plasticization. In contrast, the four-bolted connection provided superior strength and stiffness, albeit with localized stress concentrations near the outer bolts.

Strength Comparison: When the pushover curves for the three frames were compared, the results showed a significant improvement in base shear strength for both flush end-plate configurations compared to the reference frame. Frame with two-bolted flush end-plate connections showed an 22% increase while the frame with four-bolted flush end-plate connections used demonstrated a 25% increase in base shear strength compared to the pinned model. This indicates that incorporating flush end-plate connections, especially the four-bolted configuration, may significantly improve the frame's lateral load resistance compared to using pinned connections for the gravity frames. Furthermore, both connection configurations exhibit an enhancement in post-yield stiffness.

Energy Dissipation: It can be concluded that the increased strength and stiffness achieved with the flush end-plate connections resulted in improved energy dissipation compared to the pinned control frame. These connections can be considered dissipative connections due to high ductility and strength achieved.

Conclusion

The findings of this study indicate that flush end-plate beam-to-column connections incorporated within gravity frames substantially enhance the structural performance of steel systems. Both the two-bolted and four-bolted flush end-plate configurations improved lateral load resistance and overall frame stiffness relative to the baseline configuration. Notably, the four-bolted configuration provided the most significant increase in strength, exhibited superior stiffness retention, and delayed the onset of failure, thereby emerging as a more effective strategy for enhancing seismic performance.

Effect of Initial Imperfections in Short Link Beams on Frame Behavior

Bünyamin Mutlu[a], Cüneyt Vatansever[b]

Keywords : Steel Multi-Tiered Eccentrically Braced Frames, Nonlinear Pushover Analysis, Reversed Cyclic Analysis, Link Beam Buckling, Column Buckling.

Aim

Multi-tier eccentrically braced frames (MT-EBFs) provide both seismic resilience and architectural comfort due to their favored structural arrangement. In these systems, short link beams act as critical energy dissipating elements by undergoing remarkable inelastic deformation during seismic events [3]. However, in multi-tier configuration, the lack of lateral support at intermediate levels presents a particular challenge, as intermediate link beams become weaker against buckling out-of-plane. While all elements, except link beams, are designed to remain elastic, such buckling can produce unexpected nonlinear behavior in the other frame components, leading to reduction in the system's energy dissipation capacity. This study investigates the application of initial imperfections to link beams as a potential solution to maximize their energy absorption capacity in MT-EBFs while preventing out-of plane buckling in link beams.

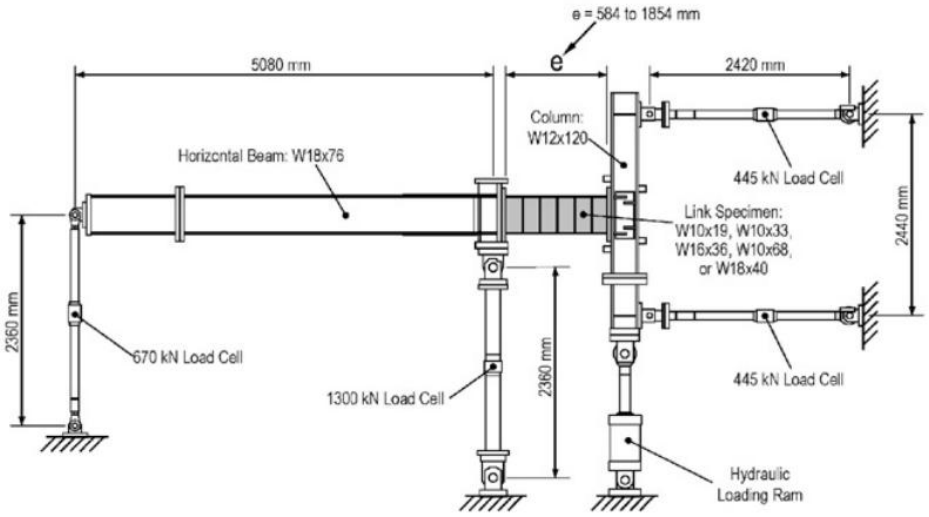

Figure 1: Okazaki and Engelhardt (2007) test setup.

Material and Method

The Open System for Earthquake Engineering Simulation (OpenSEES) [4] finite element analysis software is used for nonlinear pushover analysis. A nonlinear shear model is implemented to accurately capture the shear response of the link beam. The material properties are defined with an elastic modulus, E of 200 GPa and a yield strength, Fy of 345 MPa. Following the approach introduced by Ramadan and Ghobarah (1995) [5] and later refined and developed by Richards and Uang (2006) [6], the shear behavior is modeled using multiple springs located at both ends of the link beam. For columns, outer beams and braces the nonlinearBeamColumn command is used and 5 Gauss integration points are assigned for each element [7]. To represent the moment behavior of the link beam as well as the shear behavior, forceBeamColumn command is implemented. Steel sections are modeled using 10 fibers along the flange width and web depth and 2 fibers along the web thickness and flange thickness.

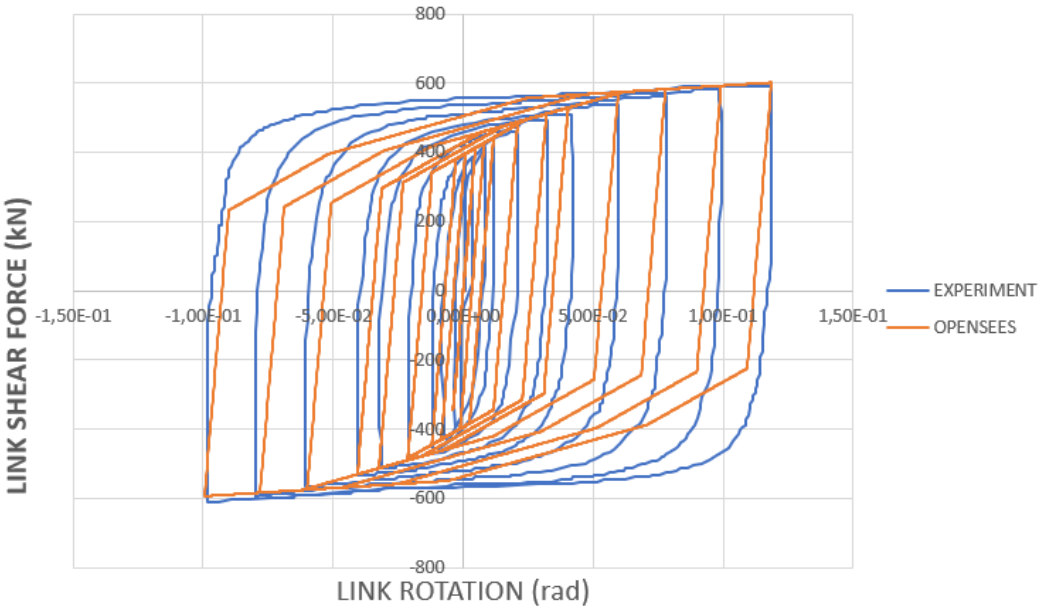

Figure 2: Verification of the link beam model against Okazaki and Engelhardt (2007) experimental data.

The numerical model is validated against experimental results from Okazaki and Engelhardt (2007) , with a comparison between the calibrated model and the test setup presented in Figure 1 and Figure 2. To simulate the combined response of the shear springs, translational springs were arranged in parallel. Nonlinear spring elements were integrated between externally and internally defined nodes, where all degrees of freedom were restrained except for the vertical displacement relative to the link beam axis. Each spring was assigned an ElasticPP material model, and their combined shear response was achieved using the ElasticPP Parallel command.

During the calibration of the numerical frame model, initial geometric imperfections were applied to properly simulate the buckling behavior of columns, outer beams, and braces. For columns, out-of-plane imperfections were defined as 0.001 times the total frame height, while in-plane imperfections were set to 0.001 times the tier height. Brace members received out-of-plane imperfections equal to 0.001 times their individual lengths. For outer beams, the out-of-plane imperfection magnitude was determined as 0.001 times the unbraced length where the unbraced length differs by level: at the roof level it is measured from the beam-column connection to the beam-brace connection, whereas at intermediate levels it corresponds to the full bay length. Boundary conditions and overall representation of frame model is given in Figure 3.

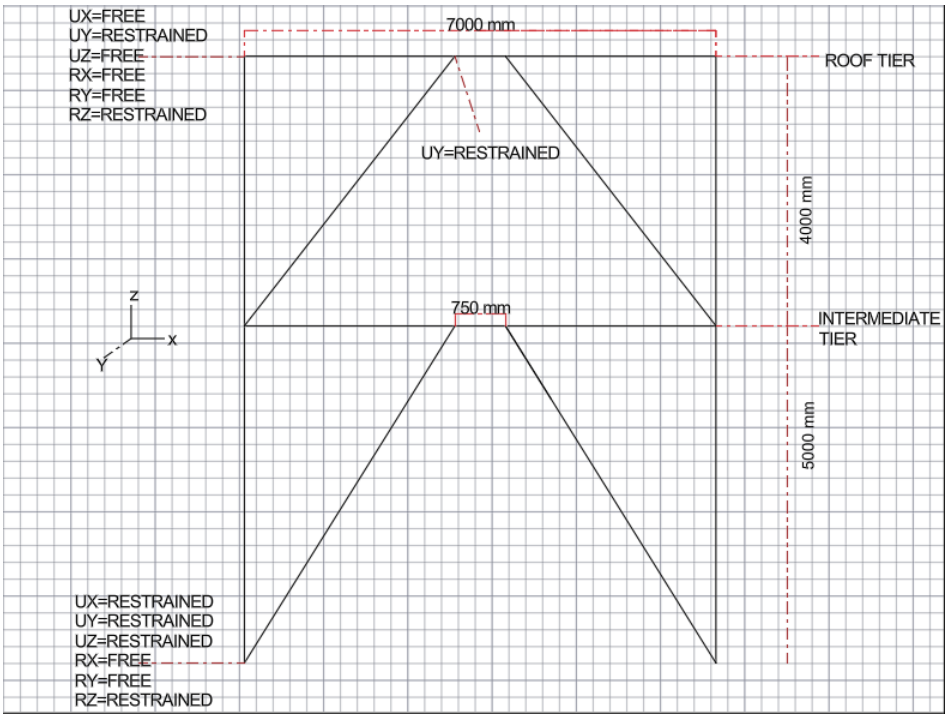

Figure 3: Overall frame information.

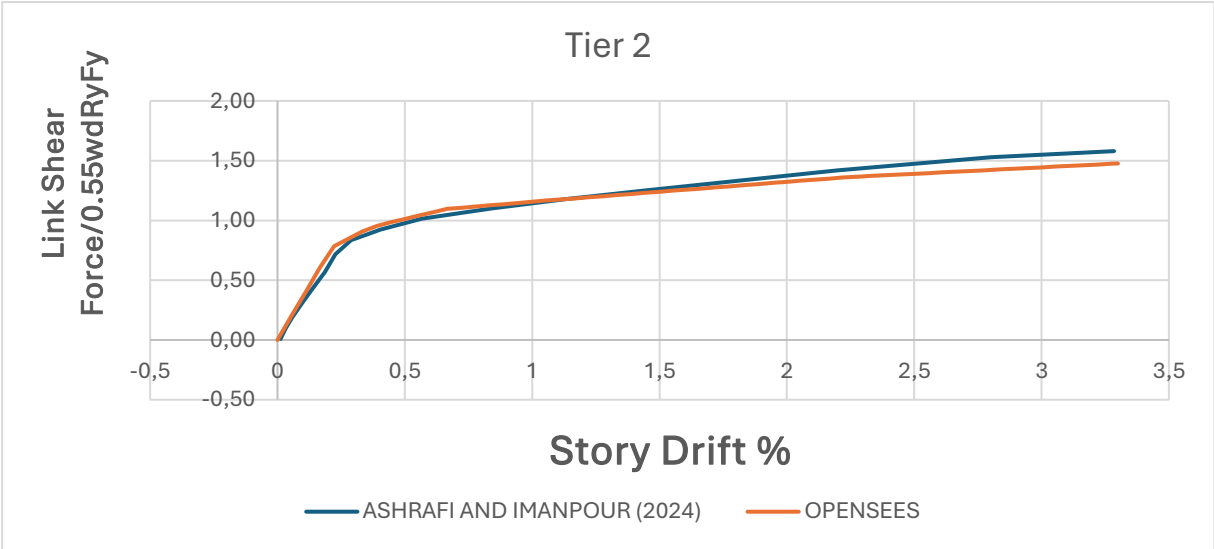

Figure 4: Frame level verification.

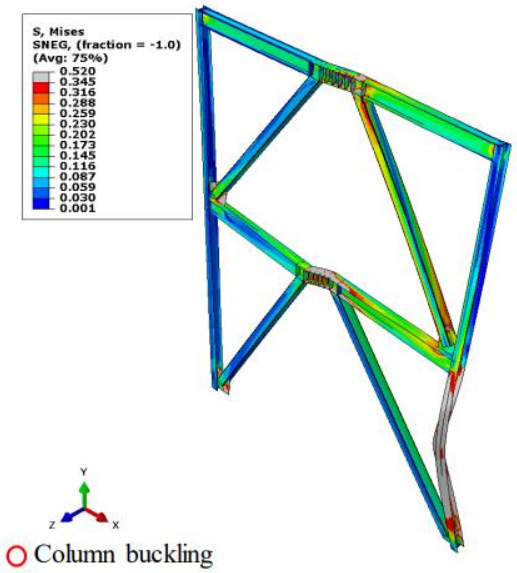

Figure 5: Column buckling in standart frame Ashrafi and Imanpour (2024)..

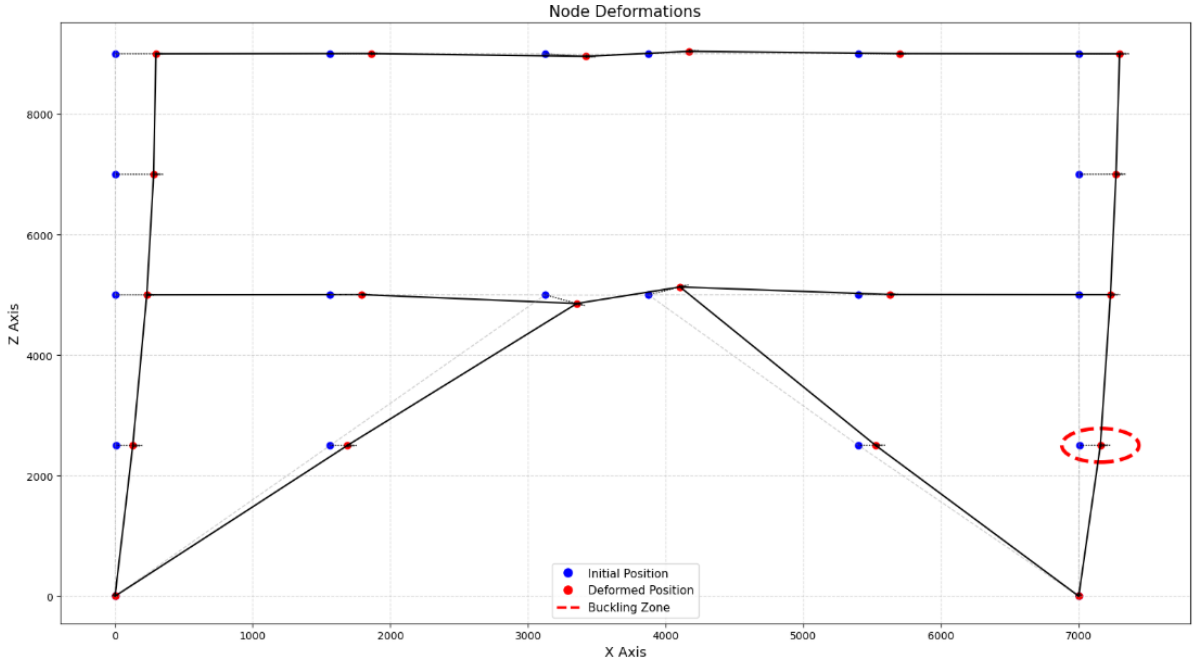

Figure 6: OpenSEES model column buckling.

Findings

In order to verify frame level behavior, two-story MT-EBF is calibrated from the reference paper data Ashrafi and Imanpour (2024) presented in Figure 4. Pushover analysis is conducted to the MT-EBF in two different frames called standart and improved. In the standard frame configuration of Ashrafi and Imanpour (2024) with W200×42 columns, W310×74 beams, and HSS203×7.9 braces column buckling occurred prior to the out-of plane buckling of the link beam (Figure 5). The nonlinear pushover analysis performed in OpenSEES software demonstrated buckling behavior in the subject column, as illustrated in Figure 6. Using W310×74 columns and W250×73 beams eliminated column buckling, confirming that optimized section design promotes structural stability. This study aims to examine how initial deviations in the link beam's alignment affect performance of the frame. This study will assess the permissible out-of-straightness at the link beam's ends, limited to a maximum of L/1000 L/500 and

L/200, with L being the combined length of the tier beam and link beam. The top view of frame with initial irregularity is illustrated in Figure 7.

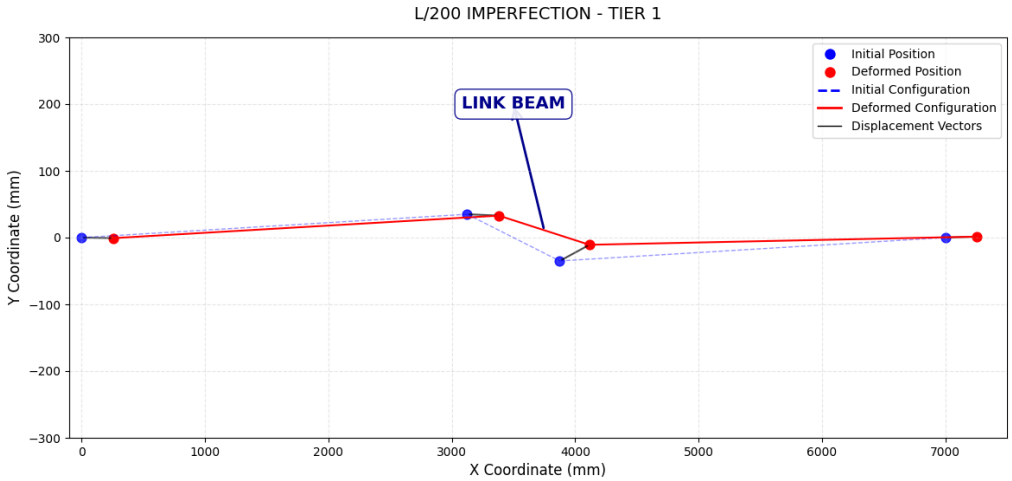

Figure 7: Top view of first tier with L/200 imperfection.

The research by Ashrafi and Imanpour (2024) demonstrated that optimized section configurations yield improved performance in both pushover and nonlinear response history analyses (NLHAs). Building on this work, the current study aspires to conduct comprehensive verifications at both element and frame levels. As the effect of link beam axis irregularities in MT-EBFs remains unexplored in existing literature, this study aims to present the first investigation of this critical aspect. The primary objective is to evaluate the seismic response of MT-EBF systems including both link beam behavior and overall frame performance when subjected to nonlinear pushover loading with introduced initial imperfections in the link beam axis.

From the pushover analysis, it is seen that while large shear force demands occurred in the first tier both in standard and improved configurations, roof link beam demands were relatively small. This phenomenon is also perceived when initial irregularity is applied.

By implementing a rotational spring in the weak axis of the link beam, capturing the nonlinear moment behavior is aimed. Results showed that the link beam is deformed in both shear and moment axes. When initial out-of straightness is increased, moment in the weak axis is also increased (Figure 8) , while shear force demand is reduced (Figure 9).

In short link beams, it can be stated that implementing initial imperfections to the link beam axis changes the yielding mechanism from only shear yielding to combined shear and weak axis flexural yielding in the link beam.

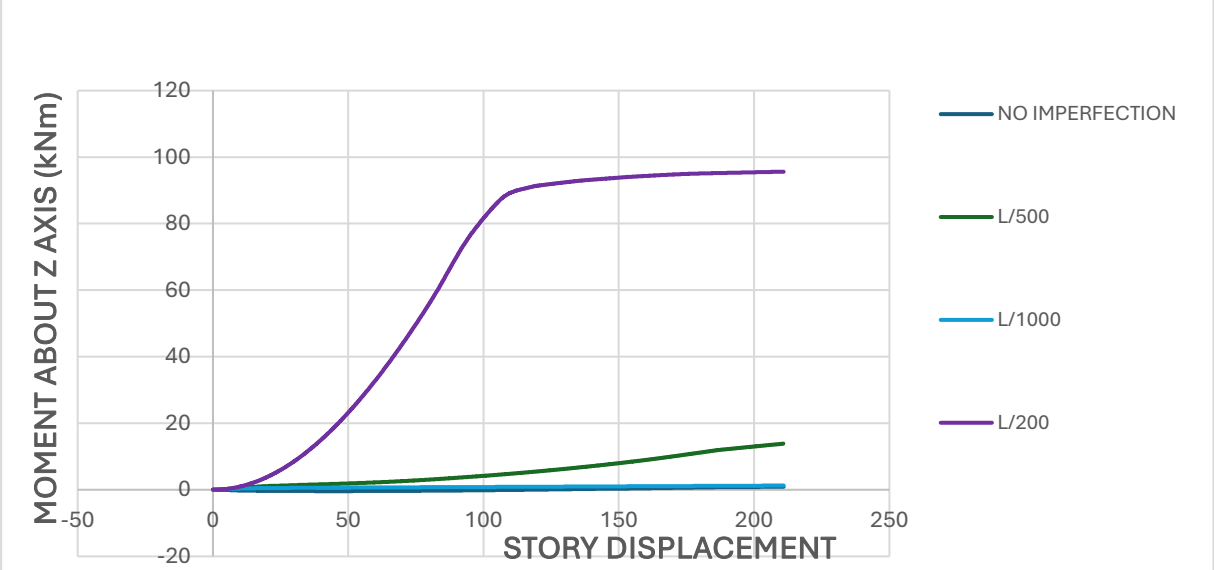

Figure 8 : Moment in weak axis/story displacement in link beam in tier 1.

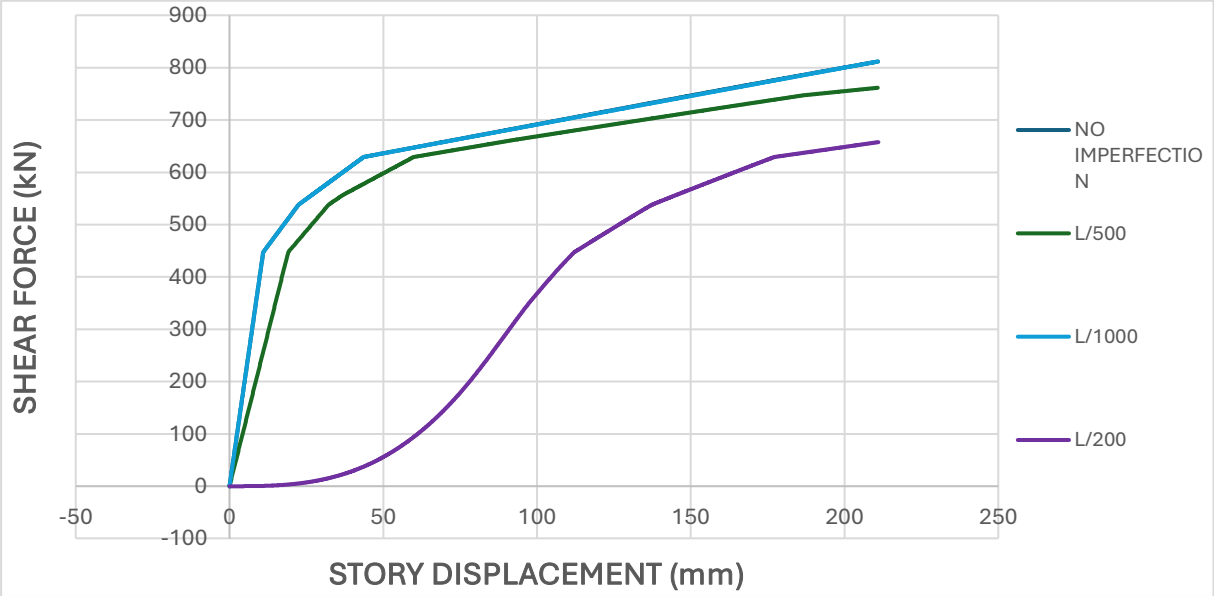

Figure 9: Shear force/story displacement in link beam in tier 1.

Conclusion

The effect of initial imperfections in short link beams on frame behavior was examined. Four different imperfeciton values including no imperfection with two different two-tiered EBF frames which were subjected to nonlinear pushover analysis.

Although the method of initial imperfection is examined only for a two-tiered eccentrically braced frame with nonlinear pushover analysis, it should be further investigated with various analysis procedures as well as in multi-tiered frame geometries.

Blast-Resistant Steel Modular Structures Design with the Comparison of Dynamic Analysis Methods: SDOF and MDOF Systems

Nur Döğer[a], Barlas Özden Çağlayan[b]

[a] Istanbul Technical University, Faculty of Civil Engineering, Structural Engineering Program, Türkiye
[b] Istanbul Technical University, Faculty of Civil Engineering, Türkiye
doger16@itu.edu.tr

Keywords: SDOF and MDOF Systems, Blast-Resistant Steel Modular Structures, Finite Element Analysis, Blast Load, Numerical Integration.

Aim

Research on blast-resistant structure design has intensified due to the increase in industrial facilities and the growing demand driven by defense industry policies in various countries. Using blast-resistant modular structures (BRMS) is a sustainable and safe approach to prevent potential loss of life and economic damage to business owners from explosions. The modular nature of these structures minimizes negative impacts associated with on-site construction activities and increases their popularity due to their portability.

In this study, since there is no dedicated section for blast-resistant structural design in the current regulations and specifications in Turkiye, internationally recognized guidelines such ASCE Design of Blast Resistant Buildings in Petrochemical Facilities and UFC 3-340-02 have been taken as a reference for calculations. To accurately characterize an explosion, it is essential to examine its effects and the types of explosives involved. The effects of shock and pressure wave loads generated by explosions, as well as the variation of pressure values over time, have been analyzed. Depending on the explosion type, parameters such as pressure, impulse, duration, velocity, and wavelength have been calculated using established methodologies. The influence of factors such as distance from the blast source, angle of incidence, and reflection characteristics has been explained in detail. Furthermore, material behavior under blast loads has been investigated by evaluating parameters such as strength increase factors, dynamic increase factors, and deformation limits, including ductility ratio and rotation capacity.

This study aims to demonstrate the step-by-step element dimensioning calculations of a modular blast-resistant structure. In this context, the applicability of the single-degree-of-freedom (SDOF) analysis method is compared with finite element analysis (FEM) to examine how all structural elements behave under both approaches.

Material and Method

The most widely used basic analytical models in blast design applications are single-degree-of-freedom (SDOF) systems because of their simplicity. The SDOF method offers significant advantages in the preliminary design stage, as it is easily applicable and does not require complex modeling techniques.

SDOF models simplify the analysis of a structure's actual Multi-Degree-of-Freedom (MDOF) behavior by considering a single-mode shape. The calculations are based on the dominant deformation mode of structural members. In the design of structural components, the SDOF method generally yields more conservative results compared to the MDOF approach. However, this method does not account for dynamic vibrations or simultaneous interactions between structural elements.

The mathematical equation for the dynamic equilibrium of a damped, linear elastic SDOF system, can be written as follows:

$$M\,a + C\,v + K\,y = F\,(t)$$

Equation 1

M: mass, a: acceleration, C: viscous damping constant, v: velocity, K: stiffness, y: displacement, F: external blast force, t: time

In blast-resistant design, damping is usually neglected because the structure reaches maximum response in a very short duration, making the effect of damping on maximum displacement negligible. Therefore Equation (1) can be simplified as:

$$M\,a + K\,y = F\,(t)$$

Equation 2

As a case study, a blast-resistant modular structure (BRMS) is designed with dimensions of 13.2 m in length, 4 m in width, and 3.5 m in height. The structure is subjected to a surface burst explosion of 500 kg at a standoff distance of 30 m from the front wall. The scaled distance (Z) of the building is calculated as 3.78 $\frac{m}{kg^{\frac{1}{3}}}$. As this value exceeds 1.2 $\frac{m}{kg^{\frac{1}{3}}}$, the structural are classified as being subjected to far-range blast loading. The structural frame members of the building were designed using seismically qualified compact hollow structural sections (HSS) to ensure that their full plastic bending capacity could be reached before any local instability occurred. The roof purlins were selected as I-sections, while the roof deck and wall panels were constructed using crimped panels with a trapezoidal cross-section, providing significantly higher ductility capacity. S235 steel grade were used in the design of roof purlins, roof deck, wall siding and S355 structural steel grade was used for main beams, wall girts and columns. Steel grades were specified according to the EN 10025 standard.

Findings

SDOF equivalent analysis approach enables structural members to balance the kinetic energy generated by the explosion with their deformation abilities, allowing them to effectively dissipate the energy. The "Simplified Blast Load Function" approach is used to make the effects of blast waves on structures more comprehensible and easier to calculate. The simplified triangular impulse model is utilized to determine blast loads by primarily considering key parameters such as reflected pressure, dynamic wind pressure, and shock wave velocity. Additionally, parameters including front wall load, roof load, and clearing time were calculated to dimension blast-resistant structural elements.

There are alternative methods for nonlinear Single Degree of Freedom (SDOF) systems which are numerical integration, also known as the time history method, graphical and closed-form solutions. In this study, the Newmark numerical integration method, utilizing the linear acceleration approach and a bilinear resistance-deflection relationship, was applied. A MATLAB code was developed for numerical integration, and each structural member was individually analyzed based on the applied blast load. The motion of a structure under blast loading was calculated step by step. At each time step, displacements were determined, followed by the updating of velocity and acceleration values using the outcomes from the preceding and current steps. This approach ensures the continuity of dynamic analysis, allowing the structural response to be observed over time. MDOF system method will be analyzed using advanced finite element analysis software and structural member responses will be compared with the SDOF system method outputs.

Conclusion

After determining the blast loads, the steel structural elements were designed using single-degree-of-freedom (SDOF) analysis through numerical integration method. This process followed the guideline of ASCE Design of Blast Resistant Buildings in Petrochemical Facilities, considering the time-dependent effects of dynamic loads which are shown in Figure (1) according to front and roof loading calculations.

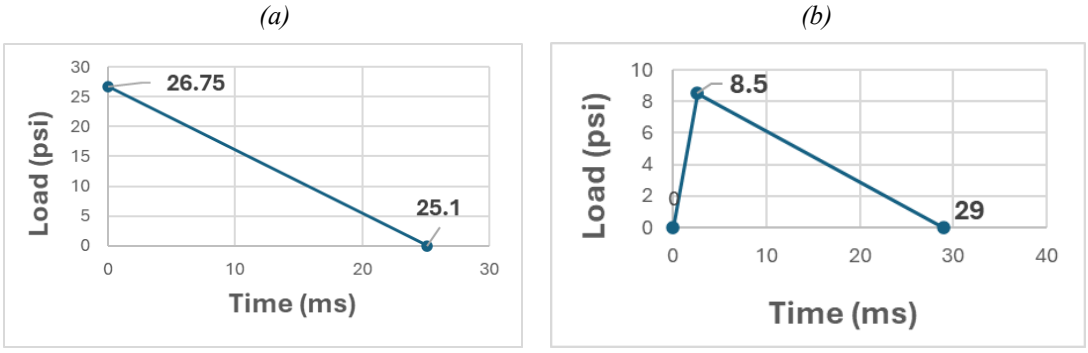

Figure 1. Pressure-time relation in front(a) and roof(b) blast loading graphs.

SDOF modeling using the numerical method was employed to calculate the maximum displacement and force demands on structural elements. After several iteration steps to determine roof deck size, the variation of time-dependent displacements and resistances of metal roof deck are shown in Figure (2) under dynamic roof blast loading impact. The maximum displacement occurs near the time when the blast load reaches its peak point. As the load decreases, the structural element attempts to return to its original position. However, due to plastic deformation and decreasing displacement and resistance amplitudes, the energy dissipation capacity gradually diminishes.

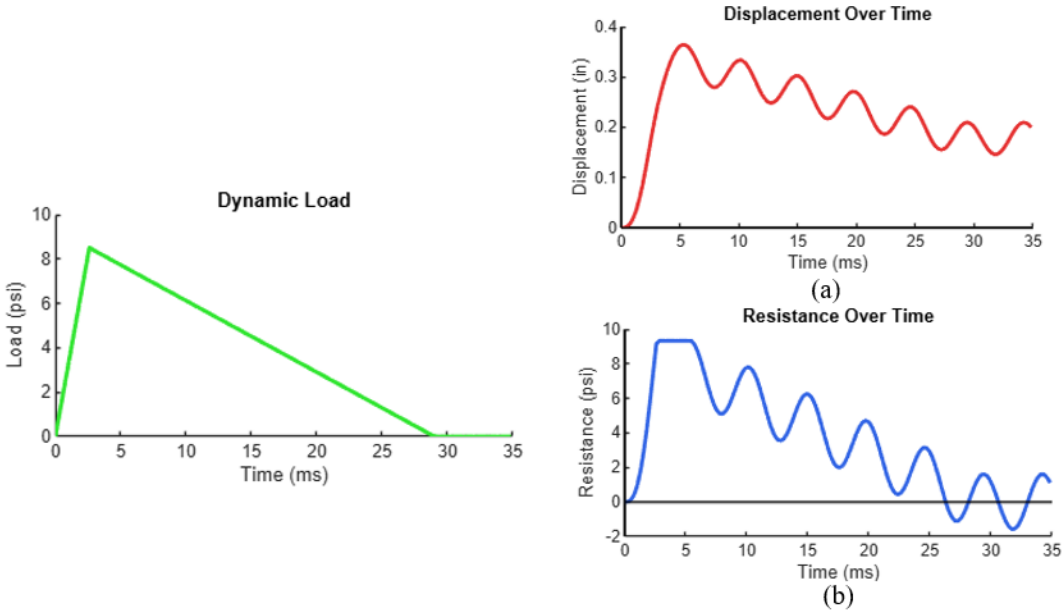

Figure 2. Displacement(a) and resistance(b) graphs of roof deck obtained from numerical integration.

Structural members were permitted to undergo plastic deformation, provided they remained within allowable limits for ductility ratio, rotation capacity, and frame sidesway at medium damage levels.

While the simplified numerical SDOF model provides conservative results suitable for preliminary design stages due to its efficiency, the MDOF model is preferred for more detailed, cost-effective designs, as it can capture complex interactions between structural elements.

Vibration Fatigue-Based Optimization of Open Hole Design in Stiffened Panels

Görkem Aşcı[a]

[a] Istanbul Technical University, Solid Mechanics, Türkiye
asci23@itu.edu.tr

Keywords: Open-Holed Plate Design, Stiffened Panels, Stress Concentration, Structural Damage, Vibration Fatigue.

Aim

Open holes are indispensable features in engineering structures, particularly in fields like aerospace, automotive, and mechanical engineering. These geometric discontinuities are often intentionally introduced for purposes such as weight reduction, access, assembly, and mounting functionalities. While such modifications are vital for achieving high-performance, lightweight structures, they inherently introduce stress concentration zones that significantly affect mechanical behavior. These zones, being susceptible to localized high stress, become critical points for crack initiation and propagation, especially under fatigue loading.

The primary objective of this study is to comprehensively analyze how variations in hole size and location affect the structural performance of flat and rectangular metal plates. We aim to provide insights into the static, dynamic, and fatigue behavior of open-holed components through both analytical and numerical approaches. Special attention is given to vibration-induced fatigue, an area often overlooked in traditional fatigue analysis, despite its relevance in operational environments characterized by random, multi-directional excitation such as in aircraft, helicopters, and ground vehicles.

The research investigates the response of plates with systematically varied hole diameters and eccentricities. The behavior is characterized through modal analysis, frequency response functions (FRFs), and fatigue life assessments under Power Spectral Density (PSD) inputs. The resulting data are used to develop a set of decision-making guidelines for engineers designing open-holed structures subjected to complex loading. Ultimately, this study addresses a gap between classical stress analysis and the needs of modern fatigue design, especially where dynamic loading governs the life expectancy of structural components.

Material and Method

1. Finite Element Modeling

Ten models were created using HyperMesh 2021 to investigate two major parameters: hole size and hole location. The plates used in the simulation measured 100 mm × 100 mm with a thickness of 3 mm, representing a simplified yet realistic cross-section of aerospace-grade panels. Material properties were chosen in accordance with MMPDS data for aluminum alloys widely used in aircraft structures: young's modulus of 72 GPa, Poisson's ratio of 0.33, and density of 2700 kg/m^3.
The hole sizes varied from 0 mm (Model 1 - control) to 5 mm, 10 mm, 15 mm, and 20 mm (Models 2–5) (Figure 1), while the remaining models (6–10) (Figure 2) maintained a 20 mm hole but varied its horizontal position from 4 mm to 16 mm offset from the center. These configurations were chosen to study the superposition effect of hole presence and eccentricity on stress concentration and fatigue (Table 1).

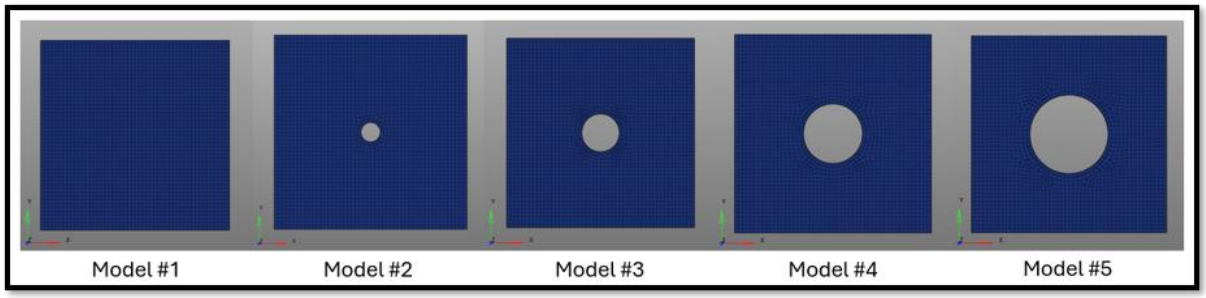

Figure 1. Comparison of First 5 Models (Increase of Hole Size).

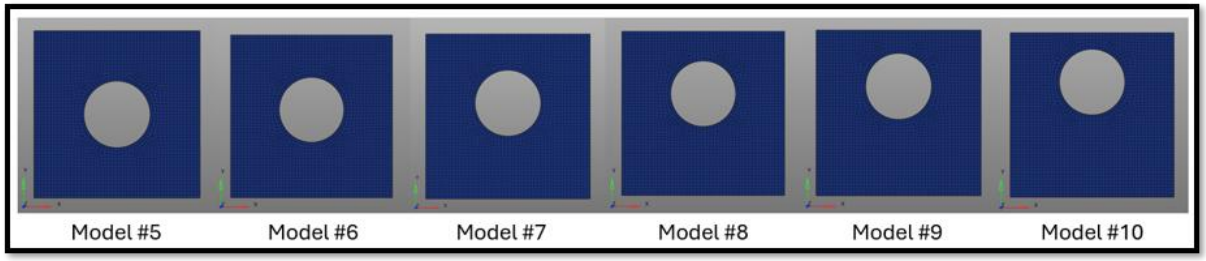

Figure 2. Comparison of Last 6 Models (Shifting of Hole).

Table 1. Explanation of 10 models to be used throughout the analyses.

Model #	Property
1	An aluminum plate without hole
2	An aluminum plate with 5mm hole at center
3	An aluminum plate with 10mm hole at center
4	An aluminum plate with 15mm hole at center
5	An aluminum plate with 20mm hole at center
6	An aluminum plate with 20mm hole at 4mm to center
7	An aluminum plate with 20mm hole at 8mm to center
8	An aluminum plate with 20mm hole at 12mm to center
9	An aluminum plate with 20mm hole at 16mm to center
10	An aluminum plate with 20mm hole at 20mm to center

2. Boundary Conditions and Load Case Selection

The study began by evaluating three different boundary conditions using modal analysis: free-free, simply supported, and clamped boundaries. Natural frequencies and mode shapes were analyzed across all conditions. The simply supported configuration was selected for detailed analysis due to its moderate stiffness response and its compatibility with theoretical validation models based on classical plate theory. The configuration is used with load-free selection.

3. Modal Analysis and Analytical Validation

MSC Nastran 2019 was used to extract the first ten natural frequencies and their corresponding mode shapes. To ensure the credibility of simulation results, MATLAB 2022 was used to calculate analytical solutions for the simply

supported plate case. These were compared with the MSC Nastran results, yielding an error range below 3% across all 10 modes, affirming the accuracy of the simulation workflow.

Findings

1. Modal Frequency Trends

The first ten natural frequencies for each model demonstrated an inverse relationship between stiffness and both hole size and eccentricity. As expected, larger holes reduced the stiffness of the plate, resulting in decreased natural frequencies. For instance, Model 1 (solid plate) had a first mode frequency of 46.39 Hz, whereas Model 5 (20 mm hole) had a slightly increased frequency due to mass reduction effects being dominant over stiffness loss.
Models 6 through 10, which varied the hole position while keeping the diameter constant, exhibited less predictable patterns. Initially, small offsets resulted in reduced frequencies, but as the hole moved closer to the edge, the mass redistribution altered the modal stiffness differently, in some cases increasing the natural frequency.
Models are required to be increased using parametric modeling techniques in future studies.

2. Frequency Response and Vibration Fatigue Framework

The Frequency Response Function (FRF) analysis was conducted by exciting the plate models with harmonic loads ranging from 1 Hz to 1000 Hz. Each model was subjected to 3-directional loads with an amplitude of 9810 N. The FRF outputs identified resonance frequencies and their associated amplification factors, which were crucial for fatigue evaluation.
A key aspect of vibration fatigue analysis is the integration of FRF data with Power Spectral Density (PSD) inputs, which define the energy distribution of excitation across frequencies. For this, standard aircraft vibration data from MIL-STD-810H was utilized.
Then, Root Mean Square (RMS) stress values were derived and used as input to the fatigue module in nCode 2019. Rainflow Counting and Miner's Rule were applied for damage accumulation.

3. Fatigue Life Trends

The fatigue lives for each model demonstrated that not only the presence of a hole but its size and location critically affect life expectancy. For example, Model 2 with a 5 mm central hole showed the highest damage (D = 3.009), translating to a very short fatigue life of 0.33 cycles. Interestingly, Model 5 with a 20 mm hole showed a damage value of only 0.0824, which is significantly lower due to the modal response being less aligned with the PSD peak frequencies.
In location studies, Model 6 (4 mm offset) had a damage value of 0.308, while Model 10 (16 mm offset) reached 1.497, indicating an almost 5x increase in damage. This trend shows that holes near edges can cause local resonance phenomena, increasing stress amplitudes drastically. The data supports a safe offset limit of 8 mm for maintaining fatigue integrity (Figure 3).

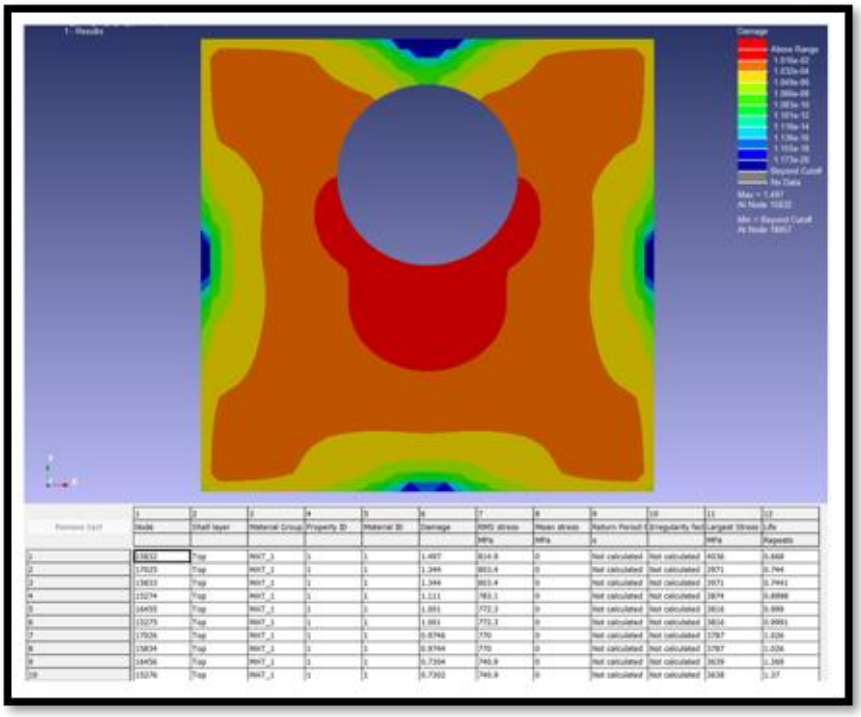

Figure 3. Outputs of Model 10.

Conclusion

This study confirms that the geometric configuration of holes in structural plates plays a vital role in their dynamic and fatigue behavior. Key findings are summarized as follows:

- Small holes can dramatically amplify local stress concentrations and cause disproportionately high fatigue damage (Figure 4).
- Increased hole size does not always correlate with increased damage due to competing effects of stiffness loss and mass redistribution.
- Off-center holes cause higher fatigue risk, especially when positioned close to plate boundaries due to modal distortion (Figure 5).
- Frequency content of excitation must be considered; resonance amplification can mislead fatigue life predictions if modal behavior is not integrated into the analysis.

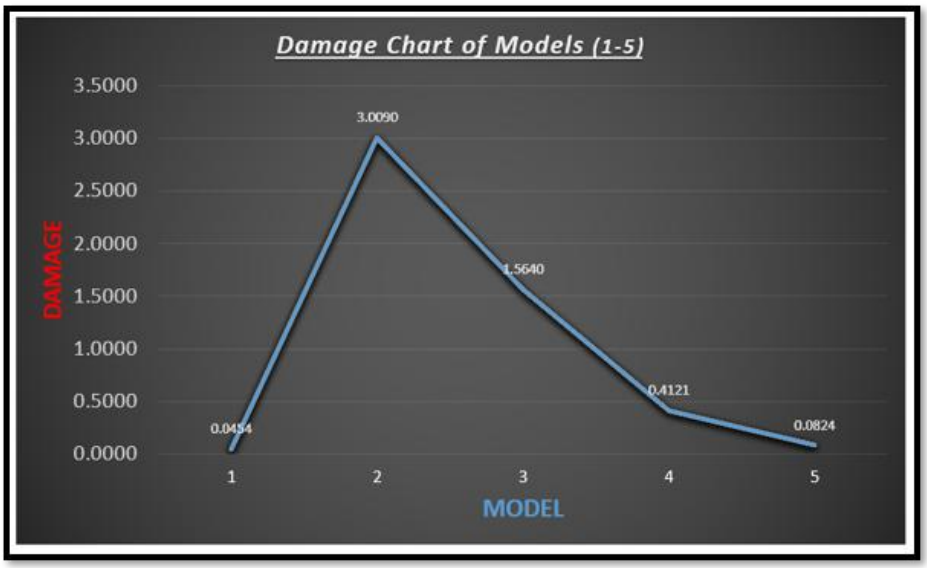

Figure 4. Damage Chart of Models (1-5).

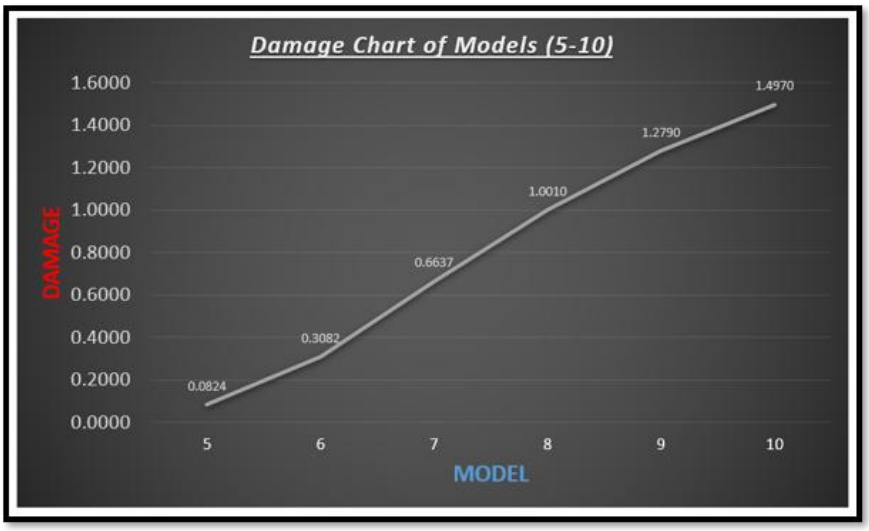

Figure 5. Damage Chart of Models (5-10).

The combined use of theoretical models, FEM simulation, and experimental standard-based PSD data has proven effective in comprehensively assessing the structural behavior under vibration fatigue. These findings are particularly relevant for engineers designing lightweight structures in vibration-prone environments such as aerospace and automotive platforms. The methodology presented in this study provides a reliable and validated workflow that balances computational efficiency with physical accuracy.

Assessing Decarbonization Strategies and Decoupling Trends of Türkiye's Private Sector Companies

Aslı Ceydanur Akbaba[a], Kadriye Elif Maçin[b], Börte Köse Mutlu[c]

[a] İstanbul Technical University, Sustainability Master of Science Program, Türkiye
[b,c] İstanbul Technical University, Civil Engineering Faculty, Department of Environmental Engineering, Türkiye
akbabaa23@itu.edu.tr, macin@itu.edu.tr, kosebo@itu.edu.tr

Keywords: Decoupling, Emission Reduction, Net Zero Targets, Decarbonization.

Aim

As businesses worldwide move toward low-carbon economies, the commitment of corporations to reduce greenhouse gas emissions has become increasingly significant in combating climate change. This study focuses on companies in Turkiye's BIST100 index (KAP, n.d.), specifically those in the Metal Products, Machinery, Electrical Devices, and Transportation sectors, to evaluate whether they can meet their emission reduction goals for 2030 and 2050. The research compares companies' publicly announced net-zero targets to their actual emission reduction trends, uncovering insights into how effective their decarbonization strategies are. Additionally, the study employs the Decoupling Index (DI) to determine whether economic growth is associated with increasing emissions or if companies are successfully reducing emissions while continuing to expand.

Material and Method

The research started with a review of 100 companies listed on the BIST100 index. The focus was on companies that publicly disclosed their sustainability or integrated reports, which included data on Scope 1, Scope 2, and relevant Scope 3 greenhouse gas emissions. The analysis was restricted to companies that have stated net-zero or emission reduction commitments for 2030 and 2050. From the initial pool of 100 companies, 46 met these criteria, demonstrating a commitment to accurate emission reporting and climate actions.

To ensure comparability, the research focused on companies within the Fabricated Metal Products, Machinery, Electrical Equipment, and Transportation Vehicles sectors, as these industries play a crucial role in Turkiye's industrial landscape and contribute significantly to national emissions. Using these criteria, seven companies were selected for an in-depth analysis, referred to as Firm 1 through Firm 7.

The study extracted each selected company's total emissions for 2023, along with their stated reduction targets for both 2030 and 2050. The research calculated the Expected Average Annual Reduction Rate (EAR) for 2030 and 2050 based on each firm's baseline emissions and their target reductions. Simultaneously, the Actual Average Annual Reduction Rate (AAR) was determined using emissions data from 2023 to gauge each company's progress toward its targets. Companies whose actual reduction rates exceeded their expected rates were deemed to be on track to fulfill their commitments; those falling short were identified as being at risk of not achieving their goals.

Furthermore, the Decoupling Index was used to explore the relationship between emissions trends and economic growth. To project Turkiye's per capita GDP for 2030 and 2050, a linear regression model was employed based on historical GDP data. The companies were classified into three categories regarding decoupling: absolute decoupling (indicating a decrease in emissions while GDP continues to grow), relative decoupling (indicating that emissions are increasing but at a slower rate than GDP), or no decoupling (where emissions are growing faster than GDP). This classification provided insights into which firms are genuinely pursuing sustainability and which ones need additional efforts to accomplish their targets (Karakaya, Bostan, & Özçağ, 2019).

Findings

The findings revealed that all seven firms reported their Scope 1, Scope 2, and Scope 3 emissions in line with the Greenhouse Gas (GHG) Protocol guidelines (Greenhouse Gas Protocol, n.d.). However, an examination of their progress in decarbonization indicated that companies in the Metal Products, Machinery, Electrical Devices, and

Transportation sectors are currently unlikely to meet their 2030 and 2050 emission reduction targets based on present trends. Many of these firms exhibited slower than required reduction trajectories, raising doubts about the feasibility of their proclaimed commitments.

Further examination of the sustainability reports highlighted companies' approaches to emission reduction. It became clear that many firms adopted intensity-based reduction targets, which focus on reducing emissions per unit of output rather than absolute reductions in total emissions. While this method improves efficiency allowing for growth alongside reduced emissions, it does not necessarily lead to significant overall decreases in emissions. Moreover, it was noted that companies had a common strategy for Scope 2 emissions reduction, primarily emphasizing the increased use of renewable energy for electricity consumption. Despite identifying renewables as a critical driver in cutting Scope 2 emissions, significant challenges remain in effectively tackling Scope 3 emissions.

For Scope 1 emissions, the companies implemented diverse energy efficiency initiatives, including optimizing compressed air systems, improving HVAC system efficiency, upgrading lighting systems, enhancing thermal insulation, utilizing heat recovery technologies, transitioning to energy-efficient motors, and adhering to LEED certification standards for manufacturing facilities. These strategies aim to cut direct emissions stemming from operations while boosting overall energy performance.

The Decoupling Index analysis provided deeper insights into the relationship between emissions trends and economic growth. By 2023, some companies successfully achieved absolute decoupling, meaning their emissions had decreased while their economic growth persisted. Others displayed relative decoupling, with emissions still rising but at a slower pace than the growth of GDP. In contrast, several firms showed no decoupling at all, indicating that their emissions were increasing more rapidly than economic growth, thereby signaling a need for more robust decarbonization measures.

The research also observed that many firms had recently enhanced their Scope 3 emissions reporting, leading to an artificial spike in total reported emissions. While increased reporting transparency can be beneficial, it complicates the measurement of progress over time and highlights the importance of accurately capturing Scope 3 emissions, which usually represent the largest component of a company's total emissions.

At the same time, comparing Expected and Actual Reduction Rates revealed that some companies might be capable of achieving their targets for 2030; however, they will likely face difficulties in meeting their 2050 commitments as the required rate of reduction escalates significantly after 2030. Notably, two companies in the white goods sector and one in transportation were found to be off-track for both their 2030 and 2050 targets. Companies showcasing a robust commitment to emission reductions tended to incorporate a range of strategies, including efficiency improvements, electrification initiatives, and substantial investments in renewable energy sources.

Conclusion

This study uncovers a critical gap between the declared decarbonization targets of companies and their actual progress in reducing emissions. While many firms have made strides in reducing Scope 2 emissions through enhanced renewable energy use, the overall trends in emissions suggest that existing strategies may not be enough to meet their 2030 and 2050 objectives. The analysis using the Decoupling Index highlighted varying success rates in dissociating emissions growth from economic expansion while certain companies achieved absolute decoupling, others still face challenges.

The findings further indicate that a number of firms continue to rely on intensity-based reduction strategies that, although beneficial, do not guarantee substantial decreases in total emissions. Furthermore, companies that broadened their Scope 3 reporting often faced an upward spike in their reported emissions, complicating the perceived progress toward targets. Moving forward, companies must adopt robust emission reduction strategies, improve their management of Scope 3 emissions, and outline realistic pathways for transition to align with broader climate goals.

The Relationship between Sustainable Finance and The Carbon Border Adjustment Mechanism (CBAM): A Policy Impact Assessment and Hypothetical Case Study of A Cement Plant

Inci Nur Cetin[a]

[a] Istanbul Technical University, Environmental Sciences, Engineering and Management Program, Türkiye
cetin22@itu.edu.tr

Keywords: Carbon Border Adjustment Mechanism (CBAM), Cement Industry, Sustainable Finance.

Aim

The research aims to conduct a comprehensive Policy Impact Assessment (PIA) of the Carbon Border Adjustment Mechanism (CBAM) on a cement plant in a third-party country, evaluating both environmental and financial impacts within the framework of sustainable finance. The European Union's (EU) CBAM is designed to reduce carbon leakage by imposing a carbon price on imported goods, with the cement sector being one of the six most critical carbon-intensive industries. This study will examine the impact of CBAM policies on the Environmental, Social, and Governance (ESG) standards of the cement plant. By integrating a sustainable finance perspective, the research aims to identify both the direct and indirect effects of CBAM on the economic management and operations of the cement sector within regulatory frameworks.

Material and Method

This study employs a hypothetical case study design to assess the environmental and financial impacts of the EU's CBAM on a cement plant operating in a third- party country. Using both quantitative and qualitative methods, the research integrates scenario simulations, financial modelling, and policy mapping. Key performance indicators include environmental (CO_2 emissions, emission intensity), economic (production and compliance costs, profitability), technological (green technology adoption), and regulatory (HS Codes, compliance standards) metrics. Hypothetical scenarios model varying CBAM enforcement levels, assessing their effects on production, costs, and emission strategies. Financial analysis includes cost-benefit and sensitivity evaluations, while environmental assessment tracks emission reductions and green technology efficiency. Policy mapping examines EU and Turkish regulations, highlighting regulatory drivers and sustainability finance implications. The study also explores how ESG standards influence investment and corporate strategies. An integrated framework combining statistical analysis, policy review, and scenario modelling ensures a comprehensive assessment. While relying on secondary data and simulations, the study provides preliminary insights into CBAM's impacts, acknowledging limitations in market dynamics and policy enforcement that future empirical research should address.

Findings

Preliminary findings suggest that climate change impacts are driving the adoption of sustainable strategies across various sectors, including finance and industry. The need to address these effects concretely has led policymakers to emphasize economic outcomes. The CBAM and the Emissions Trading System (ETS) play a key role in guiding production facilities toward both environmental sustainability and economic competitiveness.

The hypothetical cement plant may need to reassess its emissions management strategies due to CBAM implementation, potentially leading to a shift toward cleaner technologies and a re-evaluation of supply chain dynamics. Compliance is expected to result in higher operating costs, but it may also enhance competitiveness through sustainable practices. Additionally, experts suggest that aligning with CBAM could promote a circular economy within the cement industry, encouraging investment in renewable energy sources and innovation in cleaner technologies.

In their analysis of the effects of new carbon management strategies on the cement sector, Sloan et al. (2023) provide insights into how these frameworks can improve adherence to carbon border adjustments. CBAM is

gaining importance in developing countries to reduce carbon dioxide emissions and to adapt to European practices. Sharma & Srivastava (2023) propose strategies on how these mechanisms can be used to optimize transition pathways in the energy sector. In Europe, CBAM is used to avoid carbon taxes and to maintain external competitiveness. Lau et al. (2021) examine the role of carbon capture technologies (CCS) technologies in Europe's carbon transition and explain the importance of implementing this mechanism in the cement sector. Rumayor et al. (2021) evaluates the potential of carbon recycling in the cement sector and provides examples of how such a mechanism can be implemented in international trade.

Conclusion

This study highlights the importance of a comprehensive Policy Impact Assessment in understanding the effects of CBAM on the cement sector. By analysing a hypothetical cement plant, it identifies key areas where environmental engineering can play a crucial role in mitigating climate impacts and promoting sustainable outcomes. In addition to offering insights for future policymakers, the findings can help cement producers enhance their strategic planning as they transition to more environmentally friendly operational models. For the cement industry to become more sustainable, decarbonization is a vital requirement, in order to reduce greenhouse gas emissions from the production of cement, multiple environmentally friendly methods are being researched. The effect of low-carbon techniques in reducing greenhouse gas emissions from cement production in developing countries is highlighted by Cheng et al. (2023). By integrating alternative fuels with carbon dioxide capture and storage (CCS) technology, Fennell et al. (2021) highlight the necessity of minimizing greenhouse gas emissions in the cement production process. Furthermore, in cement sector, Environmental, Social and Governance (ESG) goals are becoming more and more significant. In order to achieve the cement industry's zero emission goals, Jiang et al., 2024 highlight the importance of social and environmental aspects. The significance of green technologies in the industry and their possible role in power transitions are also examined by Muhsen et al. (2023), who offer a viewpoint in favor of the incorporation of ESG standards in cement plants.

Ultimately, this research contributes to the broader discussion on engineering solutions, climate policy, and sustainable finance in the context of industrial emissions management.

The Intersection Infrastructure of LCA-BIM Inegration: Applicability in Turkey and Europe

Tuğba Ayvaz[a]

[a] Istanbul Technical University, Graduate School, Department of Architecture, Project and Construction Management, Turkey
ayvazt16@itu.edu.tr

Keywords: Life Cycle Assessment, Building Information Modeling, Carbon Emissions, Sustainability.

Aim

The construction industry faces increasing pressure to reduce carbon emissions throughout the building lifecycle, from material production to the end of its service life. Integrating Life Cycle Assessment (LCA) with Building Information Modeling (BIM) presents a promising strategy to embed environmental performance assessment into the design and operation of buildings. This paper aims to improve the feasibility of LCA-BIM integration by developing a "cross-infrastructure" that links BIM models with carbon emission data. Specifically, the focus is on directly embedding material-level carbon information (e.g., greenhouse gas emission factors) into BIM objects, proposing a dynamic framework in which each building component carries its own "carbon identity." The goal is to enable real-time calculation of both embedded and operational carbon footprints of a building within the BIM environment. The research offers solutions to data incompatibility and integration challenges in LCA-BIM, exploring the applicability of LCA-BIM integration in Turkey and Europe. By associating digital building models with dynamic carbon databases, it proposes a new BIM-based data infrastructure that could enhance decision-making for low-carbon design. As a result, the research focuses on sustainability-driven design throughout the building lifecycle in early-stage project decision-making processes, aligning with global carbon reduction goals while considering the feasibility of regional applications.

Material and Method

In the research, carbon emission statistics were obtained from the Turkish Statistical Institute (TUIK) and the European Union's Eurostat official database. A dataset on greenhouse gas emissions for EU member countries from 2010 to 2024 was created and analyzed. The data for Turkey was analyzed through TUIK. Emission factors for building materials were obtained from LCA databases such as Ecoinvent (a comprehensive life cycle inventory database), the Social Hotspot Database (SHDB), and EPDs. Additionally, industry tools such as One Click LCA and published Environmental Product Declarations were consulted to validate material-level carbon values. A systematic meta-analysis of the literature was conducted, with a notable observation that most of the literature was published within the last five years. Revit, a BIM tool, was used to develop a building model representing a typical project. Within Revit, a custom parameter schema was applied to assign a unique "Carbon Identity" to each material and component. Autodesk Dynamo, a visual programming tool, was used to script the connection between Revit and Excel-based data tables containing emission factors. One Click LCA (a commercial BIM-LCA plugin) was used as a trial for comparison, highlighting the differences between our identity-based method and the existing plugin workflows. The key methodological innovation is the direct embedding of carbon data into BIM objects through unique identities. A material library was created, and an external mapping file "XYZ123" was linked to a CO_2 emission factor (e.g., kg CO_2 per kg of material). During BIM modeling, as elements were added or quantities changed, a live calculation routine was proposed, allowing for immediate access to a tangible carbon output for the design. By embedding data at the material level, it was suggested that carbon information travel alongside the BIM model. The method was applied step by step: (1) define the identity schema and populate the LCA dataset, (2) add identity parameters to Revit families, (3) develop Dynamo scripts for real-time connection, and (4) test the system on a case study building model. In summary, it involved gathering reliable data sources, critically reviewing existing research, and proposing a prototype system within Revit that demonstrates a new approach to integrating LCA into BIM via embedded carbon identities.

Findings

A comparative analysis of CO_2 trends reveals divergent patterns between Europe and Turkey. Over the past decade, per capita emissions in countries like Germany and Italy declined steadily—from 10.9 to 8.1 tons in Germany, and 7.6 to 5.3 tons in Italy (Climate Transparency, 2024). In contrast, Turkey's total greenhouse gas emissions surged by 134% (TUIK, 2023). While Europe must further enhance LCA–BIM integration to maintain progress, Turkey faces an urgent need to adopt it to curb rising emissions. Although construction sector emissions have declined in Europe, Germany and the Netherlands still exceed Turkey in per capita values, with Germany leading in total construction-based CO_2 between 2010 and 2024 (World Bank).

Operational carbon—especially from HVAC systems—dominates a building's life cycle footprint, often comprising up to 93% of total GWP (Cheng et al., 2020). Yet, many BIM–LCA studies focus only on embodied carbon, neglecting operational impacts (Ortiz et al., 2009). Current tools typically extract material quantities for embodied calculations but omit energy use. Integrating operational simulations requires exporting BIM models to energy tools (e.g., Insight, DesignBuilder), a step often skipped due to its complexity (Cheng et al., 2020). Cheng et al.'s manual method using gbXML highlights the crucial role of operational carbon.

Neglecting operational emissions can yield misleading results—buildings with sustainable materials but poor energy performance may still have high footprints. Our proposed method addresses this by embedding operational data within BIM via Carbon IDs and Insight integration, thus closing a major gap in current practice.

Meta-analysis also identified key barriers: lack of material libraries supporting integration, reliance on manual data transfer, dataset mismatches, and absence of dynamic updating. These limitations slow down workflows and increase error potential (Chen et al., 2024). Repeated manual adjustments for every design revision remain a major obstacle to seamless BIM–LCA integration.

Uniqueness and Practical Value of the Proposed ID-Tag Method:

The proposed Carbon ID tagging system offers a unique solution for the BIM-LCA intersection infrastructure. By assigning each material/component in the BIM model a unique carbon identifier, the dynamic definition of the emission factor for each object is achieved without user intervention. This methodology was validated in a prototype building model: as materials in the BIM design were changed, the embodied carbon totals were instantly updated, confirming a live connection between design choices and LCA results. The system facilitates sustainable decision-making processes by integrating unit carbon emissions per material into the BIM environment, which project decision-makers are already familiar with. This approach is an extension of the automated data exchange proposal defined by Chen et al. (2024). Chen et al. (2024) found that automating data exchange "reduces errors in manual calculations and data collection" while improving efficiency.

If material suppliers and LCA database providers collaborate on standardizing Carbon Identities (similar to barcodes or product identifiers), BIM software could universally incorporate carbon data, providing consistent carbon emission rates across projects and regions. The meta-analysis identified the lack of such standardization as a major gap in current research. The identification of product identities in the digital environment could be facilitated through government policies. This would promote an integrated design philosophy where the carbon footprint in the BIM model becomes as instantaneous a metric as cost or structural load. Such immediacy is crucial for real-world adoption because, if seamlessly integrated into feedback workflows, design teams are more likely to consider carbon criteria. In this way, a digital copy of the building is created from early design to operation and demolition

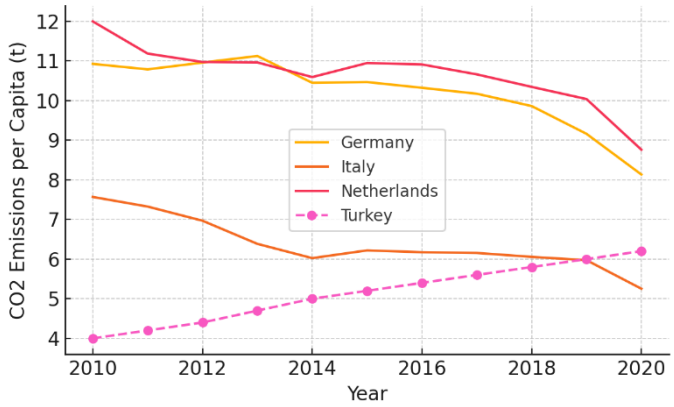

Figure 1. Per capita CO_2 emissions (building sector-based) in European countries vs. Turkey, 2010–2020.

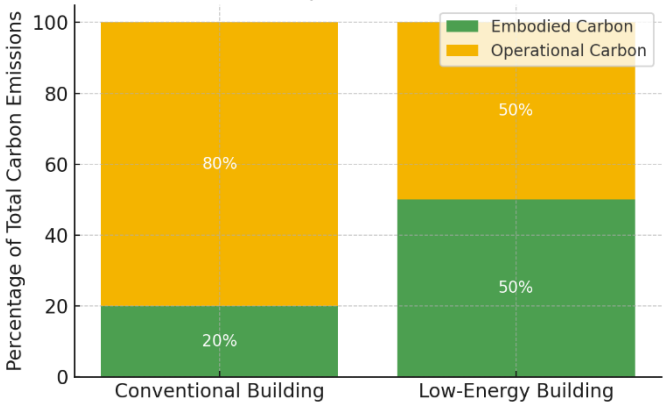

Figure 2. Illustration of embodied vs. operational carbon share in a building's life cycle.

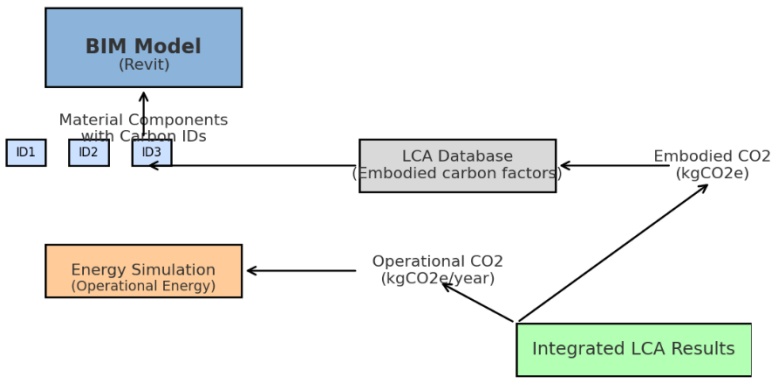

Figure 3. System architecture for the proposed BIM–LCA integration using embedded Carbon IDs.

Conclusion

This study explored the intersection of LCA and BIM, proposed a new integration framework, and assessed its applicability in Turkey and Europe. The key findings can be summarized as follows:

1. While European countries have progressively reduced construction-related carbon emissions (both embedded and operational), emissions in Turkey are rising, emphasizing the urgent need for improved carbon management in Turkey's construction sector.

2. Despite operational carbon emissions accounting for the largest share of a building's life cycle emissions, many existing BIM-LCA applications focus solely on embodied carbon. This gap in the literature indicates that neglecting the operational phase may lead to suboptimal decisions. Therefore, a robust BIM-LCA integration (including the proposed system) must incorporate energy simulation data to capture operational impacts.
3. The shift toward BIM-LCA integration has been hindered by labor-intensive manual data entry, unreliable or limited-scope plugins, and fragmented data sources, which negatively affect LCA adoption in BIM workflows. These challenges, well-documented in numerous studies, provided insights into the development of our material identity tagging strategy.
4. The proposed Revit-based Carbon Identity system was applied and tested, demonstrating clear advantages in overcoming the fundamental barriers to BIM-LCA integration. By embedding carbon emission factors at the material level within the BIM model, the system provided real-time data synchronization when designers made modifications to the model.

The steps of the system were applied sequentially: mapping LCA database entries to BIM material definitions, assigning a Carbon Identity to each material, and calculating values on a project-specific basis via Dynamo scripts. To include operational carbon, Insight was used. The total carbon output was verified against a traditional LCA conducted in parallel to ensure that the results of the ID method were within an acceptable margin of error. The consistency accuracy was found to be less than 5%.

This study highlights the importance of integrating both embodied and operational carbon into BIM models for better sustainability decision-making and shows how the proposed method can effectively address the challenges in current BIM-LCA workflows.

From a broader perspective, the proposed system offers an adaptable and scalable path toward true digital twin integration for sustainability. Essentially, every building component in the digital model carries metadata about its environmental impact, laying the foundation for a future where complete "carbon digital twins" of buildings can be maintained. In such a future scenario, a building's digital twin would continuously monitor both embedded carbon (as materials are changed or added) and operational carbon (via sensors and building management systems), providing real-time information about the building's performance relative to climate goals.

Our study is a step in this direction, enabling design-phase analysis. The research presented here paves the way for such advancements, demonstrating that LCA-BIM integration can be both technically feasible and highly practical. This brings the industry one step closer to truly sustainable building life cycles.

Effects Of Using Waste Glass Powder And Rice Husk Ash As A Partial Replacement With Cement In Mortar Productions

Mohamad Alaa Shurbaji [a], Özgür Ekincioğlu [a]

[a] Istanbul Technical University, Civil Engineering Department, Construction Engineering Program, Türkiye
shurbaji21@itu.edu.tr

Keywords: Waste Glass Powder (WGP), Rice Husk Ash (RHA), Supplementary Cementitious Materials (SCMs), Sustainable Construction, Waste Management.

Aim

The excessive use of Ordinary Portland Cement (OPC) in construction significantly contributes to energy consumption and environmental pollution due to carbon emissions. This study aims to enhance the environmental sustainability of cement-based materials by investigating the performance of mortars that incorporate rice husk ash (RHA) and waste glass powder (WGP) as supplementary cementitious materials (SCMs) to partially replace OPC. The main objective is to determine how RHA and WGP affect important mechanical characteristics including compressive and flexural strength, both separately and in combination. The study aims to find the best replacement values that improve mechanical performance and enhance sustainability by systemically changing the proportions of RHA and WGP in mortar compositions. The study also examines the synergistic advantages of combining RHA with WGP, showing how each improves microstructural properties, workability, and durability. The specific objectives include determining the optimal mix ratio of WGP and RHA in mortar and identifying the optimum percentage replacement of cement with the combined WGP-RHA mixture based on mechanical properties, workability, and durability assessments. Furthermore, the study aims to understand the pozzolanic reaction mechanism through microstructural and chemical analyses. The findings will provide valuable insights into the feasibility of utilizing these materials in construction applications, contributing to more sustainable building practices and effective waste management solutions.

Material and Method

CEN Reference sand

The sand used in this study according to EN 196-1:2016 The sand is prepared according to the same specifications and particle sizes as in the standard. The sand was prepared to meet all the requirements listed in EN 196-1:2016, including those related to particle size distribution, shape, and mineral composition. To achieve a uniform distribution and reduce variability in mortar workability and strength development, the particle sizes were carefully controlled through sieving and grading procedures.

Cement

The physical characteristics of the Portland cement, which was classified as CEM I 42.5N under the TS EN 197-1 standard, were measured to ensure adherence to the experimental structure of the study. Measured density of cement was 3.12 g/cm³.

Waste glass powder (WGP)

The waste glass powder (WGP) used in this study had an average particle size of less than 100 µm after sieving, which was provided by the company with an average particle size of 100 µm. This glass's homogeneity and purity can be due to its E-glass fiber origin. According to literature, a particle size of less than 100 µm effectively mitigates ASR expansion and enhancing the durability.

Rice husk ash (RHA)

Rice Husk Ash (RHA) is a valuable supplementary cementitious material in construction, known for its high pozzolanic properties. It consists of amorphous silica (SiO2), which can react with calcium hydroxide to form hydrated calcium silicate, enhancing the strength and durability of concrete. RHA has a high surface area due to its nanoscale particles.

Superplasticizer

Superplasticizer or a high-range water-reducing admixture with a brand name of Sika-4087 was incorporated into the mixtures to achieve the targeted slump value for ease of workability, placement, and consolidation in all concrete and mortar mixes. The used superplasticizer has a density of 1,07 g/cm3.

Method

The study aimed to identify the optimal ratio of waste glass powder (WGP) to rice husk ash (RHA) as supplementary cementitious materials (SCMs) for replacing 25% of ordinary Portland cement (OPC) by weight. Mortar samples were prepared with varying WGP:RHA ratios (0:25, 6.25:18.75, 12.5:12.5, 18.75:6.25, and 25:0) to assess their mechanical performance. A control mix containing 0% SCMs was included for baseline comparison. Following **EN 196-1:2016** standards, the mechanical properties—specifically flexural and compressive strength were evaluated at 7 and 28 days of curing to determine the influence of each combination on structural performance. Concurrently, the pozzolanic activity indices (PAI) of WGP and RHA were assessed in accordance with **EN 450-1:2013** guidelines. This involved evaluating the compressive strength of blended cement pastes containing 25% WGP or RHA against pure OPC paste, ensuring compliance with the standard's requirement of a minimum PAI of 75% at 28 days.

The chemical composition of OPC, RHA, and CCA was determined using X-ray fluorescence (XRF) analysis. For instance, RHA's high amorphous silica content (>80% SiO_2) and WGP's alkali-silica reactivity mitigation properties were confirmed through XRF.

Findings

The results of the seven-day mechanical test showed that mortars containing both rice husk ash (RHA) and waste glass powder (WGP) performed reliable results as control samples. All tested mix ratios, specifically 0R:25G (0% RHA, 25% WGP), 6.25R:18.75G (6.25% RHA, 18.75% WGP), 12.5R:12.5G (12.5% RHA, 12.5% WGP), 18.75R:6.25G (18.75% RHA, 6.25% WGP), and 25R:0G (25% RHA, 0% WGP), had noticeably high flexural and compressive strength values. These findings indicate that WGP and RHA, either separately or in combination, improved the mortar's structural integrity even when used to partially replace cement.

The pozzolanic activity index (PAI) for both RHA and WGP exceeded the minimum threshold of 75% as stipulated by **EN 450-1:2013**, validating their efficacy as supplementary cementitious materials (SCMs). For instance, RHA and WGP achieved a PAI of above 75%.

Conclusion

This study confirms that both waste glass powder (WGP) and rice husk ash (RHA) can be effectively utilized as partial substitutes for Ordinary Portland Cement (OPC) in mortar production. The findings align with the criteria outlined in the **EN 450-1:2013** standard, indicating that these materials meet the requirements for supplementary cementitious materials (SCMs).

This research highlights the broader potential of incorporating agricultural and industrial waste materials to promote more sustainable and environmentally conscious construction practices. The construction industry, a significant waste producer, can benefit from adopting circular economic principles by using materials like WGP and RHA, reducing landfill waste and lowering the demand for virgin materials.

This strategy encourages resource conservation and waste reduction, which are essential for reducing the negative effects of construction on the environment. The construction industry may decrease its carbon footprint and help create a more sustainable future through using these creative and sustainable waste management techniques.

Investigation of Green Buildings Towards Net Zero Carbon Cities: Example in ITU Ayazağa Campus

Merve Maçin[a], İsmail Toröz[a]

[a] Istanbul Technical University, Department of Environmental Engineering, Environmental Sciences Engineering and Management Program, Turkey
macin16@itu.edu.tr

Keywords: Zero-Carbon Building, Carbon Emissions, Net-Zero Carbon, Green Building Certificate, LEED.

Aim

Anthropogenic activities resulted in an increase in pre-industrial global surface temperature and led to both long-term and short-term variations in climate. Increasing greenhouse gas emissions as a result of increased global industrialization and urbanization have triggered this climate change, creating one of the biggest global problems of today. Carbon dioxide is the most abundant greenhouse gas and has the most detrimental effect on the environment (Chen et al. 2023). The goal of carbon neutrality is to reduce or eliminate greenhouse gas through carbon capture, storage, and conversion within a specific period of time, resulting in 'zero emission' of greenhouse gas emissions (Oxford Net Zero, 2022).

The development of technology and modern lifestyle is causing urbanization to increase day by day. In 2050, cities will be home to 68% of the world's population. Cities occupy just 3 percent of the Earth's land but account for 60-80% of energy consumption and at least 70 % of carbon emissions (United Nations, 2018).

The European building stock consumes approximately 40% of primary energy and it is emissions responsible for 36% of the European Union (EU) greenhouse. A significant reduction of building energy demand is a requisite to meet Europe's greenhouse gas emissions reduction targets (JRC Science for Policy Report, 2016). The building sector plays a key role in the long-term strategy on the reduction of greenhouse gas emissions for the European Union as well as to achieve other objectives of the European Green Deal (European Commission, 2023). Buildings that are designed to reduce environmental impacts by using strategies for reducing energy and natural resource use are defined as sustainable, green or zero energy buildings. The LEED system is the most popular green building rating system in the world. Because LEED is a certification system based on sustainability and discusses the topics of energy and buildings, climate and site, building envelope and building systems in detail, it includes the steps led to achieve zero energy buildings.

Governments and local authorities create their own strategy for reaching net zero goal. To solve complex systems like greenhouse gas mitigation, future pathways should be carefully planned. The fact that data collection is a difficult and time-consuming process causes many researchers to use general data from common databases such as eco-invent instead of site-specific data. Databases are updated irregularly and often years later. Therefore, the use of general database information generally reduces the suitability and representation of the study (Hauschild M.Z., 2018). Therefore, in order to obtain the most accurate data, it is necessary to increase the amount of "primary data" by narrowing the field of study to pilot region as in this thesis study. This study investigates whether the current green building certification systems, specifically LEED, provide a sufficient framework of indicators to effectively meet the net zero carbon target.

Material and Method

Istanbul Technical University Department of Information Technologies Building was selected as a case study because of the data availability. This project, designed in 2017 and completed in 2020, with an area of 8500 m². The building received the prestigious LEED Platinum Certification, the top recognition for green buildings. It incorporates sustainable design principles, including orientation, harmony with the landscape, use of natural light, efficient water usage, material optimization, as well as renewable energy and energy efficiency aiming to decrease carbon footprint.

LEED evaluates buildings in 9 main categories. These are integrative processes, location and transport, sustainable sites, water efficiency, energy and atmosphere, material and resource, indoor environmental quality, innovation, and regional priority.

The carbon footprint of the building while operating was calculated to better understand the relationship between LEED and net zero. The GHG Protocol was followed in the preparation of this greenhouse gas inventory. Scope 1; covers direct greenhouse gas emissions generated on site. Scope 2; includes net indirect emissions from energy imports and exports. Scope 3; includes other indirect greenhouse gas emissions, such as product transport by third parties, outsourcing of core activities and off-site waste disposal/ management activities, water consumption and procurement related emissions.

Findings

The Department of Information Technologies Building released 1503 tCO_2eq greenhouse gases in 2020. But it is found that it was increased to 1928 tCO_2eq in 2021. Scope 2 is the highest contributor to the greenhouse gas emissions of the building with 1112 tCO_2eq due to electricity consumption of servers in the Information Technologies Building. The total emission value of 0.23 tCO_2eq/m^2 in 2021 is noteworthy when compared to previous studies. Güereca et al. (2013) found 0.060 tCO_2eq/m^2 emissions for building in a university in Mexico. According to Ozawa-Meida et al. (2013) and Bailey and LaPoint (2016), there was a wide range of results between 0.350 tCO_2eq/m^2 and 0.150 tCO_2eq/m^2.

Although this study provides a detailed evaluation, it's necessary to recognize some limitations that could affect the accuracy of the values reported. Findings can be affected by data availability. Comparing and interpreting results can be hindered by the fact that LEED parameters do not exactly match carbon footprint emissions.

Conclusion

The implementation of green building certification systems is more expensive and takes longer than conventional systems. However, net-zero carbon emissions targeted credits of green building systems can be beneficial for the environment, society, and economy, and this can lead to sustainable development. Although this study was restricted to one building, university campus green building and carbon footprint studies are valuable benchmarks for future improvements and comparative assessments.

An Inclusive Digital Accessibility Policy for Individuals with Disabilities

Oylum Bülbül[a], Hatice Ayataç[b]

[a] Istanbul Technical University/Graduate School, Urban Design Program, Türkiye
[b] Istanbul Technical University /Faculty of Architecture, Urban and Regional Planning Department, Türkiye
bulbuloyl@itu.edu.tr

Keywords: Inclusivity in Digital Content, Web Accessibility, Accessible Web, Inclusive Web, Design for Accessibility.

Aim

Cities are a network of physical infrastructures, natural spaces, and individuals. Today, the use of urban living spaces is built around digital data. As data-based access between individuals, institutions and urban services becomes stronger, access to urban quality similarly increases.

Digital access means access to education, healthcare, financial services, civil participation, and many other areas. Beyond being an optional service, it can be considered a social human right.

Digital technology is unevenly distributed across countries, genders, ethnicities and socio-economic strata worldwide. It is expected that digital access in everyday life should be inclusive and widely available to people from all socioeconomic structures.

The global crises and natural disasters we have experienced in recent years have brought the concept of digital inclusion to the forefront as a pressing need worldwide. It is considered a fundamental human right for people with disabilities and individuals under social protection to be in contact with their relatives and to receive public services like other individuals.

According to the study of Campoverde-Molina, Luján-Mora, S. & Valverde, L. (2021), the accessibility of university websites worldwide was addressed in the form of a comprehensive and systematic literature review. This review covering the years 2002-2019 was conducted and university websites published in 42 international articles that are pioneers in the field of accessibility were selected. The results of this study were obtained through an analysis and synthesis of evaluations of 9,140 universities in 67 countries. Of the 188 university web sites, 79 were found to be accessible in 2002. The results indicated that higher education websites become progressively inaccessible as complexity increases in 2005.

Findings from research conducted in recent years on the access of disabled students in higher education institutions in Türkiye to digital platforms are noteworthy in bringing the issue of digital accessibility to the agenda. The reviewed study provides an assessment of the accessibility, usability, quality performance and readability aspects of all Turkish public and private university websites. The majority of them did not meet the WCAG 2.0 accessibility criteria. In this study, out of 110 public university websites and 69 private university websites, only 10 public and 4 private university websites achieved basic level compliance (Akgül, Y., (2021).

All these results show that usability, quality performance and readability are low and emphasize that Turkish universities need to allocate more resources to make their websites more accessible, inclusive, usable and high-quality performance for all users.

In recent years, the findings of research on the access of students with disabilities in higher education institutions in Türkiye to digital platforms are noteworthy in bringing the issue of digital accessibility to the agenda.

At this point, the question of "Why is digital accessibility important and how can it be achieved?" comes to the fore.

The goal of "Making cities and human settlements inclusive, safe, resilient and sustainable" within the scope of Article 11 "Sustainable Cities and Communities" of the United Nations Sustainable Development Goals, to which our country is a party, is also a basis for this study (UNESCO National Commission for Türkiye, 2025). In this

direction, the "National Sustainable Development Coordination Board" was established on 19.02.2022 by the Strategy and Budget Presidency of Türkiye and the dissemination of inclusion and accessibility at the national level through all public structures was institutionalized (Türkiye Strategy and Budget Presidency, 2025).

In addition to the target of "By 2030, improve inclusive and sustainable urbanization and capacities for participatory, integrated and sustainable urban planning and management in all countries" (Target 11.3), it is seen that our country supports inclusive digital access by participating in the "Digital inclusion traveler" platform created within the United Nations (Türkiye Strategy and Budget Directorate, 2025).

In this context, the following questions become a priority:

- With what methods and elements can digital web content be handled inclusively and accessible?
- What are the elements that can be developed to ensure that digital access is widespread in an inclusive manner and can be used as equally as possible by people from all segments of society?

The research focuses on examining how inclusive and accessible digital content is presented in various examples based on the smart city concept, aiming to analyze and compare recommendations developed on this subject through international and national examples. This guide will try to reveal how accessible digital web content should be for all users, primarily individuals with disabilities, by examining university websites. The study, which is aimed to be developed in this context, will primarily serve as a digital application guide for university websites.

The infrastructure to be proposed will provide clues about how websites should be designed for users with disabilities, as well as the institutional infrastructure that provides inclusive digital accessibility in this regard (Bulbul, O., 2025).

Material and Method

Starting with the basic research questions, the study first examined the conceptual framework of inclusive and accessible digital content. Comparative analyses are planned based on international and national examples. University websites were compared in terms of technical aspects within the framework of accessibility guidelines (W3C). As a result of the comparison, the institutional structures of the two universities that stand out with the optimum most inclusive, and accessible features were examined in detail, and the guide proposed in the conclusion was based on this data. The study to be developed will primarily serve as a user experience-oriented digital application guide for university websites.

Findings

The basic elements which keep accessibility on the agenda and require the development of different design themes, are defined as "web content accessibility guidelines" (Firth, A., 2020).

Web content accessibility guidelines have a common purpose not only for people with disabilities but also for all users and all designers who produce tools for these users. When a web page is accessible, it can be said that accessibility is possible for everyone who uses it. The "Accessibility Guidelines" mentioned in the introduction (TÜBİTAK BİLGEM, 2025), produced for public websites, which were formalized in our country's legislation in 2022 (Türkiye Strategy and Budget Directorate, 2025), formed the basis of the accessibility and inclusion guidelines evaluated in this study.

This study focuses on website users with disabilities. These users may not be able to see, hear, move, or process some information easily or at all. They may have difficulty reading or understanding the text. They may not be able to use a keyboard or mouse effectively. They may have a text-only screen, a small screen, or a slow and unhealthy internet connection. They may not be fluent in or understand the language in which the document is written. They may be in a situation where their hands, eyes or ears are busy. They may have an older version of a browser, a completely different browser, a voice browser, or a different operating system (Firth, A., 2020). Accessible and inclusive web design is expected to meet the needs that arise from such problems.

Design guidelines examine typical scenarios that can create problems for users with specific disabilities and provide solutions for accessible design. Through design guidelines, content developers can create pages that

transform conveniently. Conversion pages remain accessible despite any of these limitations, including physical, sensory, and cognitive disabilities, limitations, and technological barriers. Here are some elements of web design guidelines;

- Adding Appropriate Alternative Text to Images
- Correct Selection of Headings
- Accessible Subfiles
- File Extensions that Preserve the Appearance
- Using World Wide Web Association Standards and Customized Bookmarks
- Adding Labels to Form Fields
- Grouping Form Fields
- Marking Tables
- Defining Text Language
- Controlling Color Contrast
- Avoiding Small Fonts
- Spaces
- Focusing Tools
- Correct Use of Text Data

A Digital Accessibility Policy was created based on the examples evaluated with accessibility guidelines. It has been defined which units will constitute the institutional infrastructure that ensures that these guidelines are user-oriented and inclusive within universities (Figure 1. Digital Accessibility Organizational Structure; Bulbul, O.,2025).

Figure 1. Digital Accessibility Organizational Structure (Bulbul, O., 2025).

In the evaluation that emerged as a result of the analysis;

- Establishment of an implementation team that identifies areas of responsibility and supervises the work to be carried out in line with the needs,
- The need for coordination between the implementation team and platform partners,
- Continuous development of the implementation tools by the Digital Accessibility Committee and the implementation team,
- The need for regular updates to reflect new technological and structural developments and feedback from within the university,

- Promoting equal access for all users and the widespread use of digital content created to improve the online media experience were found to be the key elements of the solution for access to digital accessibility (Figure 2. Digital Accessibility Policy; Bulbul, O.,2025).

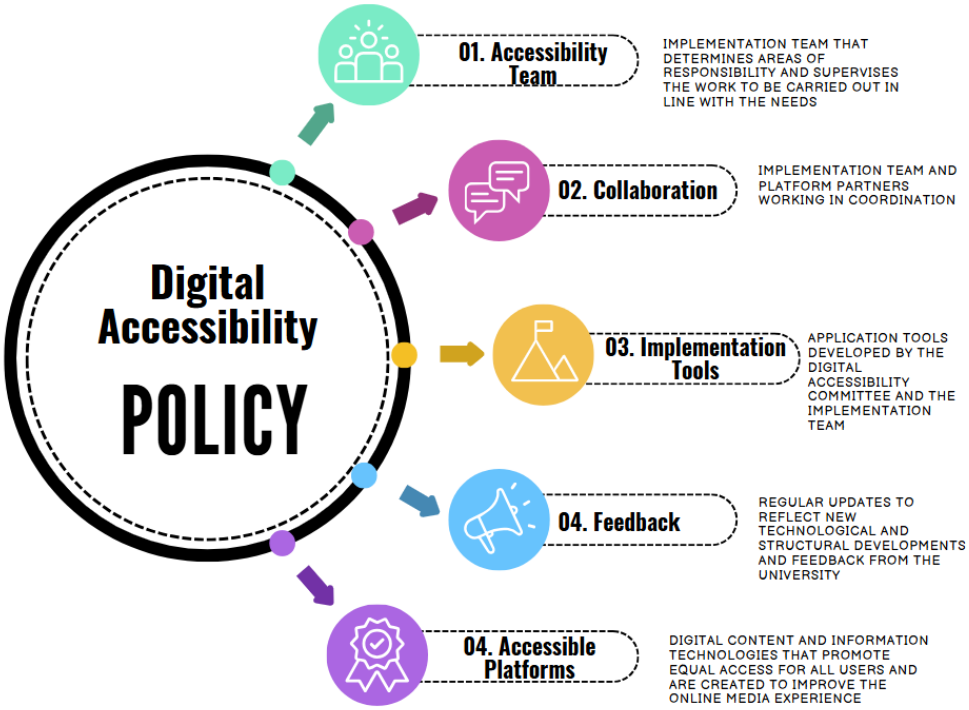

Figure 2. Digital Accessibility Policy (Bulbul, O., 2025).

There are many studies, showing that some aesthetic features (Mbipom, G., Harper, S.,2011) and visual design elements (Regan, B., 2004) that improve user experience directly interact with accessibility (Inal, Y., Guribye, F., Rajanen, D., Rajanen, M., & Rost, M. (2020).

Moreover, researches show that user experience is significantly related to perceived digital accessibility qualities (Aizpurua, A., Harper, S. & Vigo, M.,2016). It is seen that methodologies related to the user-centered digital web design approach affect accessibility (Yesilada, Y., Brajnik, G., Vigo, M., Harper, S., 2015).

Conclusion

The digital accessibility policy is established to promote equal access to digital content and information technologies for all users, with a priority on those with disabilities, and to improve the user experience of information technologies and digital/online media. This policy means that a disabled individual has the opportunity to access the same information, interact with the same people and benefit from the same services as a non-disabled individual in an equal manner and with the same ease of use.

It has been determined through the examples examined that the accessibility policy to be determined and operationalized in universities is not only a set of rules consisting of design guidelines but also inclusive and accessible when it is supported by a human, that is, a user-oriented institutional structure. This study provides clues on the elements of an accessible and inclusive institutional structure.

Enhanced Efficiency of PLA-Based Membranes via Optimizing Coagulation Bath Temperature

Rana Memarzadeh[a], Vahid Vatanpour[b], Mohhamadreza Nofar[a]

[a] Istanbul Technical University, Polymer Science and Technology Program, Türkiye
[b] Istanbul Technical University, Environmental Engineering Program, Türkiye
orumieh23@itu.edu

Keywords: Polylactide (PLA), Membrane Production, Coagulation Bath Temperature, Phase Inversion, Permeability, Porosity.

Porous membrane technology has garnered significant attention in the fields of separation because of its extraordinary contributions to green chemistry and sustainable development. The porous membranes fabricated from polylactic acid (PLA) possess numerous advantages, including high permeability, biodegradability, and excellent biocompatibility. As a result, they exhibit promising prospects for various applications, such as water purification. Therefore, studies on the fabrication of PLA- based membranes, have begun to attract much attention in world science.

Permeability, dye rejection, and mechanical properties characterized the selected membranes. The results indicate that increased coagulation bath temperatures provide higher pore size and porosity with enhanced permeability but reduced mechanical strength. Lower temperatures provided more closed structures with reduced permeability. These results provide a deep insight into process-structure-property relationships in the production of PLA membranes, which are valuable guidelines for optimizing membrane performance in different applications.

Aim

Water purification is a critical global challenge, driving the need for advanced membrane technologies that are efficient, sustainable, and environmentally friendly. Conventional membranes, typically made from petroleum-derived, non-degradable synthetic polymers like polyether sulfone (PES) and polysulfone (PSf), offer robust performance but suffer from poor biocompatibility and significant environmental drawbacks due to disposal issues(L. Zhu et al., 2015) . In response, there is growing interest in developing membranes from biobased and biodegradable materials. Poly (lactic acid) (PLA) has emerged as a promising candidate for membrane fabrication, owing to its stable crystallization for porosity formation, excellent mechanical strength, thermal resistance, and renewable, biodegradable nature(Gao et al., 2014, 2015; Xiong et al., 2016; L. J. Zhu et al., 2015) . Additionally, cellulose nanocrystals (CNCs) have garnered attention as membrane modification materials for water treatment due to their abundant, sustainable, and biodegradable properties, coupled with high strength, large surface area, and functional chemical groups that enhance porosity, hydrophilicity, permeability, tensile strength, and antifouling performance(Bai et al., 2022). To further enhance membrane functionality techniques such as blending, surface coating or grafting, and interfacial polymerization are used Mixed matrix membranes (MMMs) incorporate nanomaterials into polymer matrices through blending or coating, followed by phase inversion, to create ultrafiltration membranes with superior physicochemical properties, including increased hydrophilicity, electronegativity, and mechanical strength, as well as enhanced permeability and foulant rejection(L. Zhu et al., 2015) . This work explores the potential of PLA-based membranes, NC modifications, and MMM fabrication as sustainable solutions for advancing water purification technologies.

This research attempts to estimate improving the sustainability of membrane manufacturing to produce biocompatible membranes by replacing synthetic polymers with bio-based polymers by using organic nanomaterials and employing environmentally friendly membrane fabrication methods like phase inversion casting while minimizing waste generation and energy consumption. The phase inversion process is a common membrane preparation method that is extremely sensitive to the coagulation bath conditions, and temperature is one of the key parameters in controlling the morphology and performance of membranes(Pabby et al., 2023) . This

study investigates how coagulation bath temperature affects the structure and functionality of PLA-based membranes. The technique of non-solvent induced phase separation (NIPS) fabricated membranes at various coagulation bath temperatures.

Material and Method

3.1 Materials

Polylactic acid (Ingeo 4060D) from Nature Works LLC (Plymouth, MN, USA), Spray-dried Crystalline nanocelluloses CNCs were provided by celluForce (Montreal,Canada), Dimethyl sulfoxide (DMSO), Polyvinylpyrrolidone (PVP, Mn = 4000), reactive red 120 (RR120, Mw = 1136.3 g/mol), reactive black 5 (RB5, Mw = 991.8 g/mol), and bovine serum albumin (BSA) were gained from Sigma-Aldrich.

3.2 Preparation of Membrane

Mixed matrix membranes were prepared by using Phase inversion methods containing First, PVP (1.0 wt%) was mixed with DMSO as a solvent and stirred for 30 min. Then different amounts of CNC (0.5, 1.0, and 2.0 wt%) were added to the above solution after the sonication of mixed solutions for dispersing the nanomaterials, after that, 18 wt% of PLA was dissolved in the prepared suspension and the obtained polymeric solution was stirred for 24 h. The degassing process was carried out by putting the polymeric solution in a heating oven for 3 h at 70 ℃ to remove any air bubbles from the solutions. The fabrication of membranes was done by pouring the degassed solution over the clean glasses with a thickness of 150 µm using an applicator and immersing it into a water bath at determined temperatures (10 °C,15 °C,20°C) to accomplish the phase inversion process. Eventually, the prepared membranes were kept distilled.

3.3 Characterization of the fabricated membranes

A dead-end filtration setup with four identical cells conjoined to a 20L reservoir was implemented for all filtration proficiency experiments. The performance of the membranes was assessed by an effective surface area of 19.63 cm^2. Before running the filtration tests, all the membranes were pre-compacted by passing the distilled water under the pressure of 0.2 MPa for 20 min. Then, the filtration of pure water was done for 60 min at an operating pressure of 0.1 MPa, and the first pure water flux (Jw_1) was obtained. In addition, the filtration of different organic solutions, including BSA protein (500 mg/L), RB5 dye (150 mg/L), and RR120 dye (150 mg/L) were carried out at the same pressure of 0.2 MPa. The permeated flux (J) of membranes was determined by using Eq. (1) (Gao et al., 2014):

$$J = \frac{V}{A \times t} \quad (1)$$

Here, A, V, and t are the effective area of membrane (m^2), the permeated solution volume (L), and the time of permeation (h), respectively., The BSA solution with the initial concentration of 500 mg/L was filtered for 60 min immediately after pure water filtration for evaluation of the antifouling property of the membranes, and its flux was recorded (J_p). In the following protein solution filtering, the fouled membranes were rinsed with pure water and immersed in distilled water for 20 min for the removal of the cake layer. Afterward, the membranes were placed in cells, and the second water flux (Jw_2) was recorded for 60 min at the same operational condition. Finally, FRR was calculated by using Jw_1 and Jw_2 based on Eq (2).

$$FRR(\%) = \left(\frac{Jw_2}{Jw_1}\right) \times 100 \quad (2)$$

The rejections of RB5 and RR120 were measured by Eq. (3):

$$R(\%) = \left(1 - \left(\frac{C_P}{C_f}\right)\right) \times 100 \quad (3)$$

Where the concentration of pollutant molecules in feed and permeate solutions are defined by C_p and C_f, respectively.

Findings

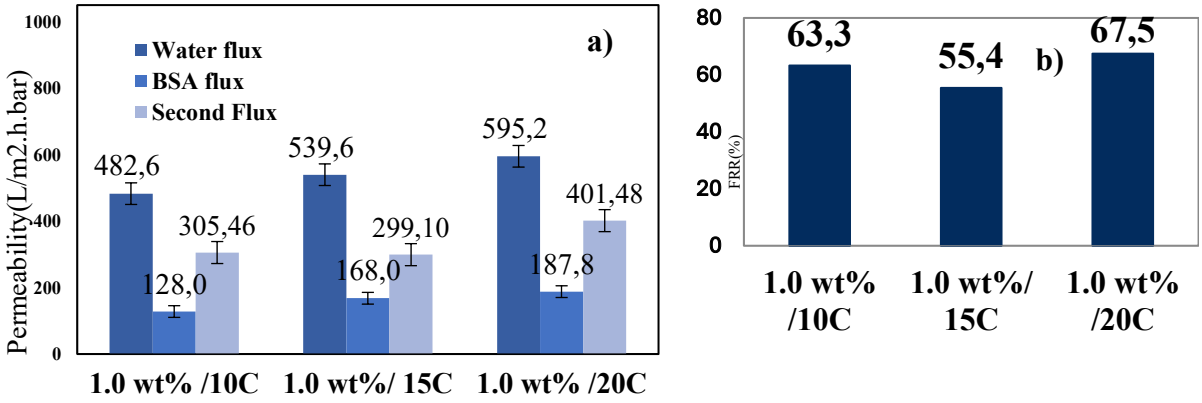
The wetting properties of membranes were evaluated by measuring the water contact angle as shown in Table 1. Membrane PLA-neat possessed high contact angles (top-surface with 77.981 ± 0.07°), which related to the intrinsic hydrophobic nature of PLA(Kian et al., 2022) . However, the addition CNCs to the membranes resulted in reduced contact angles indicating improved hydrophilicity on the surface of the membrane. These changes aligned well with the increase of pure water and Dye fluxes that penetrated through the membranes. Also, the permeability was observed to increase significantly for the 1.0 wt% CNC/20 C° membranes, which is likely due to the presence of macro void structures. Therefore, both surface wettability and pore structure were critical factors in permeability(Xiong et al., 2017).

Table 1. Contact angle, overall porosity, and tensile strength of the CNC/PLA nanoom posite membranes.

Membrane	Contact angle (°)	Overall Porosity (%)	Tensile Strength (Mpa)
1.0 wt% /10 ° C	67.01±0.17	62.20±0.86	32.98
1.0 wt% /15 ° C	67.09±0.05	67.11±1.6	27.05
1.0 wt% /20 ° C	67.01±0.35	68.05±2.9	25.1

The mechanical strength of membranes is an important characterization aspect since it is crucial in industrial applications as well as module configuration [10]. In this context, the temperature of the coagulation bath influences the rate of solvent-non solvent exchange and the solidification of the polymer solution. As reported in Table 1, the most significant enhancement is related to 0.1wt% CNC/10 °C the membrane with 32.98 MPa in comparison with 22.3 MPa of the bare membrane(Kian et al., 2021). This improvement can be attributed that lower temperatures can slow the process, allowing for more controlled mass transfer and potentially enhancing mechanical properties by reducing defects.

Membrane was evaluated for rejection of dye (Fig1.C). 0.1wt% CNC/10 °C revealed the highest removal for RB5 with 85.46% and RR120 with 96.62%. This was probably the small pore size. The highest permeate filtration through the membrane for 0.1wt% CNC/20 °C as compared to the others. Water flux penetration dramatically increased from 482.6 to 5952 L/m$^{2.}$.



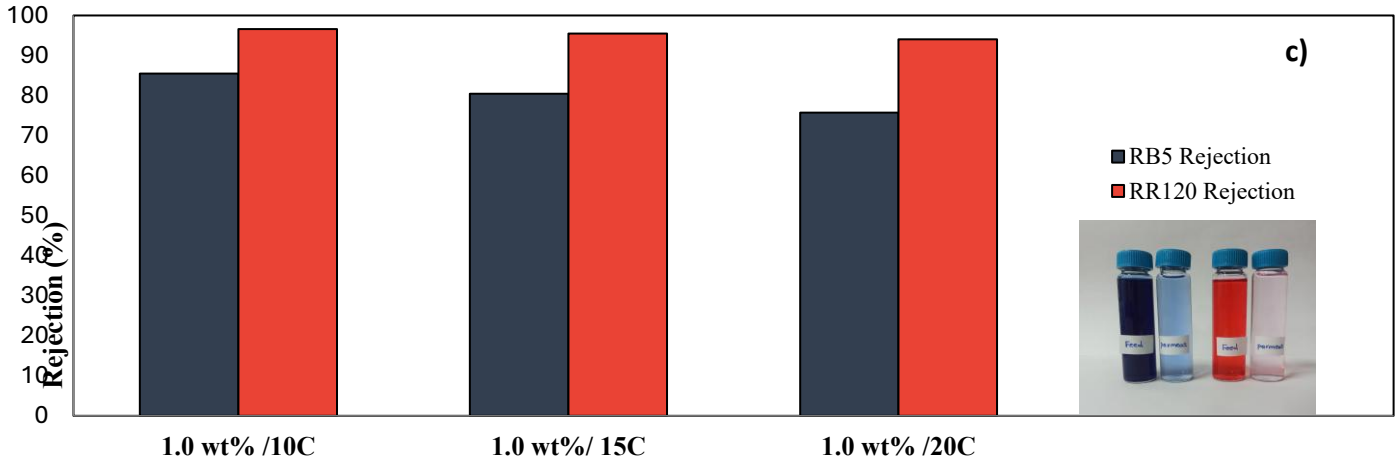


Figure 1. a) Pure water and BSA solution permeability of CNC nanocomposite membranes (average of at least four replications), b) Flux Recovery Ratio of the membranes C) Dye separation results of CNC nanocomposite membranes.

Conclusion

In this investigation, we prepared and characterized nanocellulose-enhanced PLA membranes, confirming their effectiveness systematically for water filtration application. The surface wettability was significantly improved for 0.1wt% CNC/20 °C membranes due to the presence of nanocellulose, which enhance hydrophilicity by introducing hydroxyl group on the membrane surface. In addition, 0.1 wt% CNC/10 °C membrane showed improvement in mechanical properties in terms of tensile strength, indicating their ability to withstand high pressure during water filtration. This was further evidenced by the filtration performance evaluation, which showed the 0.1wt% CNC/20 C° membranes presented the highest average water permeability of 595.2 L/m2h under the applied pressure 0.1MPa. As a result, these membranes are considered successful membranes that would be used for water filtration applications in the future.

Evaluating the Water Footprint of Textile Products: A Comparative Study of Wool and Cotton in Türkiye

Gizem Aydın[a], Börte Köse Mutlu[a]

[a]Istanbul Technical University, Department of Environmental Engineering, Environmental Sciences, Engineering and Management Programme, Türkiye
aydingi17@itu.edu.tr

Keywords: Water Footprint, Cotton Production, Wool Production, Textile Industry, Water Consumption.

Aim

Textile fibers are divided into two groups as natural fibers and chemical fibers, and natural fibers are classified as plant fibers, animal fibers and mineral fibers, forming the group obtained completely from nature. Cotton, which is a cellulose-based seed fiber, is a plant fiber, and fibers obtained from sheepskin (wool) are protein-based animal fibers [1]. The aim of this study is to calculate and evaluate the blue, green and grey water footprints of cotton production and wool production in Türkiye and to compare the water footprints of textile products with wool and cotton raw materials.

Introduction

The increasing global demand for freshwater, driven by population growth and industrial expansion, has intensified concerns over water scarcity and pollution. The concept of the water footprint, introduced by Hoekstra and Hung [2] and later refined by Chapagain and Hoekstra [3], offers a framework for assessing the freshwater required to produce goods and services [4]. The textile industry is one of the largest consumers of freshwater resources, with raw material production and industrial processing contributing significantly to global water consumption and pollution. Among textile fibers, cotton and wool stand out due to their widespread use and distinct environmental footprints [5]. Cotton, a cellulose-based seed fiber, demands extensive irrigation, resulting in a high blue water footprint. Conversely, wool, derived from sheep, has a considerable grey water footprint due to animal waste runoff and industrial processing. This study evaluates and compares the water footprints of cotton and wool production in Türkiye, highlighting their respective environmental impacts and the need for sustainable water management practices in the textile sector.

Material and Method

In this study, the concepts of water footprint and the calculation method are discussed within the framework defined by Hoekstra et al. [6]. Blue water footprint refers to the consumption of surface and groundwater resources during the production process of a product. This consumption occurs through evaporation of water, its transfer to another water source or its inclusion in the composition of the product. Green water footprint refers to the use of rainwater that does not turn into surface runoff. Grey water footprint is related to pollution and is defined as the amount of fresh water required to dilute a certain pollutant load. [6-7]

Data were collected from industry reports and agricultural statistics for Türkiye, supported by previous research. The analysis covers the entire production cycle, from raw material extraction to the initial stages of processing raw fibres into textiles, as these stages generate the highest water consumption and pollution levels. Cotton production data, including production volumes and land use, were obtained from the Turkish Ministry of Agriculture and Forestry. Wool production data, including sheep population and wool yields, were sourced from the Turkish Statistical Institute (TUIK) [8-9]. For pollutant limits, the Water Pollution Control Regulation approved on 31.12.2004 was taken as basis.

Agricultural and industrial processes were considered for the calculation of the cotton textile water footprint. Water use from precipitation was assessed to determine the contribution of cotton to the green water footprint in the agricultural process, irrigation water use was assessed to determine the contribution of cotton to the blue water

footprint, and chemical inputs from fertilisers used in cotton production were assessed to determine the contribution of cotton to the grey water footprint. In the industrial processing of cotton, bleaching, dyeing, printing and finishing processes were considered. The blue water footprint of the industrial process and the wastewater characterization of these processes were evaluated based on water consumption in these processes, and the grey water footprint was evaluated.

The water footprint of wool production was estimated according to the water consumption that must be met according to the feeding needs of the sheep, maintenance and drinking water, and the water demand spent in the industrial process of wool. The water footprint of wool production was estimated according to the water consumption that must be met according to the feeding needs of sheep, maintenance and drinking water, and the water demand spent in the industrial process of wool. The green water footprint due to grazing in the feeding needs of sheep, and the green, blue and grey water footprint required by the use of concentrated feed were taken into account. In addition, the drinking water required for sheep, maintenance, and cleaning purposes were considered within the scope of the blue water footprint. Within the scope of grey water footprint, the water footprint resulting from nutrition in sheep farming and the water footprint resulting from wastewater during the industrial process were discussed.

Findings

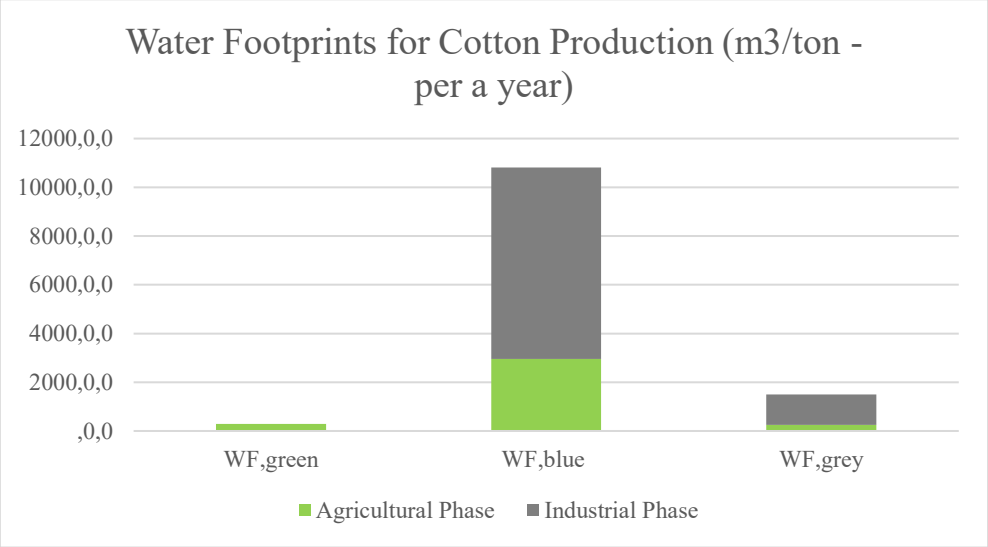

Figure 1. Water Footprints for Cotton Production.

The agricultural phase contributes to all types of water footprints, but stands out particularly in the blue water component, showing the critical impact of irrigation on cotton farming. Water-intensive processes during industrial processing (e.g. dyeing, printing, finishing), account for the largest share of total water use in the blue water footprint. The relatively low green water footprint suggests that cotton cultivation in the context studied relies more on artificial irrigation than on rainwater. The grey water footprint, although smaller in magnitude, is mainly due to the discharge of chemically contaminated wastewater from textile processes (e.g. bleaching and dyeing).

Figure 2. Water Footprints for Wool Production.

Green water footprint is the most dominant component in wool production, reaching nearly 29,000 m³/ton per year, and originates entirely from the animal husbandry phase. This reflects the substantial contribution of rain-fed grazing and feed crop cultivation to green water use. Blue water footprint remains relatively low (below 4,000 m³/ton), with minimal contribution from the industrial phase. The grey water footprint is caused by the fertilizer used in livestock grazing and the wastewater coming from processes in industrial stages.

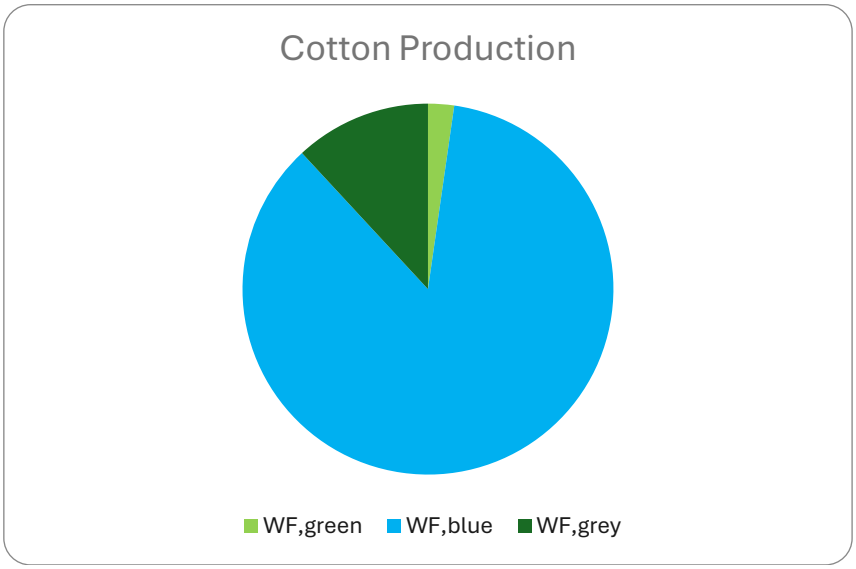

Figure 3. Distribution of Water Footprint Components: Green, Blue, and Grey Water in Cotton Production.

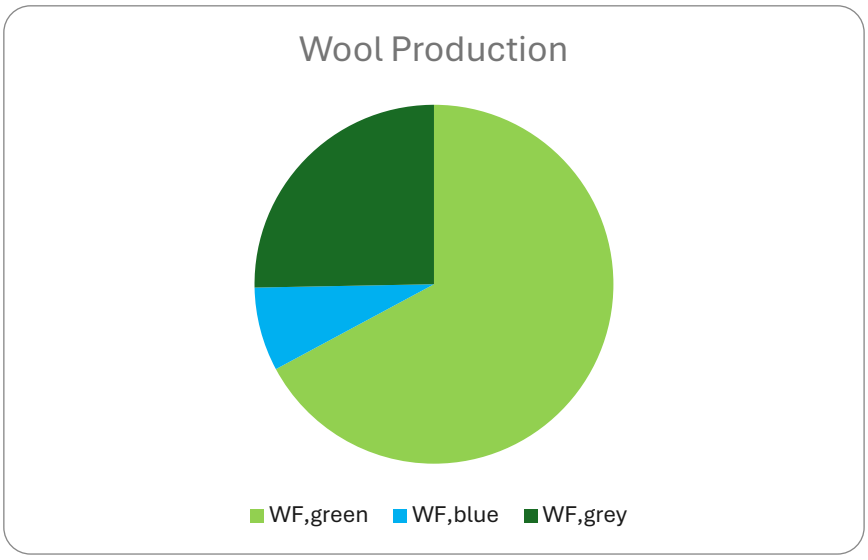

Figure 4. Distribution of Water Footprint Components: Green, Blue, and Grey Water in Wool Production.

The total water footprint of a cotton T-shirt is approximately 3 cubic meters, while that of a wool T-shirt is considerably higher, at around 11 cubic meters.

Conclusion

The study reveals that while cotton production places high pressure on freshwater resources (blue water footprint) due to irrigation, wool production makes a significant difference due to its high grey water footprint from wastewater discharge and animal waste stream. To reduce the water footprint of textile production, it is of utmost importance to implement sustainable irrigation in cotton farming and improve wastewater treatment in wool processing. These results highlight the critical role of raw material selection and process optimization in achieving water sustainability in the textile sector.

Statistical Analysis of Short Fiber Content and Tenacity Using Exponential Regression

Çağdaş Aslan[a], Selin Hanife Eryürük[b], Michael Will[c]

[a] Istanbul Technical University, Institute of Graduate Education, Textile Engineering Department, Textile Engineering, Ph.D. Program, Türkiye
[b] Istanbul Technical University, Textile Engineering Department, Textile Engineering, Türkiye
[c] Rieter AG, Textile Technology Department, Switzerland
aslancagd@itu.edu.tr

Keywords: Recycled Cotton Fibers, Recycled Ring Yarn, SFC (Short Fiber Content), Yarn Tenacity.

Aim

The increasing consumer demand for sustainable and recycled textiles has led to a rise in the use of recycled cotton fibers. Among recycling methods, mechanical recycling is one of the most effective and widely used for cotton textile materials. Mechanically recycled cotton fibers are utilized in various applications, ranging from fiber-to-fiber recycling for high-quality yarns to downcycling into insulation, filling, or non-woven textiles (Abagnato et al., 2024). From an economic perspective, fiber-to-fiber recycling is the most viable option for spinners, even though the fibers are shortened during processing. The fiber-to-fiber recycling process directly impacts fiber-to-yarn spinning technologies, influencing the choice of spinning methods based on fiber length, quality, and efficiency. For decades, the rotor yarn production process has been widely used in the recycled yarn spinning industry due to its efficiency and adaptability. Nevertheless, ring spinning remains the leading technology in yarn production, known for its superior yarn quality and versatility across various applications. Consequently, utilizing mechanically recycled cotton (rCO) in ring spinning technology is essential for the market. However, integrating mechanically recycled cotton (rCO) into the ring spinning process presents unique challenges. Mechanically recycled cotton fibers often have lower quality compared to virgin cotton fibers, in terms of higher neps, impurity (contaminants) and ratio of short fiber content due to its own natural structure and processing additional tearing processes.

A critical parameter in this context is the short fiber content (SFC) of recycled cotton fibers. A high SFC adversely affects drafting performance, increases yarn irregularities and imperfections, and leads to a higher rate of yarn breaks, reducing machine efficiency and overall production output (Thibodeaux et al., 2008). Majumdar discovered through the research that as the proportion of short fibers in cotton increases, there is a substantial rise in yarn unevenness. This unevenness occurs because of drafting waves forming between the front and back rollers during the spinning process (Majumdar, 2011). Another major concern is the decrease in yarn tensile strength, which can cause several production quality defects in the downstream processes as well.

This study investigates the correlation between yarn tenacity and varying recycled fiber content, which inherently leads to different SFC levels. Understanding this relationship will provide insights into optimizing fiber selection and processing parameters to improve yarn quality.

Material and Method

Post-industrial waste (PIW) recycled cotton fibers were used in this study. The mechanically recycled cotton fibers consisted of black fabric scraps and produced through the mechanically recycling tearing method. To investigate this correlation six combed ring spinning yarns were produced with different blend ratio of recycled cotton fibers.

The recycled and virgin cotton fibers were blended using Rieter UNIblend A81 ensuring precise mixing and blending. Rieter Mixing Bale Opener B3/4 for cotton and Rieter Mixing Bale Opener MBO B36 for recycled cotton fibers were used. The trial plan included different blending ratios for the combed yarns; Yarn Reference (100% CO), Yarn 72 (75% CO – 25% rCO), Yarn 55 L-M-H (50% CO – 50% rCO), and Yarn 27 (25% CO – 75% rCO). For the 50% CO – 50% rCO samples, three comber settings were applied to assess the impact of noil level:

L (low noil), M (medium noil) and H (high noil). The top comb penetration, the detaching distance, and the distance between nipper and circular comb were selected as parameters to see the impact of the comber setting on combed recycled yarn trials. The detailed experimental plan and combing parameters are presented in the Table 1. The fiber properties of the finisher draw frame slivers were analyzed using Uster AFIS, as this is the final stage of slivers' doubling and blending in the spinning process. To evaluate yarn tensile strength, combed recycled ring yarns were tested using Uster Tensojet 5 (measuring tensile strength in cN/tex).

Table 1. Experimental plan.

	Y10M	Y72M	Y55L	Y55M	Y55H	Y27M
Process	Combed	Combed	Combed	Combed	Combed	Combed
CO %	100	75	50	50	50	25
rCO %	0	25	50	50	50	75
Blends	CO	CO/rCO	CO/rCO	CO/rCO	CO/rCO	CO/rCO
Comber settings	M	M	L	M	H	M
Noil %	14.3	19.4	24.4	25.9	31.4	33.8
Nips/min	600	600	600	600	600	600
Top comb penetration	0.5	0.5	-	0.5	0.5	0.5
Nipper-circular comb	0.3	0.3	0.5	0.3	0.3	0.3
Detaching distance	7.0	7.0	6.5	7.0	8.0	7.0
Ne	30	30	30	30	30	30

Findings

To assess how blending ratio and noil level influence yarn strength, six combed ring yarn samples were analyzed. The recycling ratio was increased incrementally from 0% to 75%. A fully recycled yarn sample (100% rCO) could not be produced and tested due to insufficient fiber cohesion in the slivers. The main objective of this study is to focus and do deep research on impact of short fiber content of mechanically recycled cottons in recycled ring yarn spinning technology.

In this study, exponential regression analysis was used to investigate the relationship between short fiber content (SFC(n) %) of slivers and tenacity (cN/tex) in combed recycled ring yarns. An exponential model was chosen because fiber strength typically decreases exponentially as SFC(n) increases. The resulting model showed a strong correlation, with an R^2 value of 0.9861, indicating that 98.61% of the variability in SFC(n) is explained by tenacity. As shown in Figure 1, yarn tenacity decreases as the proportion of recycled cotton increases.

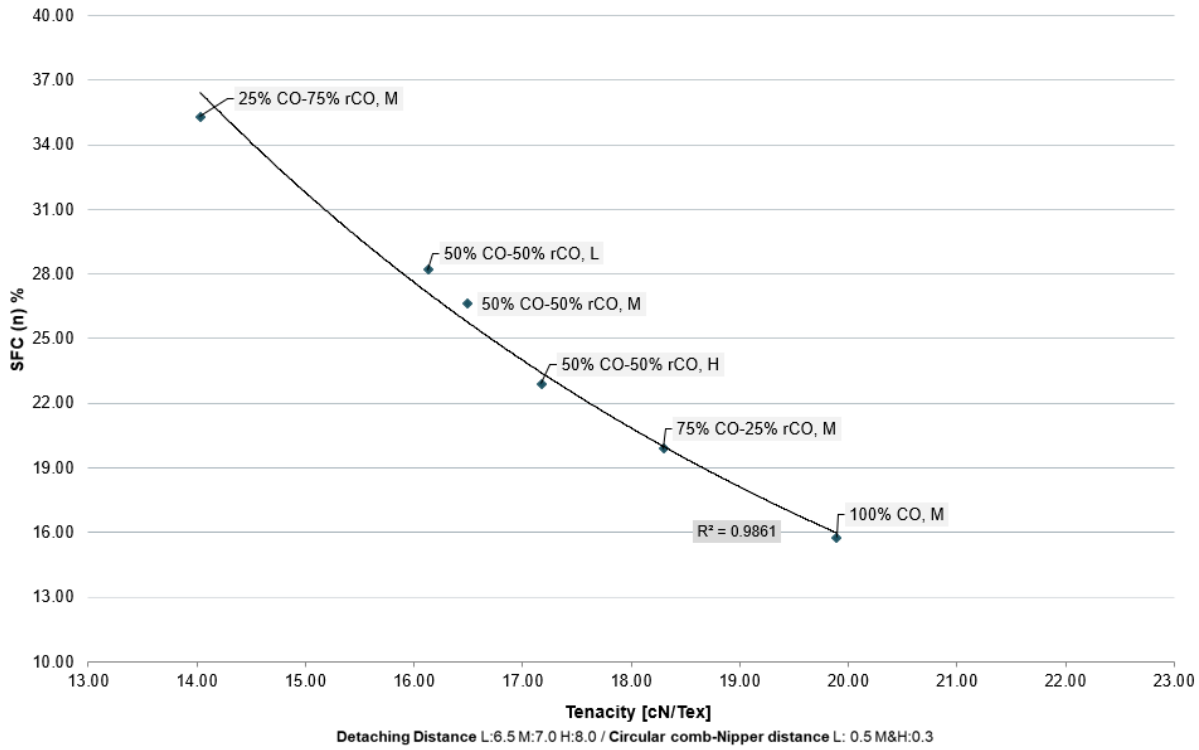

Figure 1. Relation between tenacity of ring yarn and SFC (n) of finisher draw frame slivers.

To further validate the relationship, Pearson correlation analysis was considered, but due to the non-linear trend, exponential regression provided a better fit. This approach allows for a more accurate prediction of fiber properties based on blend composition. Higher SFC was associated with increased yarn unevenness and imperfections, negatively impacting elongation and tenacity. The findings suggest that controlling short fiber content in recycled cotton blends is crucial for maintaining yarn performance and minimizing quality defects.

Conclusion

This study highlights the significant impact of short fiber content of mechanically recycled cotton on the tensile strength of combed recycled ring yarns. By optimizing fiber processing and blending techniques, the mechanical performance of recycled yarns can be improved, promoting more sustainable textile production. Further research is ongoing to explore the role of spinning parameters, the implementation of new techniques, and advanced fiber preparation methods in minimizing the negative effects of short fiber content of mechanically recycled cotton.

Real Time Production Management in Garment Manufacturing Using IoT-Based Process Monitoring Devices (PMDs)

Bülent Koç[a], Selin Hanife Eryürük[a]

[a] Istanbul Technical University, Faculty of Textile Technologies and Design, Textile Engineering Department, Türkiye
kocbul18@itu.edu.tr

Keywords: Garment Manufacturing, Digitalization, Process Monitoring Devices (PMDs), Real-time Production Management, Operational Efficiency.

Aim

The ready-made garment (RMG) industry is becoming increasingly competitive due to its dynamic structure, rapidly changing customer demands, and global market integration (Noor et al., 2021). Traditional production management approaches, which rely on manual data tracking, periodic observations, and managerial interventions, are no longer sufficient in today's highly digitalized manufacturing environment. Managing production with outdated and inefficient methods hampers competitiveness and long-term sustainability, leading to sub-optimal resource utilization, high error rates, and a misalignment between operator skills and assigned tasks.

To overcome the limitations of traditional monitoring methods, Process Monitoring Devices (PMDs) provide a data-driven solution, facilitating real-time monitoring and optimization of manufacturing processes (Bonada et al.,2020; Giusti et al., 2018). Unlike conventional tools, PMDs leverage IoT technology and edge computing to rapidly process and interpret raw data, transforming it into actionable insights. These systems autonomously collect key production metrics, including output summaries, downtime analysis, and quality performance, mitigating inefficiencies associated with manual data tracking. Additionally, Application Programming Interface (API) integration enables seamless interaction with Enterprise Resource Planning (ERP), Manufacturing Execution System (MES), and other digital platforms, optimizing inventory management, equipment utilization, production planning, and overall operational efficiency (Guo et al., 2013; Garg, 2028).

Material and Method

This study focuses on the implementation of Process Monitoring Devices (PMDs) in sewing production to enable real-time monitoring, analysis, and data-driven production management. The primary objective is to evaluate the impact of PMD integration on performance, availability, quality improvement, and the control of production costs and other key inputs. Within this framework, the ITEX PMD (Figure 1), developed by ITM Tech Soft, has been selected as the sample application. The device, integrated into sewing machines, utilizes real-time data acquisition through current and optical sensors to analyze operator performance, machine efficiency, and downtime. This system facilitates continuous production monitoring, enabling precise decision-making for process optimization and operational efficiency in garment manufacturing.

Figure 1. ITEX PMD Iot-Based Process Monitoring Device.

Introduction to the PMD Device and Function Keys:

The PMD features a user-friendly interface with function keys designed for operator use. These keys allow operators to perform basic tasks such as assigning themselves to a machine, starting, and ending tasks. Additionally, the device's screen provides operators with real-time information (e.g., completed work count, cycle time, etc.). The PMD device uses RFID cards to match operators with machines, enabling real-time tracking of which operator is working on which machine and operation.

Installation of the PMD Device on Sewing Machines and Data Generation:

The PMD can be easily mounted on sewing machines using Power I/O devices and PMD Port mechanisms. This installation process is compatible with semi-automatic, automatic, and non-automatic machines. The PMD device collects data through current sensors and optical sensors. In thread-cutting machines, the current sensor detects changes in the thread-cutting motor's current to determine work counts. In non-thread-cutting machines, work counts and operation times are measured using current changes in the machine motor and optical sensors.

Figure 2 illustrates the connection diagram between the sewing machine, Power I/O device, and PMD device. This system is designed to ensure seamless data flow and enhance the traceability of production processes. PMD devices provide flexibility by being compatible with various machine types and models, minimizing the need for frequent hardware upgrades and offering a sustainable, adaptable production infrastructure. As a result, monitoring and control processes on the sewing line can be optimized without any loss of efficiency.

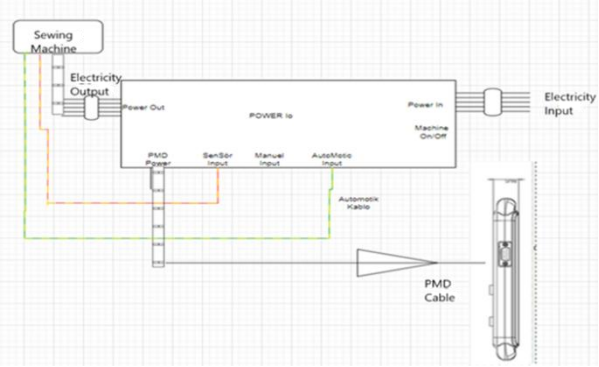

Figure 2. Connection Diagram between Sewing Machine, Power I/O ans ITEX PMD.

Data Storage and Transmission Mechanism:

As shown in the figure 3, ITEX PMDs and other data sources connect to the local server via wireless access points. Power over Ethernet (PoE) adapters provide power during data transmission to network equipment, supporting the efficient operation of the infrastructure. The local server collects, stores, and analyzes all production data, ensuring secure data processing and storage within the enterprise, reducing external dependencies.

The relational database created on the local server organizes data from PMD devices and ERP systems, making it available for line balancing and advanced analysis. As depicted, data flow is secured through a firewall, preventing unauthorized access during data transfer to the server. Data distribution via switches provides access to different departments, ensuring integrated data flow across the enterprise.

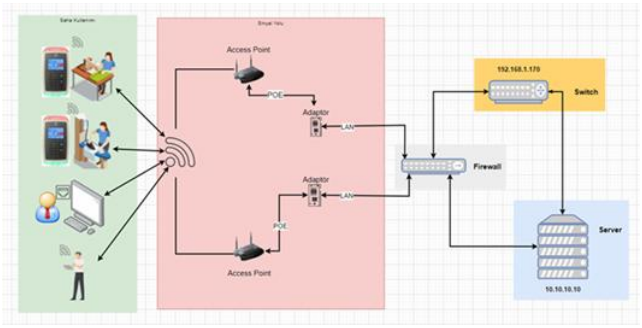

Figure 3. Integration of ITEX PMD with Central Database.

Figure 4 illustrates the seamless integration of ITEX PMDs, ITEX Soft, and the Web-Based Line Balancing Module, showcasing how real-time data translates into optimized workflows.

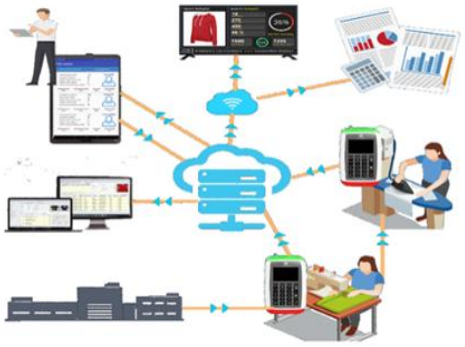

Figure 4. ITEX PMD Data Integration Eco System.

The ITEX ecosystem represents a transformative leap in garment manufacturing, combining real-time monitoring, predictive analytics, and dynamic workload balancing with lean manufacturing principles. By leveraging this synergy, the system achieves enhanced productivity, reduced waste, and sustainable operational excellence.

Operator and Machine Performance Monitoring:

The PMD monitors downtime due to operator- and factory-related delays, including breaks or operational changes, as well as operational interruptions such as machine failures or material shortages. Operators handling multiple tasks can transition between machines by removing their RFID card from one machine and scanning it on another. This system ensures that each operator's assigned tasks, completed work counts, cycle times, and performance levels are continuously tracked in real time and historically. Real-time production management dashboards, as illustrated in Figure 5, offer live data on various production metrics, helping shop floor managers make data-driven decisions quickly.

Figure 5. Examle of Real-time Production Management Dashbords.

Production Efficiency and Quality Analysis:

The Process Monitoring Device (PMD) system generates comprehensive reports that evaluate sewing line availability, performance, and efficiency. These reports offer detailed insights into the causes of downtime, including factory-level factors, and provide a robust analysis of operational efficiency across lines (Marariu et al., 2020). Table 1 presents the sewing line availability, performance, and efficiency metrics recorded over the past six months in a garment manufacturing facility.

Table 1. Example of Sewing Line Report.

Factory	Production Output Efficiency	Productivity	Performance	Availability	Production Quantity	Factory Lost Time	Factory Lost Time %	Employee Lost Time	Employee Lost Time%

In addition to efficiency monitoring, the PMD system also tracks repair and defect incidents for each production line. These are categorized using root cause analysis into machine-related problems, operator errors, stains, print and embroidery issues, or fabric-related defects. This classification enables the identification of recurring quality issues and supports the reduction of repair and rework rates while improving first-pass yield. As a result, the data derived from these analyses contributes significantly to enhancing Overall Equipment Effectiveness (OEE) (Xu et al., 2020). Table 2 summarizes the repair, rework, and defect counts observed over the same period, along with their classified causes.

Table 2. Repair, Rework and Defect Analysis of Sewing Lines.

Findings

ITEX PMD plays a key role in tracking machine malfunctions and downtime in garment production. The system monitors machine performance in real time, identifying disruptions and downtime causes, such as mechanical breakdowns or system errors, and logs the duration of these issues. It also tracks response times and resolution durations, helping minimize delays. By categorizing defects by their root causes, the system supports targeted interventions that improve efficiency and first-pass yield rates.

Table 3 shows machine malfunctions and associated downtime in minutes, while Figure 6 visually presents the causes and durations of these issues, offering insights into areas for improvement.

Table 3. Machine Malfunction and Downtime Analysis.

Group Type	Number of Faults	Fault Detection Time (minutes)	Fault Intervention Time (minutes)	Fault Completion Time (minutes)	Total Fault Downtime (minutes)	Average Downtime per Fault (minutes)	Maximum Intervention Time (minutes)
Needle Breakage	27	167	93	555	921	2	16
Needle Malfunction	860	327	193	1697	2432	2	19
Thread Breakage	58	575	122	483	1427	20	15
Technical Failure	373	2137	550	1200	4923	13	40
Stitch Skipping	91	502	189	428	1280	14	30

Feed Dog Adjustment	19	59	49	70	193	10	36
Needle Fracture	77	33	9	122	186	2	2
Machine Adjustment	293	1795	399	871	3694	12	32

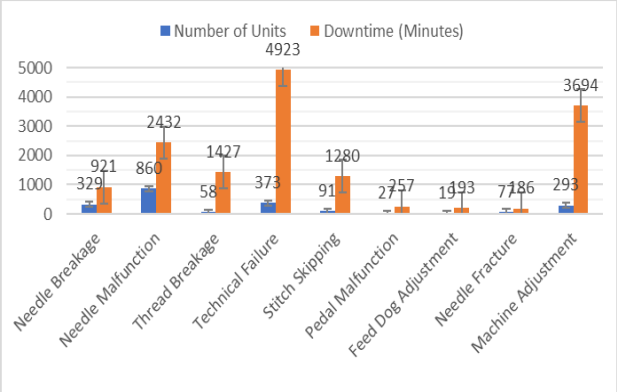

Figure 6. Distribution of Machine Malfunction Causes and Breakdown Durations.

With the ITEX PMD system, real-time traceability of sewing lines is achieved, allowing both the overall facility and individual sewing lines to be monitored for availability, performance, and sewing line efficiency. Reports generated by the system provide valuable insights into machine malfunctions, including causes, response times, resolution times, and total downtime, offering a comprehensive view of maintenance management. This data-driven approach enables better decision-making, contributing to the optimization of operational efficiency. The integration of digital lean management principles ensures that production processes are not only more transparent but also more effective, ultimately enhancing the operational performance of garment manufacturing facilities (Shahin et al., 2020).

In addition to real-time production tracking, the integration of PMD systems provides a significant contribution to digital line balancing processes. By continuously collecting performance data such as cycle times, work counts, and operator-machine interactions, PMDs enable dynamic line balancing decisions to be made in alignment with actual shop-floor conditions. These data-driven insights can be integrated with AI-powered balancing tools to automatically identify line bottlenecks, reallocate tasks based on operator skill profiles, and propose optimal operator replacements in cases of absenteeism. Moreover, by monitoring low-efficiency points in advance, the system supports proactive training planning and capacity forecasting. In this context, PMD devices serve not only as real-time monitoring tools but also as strategic enablers of agile and adaptive production planning, improving

productivity, responsiveness, and resource utilization on the sewing floor. This alignment between IoT-based monitoring and intelligent planning platforms strengthens the overall digital transformation framework in garment manufacturing.

Conclusion

Shop Floor Control devices, such as ITEX PMD, have the potential to transform factory operations, boosting overall efficiency by up to 10-30%, and significantly reducing the time burden on management and work-study officers (Koç and Eryürük, 2024). One of its standout features is its ability to maintain seamless production flow even in challenging scenarios, such as operator absenteeism. By automatically recommending replacement operators, PMD ensures that production remains on track without compromising efficiency, saving valuable time and resources for manufacturing plants (Martinez et al., 2020).

Moreover, the data-driven analytics provided by PMD facilitate the early detection of bottlenecks and enable timely interventions, effectively reducing downtime and improving line balance. This proactive approach can result in output gains of up to 30%, depending on the production context. Figure 7 illustrates the primary benefits of PMDs in the production environment.

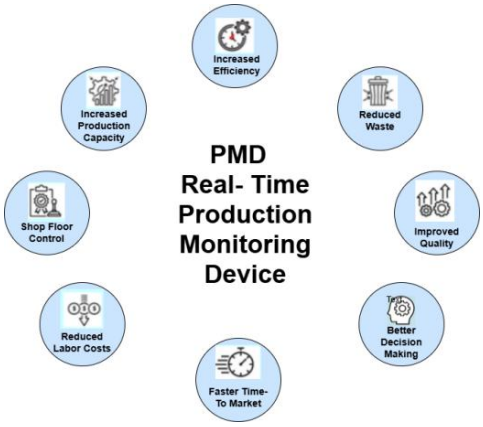

Figure 7. PMD Real-Time Production Monitoring Benefits.

In conclusion, the integration of PMD technologies represents a pivotal advancement in the digital transformation of the apparel industry. These systems contribute to enhanced operational efficiency, cost reduction, and improved sustainability by enabling data-driven decision-making. As global competition and sustainability expectations intensify, real-time monitoring tools such as ITEX PMD equip garment manufacturers with the agility and insight required to remain resilient and future-ready (Koç, 2023).

TRADITIONAL DANCES

Dance, Traditional Dances in Terms of its Role in İnterdisciplinary İnteraction in Performance Areas

The Reinterpreting Choreographic Art Through Traditional Dances in Turkey: The Shaman Dance '7EDI' Project

Gulce Su Gumus[a], Eyüp Uzunkaya[a]

[a] Istanbul Technical University, Performing Arts Dept., Traditional Dances, Turkey
gumusg21@itu.edu.tr

Keywords: 7edi Project, Choreography, Cultural Heritage, Shaman Dance Theatre, Traditional Dances.

Aim

Traditional dances are significant forms of expression that embody the cultural heritage of societies. The processes of modernization and globalization have transformed the stage representations of these dances, incorporating modern choreography techniques and adding new dimensions to their performance. However, there is a limited number of studies in the literature examining how traditional dances in Turkey are reinterpreted through the art of choreography. The primary aim of this study is to address this gap by analyzing how traditional dances are reconstructed on stage through choreography.

Accordingly, this study focuses on the "7EDİ" project staged by Shaman Dance Theater. While investigating the fusion of traditional and contemporary dance within the project, it also explores how traditional dances are reinterpreted in the present day. The "7EDİ" performance is thematically structured around Turkey's seven regions and the seven hills of Istanbul, drawing inspiration from folk dances and music to create a contemporary narrative. By bringing together various cultural elements on stage, the performance functions as a cultural compilation, highlighting the ways in which staged works serve as curated representations of traditional heritage.

The central research question of this study examines the techniques employed by the art of choreography in adapting traditional dances for the stage and the role of this process in both preserving and reproducing Turkey's cultural dance heritage. Additionally, the study investigates whether staged performances function solely as artistic expressions or also serve as cultural compilations. Ultimately, this research aims to reveal the role of choreography in the preservation and sustainability of cultural heritage.

Material and Method

This study adopts qualitative research methods, utilizing both literature review and fieldwork-based data collection techniques. To understand how traditional dances in Turkey are integrated into contemporary performing arts, academic sources, books, and articles in the fields of dance and choreography were first examined. Research focusing on the fusion of folk dances with modern choreography provided the foundation for a broader evaluation of the artistic vision of the *"7EDİ"* project. This theoretical framework established the conceptual basis of the study.

In the applied section of the research, in-depth interviews were conducted with the creative team of Shaman Dance Theater. One- to- one interviews were held with the project's choreographers, executive team, and coordinators. Through these discussions, comprehensive insights were gained into the creative process of *"7EDİ"*, staging decisions, choreographic methods, and the ways in which traditional dance motifs were adapted to a contemporary stage language.

Additionally, visual analyses of the *"7EDİ"* performance were carried out. These analyses, based on performance recordings, examined the movement language of the dance, stage design, use of music, and narrative structure. By assessing concrete examples, this approach provided an opportunity to evaluate how traditional dance elements were integrated and transformed through contemporary choreography.

Through this combination of methods, the study adopts both a theoretical and practical analytical approach. The choreographic structure of the *"7EDİ"* project is examined from both an internal perspective (through interviews with artists and the creative team) and an external perspective (through visual analyses and literature review), ensuring a comprehensive evaluation.

Furthermore, the fact that the project's choreographers are Turkish artists highlights the influence of local artistic

perspectives on the choreographic process. This aspect contributes not only to the preservation of cultural heritage but also to the development of a distinctive form of expression in contemporary dance production. Ultimately, this study offers a significant perspective on how dance as an art form is represented in both national and international contexts within Turkey.

Findings

The findings of this study reveal how the *"7EDİ"* project establishes a relationship between traditional dances and contemporary choreography. The interviews conducted and analyses performed within the scope of the research provide detailed insights into the project's choreographic methods, staging approach, and musical structure. In this context, it has been observed that *"7EDİ"* creates a unique synthesis between traditional and modern elements.

The study identifies that folk dances from Turkey's seven regions have been restructured using modern choreography techniques. According to the choreographers, regional dance motifs have been preserved; however, during the staging process, these figures were stylized and integrated into a contemporary expressive language. Similarly, the musical structure consists entirely of original compositions, with each section's music specifically composed from scratch by Oğuzhan Balcı. The characteristic structures of local music were reinterpreted using modern orchestration techniques; rather than directly replicating folk melodies, they were reconstructed. These approaches demonstrate that the work harmonizes traditional and modern elements in an original manner, functioning as a cultural compilation both choreographically and musically.

Additionally, it was found that the choreographic process allowed dancers individual expressive space, enabling movements to be reshaped through their interpretations. This finding indicates that choreography extends beyond a purely technical arrangement; rather, it is an evolving creative process enriched by the dancers' artistic contributions. Overall, the *"7EDİ"* project successfully integrates traditional and modern dance elements, demonstrating that staged performances can function both as cultural compilations and as effective tools for transmitting cultural memory through the medium of performance.

Conclusion

This study has examined how the *"7EDİ"* project integrates traditional Turkish dances with contemporary choreography and whether the staged performances function as cultural compilations. The analyses conducted and the interviews with the project team reveal that *"7EDİ"* presents a unique and cohesive synthesis in terms of choreography, music, and stage design.

One of the most significant findings of this study is that traditional dances in contemporary performing arts should not be viewed merely as representations of the past but as dynamic and adaptable art forms. The choreographers reinterpreted dance motifs from various regions using modern staging techniques, allowing dancers to contribute their individual expressive interpretations. This approach ensured that the choreographic process was not a static structure but rather an interactive and creative formation. It also demonstrates that choreography extends beyond an aesthetic discipline to serve as a cultural and artistic medium of expression.

Additionally, choreography undergoes a historical evolution, and interviews with past and present artists provide a bridge between tradition and contemporary artistic practice. This perspective enables an examination of how choreography in Turkey has adapted to historical and societal transformations. The *"7EDİ"* project can thus be seen as a contemporary reflection of this historical continuity.

From a musical perspective, the project was composed entirely of original pieces, deliberately avoiding the direct use of traditional folk melodies. Composer Oğuzhan Balcı reinterpreted the musical characteristics of different regions of Turkey through modern orchestration techniques, establishing a strong network of interaction between music and dance. As a result, the *"7EDİ"* project is not only a choreographic endeavor but also a cultural reproduction process from a musical standpoint.

Another key finding is that staged performances can serve as cultural compilations. *"7EDİ"* brings together traditional dance and musical elements from various regions of Turkey and reinterprets them within a contemporary artistic context. This process highlights that choreography is not merely a tool for aesthetic expression but also plays an active role in preserving, transforming, and transmitting cultural heritage to future

generations. Media coverage supports this view, describing *"7EDİ"* as an innovative performance that brings Istanbul's historical and cultural identity to the stage. Critics and artistic communities have emphasized that the project successfully bridges tradition and modernity and possesses the qualities necessary for international festival participation.

In conclusion, this study has demonstrated how traditional dances can be adapted to modern performing arts through choreography and has provided significant contributions to the sustainability of cultural heritage. Projects like *"7EDİ"* serve as models for preserving, developing, and representing cultural heritage through artistic expression, while also holding the potential to inspire similar projects in the future.

Climate Change Adaptation in Urban Heritage Sites: The Case Of Istanbul Historic Peninsula

Tuğçe Türk[a], Turgay Kerem Koramaz[b]

[a] Istanbul Technical University, Graduate School, Urban Planning Graduate Program, Türkiye
[b] Istanbul Technical University Faculty of Architecture, Department of Urban and Regional Planning, Türkiye
turkt16@itu.edu.tr

Keywords: Climate Resilient Heritage, Climate-Friendly Heritage Conservation, Conservation Planning in Istanbul Urban Heritage Sites, Heritage Planning, Vulnerability Index.

Aim

The adverse impacts of global warming, which are happening faster than predicted, are beyond scientific discussion. Cities, where more than half of the world's population lives and where approximately 70% of the carbon footprint is created, are also the areas where the effects of climate change are felt the most and will be affected the most, considering that approximately 9.7 billion people will be sheltering by 2050 (UN, 2009). Since the 20th century, with the impact of accelerated urbanization, the implementation of adaptation policies to mitigate the current and future impacts of climate change and the development of prevention policies that reduce carbon emissions in all urban sectors to keep global warming under control have become the main problems and goals of urban governments, which has triggered interest in urban climate research that underpins current planning approaches. On the other hand, it is observed that urban climate risk is not sufficiently addressed in the planning processes of historic city centers, which are more vulnerable to the effects of climate change compared to modern cities and struggle with many more planning problems. Although many studies have been conducted to examine the issues raised in the planning of urban climate and urban heritage areas, respectively, studies aiming to increase the climate resilience of historic cities through conservation planning tools are not prominent enough (Baillie & Bayne, 2019; Kaushal et al., 2015; Riedinger-Whitmore, 2016; Vitkova et al., 2017; Wichansky et al., 2008). However, establishing a link between combating climate change and protecting historic cities is an issue that should be emphasized in the planning literature. Because the planning and management of historic cities are based on the complex interaction between climatic, social, economic, and cultural layers (Romero-Lankao et al., 2018), the climate-friendly historic city model contributes to the climate-sensitive design and sustainable urban development strategies through the use of traditional knowledge and techniques in the climate adaptation process. On the other hand, since the planning of cultural heritage areas that need to be protected requires an integrated and multidisciplinary approach that includes urban climate information, conducting climate impacts and vulnerability assessments in these areas strengthens the sustainability of conservation planning.

In this context, this study examines the strategies applied for climate-compatible planning of historic cities within the framework of conservation planning discipline. Because the information obtained in extensive research on climate-compatible planning of modern urban areas may not be sensitive enough to urban heritage areas (Bigio, 2014). When the literature is examined, it is seen that urban climate research is focused on environmental and ecological sciences, and studies on climate-oriented planning of historical urban areas are insufficient. In this respect, in order to protect cultural heritage sites and increase urban climate resilience, it is necessary to identify the main challenges faced, examine how vulnerable these areas are, and utilize the knowledge of heritage for climate-compatible planning. This study aims to raise academic awareness about the importance of incorporating traditional urban design practices into climate management by examining urban climate issues in conservation planning for cultural heritage sites. This focus aligns with the historic urban landscape (HUL) approach to managing and protecting urban landscapes proposed by UNESCO in 2011, which was developed to help historic cities cope with emerging climate challenges and inspire future urban development. The study hypothesizes that districts with urban heritage sites in Istanbul are more vulnerable to the climate crisis than other districts. In this context, when a climate change vulnerability index is created for the districts of Istanbul, it is investigated where

the most vulnerable cultural heritage sites are, the capacity of planning approaches in Istanbul's cultural heritage sites to accommodate other ecological attitudes such as adaptation to climate change, and how Istanbul's cultural heritage sites can be adapted to the climate crisis.
The main objective of the study is to assess the vulnerability of Istanbul's urban heritage sites to climate change and develop conservation planning tools to mitigate these impacts. The research establishes a quantitative framework based on district-level vulnerability indicators.

Material and Method

The study uses both qualitative and quantitative methods. Air quality and temperature measurements, carbon emission data, historical climate events and disasters (frequency of fires and floods), planning data (population, population development trends, building density, permeable surface ratio, water-energy-waste consumption, large land use data), protected area boundaries, Geographic Information Systems (GIS) and climate performance measurement models, as well as field surveys, questionnaires, and focus group discussions are used.
The study's methodology can be summarized in five stages (See Figure 1 Methodology Flowchart).

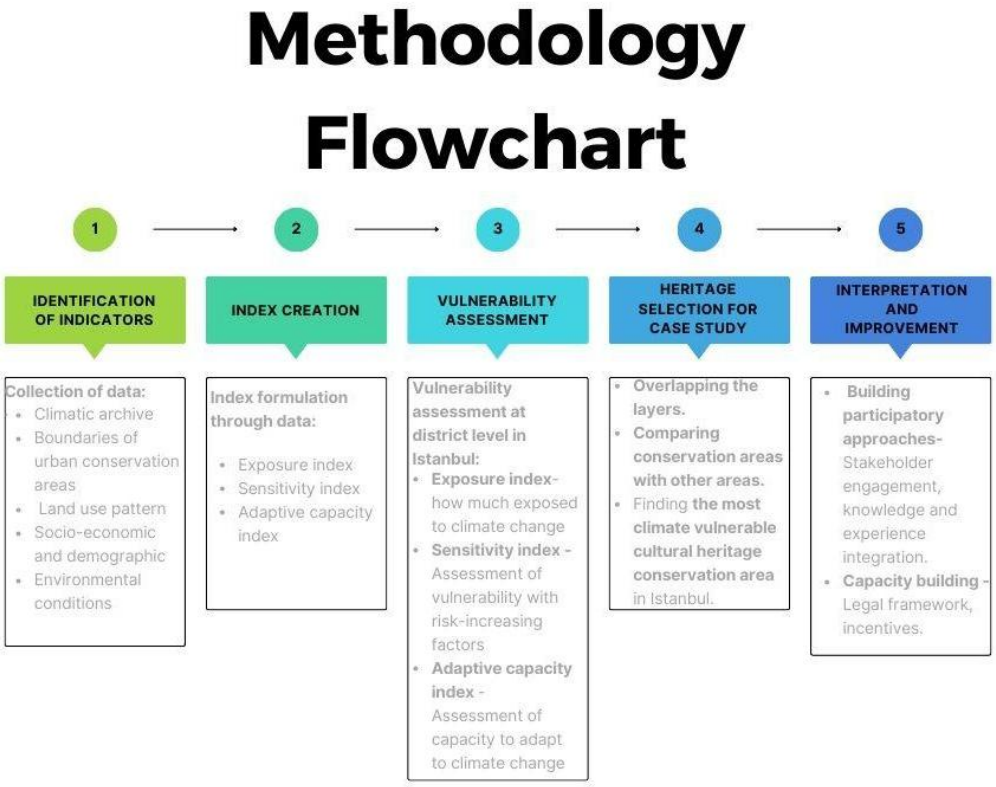

Figure 1: Methodology Flowchart **(**Flowchart summarizes 5 stages of methodology).

In the first stage, data collection is carried out at the level of neighborhoods and districts of Istanbul in order to determine the indicators. With the 20-year climate archive data obtained from the General Directorate of Meteorology, data on temperature and precipitation regime at the locations of the Observation Stations are analyzed. In order to analyze the relationship between climate data and land use data, land use data of Istanbul at the neighborhood level and the boundaries of registered natural and cultural protected areas are obtained from the relevant administrations and listed at the neighborhood level in order to reach the presence of natural and cultural protected areas, building-land density ratios, population density and the number of newly licensed projects. Various socio-economic data such as age distribution, child and elderly dependency ratios, and per capita household income at the neighborhood level from the General Directorate of Population and Citizenship, as well as the Istanbul Metropolitan Municipality's Data-Based Management Model research, which helps to analyze social awareness and usage habits regarding the environment, and the open data portal published as a result of socio-

demographic surveys of Istanbul residents are used. Finally, environmental data such as the amount of active and passive green space and the size of green space per capita at the neighborhood level are obtained from the relevant administrations, and data are collected at the neighborhood level.

In the second stage, indicator data is constructed by collecting exposure, sensitivity, and adaptive capacity indices.

In the third stage, a district-based vulnerability index is developed using a set of indicators consisting of socio-ecological, physical, and governance parameters, and spatial distribution is analyzed. This index integrates multidimensional factors such as exposure to climate risks (e.g., temperature increase, extreme precipitation, sea level rise), physical vulnerability of heritage sites, and adaptive capacity. Exposure analysis on how much the impacts of climate change are felt in order to make a comparison between protected areas and other areas, sensitivity analysis where risk multipliers such as historic building stock and vulnerable population groups are identified, and finally, adaptive capacity analysis, which can be defined as institutional and demographic strengths in combating climate change, are carried out.

In the fourth stage, based on the index results, the most vulnerable cultural heritage sites in Istanbul are identified, and the mechanisms of climate-induced degradation (chemical-physical erosion, moisture deformation) are examined in detail.

Finally, at the interpretation and improvement stage, climate adaptation strategies (passive cooling systems, increasing material resilience, risk mapping) are produced in a pilot cultural heritage site and integrated with policy recommendations.

Findings

Site selection for the case study on climate-sensitive planning in cultural heritage sites is made within the scope of the "climate vulnerability index" study prepared for Istanbul districts. This index study identifies cultural heritage areas in Istanbul that are most exposed and vulnerable to climate change.
The main finding of the study is that the districts of Istanbul with dense urban heritage areas are more vulnerable to the climate crisis than other districts. The other findings of the study will be presented as the most vulnerable urban heritage areas when a climate change vulnerability index is created for the districts of Istanbul, the capacity of planning approaches in Istanbul's urban heritage areas to accommodate other ecological attitudes such as adaptation to climate change, and the adaptation strategies of Istanbul's heritage areas to the climate crisis.

Conclusion

In conclusion, combating climate change and protecting urban heritage are two important issues that cannot be considered separately. Climate-smart urban planning in historic areas requires a multidisciplinary approach that integrates the protection of cultural heritage and the mitigation of risks posed by climate change. In this context, green infrastructure and planting strategies offer solutions compatible with traditional architecture to mitigate the heat island effect and optimize stormwater management without degrading the historic fabric (Fatorić & Biesbroek, 2020). At the same time, community participation supports socio-cultural sustainability by incorporating the traditional knowledge of local actors into planning processes (Labadi, 2017). Geographic information systems (GIS)-based risk mapping and adaptive planning models enable dynamic management of historic sites according to climate scenarios (Sesana et al., 2021). These strategies offer a holistic framework that places climate adaptation at the center of urban heritage management while balancing physical resilience with the preservation of cultural identity.
This study assesses the vulnerability of urban heritage sites in Istanbul to climate change through the demographic profile and key characteristics of the built environment, and develops strategies for their conservation and climate-adaptive planning. New tools and policies for climate-compatible planning in protected areas support capacity development for climate adaptation. The vulnerability index and conservation planning tools developed in the study directly contribute to the climate adaptation strategies of local governments.

City Information Modeling: Identifying Knowledge Gaps and Research Priorities

Abdalrahman T. Y. Alashi[a], Özhan Ertekin[a]

[a] Istanbul Technical University/Graduate School, Department of Urban and Regional Planning, Doctor of Philosophy Program, Türkiye
alashi17@itu.edu.tr

Keywords: 3D City Modeling, City Information Modeling, PRISMA, Systematic Literature Review.

Aim

In recent years, City Information Modeling (CIM) has emerged as a powerful tool due to its potential in urban applications, gaining significant interest in both research and practical fields. This attention can be attributed to the effectiveness of Building Information Modeling (BIM) at a building scale. Recent research has delved into various aspects of CIM, ranging from the development of conceptual frameworks and testing integration frameworks for diverse data sources to the introduction of conceptual data models, literature reviews, commentary analysis, and more.

The scope of this research is twofold. Firstly, it aims to address this gap by conducting a systematic review using the Urban Planner PRISMA research process. By employing this methodology, the study seeks to shed light on the existing research gaps regarding CIM as an urban tool. Secondly, the research attempts to identify and evaluate the most efficient conceptual frameworks for data integration and processing within the realm of CIM. Additionally, the study aims to identify and highlight the most relevant and impactful literature reviews according to their mentioned scope.

Accordingly, this study aims to address that gap by conducting a comprehensive systematic literature review. The primary goals are to:

1. Highlight existing research gaps related to the urban-scale implementation of CIM.
2. Evaluate the most efficient conceptual frameworks for data integration and processing within CIM.
3. Identify the most relevant and impactful literature reviews in the field and analyze their scope.

Material and Method

Systematic literature reviews are commonly employed across different study areas by researchers to analyze literature with specific objectives and defined methodologies, ultimately yielding well-defined research outcomes. Page et al. (2021) have developed an updated version of the PRISMA statement, a systematic review guideline intended to enhance research outcomes across diverse fields. Given that the PRISMA statement may not fully meet the needs of urban planning studies, Abusaada and Elshater (2022) devised a PRISMA-based research BSMS review process customized for application by urban planners and urban designers, addressing the specific requirements of these fields.

For access to pertinent studies, researchers primarily rely on scholarly repositories like Scopus (Elsevier) and Web of Science (WoS). These yield a vast range of scholarly writings — from academic papers to book chapters — along with advanced bibliometric data like keywords, abstracts, and citation counts. This makes monitoring the frequency of important words more convenient, watching trends, ascertaining gaps in knowledge, and finding new research directions.

Findings

The review revealed several key insights:

- While interest in CIM has grown, practical applications remain limited due to the lack of standardized software, fragmented data systems, and unclear workflows.
- Existing literature heavily leans toward conceptual development, with relatively fewer studies offering empirical or software-based implementations.
- Data integration across various urban layers (e.g., infrastructure, environmental data, and social indicators) is still underdeveloped in most CIM applications.
- The most impactful literature reviews emphasized the interoperability between BIM, GIS, and CIM, yet offered varying conclusions regarding the feasibility of implementation.
- The adapted PRISMA-based method proved effective in highlighting thematic gaps, especially regarding the standardization of CIM practices, tool development, and scalability of frameworks.

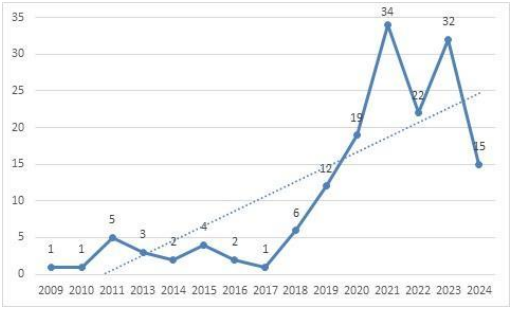

Figure 1. The document count for the 159 documents (SCOPUS).

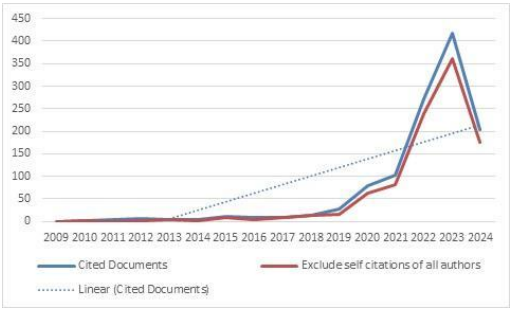

Figure 2. The citation count for the 159 documents, Self-citations included and excluded (SCOPUS).

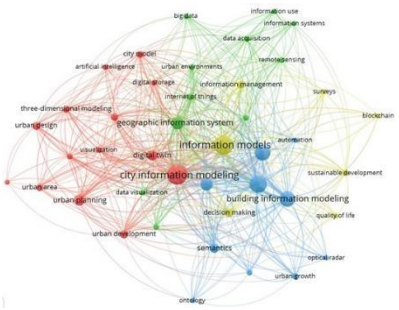

Figure 3. Analysis of the 159 documents retrieved from Scopus focusing on their keywords using VOSviewer (By Author).

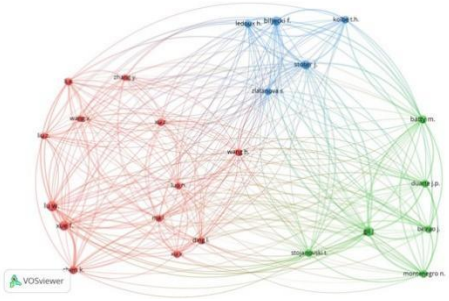

Figure 4. Network analysis based on co-citations of authors using VOSviewer (By Author).

Conclusion

While there is ample literature discussing CIM, there remains a considerable gap between conceptual understanding and practical implementation. This disparity is primarily attributed to the scarcity of CIM software solutions, the complexity of integrating diverse databases into the model, and the absence of clear guidelines regarding the most efficient workflows. This study demonstrates the critical need for a cohesive and actionable approach to implementing City Information Modeling at an urban scale. Through a systematic literature review using a PRISMA-based methodology tailored for urban planning, the research reveals a persistent gap between conceptualization and practical deployment. Key areas requiring further exploration include:

- The development of interoperable CIM tools.
- Standardization of data integration workflows.
- Emphasis on multi-scalar, real-world applications that bridge theory with practice.

Future research should focus on closing these gaps through cross-disciplinary collaboration, urban-scale UAV projects, and the creation of adaptable CIM platforms capable of handling complex urban datasets.

Deprivation Analysis In Turkey And Its Provinces: A Study Based On English Index Of Deprivation And Turkish Statistical Institute

Abdalrahman T. Y. Alashi[a], Özhan Ertekin[a]

[a] Istanbul Technical University/Graduate School, Department of Urban and Regional Planning, Doctor of Philosophy Program, Türkiye
alashi17@itu.edu.tr

Keywords: Deprivation Index, Deprivation Index of Turkey, Index of Multiple Deprivation, Regional Disparities, Spatial Inequality.

Aim

This study aims to construct a multidimensional deprivation index for Turkey and its provinces using domain-based indicators inspired by the English Indices of Deprivation (IoD). The objective is to reveal relative spatial inequalities and patterns of deprivation across the 81 provinces of Turkey using 2023 TURKSTAT data. The analysis seeks to support evidence-based planning, identify high-need areas, and inform equitable policy development.

Material and Method

The Composite Deprivation Index (CDI) was developed using seven domains: Income, Employment, Education, Health, Crime and Social Distress, Housing, and Living Environment. All domains were constructed based on 2023 provincial-level data from the Turkish Statistical Institute (TURKSTAT). Indicators within each domain were normalized using min-max scaling to allow comparability, and domains were weighted according to the English Indices of Deprivation 2019 model. The assigned weights were as follows:

- Income: 22.5%
- Employment: 22.5%
- Education: 13.5%
- Health: 13.5%
- Crime and Social Distress: 9.3%
- Housing: 9.3%
- Living Environment: 9.3%

Each domain score represents the normalized average of its selected indicators. All data processing and index calculations were conducted in Excel and SPSS. Spatial visualizations were developed using ArcGIS Pro software. Provinces were then ranked from the most deprived (rank 1) to the least deprived (rank 81).

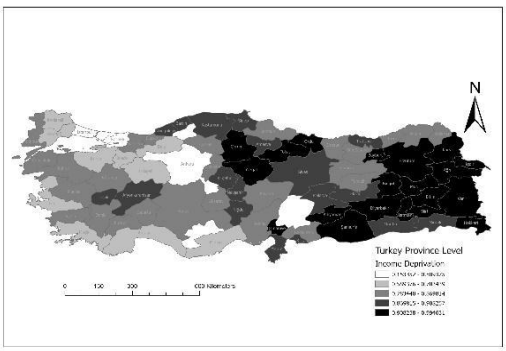

Figure 1. Income deprivation domain map 2023 (By Author).

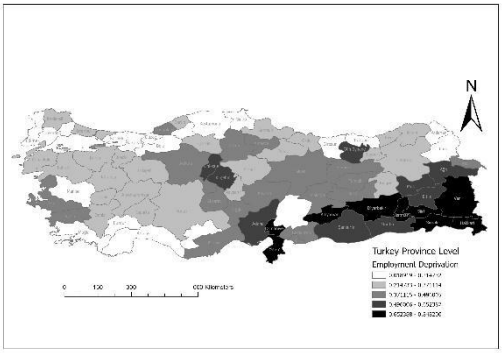

Figure 2. Employment deprivation domain map 2023 (By Author).

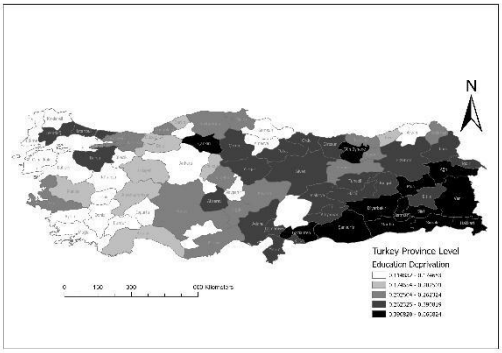

Figure 3. Education deprivation domain map 2023 (By Author).

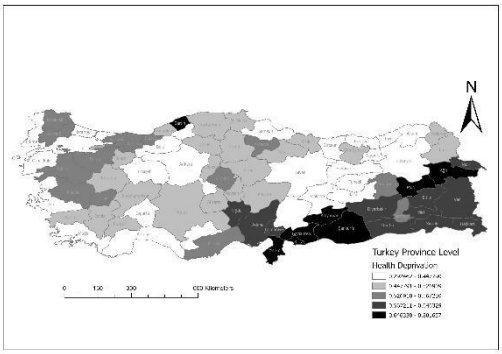

Figure 4. Health deprivation domain map 2023 (By Author).

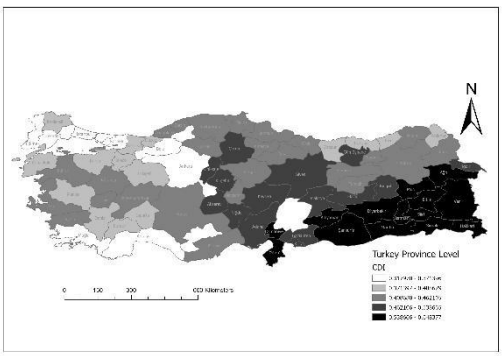

Figure 5. Overall Turkey Index of Multiple Deprivation 2023 (By Author).

Findings

The domain-level results show significant spatial disparities across Turkey. A strong east–west divide is visible across most domains, particularly in income, employment, education, and health deprivation. Provinces such as Şanlıurfa, Ağrı, Şırnak, Mardin, and Iğdır consistently appeared among the most deprived, while İstanbul, Ankara, Kocaeli, Tekirdağ, and Eskişehir were identified as the least deprived.

Income and Employment: Eastern provinces reported the highest levels of income and employment deprivation. Ağrı, Hakkari, Şırnak, and Muş were consistently ranked among the most deprived in both domains. In contrast, İstanbul, Tekirdağ, and Kocaeli achieved the lowest deprivation scores due to their strong economies and low unemployment rates.

Education and Health: The education domain revealed underperformance in literacy rates and school completion in provinces such as Şırnak, Bitlis, and Ağrı. Health deprivation was also severe in the southeastern provinces due to limited access to medical infrastructure and personnel. Western and central regions, such as Ankara and Eskişehir, performed best in both domains.

Crime and Social Distress: Deprivation related to crime and social distress was highest in large metropolitan areas like İstanbul, Ankara, and İzmir. The high incidence of recorded crimes, convictions, and suicides contributed to elevated scores in these urban provinces. Meanwhile, eastern and rural provinces showed lower recorded levels of social distress.

Housing and Living Environment: Housing deprivation was observed in both underdeveloped and rapidly urbanizing provinces, including Şırnak, Mardin, and Gaziantep. The living environment domain showed that provinces like Ardahan, Iğdır, and Ağrı faced severe infrastructural and environmental challenges, including a lack of access to piped water, electricity, and modern housing.

Composite Deprivation Index Results: The overall CDI scores reflected the cumulative impact of domain-based deprivation. Şanlıurfa, Ağrı, Şırnak, Mardin, and Iğdır emerged as the top five most deprived provinces, indicating persistent socio-economic and infrastructural challenges. In contrast, İstanbul, Ankara, Kocaeli, Tekirdağ, and Eskişehir ranked as the five least deprived provinces

Conclusion

The deprivation index developed in this study demonstrates that spatial deprivation in Turkey is not evenly distributed but rather concentrated in structurally disadvantaged provinces, particularly in the east and southeast. The findings emphasize the importance of multidimensional assessment and the role of spatial analysis in regional planning. Since the CDI is a comparative measure, even small changes in the deprivation scores of a few provinces can affect the overall ranking. This study contributes an adaptable deprivation index using only open, official statistical sources. It may serve as a planning tool for identifying priority areas, allocating resources, and promoting balanced regional development.

Rethinking Heritage-Tourism Relations: Critical Perspectives and Sustainable Futures for Cultural Sites

Büşra Yalçın[a], Turgay Kerem Koramaz[a]

[a] Istanbul Technical University, Urban and Regional Planning, Urban and Regional Planning, İstanbul
yalcinbus15@itu.edu.tr

Keywords: Heritage Conservation, Heritage Tourism, Responsible Tourism, Sustainable Tourism.

Aim

Traditionally, the concept of heritage has often been associated with a single cultural period or a specific political narrative, and its presentation, promotion, and economic utilization have been shaped accordingly (Hernandez et al., 2016). However, increasing global tourism mobility and its impacts on heritage sites have questioned the adequacy of traditional perspectives (Szromek et al., 2021; Aylan and Aylan, 2020). This study aims to examine the relationship between heritage and tourism from an interdisciplinary perspective, especially the way heritage is defined, the impacts of tourism on these areas, and sustainability-based solution approaches.

Material and Method

The main source data for this study is based on a comprehensive literature review conducted in the Web of Science (WOS) database using the keywords *"heritage," "tourism,"* and *"sustainability"*. During the search, the following categories were used as a basis: *"urban studies," "architectural studies," "regional urban planning," "area studies," "social studies,"* and *"cultural studies"*. The publications were filtered to include only those from recent years. The 66 articles obtained through the search were analyzed using content analysis methods. The titles, abstracts, and keywords of the studies were subjected to a preliminary evaluation and were evaluated according to three main groups: (1) perspectives on the concept of heritage, (2) problems identified in the relationship between heritage and tourism, and (3) solution-oriented sustainability strategies. Similar examples were evaluated together under each theme, and common trends and conceptual intersections were identified in studies from different geographical regions. Both theoretical approaches and empirical studies containing field data were taken into consideration; in this regard, publications with a critical perspective were prioritized for inclusion in the study. Additionally, the geographical distribution of publications, trends in their increase over the years, and the levels of interdisciplinary approaches were analyzed comparatively.

Findings

First, the publication information of the 66 articles reached was analyzed, and it was observed that the topic showed an increasing trend over the years. It was determined that 10 new articles were added to the literature between 2016 and 2019, 29 between 2020 and 2023, 20 in 2024, and 7 in the first months of 2025. This increase indicates that the subject has received growing international attention and has begun to be addressed with sensitivity. When examining the geographical distribution of the literature, it is observed that most studies are concentrated in countries such as China, Italy, and Spain, with a significant increase in academic interest, particularly in China, due to its intensive applications to UNESCO since 1985. The fact that only four studies from Turkey could be included in the review highlights the gap in the national literature (Çatalbaş et al., 2022; İsmailoğlu & Sipahi, 2021; Umar et al., 2022; Varolgüneş & Canan, 2018)

Perspectives to the concept of heritage in the studies

The study first examines approaches to the concept of heritage. The classification of cultural, natural, and mixed heritage defined by UNESCO has brought with it not only the prestige of being a world heritage site but also the effects of increasing tourist pressure (UNESCO, 1972). In cities such as Venice, Dubrovnik, and Barcelona, increased tourism activity following heritage status has led to the deterioration of the social fabric, rising housing

prices, and the loss of cultural authenticity (Bobic & Akhavan, 2022; Mihalic et al., 2021). In addition to these issues, the potential of unlisted heritage sites is also significant. The literature reveals that these insufficiently recognized areas offer great opportunities to preserve local identity, develop alternative types of tourism, and sustain cultural diversity (Imon, 2017; Zhang, 2021). For example, Ye's (2021) study on the St. Lazarus Neighborhood in Macau examines how an unlisted area was reintroduced to tourism and how the local community's living practices were transformed from a socio-political perspective. Similarly, Tang et al. (2025) examined traditional rural tourism villages in China and demonstrated how spatial planning elements such as settlement patterns, structures, street layouts, and architectural details significantly influence tourists' willingness to revisit. The findings support the idea that the design and experiential quality of heritage environments directly influence visitor satisfaction and participation, and offer concrete strategies for the development of sustainable rural heritage tourism.

Problems identified in the relationship between heritage and tourism

Secondly, critical approaches to tourism emerge as a key area of discussion in this study. In particular, excessive tourism in heritage areas leads to consequences such as exceeding carrying capacity, exclusion of local people from their neighborhoods, and erosion of cultural identity (Phi, 2020).
Along with excessive tourism, authenticity, social memory, and spatial belonging are rapidly being replaced by commercialized and reproduced superficial experiences. The theoretical framework developed by MacCannell (1976) through the concept of authenticity discusses this transformation with reference to the depth within the social structure. Zukin (2009) emphasizes that heritage is instrumentalized not only in aesthetic but also in economic and cultural branding processes. In a similar context, Wise (2016) highlights the importance of the triple bottom line approach in the renewal of urban tourism, noting that while economic and environmental sustainability are often prioritized, social sustainability, which includes elements such as community pride, local entrepreneurship, education, and volunteerism, is increasingly gaining attention. The study underscores the need to integrate these dimensions for a more holistic and context-sensitive understanding of urban tourism planning and renewal (Wise, 2016). In addition to these findings, Kang et al. (2025) investigated how emotional solidarity, particularly the feeling of welcome, affects tourist satisfaction and loyalty in heritage cities. In their studies focused on South Korea, they also revealed that nostalgia acts as a moderating factor that strengthens the relationship between tourists' emotional attachment and destination loyalty. By conceptualizing this within the framework of productive nostalgia, they offer a unique perspective on how emotional experiences can be integrated into sustainable heritage tourism strategies. Empirical studies conducted by Rasoolimanesh and Jaafar (2017), Orgaz-Agüera et al. (2020) emphasize that the sustainability of heritage tourism is significantly influenced by community participation, local perceptions, and equitable benefit sharing. These studies demonstrate that involving local stakeholders in tourism decision-making processes is one of the fundamental principles of sustainable tourism. Additionally, they underscore the importance of balancing heritage conservation, socio-economic development, and conflict mediation through inclusive governance models.

Solution-oriented sustainability strategies

The final section focuses on sustainable and responsible tourism practices as a solution approach. The concept of sustainable development, which was included in the 1987 Brundtland Report, Our Common Future, has been echoed in tourism practices over time and has become an international standard through the UNWTO's sustainable tourism guidelines (WCED, 1987; World Tourism Organization, 2019). Sustainable tourism aims to protect heritage sites through an approach that balances environmental, socio-cultural, and economic dimensions (Salazar, 2016). A notable example of this multi-dimensional approach is presented by Sarkar and colleagues (2025), who used CBS-based geo-spatial analysis to assess the ecotourism potential of the "Seven Sister States" in Northeast India. In their study, they classified regions based on their environmental and cultural capacities and provided applicable recommendations for developing sustainable tourism while preserving ecological and cultural integrity, including infrastructure development, community participation, and strategic marketing. However, the expansion of the concept's content and its lack of concrete application in practice led to the emergence of the concept of

responsibility as one of the sub-components of sustainability. This increasingly prominent approach has evolved into a separate conceptual framework in the literature under the name "responsible tourism."

Conclusion

The results of the study reveal that heritage sites must be protected not only physically, but also in terms of their cultural uniqueness, social continuity, and relationships with local communities. The prestige and promotional value provided by UNESCO status can become a new pressure mechanism for sites if it is not addressed in conjunction with sustainability and local sensitivity. On the other hand, making non-listed areas more visible, supporting alternative forms of tourism, and actively involving local actors in the process can help establish a healthier and more sustainable balance between heritage and tourism. Within this framework, the study aims to offer a holistic perspective that addresses the relationship between heritage and tourism not only from an economic perspective but also from cultural, social, and ethical dimensions.

Determination of Saturation Flow Rate Right-Turn Adjustment Factor for Large Radii in Istanbul

Ozan Emekter[a], Kemal Selçuk Öğüt[a]

[a] Istanbul Technical University, Department of Civil Engineering, Civil Engineering, Turkey
emekter18@itu.edu.tr

Keywords: Right-Turn Adjustment Factor, Saturation Flow Rate, Signalized Intersections.

Aim

Signalized intersections are the most crucial chokepoints in urban traffic regarding safety and travel time. Conflicting traffic flows, including pedestrians, need to wait and give way to each other to avoid hazardous conditions and accidents. These points, then, naturally represent a significant impact on travel time experienced by all traffic users. Therefore, it is of utmost importance to design them properly and to avoid wasting time; timing the red and green traffic signals is an important part of this design. "Saturation flow rate" is a parameter used commonly in the process of signal timing, which is why it is important to determine its correct value. It describes the maximum hourly traffic volume that can pass through a certain section of road given unrestricted flow conditions. While it can be measured directly at an existing intersection, there are correspondingly similar ways of mathematically estimating this value in case fieldwork is not to be conducted or for planned new intersections.

The mathematical estimation method assumes an ideal base value for the saturation flow rate and adjusts this base value for various geometrical and operational factors of the intersection. As these factors are affected by drivers' perceptions, quite a few studies have been conducted all over the world to determine their mathematical models. This paper focuses on the right-turn adjustment factor for mixed lanes where both through and right-turning flows are present. Developing an accurate mathematical model for this adjustment factor will permit the correct determination of signal times that minimize delays. This study involves field measurements for three intersection approaches with similar characteristics and turning radii in Istanbul to develop a mathematical model that can be used as the right-turn adjustment factor for large right-turning radii in an urban setting.

This study aims to put forward a mathematical model to determine the saturation flow rate right-turn adjustment factor for large turning radii, namely 20 meters or higher. The saturation flow rate, SFR, is the key variable of traffic signalization in calculating the flow ratio, which is used to determine the cycle time and green times of each phase. Three approaches from existing intersections in the city of Istanbul have been selected for fieldwork, as seen in Figure 1, which are the East approach of the intersection between Okul St. and M. Ali Birand St. in Beykoz (Intersection 1), the South approach of the intersection between Büyükdere St. and Darüşşafaka St. in Sarıyer (Intersection 2), and the West approach of the intersection between Mareşal Fevzi Çakmak St. and Yavuz Selim Köprüsü St. in Eyüpsultan (Intersection 3). Their turning radii are 23, 20, and 20 meters, respectively. The only difference between them is that they have one, two, and three traffic lanes in the measured approaches. The study similarly aims to find whether the number of lanes affects the significance of the rate of right turns.

As SFR is affected by several factors, such as lane width, grade, vehicle composition, parking, and so on, these intersections have been selected with care so that all these factors, except the right-turn factor, are equal to their default values, which is one.

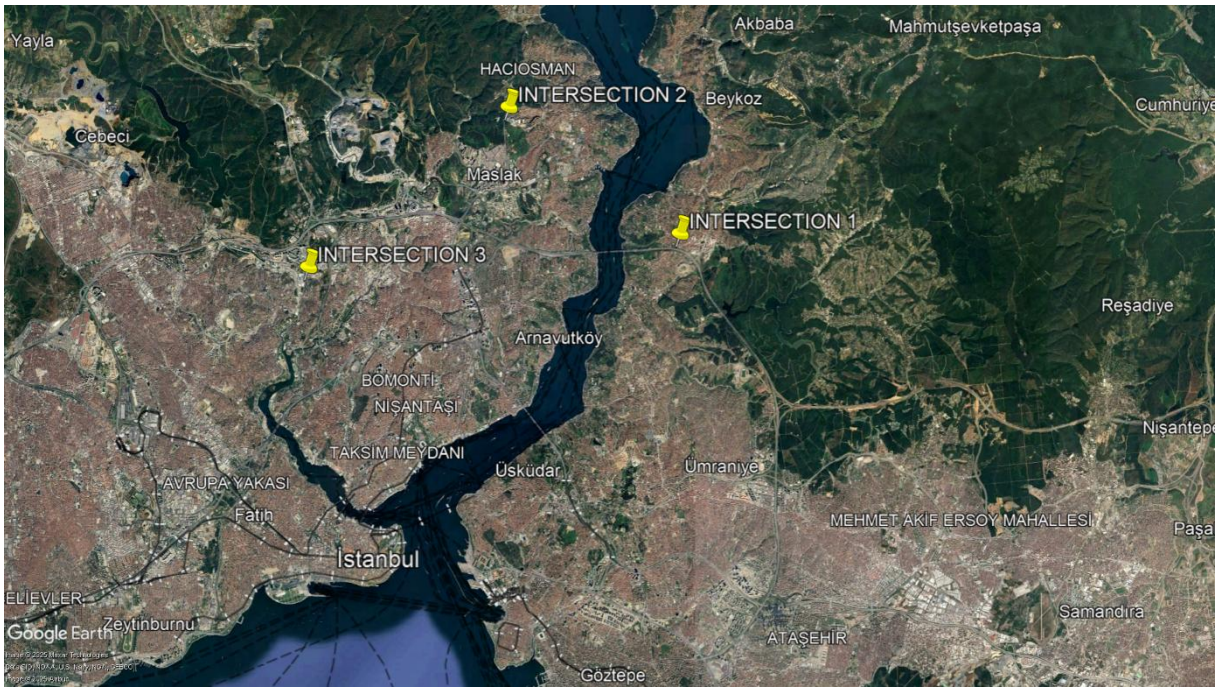

Figure 1. Intersections selected for fieldwork.

Material and Method

SFR is defined as the "equivalent hourly rate at which previously queued vehicles can traverse an intersection approach, assuming the green signal is available at all times and no lost times are experienced" (TRB, 2022). In other words, it is the maximum number of vehicles that a lane or lane group in an intersection approach can accommodate, given no restrictions and a constant supply of vehicles traveling at the highest flow rate possible. The first way to determine the SFR is to measure the headway at which vehicles discharge from a red-light queue and divide an hour by it, as seen in Equation 1.

$$s = \frac{3600}{h_s} \#(1)$$

$$where, s: saturation\ flow\ rate\ (veh/h) h_s: saturation\ headway\ (sec/veh)$$

The second way is multiplying its default value (base saturation flow rate, s_0) by adjustment factors as seen in Equation 2 when fieldwork is not performed (TRB, 2022, Chapter 19).

$$s = s_0 \times \prod_{i=1}^{13} f_i \#(2)$$

These adjustment factors are for lane width, heavy vehicles, and grade, existence of a parking lane and parking activity, the blocking effect of local buses, area type, lane utilization, right-turning vehicles, left-turning vehicles, pedestrian activity, bicycle activity, work zone presence, downstream lane blockage, and sustained spillback. As mentioned, the intersections selected for fieldwork in this study do not exhibit any of these factors other than right-turning vehicles, whose adjustment factor, f_{RT}, is to be determined. Therefore, the resulting relation is as shown in Equation 3.

$$s = s_0 \times f_{RT} \#(3)$$

Previous research into the right-turn adjustment factor includes Ibrahim et al. (2007), who presented Equation 4 as a result of their study for traffic conditions in Malaysia (p. 76).

$$f_{RT} = \frac{1}{1 + 0.54\sqrt{\frac{P_{RT}}{r}}} \#(4)$$

$$where, f_{RT}: right - turn\ adjustment\ factor P_{RT}: rate\ of\ right - turns r: turning\ radius\ (m)$$

Savitha et al. (2017) developed the model seen in Equation 5 for the turning radius in their study conducted in Bangalore, India.

$$f_{RT} = 1 + 4 \times \frac{r}{1000} \#(5)$$

$$where, r: turning\ radius\ (m)$$

This study, by contrast, does not utilize the turning radius in its proposed model and rather seeks to eliminate its influence by studying three turning movements with similar and large radii. Therefore, the model seen in Equation 6 is a better fit (TRB, 2022, Chapter 31).

$$f_{RT} = \frac{1}{1 + 0.18P_{RT}} \#(6)$$

Çalışkanelli and Tanyel (2017) developed Equation 7 for the city of İzmir in Turkey.

$$f_{RT} = \frac{1}{1 + 0.40P_{RT}} \#(7)$$

The proposed model in this study is shown in Equation 8, where α, β, and γ are parameters.

$$f_{RT} = \frac{1}{\alpha + \beta \times {P_{RT}}^{\gamma}} \#(8)$$

Equations 9 – 11 show how the parameters α and β were determined.

$$s = \frac{s_0}{\alpha + \beta \times {P_{RT}}^{\gamma}} \#(9)$$

$$\frac{1}{s} = \frac{\alpha}{s_0} + \frac{\beta \times {P_{RT}}^{\gamma}}{s_0} \rightarrow \frac{\alpha}{s_0} = A, \qquad \frac{\beta}{s_0} = B \#(10)$$

$$\frac{1}{s} = A + B \times {P_{RT}}^{\gamma} \#(11)$$

A regression analysis was conducted to calculate A and B, which then revealed α and β. The γ value is determined by assigning values that minimize the Sum of Squared Errors of the regression model. The base SFR, s_0, was determined to be about 1890 pcu/h in Istanbul (Dündar, 2018), which is used in this paper.

The SFR needs to be calculated based on the saturation headway, which is exhibited after the first few vehicles in a queue due to the time it takes them to react to the signal change and accelerate (Urbanik et al., 2015, Chapter 5). The first few vehicles do not have sufficient time or space to accelerate to the design speed by the time they reach the stop line, which increases their headways beyond the saturation headway. In order to accurately determine the SFR, the first few vehicles need to be disregarded in each cycle. This decision is made by using a one-way ANOVA test. The test is first conducted with all vehicles in the queue. Then, the first vehicles are excluded from the data set, and the test is repeated. The elimination of the first vehicles lasts till all vehicles have stable headways.

The headway measurements were taken for at least 30 cycles at each intersection. Afterward, the aforementioned regression analysis was performed to determine the parameters in the proposed model that show the relation between the rate of right turns and SFR.

Findings

The vehicle positions in the queue and their headways can be seen in Figure 2 for Intersection 1. The dashed line shows the saturation headway.

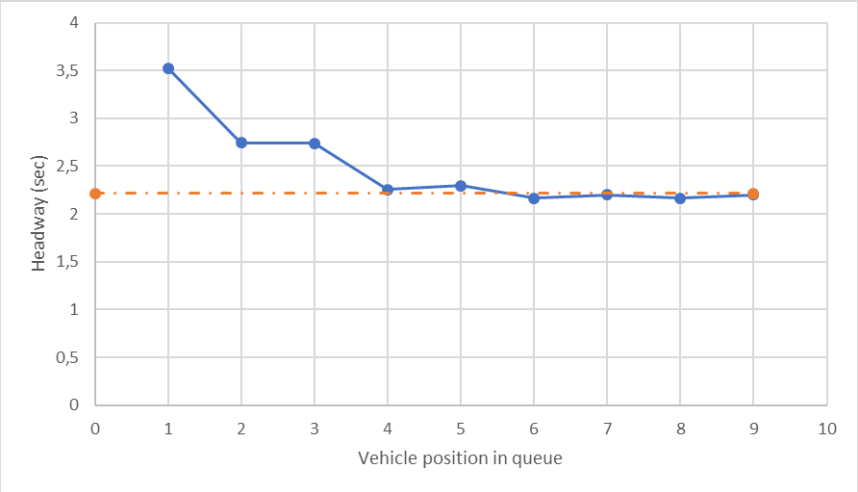

Figure 2. Through-only average headways for Intersection I.

A one-way ANOVA test concluded that the first three vehicles should be discarded as their means deviate too much from the rest due to the effects of reaction time and acceleration discussed earlier. After the third vehicle, the headways are stable. The vehicles between the fourth and last vehicle in the queue were considered in this study for calculations hereafter.

Accordingly, the saturation headway (h_s) for each measured cycle with right turns was calculated as the average headway without considering the first three vehicles. SFR (s) was then calculated for each cycle as per Equation 1.

The right-turn ratio (P_{RT}) in each cycle was calculated as the number of right-turning vehicles divided by the total number of vehicles, again, without considering the first three vehicles.

The initial regression model was conducted for $\gamma=1$, where 1/s is the dependent variable and P_{RT} is the independent variable. Then, by changing the γ value from 0.1 to 2.0 at intervals of 0.01, the regression models were calibrated. The model with the lowest Sum of Squared Errors was achieved when $\gamma=0.84$.

The scatter diagram of the regression analysis can be seen in Figure 3 for $P_{RT}^{0.84}$ and 1/s for all intersections.

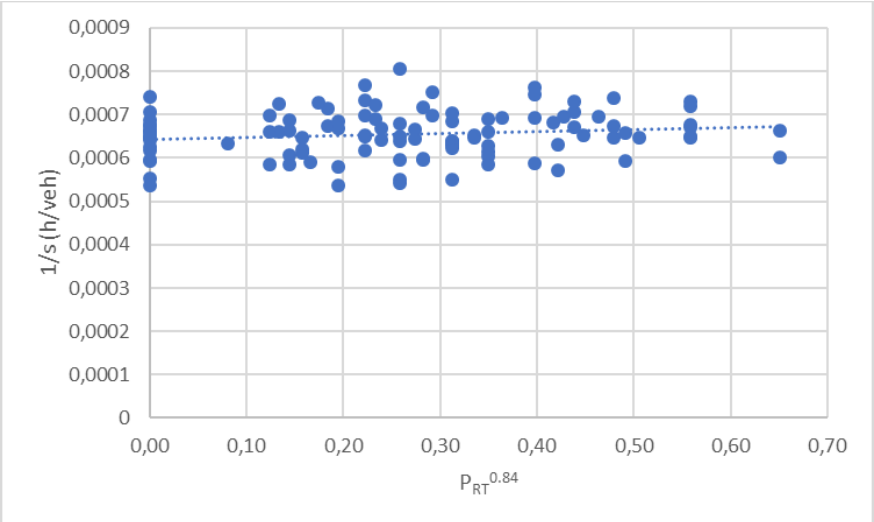

Figure 3. Scatter diagram of regression analysis.

The proposed right-turn adjustment factor was then determined as seen in the Equations. 12 – 15.

$$\frac{1}{s} = 0.000643536 + 4.502 \times 10^{-5} \times {P_{RT}}^{0.84} \#(12)$$

$$\alpha = A \times s_0 = 0.000643536 \times 1890 = 1.216 \#(13)$$

$$\beta = B \times s_0 = 4.502 \times 10^{-5} \times 1890 = 0.085 \#(14)$$

$$f_{RT} = \frac{1}{1.216 + 0.085{P_{RT}}^{0.84}} \#(15)$$

It should be noted that this model was derived from data for turning radii of 20 to 23 meters and is intended to be used for this interval.

The resulting model for SFR concerning right-turns is shown in Equation 16 and Figure 4.

$$s = \frac{1{,}890}{1.216 + 0.085{P_{RT}}^{0.84}} \#(16)$$

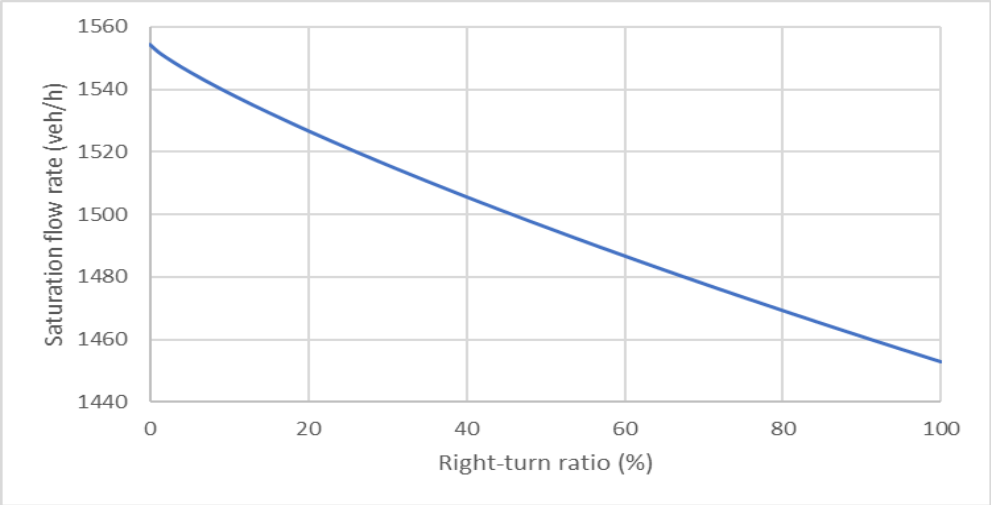

Figure 4. The change of SFR with respect to the right-turn ratio.

Conclusion

As the number of right-turning vehicles affects the SFR and this effect is represented by the right-turn adjustment factor, in this study, this effect with a turning radius of 20 meters or larger was studied, and an empirical model for this has been derived.

Initially, it can be observed that the rate of right-turns has less than a substantial effect on the saturation flow rate when the turning radius is large, but it is nevertheless there. In other words, the component involving this rate in the right-turn adjustment factor model has turned out to be small, yet significant.

As the results were quite similar across the three studied intersections, it has been concluded that the number of lanes does not have a significant influence on the right-turn adjustment factor when the turning radius is 20 meters or larger.

Crucially, the rightmost lane being mixed was found to affect the SFR as the measurements consistently yielded values less than s_0 even with no right-turns. This effect may be studied further.

Further research should focus on the effect of turning radii smaller than 20 m. Smaller radii should, in theory, result in increased hindrance caused by turning movements, and potentially the number of lanes playing a significant role.

Towards Walkable and Green University Campuses: Observational Assessment of ITU Maslak Campus for Advancing the Sustainable Development Goals

Amira Moursy[a], Hatice Ayataç[a]

[a] Istanbul Technical University, City and Regional Planning Department, Türkiye.
ammar19@itu.edu.tr

Keywords: Composite Indicators, Green Campus, ITU Maslak Campus, Sustainable Development Goals, Walkability.

Aim

As global environmental and social challenges escalate, the role of university campuses in modeling sustainable development has become increasingly significant. University campuses serve as educational environments and living laboratories where sustainable development goals (SDGs) can be implemented and tested. In this context, promoting walkable and green campuses contributes directly to multiple SDGs, including SDG 3 (Good Health and Well-being), SDG 11 (Sustainable Cities and Communities), and SDG 13 (Climate Action). When integrated with green infrastructure and sustainable waste management, walkability can help reduce carbon footprints, encourage healthier lifestyles, and foster inclusive and vibrant academic communities (United Nations, 2015).

This study, conducted on Istanbul Technical University (ITU) Maslak Campus, forms part of a broader PhD project that examines the spatial, environmental, and experiential factors contributing to campus walkability. The key innovation in this research is the development and application of a multi-dimensional evaluation method for assessing the walkability of the campus. The assessment is structured around a hybrid set of 14 composite indicators, synthesized from existing walkability indexes and the UI Green Metric World University Ranking (UI Green Metric, 2023).

These indicators are grouped into three thematic categories: safe and secure green walking, convenience and attractiveness, and waste and pollution. The aim is to evaluate how these integrated indicators can guide progress toward more sustainable, livable, and inclusive campus environments, in alignment with the SDGs (Speck, 2013).

This extended abstract presents the observation-based phase of the study. While the research will ultimately include survey-based assessments of user perception, survey data collection is pending ethics committee approval. As such, this paper focuses on field observations conducted by the researcher using the composite indicators to evaluate pedestrian routes across the ITU Maslak Campus.

In this sense, the main objective of this study is to evaluate the walkability of ITU Maslak Campus through a detailed observational study guided by a composite indicator framework that integrates walkability indices and green campus sustainability criteria. Specific objectives include:

- Developing an indicator-based tool to assess campus walkability in alignment with SDGs.
- Applying this tool across multiple routes within the campus using structured observations.
- Identifying spatial patterns, strengths, and deficiencies in pedestrian infrastructure.
- Supporting strategic campus planning for sustainable mobility and enhanced quality of life.

The findings are intended to provide actionable recommendations for campus planning, aimed at fostering a more livable, equitable, and sustainable campus environment.

Material and Method

The methodology is based on a mixed-methods approach, integrating observational analysis with future participatory research involving students. Currently, the study focuses on the observation phase due to pending approval from the university's ethics committee for survey implementation.

The observational study involves walking through multiple selected routes across the ITU Maslak Campus, systematically applying the 14 composite indicators. These indicators are designed to assess both the physical infrastructure and subjective qualities of the walking experience.

1. Study Area and Route Selection

ITU Maslak Campus is one of Turkey's leading technical university campuses, located in Istanbul's urban core and serving thousands of students, faculty, and staff. The campus is characterized by diverse land uses, topographical variation, and a mixture of historical and modern buildings. The study area includes both primary and secondary pedestrian routes, selected to capture a range of conditions (e.g., flat vs. sloped areas, shaded vs. unshaded routes, proximity to services, and green spaces).
Twelve representative pedestrian routes were selected, capturing a range of spatial contexts such as:

- Central pedestrian spine.
- Dormitory access corridors.
- Sloped paths in green areas.
- Mixed pedestrian-vehicular routes.
- Peripheral academic building connectors.

2. Development of Composite Indicators

According to the walkability research literature (Southworth, 2005; Forsyth, 2015), the Green Metric University Ranking dimensions related to transportation, land use, and environment (UI Green Metric, 2023), and the analytical study of merging their criteria, a list of 14 composite measuring indicators is formulated. These indicators achieve common green and walkability goals, designed to assess the physical infrastructure and subjective qualities of the walking experience, and consist of a list of 7 goals within 3 major sectors specifically for campuses as follows (Table 1):

Table 1. Composite indicators list for walkable green campus (Source: the researcher).

Sectors	Goals	Indicators
1. Safe and secure green walking	1.1. Promote crossing safety	Indicator 1.1.1. Availability of crossings along streets.
		Indicator 1.1.2. Intersections with curb cut ramp
	1.2. Promote sidewalks and walking paths quality	Indicator 1.2.1. Sidewalk condition.
		Indicator 1.2.2. Sidewalks' coverage (building Awning, tree, arcade, etc.).
		Indicator 1.2.3. Sidewalk width
	1.3. Promote traffic security and behavior	Indicator 1.3.1. The proportion of well-lit streets.
		Indicator 1.3.2. Safe driving speeds.
2. Convenience and attractiveness	2.1. Promote pedestrians' amenities quality	Indicator 2.1.1. Permanent and temporary obstructions on streets.
		Indicator 2.1.2. Maintenance of building facade materials.
	2.2. Provide live streets	Indicator 2.2.1. The existence of accessible parks, open spaces, and recreation areas
3. Waste and pollution	3.1. Promote Air Quality	Indicator 3.1.1 Number of trees per linear kilometer.
		Indicator 3.1.2. The ratio of automobile streets to pedestrian streets.
	3.2. Promote cleanliness	Indicator 3.2.1. Drainage system to prevent puddles.
		Indicator 3.2.2. Sidewalk cleanliness.

Each of these indicators is evaluated using a combination of quantitative and qualitative field notes according to measuring levels (Table 2). These observations are carried out across varied routes during multiple site visits under varied conditions (morning/evening, weekday/weekend) to capture temporal variation. For each indicator, specific descriptive criteria were developed to minimize subjectivity and guide consistent scoring.

Table 2. Constructing criteria for measuring indicator levels (Source: the researcher).

Sectors	Goals	Indicators	Level 1	Level 2	Level 3	Level 4	Level5
1.Safe and secure green walking	1. Promote crossing safety	Indicator 1.1. Availability of crossings along streets.	with sufficient crossings	non-sufficient crossings			
		Indicator 1.2. Intersections with curb cut ramp.	with curb cut ramps	one-sided curb cut ramps	non-curb cut ramps		
	2. Promote sidewalks and walking paths quality	Indicator 2.1. Sidewalk condition.	excellent	good	fair	poor	
		Indicator 2.2. Sidewalks' coverage,	contains cover	no cover			
		Indicator 2.3. Sidewalk width	w>3	1.2<w<1.8	0.9<w<1.2	w<09	
	3. Prom	Indicator 3.1. The proportion of well-lit streets.	well-lit street	poor-lit street	not lit street		

	ote traffic security and behavior	Indicator 3.2. Safe driving speeds.	safe	not safe			
2.Convenience and attractiveness	4. Promote pedestrians' amenities quality	Indicator 4.1. Permanent and temporary obstructions on streets.	0-1 obstacles	2-3 obstacles	4-5 obstacles	>5 obstacles	
		Indicator 4.2. Maintenance of building facades materials.	excellent	good	fair	poor	
	5. Provide alive streets	Indicator 5.1. Existence of accessible parks, open spaces, and recreation areas.	exist	do not exist			
3. Was	6. Pr	Indicator 6.1. Number of trees per linear kilometers.	n>50	30<n<50	15<n<30	5<n<15	n<5

te and pollution	o mote Air Quality	Indicator 6.2. The ratio of automobile streets to pedestrian streets.	auto-street	pedestrian street			
	7. Promote cleanliness	Indicator 7.1. Drainage system to prevent puddles.	excellent	good	fair	poor	
		Indicator 7.2. Sidewalk cleanliness.	no litter	small amount of litter	some amount of litter	large amount of litter	

3. Observation Process

Field observations were conducted using the selected indicators for each route. Photos, sketches, and notes supported the data collection. Additional walks were conducted during different times of the day to capture variations in lighting, usage, and comfort conditions. The observational study was informed by subjective impressions related to spatial comfort, safety, and accessibility, thereby bridging quantitative and qualitative approaches.

4. Data Gathering

This stage has been conducted through contention and continuous visits to the study area to record the detailed and audit data into freehand sketched maps (Figure 1), and hand-written table sheets as a guideline sheet (Figure 2). It have been provided some materials to aid the process of data gathering as follows:

- Map outlining the case study area and mobile camera.
- Data collection table form for the selected indicators with their levels.
- A piece of 1-meter length string (to estimate sidewalk widths).
- Clipboard, white A4 sheets and pencils.

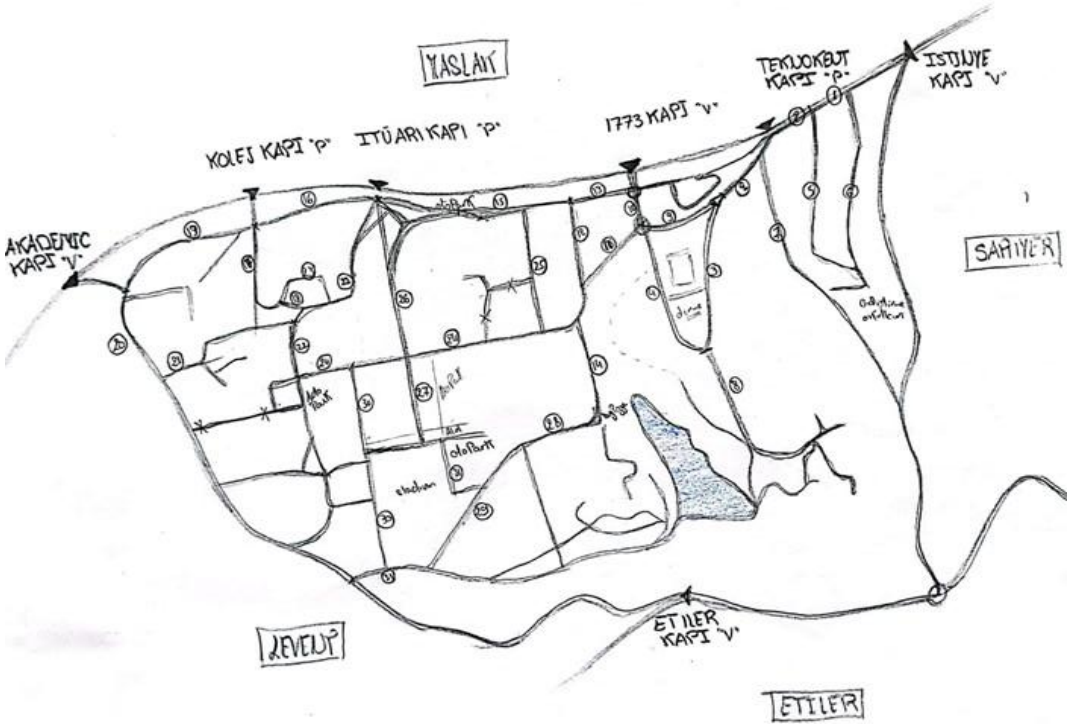

Figure 1. Freehand sketched map for data gathering (Source: the researcher).

Findings

Preliminary findings from the observation-based analysis suggest a mixed landscape of walkability on the ITU Maslak Campus. While the campus features numerous strengths like shaded walkways, pedestrian corridors, and green spaces, some challenges persist, particularly in terms of continuity, accessibility, and environmental quality.

- Strengths:
  - Abundance of green spaces and shaded walking paths in certain areas.
  - Proximity of key destinations within a walkable radius.
  - Strong potential for improvement through minor interventions.
- Challenges:
  - Inconsistent pedestrian infrastructure (e.g., sudden changes in sidewalk materials).
  - Insufficient seating, lighting, and wayfinding in some zones.
  - Barriers created by topography and vehicle-priority road design in central areas.

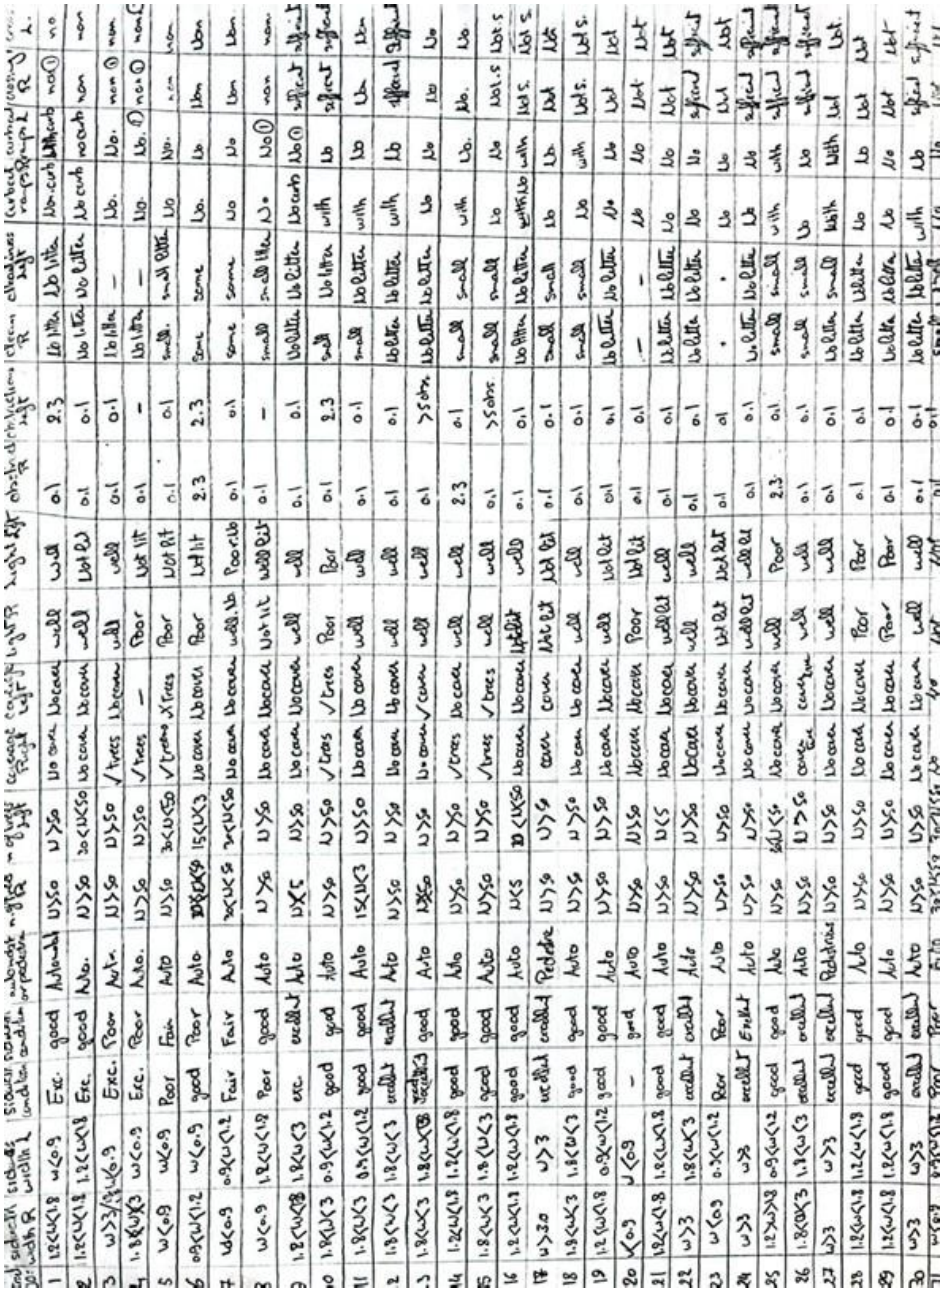

Figure 2. Data gathering manual sheet (Source: the researcher) .

In the category of Safe and Secure Green Walking, well-lit main corridors and large pedestrian plazas performed well. However, secondary paths and connectors between buildings were sometimes poorly lit or adjacent to vehicular traffic, reducing perceived safety, especially at night. Some routes, despite being lush and green, lacked protective buffers from nearby roads or had uneven pavement.

In terms of Convenience and Attractiveness, the central spine of the campus connecting major faculties and administrative buildings showed high walkability scores. This area included consistent walkway paving, visual interest, and gathering spaces with benches and shaded areas. However, peripheral areas such as dormitory access routes and hillside walkways were often disconnected, lacked signage, and presented steep or inaccessible gradients for some users.

Under the Waste and Pollution category, many walkways near academic buildings were clean and adequately equipped with waste bins. However, areas closer to vehicle parking lots, loading zones, and construction areas

were noisier, more polluted, and suffered from littering. These disparities indicate the need for targeted interventions in specific zones.

Conclusion

This extended abstract presents the results of an observational assessment of walkability on the ITU Maslak Campus using a composite indicator framework that merges walkability and green campus criteria. The analysis revealed a mixed walkability profile across the campus:

- Core pedestrian routes (e.g., the central spine) exhibited strong performance in terms of sidewalk quality, shade, and accessibility to key destinations.
- Peripheral and sloped areas, such as dormitory access routes and hillside paths, faced challenges related to lighting, walk surface uniformity, and wayfinding.
- While green space coverage and tree density contributed positively to perceived air quality, areas adjacent to roads and parking lots were more polluted and noisier.

These findings suggest that while the ITU Maslak Campus has a strong foundation for walkability, targeted improvements, such as better signage, enhanced lighting, and more continuous pedestrian infrastructure, are needed to create a more inclusive and sustainable walking environment.
The next phase of the study will incorporate user perspectives through surveys and daily walk diaries, which will deepen our understanding of how spatial features influence campus life, well-being, and sustainability. By integrating observational and participatory data, this research aims to inform both ITU's future mobility planning and broader green campus strategies aligned with the Sustainable Development Goals.

The Transformative Effect of Digital Art Installations on Public Spaces: The Case of Border Tuner

Gülay Didir[a], İsmail Eren Kürkçüoğlu[b]

[a] Istanbul Technical University, Graduate School, Urban Design Master Program, Türkiye
[b] Istanbul Technical University, Faculty of Architecture, Department of Urban Design, Türkiye
didir22@itu.edu.tr, ekurkcuoglu@itu.edu.tr

Keywords: Digital Art, Public Space, Spatial Transformation, Interactive İnstallation, Border Dynamics.

Aim

This study aims to explain clearly how digital art can change public spaces in three ways: the way the place looks and works, the way people feel and think while they are there, and the way the event is remembered later on. First, key ideas such as *space, place, public space,* and *digital art* are reviewed to set a solid base. Next, five well-known digital-art projects from different countries are compared to see which tools and methods are used most often and how the public reacts. After that, the research focuses on Rafael Lozano-Hemmer's *Border Tuner* and asks three main questions: (1) How did the light-and-sound system change the border zone between the two sides of the border while it was active? (2) How did the interactive parts help people on both sides talk to each other? (3) How did people continue to talk about the project after it was gone? By answering these questions, the study hopes to give artists, city planners, and decision-makers practical advice on choosing the right place, technology, and audience approach when they use digital art in cities.

Material and Method

The methodology begins with a theoretical exploration of the notions of space, place, public space, and digital art, tracing their historical development and mutual relations in the literature. This conceptual groundwork is followed by a comparative review of five digital-art interventions from around the world. The insights gleaned from these global examples then frame the case study of Rafael Lozano-Hemmer's *Border Tuner*. All spatial and perceptual findings are finally cross-referenced with the initial theoretical discussion and international precedents to evaluate the transformative capacity of digital art in public space.

Findings

Maps drawn before, during, and after the show show that *Border Tuner* changed how people used the border space for a short time: crowds gathered around the microphone towers, new meeting spots formed under the crossing light beams, and night-time activity in the area grew beyond its usual limits. A look at five other big digital artworks around the world confirms that temporary gear—projectors, sensors, and small stages—can quickly turn a quiet square or façade into a lively landmark without any permanent building work. Comments from about 1,200 social-media posts and interviews use strong words such as "together," "hope," and "moving," and a simple sentiment check shows that almost three-quarters of the reactions were positive. This boost in mood is strongest when visitors can control the light or sound themselves, so they feel like co-creators instead of passive viewers. Even after the equipment was removed, local news and community forums kept referring to the piece when discussing border issues, showing that the memory of a digital artwork can last much longer than the event itself and can fuel ongoing public debate.

Conclusion

The findings confirm that even time-bounded digital installations can leave a measurable imprint on the city. On a physical level, large-scale projections, multi-channel sound and responsive sensors can transform an otherwise unremarkable façade or plaza into a temporary landmark, drawing dense evening crowds and recalibrating pedestrian flows. This spatial re-programming, though short-lived, demonstrates that digital media provide urban

designers with a nimble toolset for testing alternative uses of public space without permanent construction. Equally important is the perceptual shift triggered by interactivity: when visitors modulate light, voice or data in real time, strangers are prompted to converse, exchange stories and view both the city and one another from a refreshed perspective. Such encounters nurture empathy across social or geopolitical divides—an effect clearly observed in *Border Tuner's* cross-border dialogues. Finally, the project's legacy endures beyond its dismantling; the shared memory of a luminous, participatory event can reinforce place identity and spark new debates over who public space is meant to serve. Taken together, these physical, perceptual and mnemonic impacts show that digitally mediated art is not merely a spectacle but a catalyst for civic reflection. Future studies should therefore track how long these layered impacts persist, compare results across cultural contexts and explore policies that encourage municipalities to host—and learn from—similar interventions.

To build on these insights, researchers could adopt longitudinal ethnographic approaches—returning to installation sites months or even years later to document whether initial behavioural changes become embedded in everyday routines. Mixed-method evaluations, combining pedestrian counts, GPS mobility traces and follow-up interviews, would shed light on the durability of spatial and social re-configurations. Moreover, comparative work across cities of varying size, governance style and technological capacity can reveal which institutional conditions best support inclusive digital art practices. At the policy level, cultural agencies might establish micro-grant schemes that pair artists with urban planners, ensuring that temporary interventions are aligned with broader regeneration or placemaking goals rather than remaining one-off spectacles. Ethical guidelines will also be essential: while sensors and data streams enrich interactivity, they raise privacy concerns that must be addressed through transparent data stewardship and community consent. Finally, sustainability should not be overlooked. Future projects could experiment with low-energy LED systems, solar-powered rigs and modular hardware that can be reused at multiple sites, thereby reducing the environmental footprint of large-scale digital artworks. By integrating such evaluative, institutional and ecological considerations, cities can move beyond the "wow" factor and harness digital art as a pragmatic, sustainable and socially responsive instrument for shaping public space.

The Impacts of Building-Street Interaction on Behavior: A case Study on Privacy in Kadıköy

İrem İncetuzcu[a], Gülden Demet Oruç Ertekin[b]

[a] Istanbul Technical University, Graduate School, Interdisciplinary Urban Design (MSc), Türkiye

Keywords: Street & Building Types, Behavior, Privacy, Territoriality, Defensible Space.

The interaction between individuals and urban space has long been a central concern in environmental psychology and urban design. Scholars such as Bechtel and Churchman (2002), Lang (1987), and Göregenli (2005) have emphasized the role of spatial variables in shaping human behavior, particularly through the dynamic negotiation between private and public domains. Within the Turkish context, a study by Barlas (2014) have further explored how the physical environment influences everyday practices and collective urban life. This research builds on these interdisciplinary foundations, with a specific focus on privacy as a mediator of spatial behavior. It draws on Jan Gehl's (1971; 2013) work on human-scale urbanism and street life, as well as Oscar Newman's (1972) Defensible Space Theory, to analyze how morphological interfaces between buildings and streets influence behavior.

Rather than viewing privacy solely as a static boundary, this study conceptualizes it as a layered and context-dependent construct that shapes spatial use, visibility, and public engagement. By adopting this framework, the research contributes to a broader understanding of how built environments structure human activities and perceptions in urban space. Focusing on three morphologically distinct streets in Kadıköy, Istanbul, this study explores how variations in street and building typologies contribute to different behavioral outcomes, particularly in terms of spatial accessibility, visibility, and use. The research is situated within a broader inquiry into how urban form shapes lived experience and seeks to contribute to the ongoing discourse on human-centered urban design.

Aim

This study aims to investigate how variations in building-street interactions influence spatial behavior in urban settings, with a particular focus on privacy as a mediating factor. By analyzing three morphologically distinct streets in Kadıköy, Istanbul, the research seeks to:

- Understand how architectural features such as visibility, access, and enclosure shape human engagement with public space;
- Examine how different degrees of privacy affect the diversity, intensity, and duration of behavioral patterns;
- Map behavioral dynamics in relation to street morphology using spatial analysis and observational techniques;
- Contribute to urban design and environmental psychology by framing privacy not merely as a limiting condition, but as a formative element of public life.

Material and Method

The study was conducted in three selected streets in Kadıköy, Istanbul, chosen based on their distinct building-street interactions and varying levels of privacy. These streets feature a mix of residential and commercial uses, influencing how privacy is manifested and experienced in public spaces.

A multi-method approach was employed, combining spatial analysis, on-site observation, and behavioral mapping to examine how urban morphology affects human interactions. On-site observations were carried out to systematically record spatial behaviors of individuals on these streets, while behavioral mapping techniques were used to analyze how different street morphologies shape user interactions. To further assess the impact of privacy, the study incorporated urban design frameworks, specifically Oscar Newman's Defensible Space Theory and Jan Gehl's studies on urban life, to evaluate how spatial boundaries influence public engagement. Additionally, cross-sectional street drawings were analyzed to determine how visibility and access affect privacy and human behavior in urban settings.

To identify key areas of interaction, the study mapped the most lively points where people spent significant time, correlating spatial behavior with privacy dynamics. Special attention was given to thresholds, stairs, and ground-floor windows, which were recognized as critical elements shaping the interaction between buildings and streets. By integrating these qualitative and spatial methods, the research provides a comprehensive understanding of how privacy influences street behavior and contributes to urban design and environmental psychology.

Findings

The findings of the study underscore the significant influence of privacy on shaping behavioral patterns in urban streets. The observations revealed that the spatial morphology of buildings, particularly the degree of visual access, the presence of thresholds, and the configuration of street-facing elements, directly affects how individuals interact with public space. Three key behavioral dimensions were observed: duration of presence, diversity of activity, and type of user interaction (residents vs. regulars).

Zuhal Street displayed the highest degree of architectural surveillance due to its wide cross-section and elevated visual exposure from residential buildings (Figure 1). Despite the presence of some regular users, most individuals engaged only in transitory actions such as walking or pausing briefly. The front gardens and set-back entrances appeared to discourage long-term presence, signaling stronger privacy boundaries. This resulted in spatial behavior that was more cautious, quiet, and brief in nature.

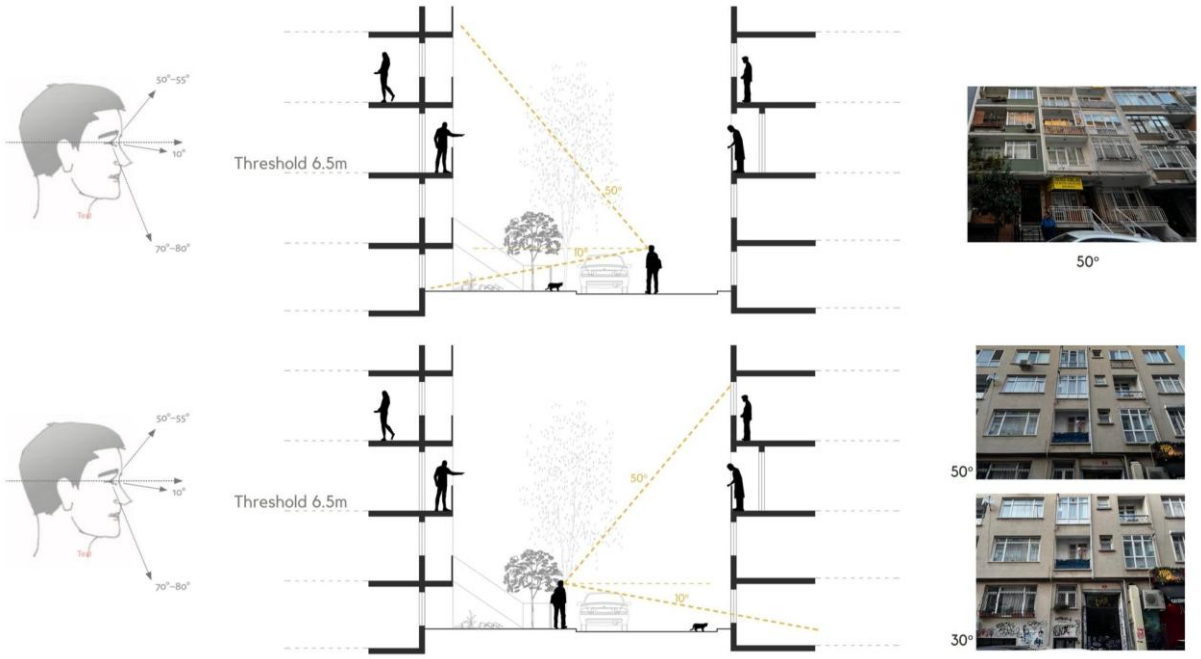

Figure 1. Section and the View of Left & Right Side from Zuhal Street.

Hacı Şükrü Street, with a moderate privacy profile, exhibited a more complex behavioral pattern. The most prominent point of engagement was the church wall, a non-residential structure that offered a visually open but socially protected edge. This created a semi-autonomous zone where people could sit, rest, or socialize without feeling surveilled (Figure 2). Residents were rarely visible in this space, whereas regulars used it as a gathering point. The spatial enclosure offered by the wall, combined with the lack of residential windows, contributed to more sustained informal use.

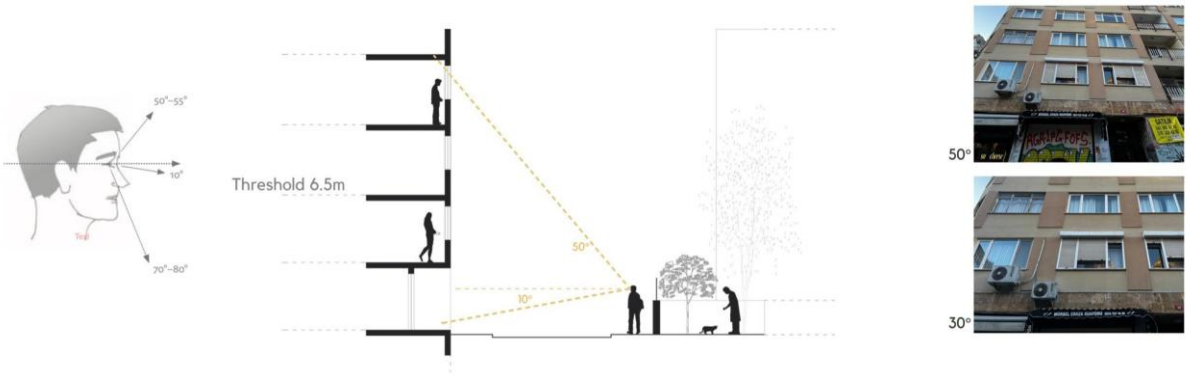

Figure 2. Section and the View of Left Side from Hacı Şükrü Street.

Kadife Street was the most socially active street, featuring minimal privacy enforcement and a dense mix of commercial and residential uses (Figure 3). The narrowness of the street limited visual control from buildings, and spatial elements such as wide doorsteps, low windows, and small thresholds were appropriated by users for a variety of informal activities—chatting, sitting, playing music, or simply lingering. The behavior here was diverse, interactive, and prolonged, highlighting the role of reduced spatial surveillance in enabling rich social dynamics.

Overall, the study confirms that as privacy thresholds increase, the publicness of the street diminishes, not just in terms of presence, but also in terms of behavioral spontaneity and social expressiveness. Conversely, when privacy boundaries are softened or blurred, streets accommodate a wider range of uses and users, fostering more vibrant public life.

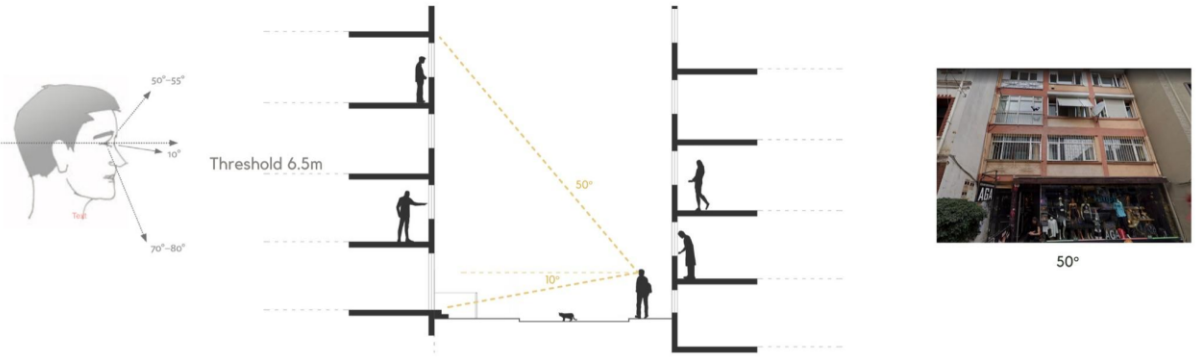

Figure 3. Section and the View of Left Side from Kadife Street.

Conclusion

The research demonstrates that the interaction between buildings and streets directly impacts urban behavior, particularly through the lens of privacy. The findings affirm that privacy can override public accessibility, influencing both the duration and nature of street interactions.

By mapping privacy levels and behavioral patterns, the study highlights the importance of urban design elements such as front gardens, staircases, door thresholds, and windows in shaping privacy dynamics. The results indicate

that wider streets intensify privacy effects, limiting public behavior, while narrower streets encourage social interactions.

This study contributes to urban design, environmental psychology, and public space planning by providing insights into how privacy should be strategically integrated into urban environments. Future research could expand these findings by examining the influence of cultural contexts and technological interventions in urban space management.

A Study Of Meaning In Ruins: Ancient Cities As Open-Air Museums

Bahar Çalışkan[a], Mehmet Emin Şalgamcıoğlu[b]

[a] İstanbul Technical University, Departmant of Architecture, Urban Design Master Program, Turkey
[b] İstanbul Technical University, Departmant of Architecture, Turkey
caliskanb23@itu.edu.tr

Keywords: Musealisation, Spatial Layout, Informal Education, Ancient City, UNESCO World Heritage List.

Aim

Ancient cities are the ruins of urban organizations that carry permanent settlement traces of the social, economic, and cultural activities of past civilizations to the present day. Today, the ruins that exist as a storyteller of the past have become an open-air museum. The architectural or urban design, religious, social, and cultural innovations that they witnessed or pioneered in history are the features that distinguish these city organizations from any other ruins, and how they present these features to audiences today is important. The aim of the study understand how ruin areas become meaningful perceptual space as an exhibition area and how ruin areas can narrate their heritage value to visitor with their exhibition route configuration and other information elements.

Material and Method

The material and method section should be written in Times New Roman font, justified alignment and in 10-point size. The study covers five ancient city settlements, Aphrodisias, Ephesus, Pergamon, Troy, and Xanthos, which are included in the UNESCO World Heritage List (WHL) and ancient Helenistic and Roman cities in Turkiye. Methodology applies in five stages. In the first stage, justified graphs were prepared to understand the organization of the exhibition paths. The j-graph gives a picture of the depth for all spaces in the structure, and it also shows ring properties of the spatial layout. Drawing on these ancient cities organization divides into two types, the first one is the ring type, where the entrance and exit of the exhibition on the same place, and the second type is the linear one, where the entrance and exit of the exhibition are located in different places. In the second stage, the UNESCO WHL selection criteria, representation like original structures, text, model, diagram, and other representations, and exhibition techniques are determined on site. In the third stage, human movement data was analyzed, according to visiting pattern and visiting sequences, and these data were combined with UNESCO criterias and determined the engagement of visitors with these values. In the fourth stage, space syntax analysis was created with the syntax2D program. Mean depth, integration-n, connectivity, and integibility analyses prepared from the syntax2D program. In the fifth stage, human movement data, spatial data, and syntactic data are analyzed together to understand which features guide and affect human movement in the ruin areas.

Findings

The Troy ancient city exhibition path has a ring-type exhibitioı road and the route is fully defined with wooden platforms. According to movement observation, people follow this road and integrate with UNESCO WHL criterias at the site. In the convex space 6, connectivity and integration data is higher than the average of the exhibition path, Also, this place is a high-speed area because of that some visitors skip visiting the northeast bastion of Troy, and this location is also an important feature of the site according to UNESCO. The Pergamon ancient city exhibition has a linear type of exhibition path, and the route is semi-defined with wooden material. but visitors use the exhibition road like a ring. According to movement observations and syntax data, visitors integrate just half of the UNESCO WHL criterias on the exhibition path. Convex space 2 Sanctuary of Athena, convex space 10 the sanctuary of Trajan, convex space 21 stage of theater and convexs space 30 gymnasium of the Demeter connectivity and integration datas higher than the average of the whole exhibition paths and these points works as returning points because of that visitors skipping half of the features of the sites UNESCO WHL critearia locations. The Ephesus ancient city exhibition path has a linear type exhibition road and is defined by original ancient roads and wooden covers. According to movement observation, people follow this road and integrate with UNESCO

WHL criterias at the site. In convex space 14 and convex space 29 start of the Curetes Streets connection and integration value are higher than the average value of the exhibition path, and a few visitors do not complete the road and return to these points. The Aphrodisias ancient city exhibition path has a ring-type exhibition road and is defined with stone stone-covered path and in some parts with a wooden platform. According to movement observation, people follow this road and fully integrate with UNESCO WHL criterias. In a convex space, 2 connectivity and integration data are higher than the average exhibition path, people do not skip any exhibited element in this area. In a convex space, 12 connectivity and integration value is higher than the average values, and some visitors skip visiting the sculptor's workshops and the council house. Xanthos exhibition road is a linear and non-defined, fully flexible exhibition path. UNESCO WHL criteria (ii) is not exhibited in the area, people can integrate criteria (iii) in the area, and it's shown in three parts, and some visitors skip the 17th mausoleum part.

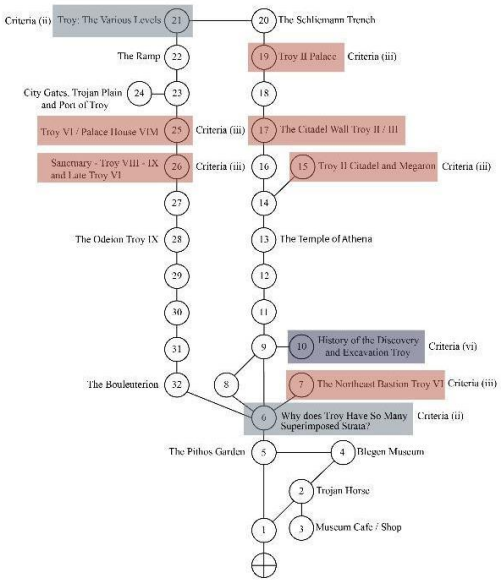

Figure 1. Troy J-Graph and Unesco Criterias.

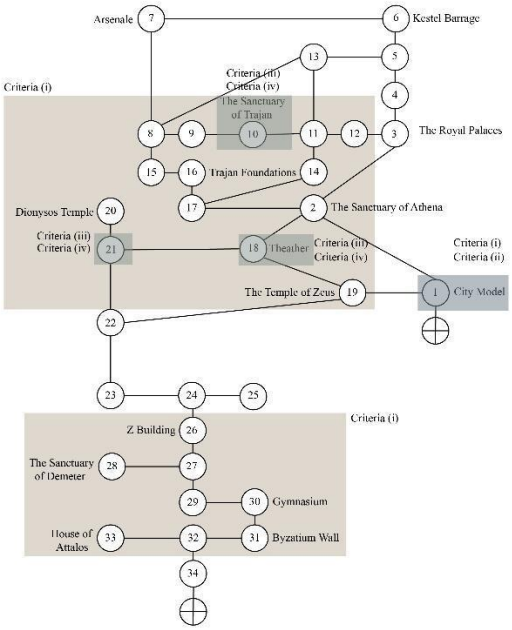

Figure 1. Pergamon J-Graph and Unesco Criterias.

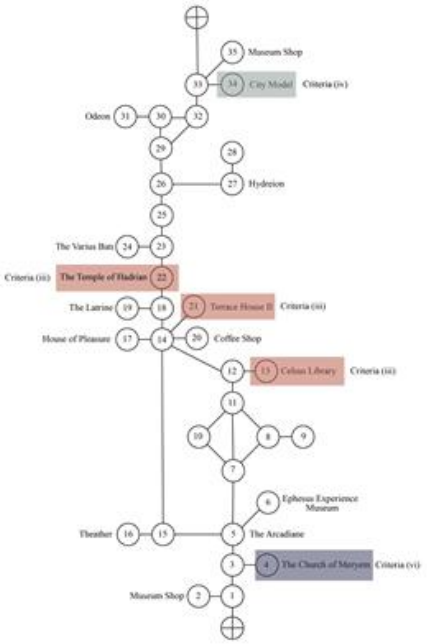

Figure 1. Ephesus J-Graph and UNESCO Criteria.

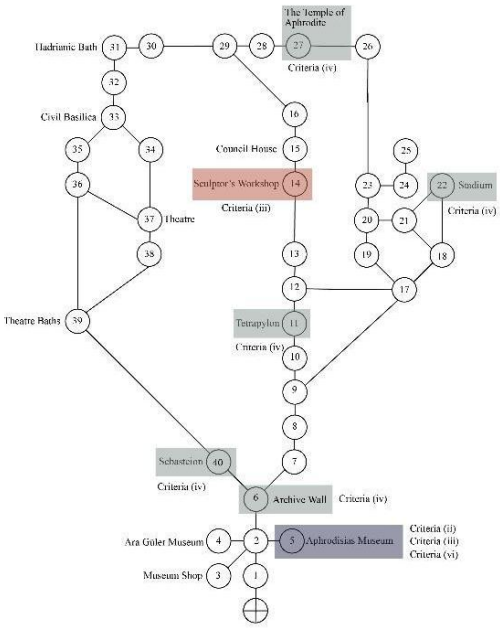

Figure 1. Aphrodisias J-Graph and Unesco Criterias.

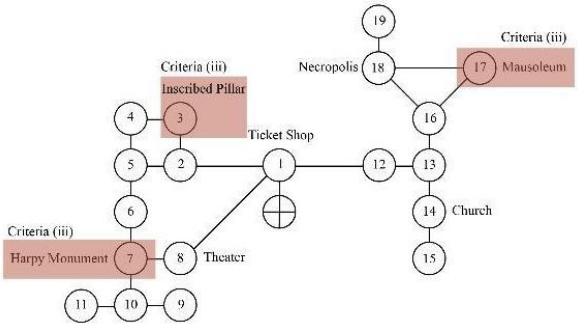

Figure 1. Xanthos J-Graph and UNESCO Criteria.

Conclusion

The evidence presented leads to the conclusion that when open-air ancient city exhibition paths have more than one space that has higher integration and connectivity value, in these places people move more flexibly, and these points can work as a returning Point and its cause that some visitors do not integrate with whole value of the city. As a secondary point, information boards placed which work with exhibited elements like ruins, architectural models, etc., and anastilosised and restored architectural elements work as stop points where people engage them, but people generally do not engage with information boards that do not work with any ruin or other representative object. All thing considered, anastilosited, restored architectural elements and their information board; also defined exhibition paths affect people's wayfinding and movement activities in ancient city areas.

The Impact of Space on Sound Perception: The Relationship Between Sound and Context

Kübra Türk[a], Meltem Erdem Kaya[b]

[a] Istanbul Technical University, Graduate School, Urban Design Program, Türkiye
[b] Istanbul Technical University, Faculty of Architecture, Landscape Architecture Program, Türkiye
turkk16@itu.edu.tr

Keywords: Soundscape, Contextual Perception, Auditory Cognition, Sonic Identity.

In the human sensory system, vision has always been regarded as the dominant mode of perception. This dominance also persists in spatial perception, where studies conducted by designers, urban planners, and architects are predominantly shaped by a visual-centric approach. However, spatial experience cannot be confined to visual input alone; space is fully perceived and experienced through the interaction of multiple senses. Alongside sight, senses such as hearing, touch, smell, and movement are fundamental components that influence an individual's spatial awareness. In particular, hearing offers powerful cues about the identity and character of a space. Despite sound being an element that defines space and shapes its atmosphere, it is often neglected in spatial design processes and is generally limited to acoustic control or noise management (Porteous, 1990). Nevertheless, the perceptual and semantic dimensions of sound make it a far more comprehensive subject of investigation.

One of the pioneering studies examining the role of sound in spatial perception is the World Soundscape Project (WSP), established in the 1970s at Simon Fraser University by Murray Schafer and his team. Under Schafer's leadership, this research group introduced the concept of the soundscape to the academic literature and brought an interdisciplinary perspective to the interaction between sound and environment. According to Schafer, a soundscape encompasses all the sounds perceived by individuals or communities within a specific environment (Fiebig, 2023). Schafer (1994) did not regard sounds solely as physical phenomena; instead, he classified them from acoustic, psychoacoustic, semantic, and aesthetic perspectives, revealing the multilayered structure of sound. He particularly focused on sound's ability to acquire different meanings depending on the context in which it is heard, thereby highlighting the dynamic relationship between sound and context. Schafer emphasized that two sounds with similar acoustic characteristics could evoke distinct perceptual and aesthetic responses depending on their context and argued that sounds might lose their identity when removed from their context. Indeed, the auditory system often fails to perceive the physical variations in sounds when they are listened to out of context, leading to alternative interpretations (Schafer, 1994).

Based on Schafer's exploration of the relationship between sound and context, this research investigates how sound perception can be manipulated depending on its context. Accordingly, the study analyzes how sounds are perceived under different contexts using urban sound recordings and a sound installation by Zimoun, who is known for creating kinetic sound sculptures with industrial materials (Öner, 2022). Similar to Zimoun's works, the research focuses on how sounds generated with familiar materials in everyday life can transform their identity when divorced from their original context. This relationship between sound and context reveals that spatial perception is not shaped solely by vision and that auditory input significantly influences the mental representation of space.

Aim

This study aims to emphasize the significance of sound and examine the determining role of context in sound perception. Specifically, it investigates how sounds that carry meaning and identity undergo perceptual changes when detached from their original context and presented in different environments. The study addresses the reciprocal interaction between sound and context and its effect on how individuals define, interpret, and mentally represent sounds.

Material and Method

This research was structured within a qualitative framework and is based on a survey conducted by digitally playing sound recordings to participants. The study involved 20 participants with diverse demographic backgrounds, including differences in age and occupation. During the research process, a total of 5 sound recordings, each carrying distinct semantic features, were utilized. These sound samples were categorized into two main groups: the first group consisted of industrial and mechanical sounds used in Zimoun's installations, while the second group comprised everyday urban sounds recorded in public spaces. This diversity aimed to analyze perceptual shifts in the participants' interpretations of sounds in relation to context.

The survey was conducted via an online platform, and participants were instructed to listen to the sounds in a quiet setting using headphones. This requirement was emphasized throughout the research to ensure consistency in listening conditions. To avoid guiding participants' perceptions, open-ended, straightforward, and non-leading questions were prepared.

For each sound recording, participants were asked two core questions: "What sound do you think you are hearing?" and "Where do you think you might have heard this sound? Please describe this environment with five words." Through these questions, the study aimed to gather data on how sounds were identified and to determine the assumed spatial contexts of these sounds. The collected responses were later processed and interpreted through word cloud analyses and qualitative evaluations.

Findings

The findings of this research clearly demonstrate the relationship between sound and context and its impact on sound perception. Participants' responses revealed that sounds tend to lose their identity when listened to out of context, resulting in misinterpretation or alternative identification of the sounds. In samples taken from Zimoun's sound installations, the majority of participants associated these sounds with different auditory environments, matching them with industrial settings such as factories, workshops, or construction sites. However, these sounds were actually produced by Zimoun using everyday objects and mechanical systems within an artistic context. This indicates that when sounds are removed from their context, they acquire new layers of meaning and that perceptions regarding the origin of sounds are shaped by listeners' spatial experiences and personal memories.

In urban sound samples, this perceptual deviation was also present but to a lesser extent. Most participants were able to identify the sounds as related to a coastal area, but there was still a noticeable dispersion in perception, with alternative interpretations present.

The research findings support Schafer's argument that sounds tend to lose their identity when removed from context. The participants' responses show that sound is perceived not merely based on its physical attributes but also through individual experiences, spatial memory, and contextual knowledge. These results reveal that sound functions not only as an acoustic datum but also as a tool for spatial and cultural interpretation, with sensory perception being closely tied to context.

Conclusion

This study explored the relationship between sound and context, revealing how sounds change identity on a perceptual level and how they can transform spatial contexts. The findings confirmed the initial hypothesis, showing that sounds tend to be perceived differently when detached from their original context. Notably, the fact that participants often misidentified or associated Zimoun's artistic sound installations and urban sound samples with incorrect spatial contexts demonstrates that sounds lose meaning when separated from their "place." This supports Schafer's assertion regarding the decisive role of context in perception.

Another significant finding of the study is that some sounds not only lose their identity but also possess the potential to manipulate and alter the listener's perception of the surrounding environment. This highlights that, in fields such as architecture and spatial design, sound should be regarded not merely as an auditory element but as a powerful design component capable of transforming spatial perception and memory.

In the future, the creation of a comprehensive research platform that classifies sounds capable of manipulating their context and brings such sounds together could contribute to a deeper exploration of the sound-space relationship.

Urban Resilience

Pedestrianization as a Tool to Create Resilient Cities Through Open Space Networks

Keywords: Pedestrianization, Urban Resilience, Open Spaces, Open Space Network.

Aim

Urban resilience is increasingly important for densely populated areas facing challenges such as fragmented urban form, ecological degradation, and social inequality. In high-density districts with limited intervention, failure to build resilience often leads to further decline in quality of life. This study explores how open space networks strengthened by pedestrianization can enhance resilience by promoting ecological continuity, social interaction, and spatial cohesion. Focusing on Bayrampaşa's Yenidoğan neighborhood, it examines the potential of pedestrian-oriented design to reconnect urban spaces and support adaptive environments.

Material and Method

This study is based on an in-depth literature review, urban morphology analysis, and field observation. The theoretical framework explores urban resilience, open space, and pedestrianization concepts focusing especially on the evolution of pedestrian-oriented design, walkability, and strategy typologies. These themes were examined both individually and in relation to each other, supported by key urban planning models that illustrate their spatial and social implications.

The case study focuses on Bayrampaşa, a densely built district in Istanbul characterized by mixed land uses, insufficient open space, and limited pedestrian infrastructure. Within this context, Yenidoğan neighborhood was selected for detailed analysis. Using 1/5000 land use data, street observations, and morphological mapping, urban patterns were analysed. Specific zones with varying physical characteristics were examined, and pedestrianization strategies were proposed based on observed spatial challenges.

Findings

As cities are transformed by environmental, social, and economic changes, the ways we plan and intervene in urban environments should also evolve. Urban resilience is defined as a city's capacity to withstand disruptions while continuing to function effectively (Mehmood, 2015). While sustainability focuses on maintaining balance, resilience emphasizes adaptability and flexibility. As urban populations exceed 50% of the global total (UNDRR, 2017), the increasing pressures of growth and spatial demand make resilience more critical.

Since the early 20th century, the adoption of automobiles has transformed the structure of cities. The freedom to travel long distances led to the rise of suburbs and reshaped urban planning priorities.

Table 1. Important Planning Ideas that Influenced by Automobile.

Planning Idea	Implications in urban morphology
Linear Urban Development (Arturo "Sorio y Mata)	● Aim: To preserve the relationship between nature and the city. ● Linear cities then became car oriented as the use of cars increase (Filippov, 2017).
Garden City (Ebenezer Howard)	● Aim: Decentralizing the overcrowded industrial city by creating self-contained settlements (Howard, 1902; Hall, 2002) ● Suburban development caused wide roads, parking lots and single-use zoning. It unintentionally encouraged automobile dependency and spatial fragmentation (Banister, 2005).
Neighborhood Unit (Clarence Perry)	● Aim: Organizing the city around walkable, self-contained communities (Perry, 1929). ● Resulted in an overemphasis on road hierarchy and urban segregation, which unintentionally increased automobile dependency (Southworth & Owens, 1993).
Satellite City (Raymond Unwin)	● Aim: To create smaller, self-contained urban areas located outside the big metropolitan centers (Unwin, 1909). ● Mid to late 20th century, dominance of the automobile has increased. The spatial segregation links central urban cores caused automobile dependency (Hall, 2002).
Broadacre City (Frank Lloyd Wright)	● Low density living areas caused spreading out homes and jobs. ● It was criticized for its effects on nature because of the urban sprawl impacts (Watson, 2018). ● It also increased the dependency on automobile and negatively impact the walkability in urban areas.
Radiant City/Villa Radieuse (Le Corbusier)	● Aim: Vertically organized urban structure defined by high-rise residential towers, large green open spaces, strict zoning and efficient infrastructure (Le Corbusier, 1935). Seperating pedestrian and vehicle traffic, placing the automobile at the center of urban mobility. ● Zoning and automobile infrastructure caused the rise of car dependency. Wide highways crossing urban centers, single-function districts, has led to the gradual disappearance of mixed-use, walkable environments (Jacobs, 1962).
Radburn (Clarence Perry, Henry Wright, Clarence Stein)	● Aim: Creating cul-de-sacs and traffic-free superblocks, seperating pedestrian movement and vehicle traffic, locating public areas were on pedestrian networks and in open spaces (Sharifi, 2016). ● Car was still needed for daily activities because superblocks often segregate these different activities (Southworth, M., & Ben-Joseph, E., 2003).

Table 2. Different Pedestrianization Strategy Classifications.

Source	Pedestrianization Strategies
European Commision (2024)	● Full Pedestrianization ● Phased Pedestrianization ● Multi-modal Prioritization (like Transit Oriented Development) ● Tactical Pedestrianization ● Traffic Calming
Project for Public Spaces (2019)	● Seasonal/Event Based Pedestrianization ● Traffic Calming ● Transit Oriented Development ● Parklets ● Tactical/Pop-up Pedestrianization ● Shared Streets ● Full Pedestrianization
Istanbul Historic Peninsula Context (EMBARQ Turkey, 2014)	● Seasonal/Event Based Pedestrianization ● Traffic Calming ● Transit Oriented Development ● Parklets ● Tactical/Pop-up Pedestrianization ● Shared Streets ● Full Pedestrianization
Hass-Klau (2015)	● Seasonal/Event Based Pedestrianization ● Traffic Calming ● Transit Oriented Development ● Parklets ● Tactical/Pop-up Pedestrianization ● Shared Streets ● Full Pedestrianization

Open space networks become essential infrastructure for climate adaptation and disaster resilience. Both people and ecosystems benefit from compact and connected cities where pedestrian pathways and green spaces blend together. Such environments enable flexible movement during disruptions, improve quality of life and enable cities to develop with change, not just survive it. According to these, Bayrampaşa Yenidoğan neighborhood was analysed because of its unique urban characteristics.

Figure 1. Land Use, Open Space and Solid&Void Analysis of Bayrampaşa (Produced by author from ArcGIS data of the 1/5000 plan).

Examining the data, there is no enough open spaces except than small, fragmented or useless green areas. The district divided by 2 highways in the east-west direction. It is characterized by old building inventory, very dense urban population, very dense urban development, industrial areas are intertwined with living areas, lack of open space, traffic congestion, limited pedestrian facilities and earthquake risk.

After analysing Bayrampaşa, Yenidoğan neighborhood was analysed in details. The neighborhood, where Bayrampaşa Municipality building is located, includes many different uses and daily visits are high, except for residents. The complex structuring in Bayrampaşa also shows itself here. Business centers, many of which house small producers, are part of daily life here. Residential areas are mostly in the form of long blocks, with low permeability. Streets are narrow and the distances between buildings are very limited.

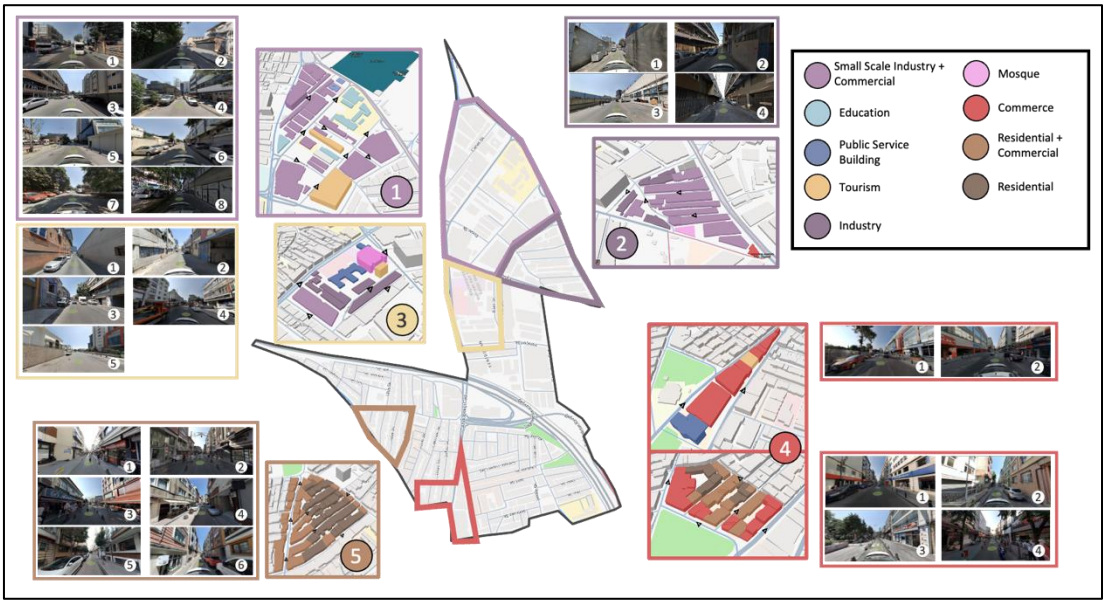

Figure 2. Land Use, Open Space and Solid&Void Analysis of Bayrampaşa (Produced by author from ArcGIS data of the 1/5000 plan).

Functions of the buildings in specific areas were identified with site observation and mapping. The problems in these areas also defined. The analysis of five sub-areas in Yenidoğan reveals pedestrian challenges. In the first and second areas, dominated by small-scale industry and commerce, sidewalks are either missing or blocked by vehicles, and green areas are nearly absent. Pedestrian access is unsafe due to high walls, and heavy traffic. The third area contains mixed uses but lacks a stable pedestrian infrastructure which goes beyond the main street where sidewalks are still partially inaccessible. The fourth zone is mainly residential, with some pedestrian improvements in the commercial areas. However, sidewalk invasions and lack of open spaces continue, and long, continuous

blocks limit walkability. The fifth area, which includes the municipality building and continues along a major transit corridor, shows potential due to a large vacant open space. However, this area remains underused and disconnected from the surrounding pedestrian network. According to these analysis, different pedestrianization strategies were matched with the area.

Table 3. Pedestrianization Strategies and Area Matching.

	Area				
Strategy	1	2	3	4	5
Full Pedestrianization				x	
Phased pedestrianization				x	
Multi-modal pedestrianization/TOD	x			x	
Tactical/Pop-up/Seasonal/Event based pedestrianization	x		x	x	
Traffic Calming	x			x	x
Parklets	x	x		x	x
Shared Streets			x	x	
Timed/Time Restricted pedestrianization	x	x		x	x
Green axes/Ecological Corridors					

Conclusion

This study concludes that pedestrianization is more than a mobility intervention, it is a necessary spatial strategy for building resilient urban environments. In areas like Yenidoğan, where density and fragmentation come together, pedestrianization can restructure the urban fabric by improving spatial continuity, social cohesion and ecological infrastructure. When open spaces are connected by well-designed pedestrian networks, they provide adaptive urban ecosystems that can absorb change, support biodiversity and improve public well-being.

Integrating open space networks with pedestrian routes is a step towards reimagining how urban infrastructure supports people and ecosystems. Pedestrianization offers a participatory and progressive way of urban regeneration. This approach reflects the values of sustainability, inclusiveness and long-term adaptability. The Bayrampaşa case demonstrates that even in highly dense urban environments, meaningful change is possible with location-specific design interventions and strategic reconfiguration of the open space system. Future studies should continue to explore the interaction of social equity, environmental health and spatial justice in pedestrianization initiatives, especially in rapidly urbanizing global cities to enhance urban resilience through open space systems.

Keywords: Twist Ratio, Helicopter Theory, Performance.

Aim

The scope of thesis study is to investigate the effect of twist ratio in hover and forward flight conditions via helicopter theory. After the outcome of the helicopter theory, the type of twist distributions have been examined such as ideal, linear and quadratic. Various flight conditions, flight speeds and twist ratios were reflected in performance equations and resulting graphs were obtained via MATLAB.

In order to satisfy the rotorcraft's needs, structural stresses, fuel consumption, and overall flight performance are all influenced by the aerodynamic efficiency of the helicopter rotor. One of the numerous design components that regulate rotor behaviour is the twist ratio, which is the variation in pitch angle along the rotor blade. The ability to passively or actively adjust the twist ratio allows for improved flying qualities in a variety of operating regimes. The goal of the thesis is to comprehend how twist affects performance characteristics in order to lower the power required for rotorcrafts to hover and fly forward. Moreover, the subsequent aim is to discover how the active twist ratio concepts are implemented.

Morphing structures are flexible and adaptive structural systems that can change their geometry, shape in order to meet the requirements for flight conditions of the rotorcraft. Morphing systems are made to dynamically optimise performance, lower drag, increase lift, or obtain stability while in flight, in contrast to traditional rigid components [1]. In order to accomplish smooth, continuous, or discrete deformations without the use of conventional mechanical joints or hinges, these structures usually combine smart materials (such as shape memory alloys, piezoelectric actuators, or compliant mechanisms) with sophisticated control systems. The active twist rotor (ATR) concept is a promising morphing rotor technology that enhances aerodynamic efficiency, reduces noise, and suppresses vibration by controlling the torsional deformation of rotor blades in real time [1]. Active twist rotors, in contrast to conventional passive or mechanically driven designs, use smart materials incorporated in or bonded to the blade structure, particularly shape memory alloys (SMAs) and piezoelectric actuators, to achieve distributed, adaptive twist control across the blade's span. In this paper, the main goal is to investigate the power consumption reduction by using this active twist rotor (ATR).

Material and Method

In order to calculate the effect of twist of the blade, the helicopter theory discipline must be studied. One of the most basic aerodynamic models for examining helicopter rotors, particularly in hover and vertical flight, is Momentum Theory, often referred to the Actuator Disc Theory. It views the rotor as an idealised, continually thin disc that accelerates the wind downward to produce thrust by giving it a pressure difference. It basically depends on conservation of mass, momentum and energy through the rotor-disk section shown if Figure 1.

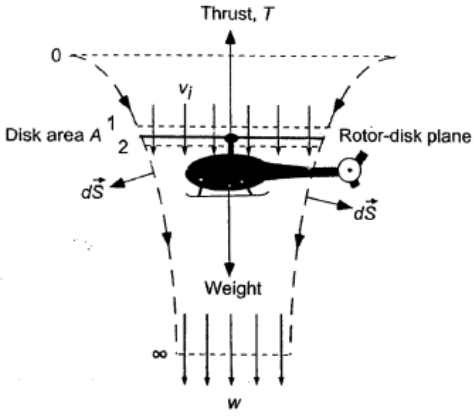

Figure 1. Flow representation for momentum theory in hover condition [2].

Conservation of mass between stations 2 and station ∞ could be written as in the Equation 1.

$$\dot{m} = \iint_{\infty} \rho \vec{w} \cdot d\vec{S} = \iint_{2} \rho \vec{v_i} \cdot d\vec{S}$$

$$\dot{m} = \rho w A_{\infty} = \rho v_i A \tag{1}$$

In the equation $\dot{m}$ is mass flux, ρ is air density, w is far wake velocity, v_i is induced velocity and and $d\vec{S}$ stands for area. Second approach for momentum theory is the application of conservation of momentum as in Equation 2.

$$F = T = \iint_{\infty} \rho(\vec{w}\, d\vec{S}) \cdot \vec{w} - \iint_{0} \rho(\vec{V}\, d\vec{S}) \cdot \vec{V}_{\hookrightarrow Equals\ to\ zero\ (\vec{V}=0)})$$

$$T = \dot{m} \cdot w \tag{2}$$

In this formula the F represents the force and will be equal to thrust generated by the rotorcraft which can be seen with the notation as T in the equation. Final principle for completing the theory is the conservation of energy [2]. Before considering this principle, work-energy relation must be introduced as in Equation 3, U is the energy and W is the work done through station 1 to 2 respectively.

$$U_1 + W_{1\to 2} = U_2 \tag{3}$$

After the definition of power in Equation 4, formula can be written for the conservation of energy in Equation 5.

$$Power = \frac{Work\ done}{time} = \frac{Force \times Distance}{time} = Force \times Velocity \tag{4}$$

$$(P_{ind})_{ideal} = T \cdot v_i = \iint_{\infty} \frac{1}{2} \rho(\vec{w}\, d\vec{S}) \cdot \overrightarrow{w^2}_{\hookrightarrow Equals\ to\ \frac{1}{2}\dot{m}} - \iint_{0} \frac{1}{2} \rho(\vec{V}\, d\vec{S}) \cdot \overrightarrow{V^2}_{\hookrightarrow Equals\ to\ zero\ (\vec{V}=0)}$$

$$(P_{ind})_{ideal} = T \cdot v_i = \frac{1}{2} \dot{m}\, w^2 \tag{5}$$

Afterwards, a nondimensionless paratemeter power coefficient can be determined respectively. Power coefficient is a critical parameter for comparing different rotorcrafts in the name of power efficiency. In hover there are two power coefficient definitions such as induced power coefficient C_{P_i} and the profile power coefficient C_{P_0} their formulas can be seen in Equation 6.

$$C_P = C_{P_i} + C_{P_0} = \frac{\kappa C_T^{3/2}}{\sqrt{2}} + \frac{\sigma C_{d_0}}{8} \tag{6}$$

In this formula, C_T is the thrust coefficient, σ is the correction factor from ideal to nonideal conditions, σ is the rotor solidity and the formula can be seen in Equation 7, C_{d_0} is the constant drag coefficient.

$$\sigma = \frac{N_b R c}{\pi R^2} = \frac{N_b c}{\pi R} \tag{7}$$

In rotor solidity formula the N_b is the number of blades and c is chord length of the airfoil and the R is the radius of the disk area. Induced power is the required power to provide an adequate thrust, profile power is to drag related power loss from the rotor blades.

In order to improve on momentum theory, Blade Element Theory (BET) examines the forces acting on each rotor blade's small differential sections, or elements. Lift and drag are locally calculated using the relative airflow, and

each blade is segmented along its span [2]. Figure 2 represents the top view for the blade, U_R is the radial component, U_T is the tangential component, U is the resultant velocity and Ω is the angular velocity.

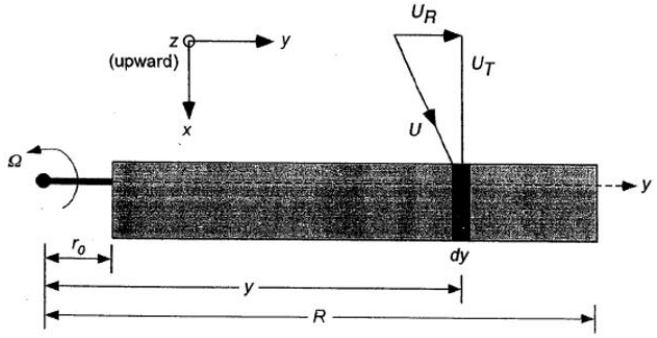

Figure 2. Top view of the rotor blade [2].

Figure 3 shows the blade element where U_P is perpendicular component, θ is the pitch angle, ϕ is the induced angle and α is the effective angle of attack.

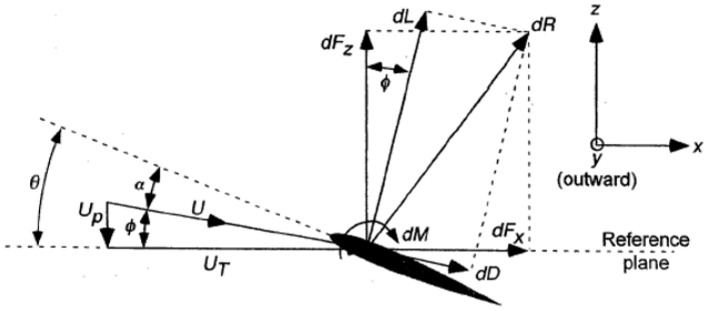

Figure 3. Side view of the rotor blade [2].

Final theory to obtain the performance results of a rotorcraft is the blade element momentum theory (BEMT) which is the combination of both momentum and blade element theory. In addition to accounting for the induced velocity resulting from momentum theory, it models the rotor by breaking the blades into small spanwise parts and computing the aerodynamic forces acting on each. In this section pitch angle will be a function of r nondimensional radial position. By using the BEMT, inflow ratio λ can be determined as in the Equation 8.

$$\lambda(r) = \lambda_i(r) = \frac{\sigma C_{l_\alpha}}{16}\left(\sqrt{1 + \frac{32}{\sigma C_{l_\alpha}}\theta r} - 1\right) \tag{8}$$

The inflow ratio is basically a dimensionless parameter for axial velocity component as it can be defined as the ratio of induced velocity to the rotor tip speed. By using inflow ratio and the pitch angle distribution as a function, thrust coefficient can be calculated as in the Equation 9.

$$C_T = \frac{1}{2}\sigma C_{l_\alpha}\int_0^1 (\theta r^2 - \lambda r)\, dr \tag{9}$$

Since the thrust coefficient is obtained, power coefficient can be found which indicates the power consumption.

Findings

Another challenge is to make inflow ratio more homogeneous distribution along the blade. Application of negative twist along the blade can make this possible, twist function is defined in Equation 10 as ideally twisted blade.

$$\theta(r) = \frac{\theta_{tip}}{r} \tag{10}$$

Rotorcraft can be untwisted, linearly twisted, quadratically twisted or ideally twisted. By the type of twist, corresponding twist formula will change. A linearly twisted function example can be seen in Equation 11.

$$\theta(r) = \theta_0 + r \cdot \theta_{tw} \tag{11}$$

By changing the twist rate θ_{tw}, the representative inflow ratio can be seen in Figure 4.

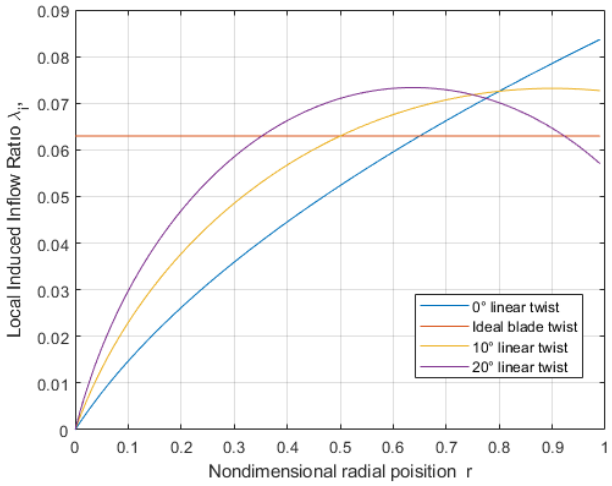

Figure 4. Inflow ratio distributions with various twist distributions.

Afterwards, thrust coefficient can be calculated in hover condition, subsequently the power coefficient can be found. For these calculations UH-60-A Sikorsky rotorcraft has been selected [3]. Required parameters from main rotor for computation the power coefficients are listed in Table 1.

Table 1. Sikorsky UH60A Characteristic Parameters [3].

Main Rotor Parameters	
Rotor Radius	8.1788 m
Rotor Speed	27.0 rad/s
Blade Chord Length	0.5273 m
Blade Twist Type	Nonlinear
Blade Airfoil	SC 1095 / SC 1094R8
Number of Blades	4
Blade Mass per Unit Length	13.92 kg/m

By using MATLAB, representative power coefficients are calculated for linearly twisted rotorcraft for various amount of linear twist angles as 0°, -4°, -8°, -12°, -16°. It can be clearly seen the negatively twisted blades consume less power for hovering as in shown in Figure 5.

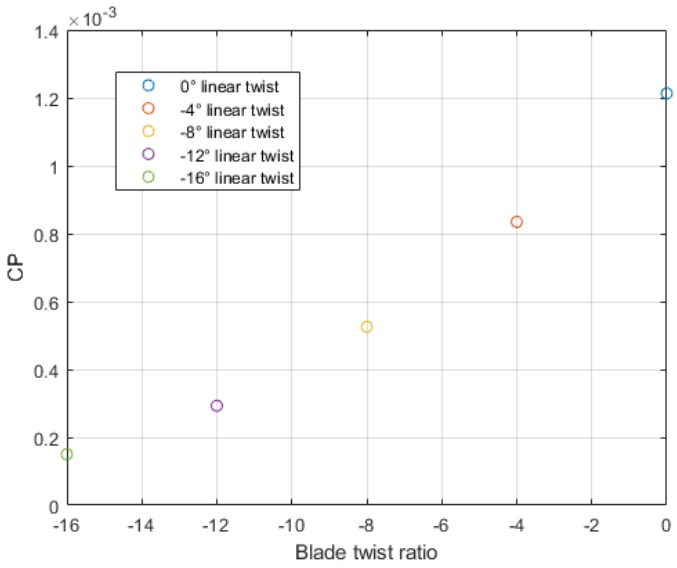

Figure 5. Power coefficient for various twist distributions for Hover.

Since the effect of twist distribution is determined, the method of active twist rotor must be decided. Active Fiber Composite (AFC) and Macro Fiber Composite structures can the examples for morphing the rotor blades. AFC structures as shown in Figure 6, includes embedded electrodes to have a high in-plane deflection and they are used in considerable high actuation cases [4].

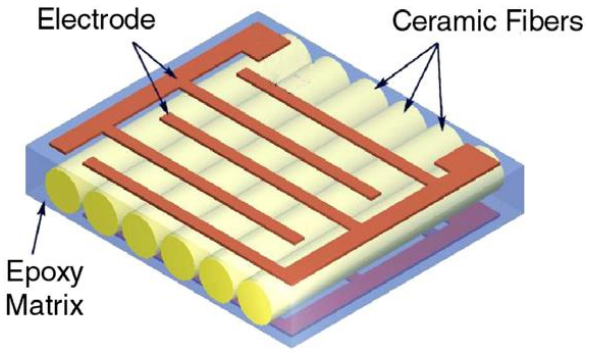

Figure 6. AFC (Active Fiber Composite) [5].

MFC structures are stacked as multi-layers and includes kapton, epoxy and piezoelectric PZT layers which can be seen in Figure 7.

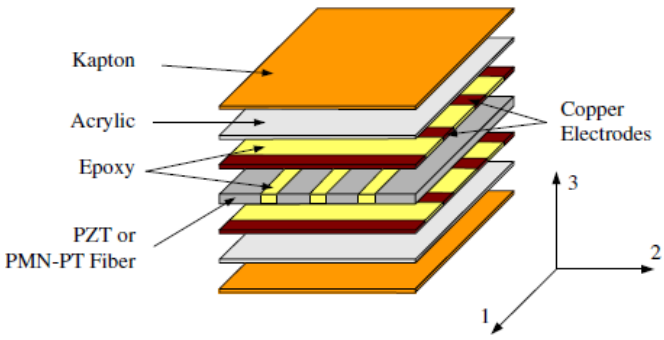

Figure 7. Layer structure of MFC [5].

The actuation performance and flexibility of a MFC piezoelectric fiber composite AMFC actuator are significantly better than those of a monolithic piezoceramic actuator. In ATR applications, MFC patches are usually oriented

along the longitudinal axis and bonded or integrated within the rotor blade's composite skin. The anisotropic composite structure of the blade interacts with the produced strain of the MFCs during activation, producing a torsional moment that modifies the blade's local pitch angle. Without the use of mechanical links or moving parts, system may generate dispersed twist profiles along the blade span by accurately adjusting the input voltage in response to flight conditions or closed-loop control signals. An example of MFC structure is shown in Figure 8 [6].

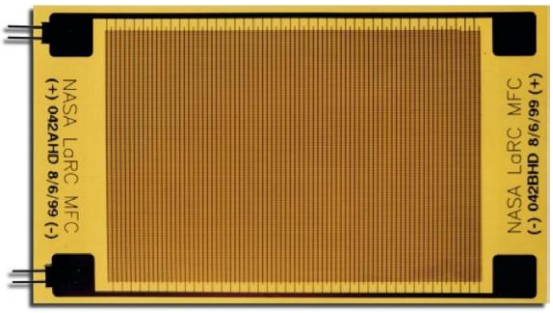

Figure 8. MFC Macro Fiber Composite [5].

A number of variables, including actuator location, blade stiffness distribution, material coupling effects, and control bandwidth, affect how successful MFC-based active twist systems are. Additionally, MFCs are a potential and versatile alternative for evolving rotor technologies due to their low weight, great durability, and compatibility with composite materials [7].

Conclusion

Rotorcraft performance is directly related to its power coefficient. In this research, the fund**a**mentals of helicopter theory have been understood. Afterwards, thrust coefficient is calculated in hover condition, subsequently the power coefficient can be found. It was critical to have homogenous inflow ratio distribution along the spanwise direction of the rotor in order to reduce the power consumption. With the scope of helicopter theory, various twist cases were compared to analyze the **e**ffect of twist. In the following stage, the methods of active twist rotor structures have been introduced and these methods compared and understood.

Span-Morphing Rotorcrafts: Performance Analysis and Mechanism Selection

Öykü Etçi[a], Özge Özdemir[a]

[a] Istanbul Technical University, Department of Aeronautical and Astronautical Engineering, Rotary Wing Aircraft, Türkiye
etci17@itu.edu.tr

Keywords: Variable Span Morphing, Rotorcraft Performance, Flight Efficiency.

Aim

The concept of morphing in the aerospace industry began with changing the shape of the wings in order to enhance the aircraft's performance, efficiency, and adaptability to different flight conditions. In rotorcraft applications, morphing structures can be used to modify blade geometry, including span length, chord length, twist distribution, and adaptive airfoil, to optimize the rotorcraft's aerodynamic performance [2].

During hover operation, power consumption is maximum in a rotorcraft as it requires continuous thrust equal to its weight without the assistance of aerodynamic lift. Since it also happens to be the flight condition where a rotorcraft spends most of its time, they are specifically designed to maximize performance in this flight regime [1].

A larger rotor area corresponds to a larger swept area, which generally results in better hover efficiency. In the hover condition, the efficiency is increased by enhancing thrust while reducing the required power. Therefore, increasing the rotor area by adjusting the span length is preferable, provided that the blade tip speed, V_{tip}, does not exceed the operational Mach number. However, in forward flight conditions, increased rotor diameter leads to higher profile drag, which can potentially reduce cruise performance. Thus, adjusting the rotor diameter based on the flight condition can significantly enhance the rotorcraft's efficiency.

The aim of this thesis is to enhance the efficiency of a rotorcraft during hover, climb, and forward flight conditions by dynamically adjusting the rotor diameter using mechanisms suitable for the related rotorcraft.

Material and Method

For analysis presented in this study, MATLAB was utilized as the primary computational tool. Three different mathematical approach were employed during performance analysis of rotorcrafts. Momentum Theory, Blade Element Theory (BET), and Blade Element Momentum Theory (BEMT).

Hover and axial climb regimes are relatively easy to model with Momentum Theory, which treats the rotor as an infinitely thin disc and assumes a constant velocity along the axis of rotation. This method provides an initial approximation of rotor thrust and power based on the conservation of fluid mass, momentum, and energy for more advanced analyses of rotor aerodynamics. The ideal power required to hover is given in Eq. (1) [1].

In momentum theory, nondimensionalizing velocities by blade tip speed (V_{tip}), Eq. (2), is essential to reduce the complexity of the mathematical equations and make the results more universally applicable. These nondimensional parameters include induced inflow ratio (λ_h), thrust coefficient, rotor power coefficient, and ideal power coefficient given in Eq. (3), Eq. (4), Eq. (5), Eq. (6) respectively.

Due to nonideal effects such as viscosity, Momentum Theory tends to underpredict the actual power required. However, since it is proportional to the required power calculated by the Momentum Theory, an induced power correction factor (κ) is introduced. This factor is calculated through various rotor measurements and flight tests [1]. For the hovering regime, the power coefficient is divided into two parameters. Induced ($C_{p,i}$), and profile ($C_{p,0}$) power coefficients are given in Eq. (7) Where σ is rotor solidity Eq. (8) and c_{d_0} is constant drag coefficient.

Forward flight condition requires a different approach than the hovering regime due to the aerodynamic complexity. The induced velocity for forward flight can be calculated using Eq. (9) which often requires numerical approaches like fixed-point iteration or the Newton-Raphson iteration method. The Newton-Raphson method for

calculating the inflow ratio is given in Eq. (10), where the initial inflow ratio is typically taken as the hover inflow ratio, $\lambda_0 = \lambda_h$. Since the rotorcraft is moving through the air, parasitic power must be accounted for to overcome skin friction and form drag. These drag components contribute to the required total power in forward flight along with induced power and profile power as given in Eq. (11) [1].

To further refine momentum theory, Blade Element Theory applies conventional airfoil theory to the rotating blades. In BET, rotor blades are considered rigid, despite their flexibility, as the dominant force generated by the rotation of the blades, centrifugal force, maintains the blades rigidity. BET analyzes the aerodynamic performance of the rotating blades by dividing them into small segments along the span and determining the overall behavior of the blade by summing the contributions of these individual sections [5].

Blade Element Momentum Theory becomes important as it combines both Momentum Theory and Blade Element Theory to provide a more accurate representation of aerodynamic effects by defining the effects of taper and twist on parameters such as thrust coefficient C_T, induced power coefficient C_{P_i}, and inflow ratio λ.

Findings

To evaluate rotorcraft performance, a disk loading versus power loading graph is important as it illustrates the trade-off between maximum hovering efficiency and high-speed forward flight, Figure 1. For a single-rotor aircraft in hover, disk loading is the ratio of thrust to rotor area Eq. (12), where rotor thrust equals the rotorcraft's weight, and power loading is defined as the ratio of thrust to the power required to hover. It is also inversely proportional to the induced velocity (Eq. (13)).

Conventional helicopters typically operate in the low disk loading, high power loading region, prioritizing hover efficiency with large rotors. In contrast, high-speed rotorcraft, such as tiltrotors and compound helicopters, feature higher disk loading, which enhances cruise performance at the cost of hover efficiency.

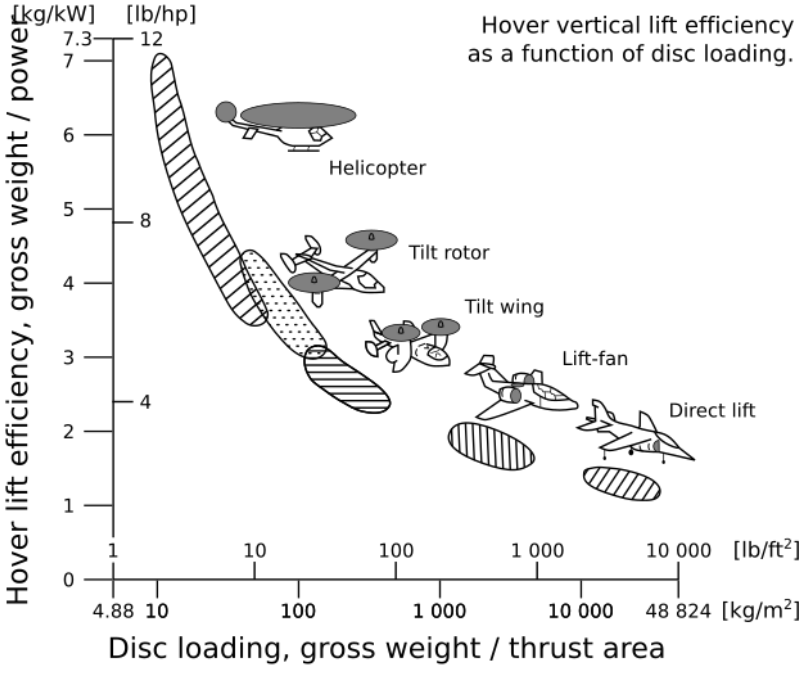

Figure 1. Hover vertical lift efficiency as a function of disc loading [4].

For several single-rotor UAVs given in Table 1, a disk loading versus power loading graph is plotted in Figure 2 to compare their efficiencies in hover. The equations below demonstrate that modifying the rotor area directly affects the performance, highlighting the trade-offs between hover efficiency and forward flight characteristics of the rotorcraft.

Table 1. UAV specifications.

UAV Name	Weight (kg)	Main Rotor Diameter (mm)
Blade 600X	4	1342
The Galaxy	8	1980
Vapor 55	24.9	2291

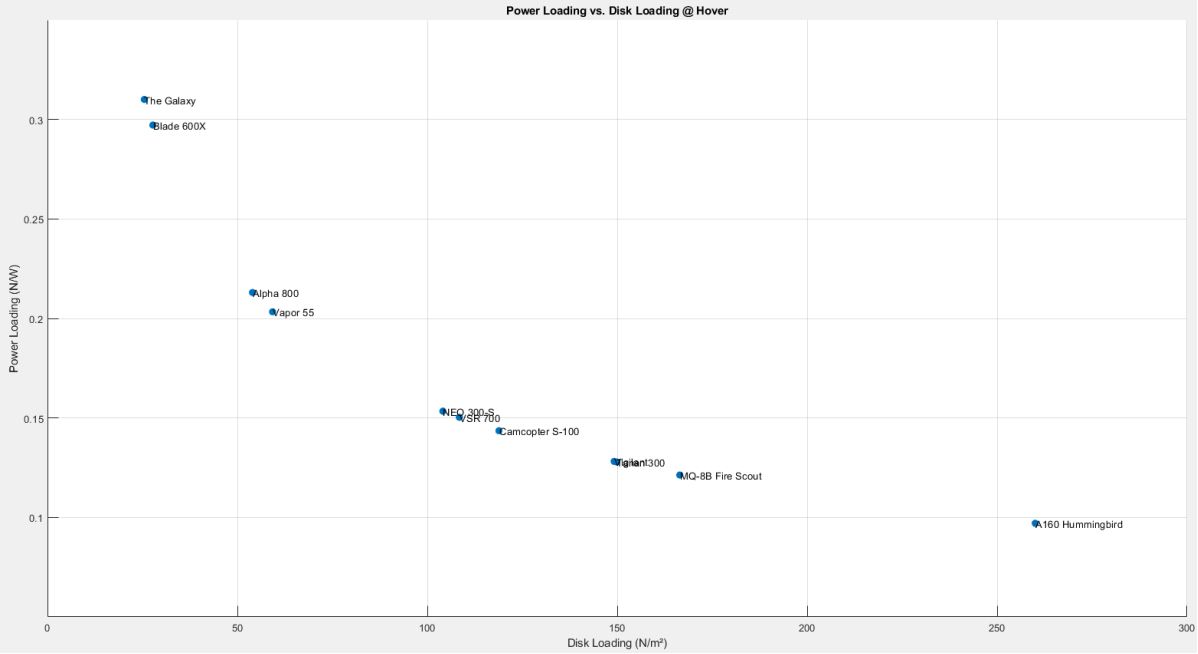

Figure 2. DL - PL for several UAVs.

Span morphing in rotorcrafts can be achieved through various mechanisms, each changing the blade construction in different ways. These mechanisms include telescoping blades, folding blades, and flexible blades which can be either passive or active depending on the system [3]. Active systems such as those using hydraulic or pneumatic actuators or smart materials require an external power source, allowing the user to precisely control the movement. On the other hand, a passive morphing system relies on forces acting on the structure, such as aerodynamic or structural forces, without needing any external power input, making them more energy-efficient but less controllable.

Active morphing includes systems like folding sections actuated by motors or hinges, shape memory alloy materials actuated by heat or an electrical input, hydraulic or pneumatic systems actuated by electric motors. For passive morphing systems, centrifugal force actuated telescoping blades by using a spring or a tensioned cable can be given as example.

Conclusion

By adjusting the span length dynamically, span morphing rotorcrafts have a unique advantage on optimizing the performance across different flight regimes achieving a balance between hover and forward flight efficiency. This can enhance mission flexibility, and improve overall operational efficiency while reducing the power consumption of a rotorcraft.

Depending on their size, performance, and mission requirements, different rotorcraft types use different morphing mechanisms. Smart materials such as piezoelectric actuators or shape memory alloys are often used in lightweight rotorcraft to provide precise control while minimizing the weight. There are also centrifugal force-actuated systems where rotor blades extend or retract based on rotor speed, making them simple and energy-efficient. Hydraulic and pneumatic actuators are frequently used in medium to large helicopters like military or commercial rotorcraft to precisely control the shape of the rotor blade, allowing them to adjust to changing flight conditions.

Keywords: Optimization, Impact, Metamodel, Multiobjective, LS-Dyna.

Aim

This study aims to optimize the thickness of an AL7050 aluminum alloy plate subjected to an impact load, with the goal of minimizing both the maximum stress and mass of the plate. The define of the problem is metamodel based multiobjective function optimization which is used for more than one objective function and can not find mathematical express of problem. The optimization process is based on FEM data obtained from LS-Dyna, which is used for impact analysis. Then surragated model is obtained using kringing method and than genetic algortihm is used as optimization method. The matemodels significantly reduces the computational cost of the optimization process by approximating the system's behavior, enabling more efficient exploration of the design space.

Material and Method

The material considered in this study is AL7050 plate, a high-strength aluminum alloys are widely used in aerospace and structural applications due to its exceptional strength-to-weight ratio, ease of processing and accesibility. Mechanical properties of aluminum plate are given in Table 1.

Table 1. Material Properties of AL 7050 plate [3].

Properties	Properties Value
Density	2.70 g/cm^3
Modulus of Elasticity	72 GPa
Yield Strength	455 MPa

The aluminum alloy plate dimensions are 100 mm by 100 mm, with the thickness being the key design variable to be optimized. To demonstrate out of plane impact loading finite element analysis (FEA) is performed using LS-Dyna which is used for especially explicit or implicit impact analysis. The plate is modeled with 2D quad elements, because a lot of analysis are runned to create design variable space, therefore, the analysis run time is important. The boundary conditions to represent fixed edges, 3 DOF (x, y and z) constrain is applied to all edges. The impact object is modeled as a spherical rigid ball which is modelled as 3D, hexa elements, impact the center of the plate with 10 m/s which is shown in Figure 1.

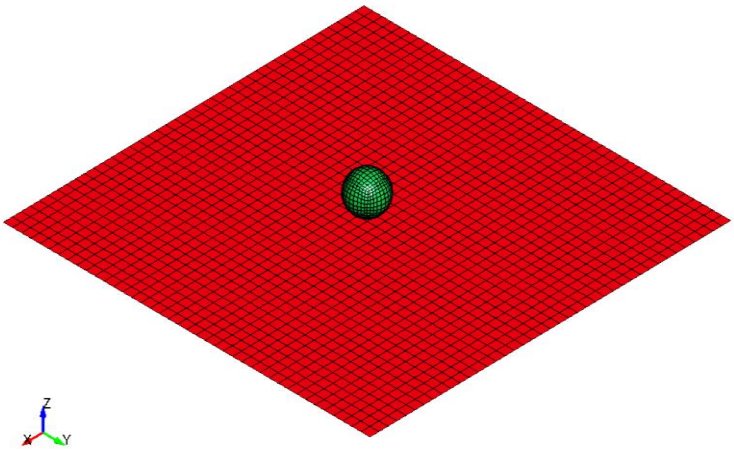

Figure 1. AL 7050 plate under out of plane impact loading FEM demonstration.

To optimize the problem, the objective function is used, which is mostly the mathematical expression. The mathematical expression of out of plane impact loading analysis is very complicated. Therefore, the surragated model is used. Kriging is a widely used surrogate modeling technique in computational engineering that is a mathematical interpolation technique associated with mining engineer Krige. Jack P.C. Kleijnen (2017) said that, Krige solved the problem of combining results (outputs, responses) obtained from a limited number of locations in gold mining. Later, this method was further developed by the French mathematician Matheron, who created the field of geostatistics or spatial statistics. The foundation of this approach is the stationary Gaussian process (GP), which means the GP has a constant average, expected value, a constant variance, and covariances that only depend on the distances between "points" in a 3D space, length, width and height. This process defines a multivariate normal or Gaussian distribution [1]. The Kriging model is trained using a set of simulation results obtained from LS-Dyna, where different plate thickness values and the corresponding impact responses are used as input-output data pairs. The kringing models and simulation data of thickness to stress and mass are given in Figure 2 and Figure 3 which are created by MATLAB, the optimized values are shown with a star mark.

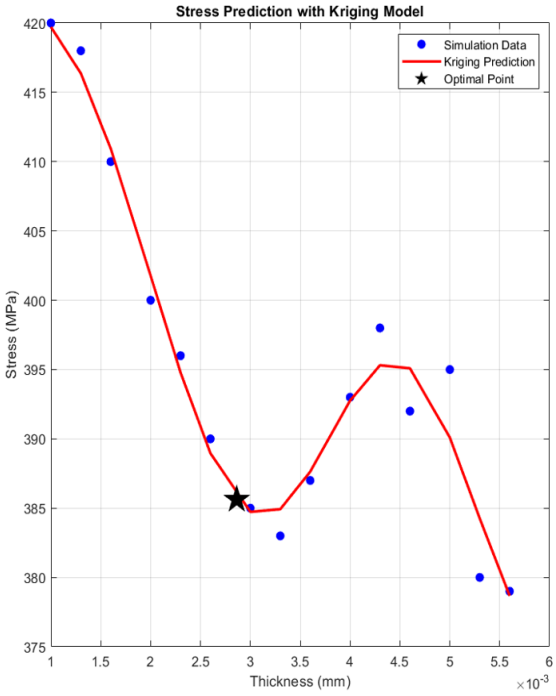

Figure 2. Graph of Thicknes -Stress in Matlab.

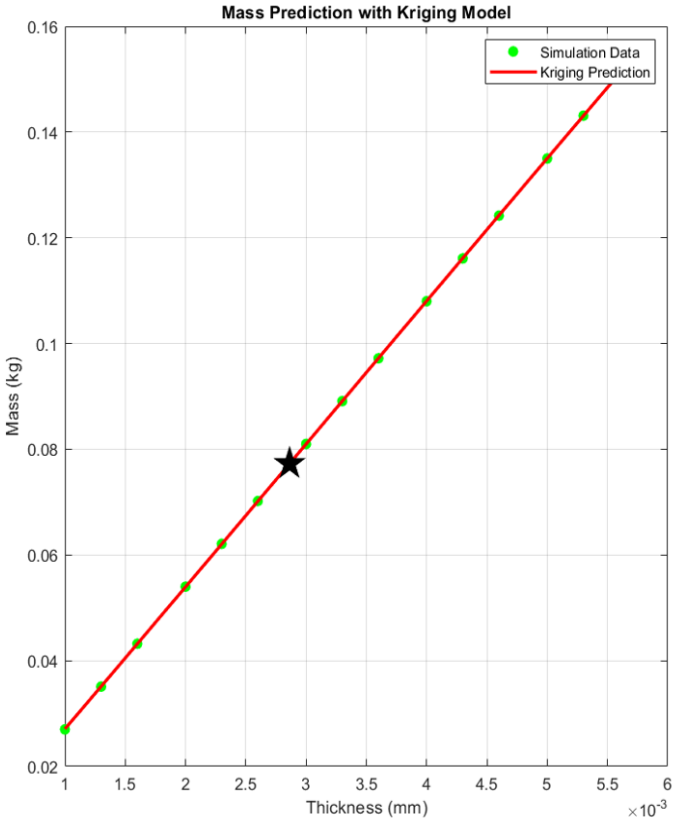

Figure 3. Graph of Thicknes -Mass in Matlab.

In addition, there is more than one objective function, stress and mass. The purpose of optimization is minimize stress and minimize mass, for that reason the problem becomes multiobjective optimization problem. To combine these objective function the weighted function is used which is shown in Figure 4.

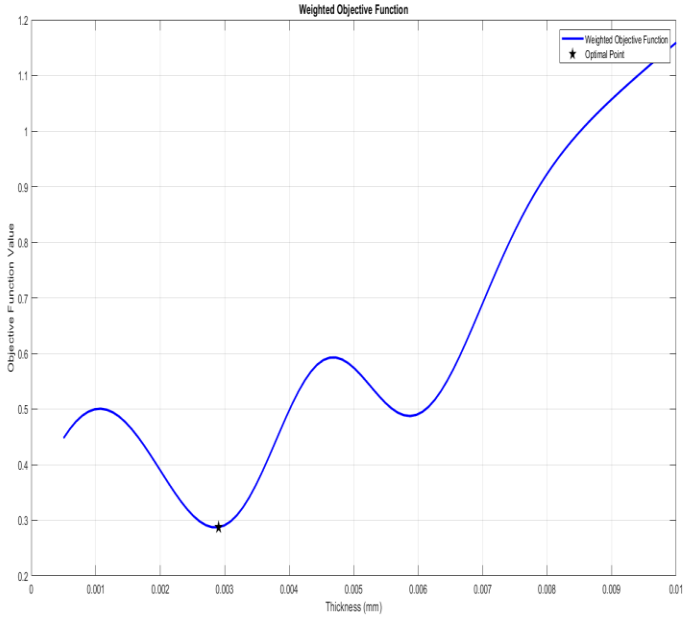

Figure 4. The weighted function to thickness graph of combination of two objective functions.

The optimization algorithm utilized is based on the genetic alghoritm (GA) method, which is well-suited for solving optimization problems. Saraswat and Sharma (2013) stated that MATLAB can be used to implement a genetic algorithm for solving optimization problems. It takes advantage of the power of genetic algorithms to quickly find good solutions in real time. The experimental results show that GATool can improve the fitness value by providing a set of nearly optimal solutions quickly. When looking at the effect of different genetic algorthmn parameters, it was found that increasing the population size can improve the system's performance. The crossover rate, however, does not have a big impact on the solution quality. [2]

Findings

The optimization study of the AL 7050 plate under out-of-plane impact loading consists of four main steps. First step is to obtain simulation data from LS-Dyna. The challenge of this part is identifying the maximum stress elements and the corresponding time. The maximum stress occurs at different times but the time step is kept constant for each analysis. Although, the maximum stress can occur between time intervals, it is observed that the maximum stress is reached when the impactor ball contacts the plate. The solution is to set the distance between the impactor ball and the aluminum plate to zero. An example of simulation data is shown in Figure 5.

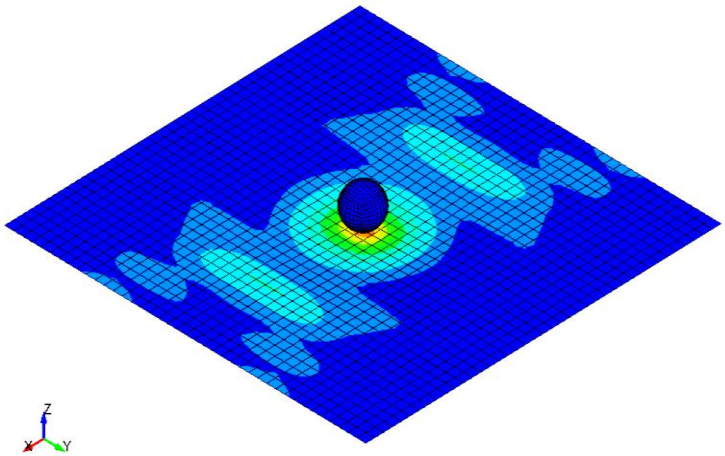

Figure 5. Von Mises Stress Distribution of Al7050 Plate Under Impact Load in LS-Dyna software.

The metamodel creation is the second part of the problem. The Kriging-based metamodel is used for this purpose and it provides accurate approximations of the maximum stress and mass for various plate thickness values. The mass to thickness kringing model is linear regression but the stress to thickness kringing model is polynomial function. This method also can used for obtained approximation results without any analysis. As a conclusion, the kringing model is provided to save time and to obtain objective functions.

After creation of the two objective functions, combination of these functions is the third step of this project. Also, the importances of objective functions are provided a solution for more complex optimization problems. For example, for this problem the weight of objective functions are given as equal, but if stress objective function weight is given more, the optimized thickness is found as thicker. To be conclude, Weighted function is usefull and easy applied method even if complex object functions.

The last step is genetic algothm optimization method. Genetic algorithm provide optimization for wide design of space results. The optimization process identifies an optimal thickness that balances structural performance in terms of stress with material efficiency. The optimal thickness minimizes both the maximum stress and mass, while ensuring that the plate remains within acceptable limits.

Conclusion

In conclusion, this study successfully optimized the thickness of an AL 7050 aluminum alloy plate under out of plane impact loading by minimizing both maximum stress and mass. A metamodel-based multiobjective optimization approach was employed, utilizing Kriging surrogate modeling to approximate the complex

relationships between plate thickness, stress, and mass, significantly reducing computational costs. The optimization process, driven by a weighted combination of stress and mass objectives, was efficiently executed using a genetic algorithm (GA), providing an optimal solution that balances structural performance and material efficiency. This approach demonstrates the effectiveness of advanced optimization techniques in achieving optimal designs while saving time and resources, particularly in aerospace and structural applications.

Optimum Rudder Torque Tube Design for a Light Training Aircraft

Berkay Temizkan[a], Zahit Mecitoğlu[a]

[a] İstanbul Technical University, Aeronautical and Astronautical Engineering, Computational and Experimental Structural Analysis And Design Program, Turkey
temizkan16@itu.edu.tr

Keywords: Design, Light Training Aircraft, Optimization, Rudder Torque Tube.

Aim

The design and reliability of control systems in aviation are critically important, particularly for basic training aircraft in the light-category used in pilot training. Flight control systems are categorized into primary and secondary systems. The rudder control mechanism, a component of the primary flight control system, commands the aircraft's rightward yaw when the pilot presses the associated pedal (Federal Aviation Administration, 2023, p. 6-2). This study aims to determine the optimum design for the rudder torque tube, which is one of the main components of the rudder control system for a light training aircraft.

For this purpose, a preliminary design for the rudder control system was first developed by examining existing light training aircraft in the literature. Loads were determined in accordance with CS-23 Certification Specifications for Normal, Utility, Aerobatic, and Commuter Category Aeroplanes (European Aviation Safety Agency, 2010). An analytical model was created for the torque tube using beam theory and verified via the finite element method (FEM) model. An appropriate optimization method was selected for the optimization of the structure. After determining the appropriate constraints and objective function for the determined method, the structure was optimized, results were evaluated, and tube geometry was finalized. Fastener, gear and bearing were selected for the design. A detailed 3D CAD model was developed, and FEM analysis confirmed the safety of the final design.

Material and Method

A literature review was conducted to design an optimum rudder torque tube for a light training aircraft. Through this review, various aircraft within the light training aircraft category were examined. By obtaining the external geometric specifications of these aircraft, parameters such as average fuselage length, pedal position, distance between pedals, and fuselage width were determined. An analytical model was created to calculate the rudder control system loads using these parameters. The maximum load scenarios that the pilot can apply were obtained with requirements in the CS-23 Certification Specifications for Normal, Utility, Aerobatic, and Commuter Category Aeroplanes document. The resulting forces and moments acting on the torque tube were then determined. The rudder torque tube was analytically modeled in the frame of beam theory employing analytical formulas in Mechanics of Materials Book and Machinery's Handbook (Hibbeler, 2011; Oberg et al., 2016). The analytic model was coded in a computational environment using the MATLAB 2019b (The MathWotks Inc., 2019). The code first calculates the reaction forces and moments using static equilibrium equations. Then, the shear force and bending moment diagrams are obtained along the length of the rudder torque tube. In this methodology, shear force and bending moments are obtained in each section, which are used to compute the maximum von Mises stress.

In order to verify calculations in the code written using the MATLAB R2019b, finite element models were developed using the Hypermesh 2017 (Altair Engineering, 2018). Separate finite element model (FEM) models were created in order to model torque tube utilizing 1D CBAR, 2D SHELL and 3D TETRA elements. After applying appropriate boundary conditions and loads for each model, the finite element analysis was conducted using MSC NASTRAN 2019.0 (MSC Patran/Nastran, 2019). The results were evaluated to verify MATLAB generated calculations.

Various algorithms for the optimization of the rudder torque tube were examined and the genetic algorithm was determined as the most suitable approach. The boundary conditions and objective function for optimization were determined with the code created on MATLAB. The optimization was performed using MATLAB's Global Optimization toolbox. As a result of the optimization, values such as section thickness, outer diameter size, inner

diameter size, were obtained. Additionally, fastener, gear, and bearing selection were performed using analytical formulas. The loads acting on each fastener were calculated using analytical formulas. The diameter and type of the fasteners were determined using the formulations in the Airframe Structural Design book (Niu, 1999). For gear selection, calculations in the "Relatively Large Depth Beams" section in the Roark's stress and strain book were used (Roark et al., 2002). For bearing selection, the manufacturer documents of the bearings were examined. Suitable bearing was selected evaluating axial and lateral load capacities.
A detailed design model, which met specified design features, was created using the CATIA V5 6R2018 (Dassault Systemes, 2018). The STEP file of the detailed design model was exported from the CATIA program and imported to the Hypermesh. Then, the solution networks that will reflect this geometry were created using three-dimensional tetrahedral elements.

Findings

This study has several findings related to optimum design of the rudder torque tube for a light training aircraft.
One of the most important finding is the minimum wall thicknesses obtained in the torque tube as a result of optimization. The maximum force a pilot can apply to the pedal was determined by relevant articles in the CS-23 document. The maximum load that the pilot can apply to the rudder pedal under the limit condition is 890 N according to CS.23.397. For aircraft exceeding a design weight of 2268 kg, this load must be multiplied by 1.18. Additionally, CS.23.395 states that each flight control system and its supporting structure must withstand 125% of the calculated hinge moment. Therefore, the maximum applied force was determined as 1312.75 N. Furthermore, the fitting factor of 1.15 in CS.23.625 was included when calculating the final strength. The force moment values created by this load in the torque tube were calculated with static equilibrium equations. The schematic representation of the model used for these calculations is presented in Figure 1.

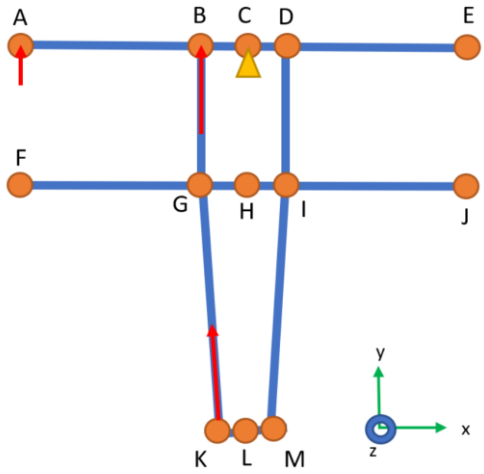

Figure 1. The schematic representation of rudder control system.

In this diagram, the pedal force applied at point A is transferred via cables at points B, G and K and through the torque tube bell-crank at point L. The forces and moments at this point were obtained in Table 1.

Table 1. Force and moments at point L.

Axis	Force [N]	Moment [N.mm]
X	6.67	23.48
Y	4071.79	1618.44
Z	186.81	366460.57

These obtained forces and moments were applied to the beam model representing the torque tube in figure 2. The forces were distributed along the bell-crank - torque tube connection. The boundary condition at the location where a spherical bearing was placed allowed for free rotation, whereas a fixed support was applied at the connection point between the torque tube and the rib.

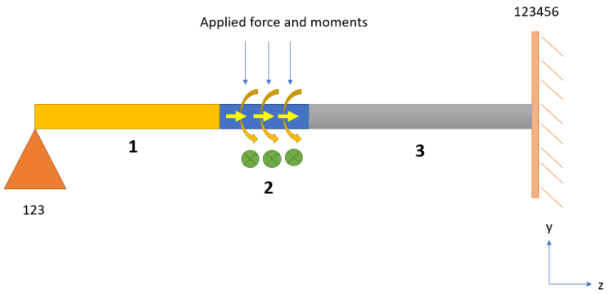

Figure 2. Beam model.

The calculations were made via MATLAB and the optimization was performed using the genetic algorithm with the Global Optimization toolbox of MATLAB. The objective function was defined as minimizing the volume of the torque tube while satisfying the constraints resulting from the forces and moments outlined in Table 1. As a result of the optimization, the optimum inner and outer radius values were determined for 3 different regions shown in Figure 2. As a result of the multiple iterations, the refined parameters for the optimization were determined. The best value and penalty values obtained at each generation in the optimization were plotted in the graph in Figure 3. The minimum inner and outer radius values for the torque tube are shown in Table 2.

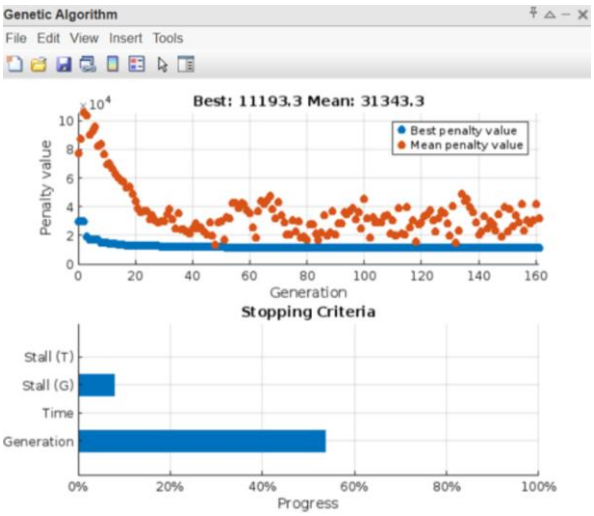

Figure 3. Genetic optimization results.

Table 2. The minimum inner and outer radius values for the torque tube.

Region	Inner Radius [mm]	Outer Radius [mm]
1	7	8
2	13.5	15.0
3	15.7	16.9

Conclusion

This study successfully developed an optimized design of the rudder torque tube for a light training aircraft. The maximum forces and moments acting on the torque tube were obtained in accordance with the CS-23 Certification Specifications. The torque tube was analytically modeled, and force and moment distributions across its length were computed. An optimization study was conducted using a genetic algorithm to determine the optimal inner and outer radius values in different regions of the tube, resulting in a preliminary design. Finally, a detailed design was developed by selecting appropriate fastener, gear and bearing. The structural integrity of the optimized design was validated through finite element analysis.

Structural Design and Analysis of Engine Mount Structure for Propeller Training Aircraft

Alper Aslan[a], Kaan Yıldız[b]

[a] Istanbul Technical University/Department of Aeronautical Engineering, Department, Theoretical, Computational And Experimental Structural Analysis And Design, Türkiye
[b] Istanbul Technical University/Aviation Institute, Theoretical, Computational And Experimental Structural Analysis And Design, Türkiye
aslana16@itu.edu.tr

Keywords: Engine Mount, Propeller Aircraft, Sizing, Static Analysis.

Aim

This project involves the determination and calculation of the load conditions for the engine mount structure of a propeller training aircraft. Furthermore, the identification of the engine mount members with the most appropriate thickness was achieved through both Hypermesh modeling and the MATLAB interface. The load conditions play a decisive role in the engine mount structure's concept and thickness. In order to perform the structural design and static analyses, it is essential to calculate the load conditions of the structure. The load conditions have been calculated using the aviation certifications outlined in CS-23 (European Aviation Safety Agency, 2012).

The engine mount structure consists of the structural elements that establish the connection between the engine and the fuselage of the aircraft. These components are subjected to significant loading conditions due to the forces exerted by the engine. Consequently, engine mount members must exhibit high resistance to both stress and buckling induced by these loading conditions.

This project is to calculate the engine loading conditions of a nose-propeller training aircraft and to design the most suitable and reliable engine mount structure that can withstand the calculated loading conditions. Therefore, a toolbox has been developed to calculate the engine mount structure thicknesses. Within the toolbox, a graphical output is provided for each 1D member. The figures display the reserve factor values as a result of a small increase in thickness. The person performing the calculation is given the opportunity to select the member thicknesses, thereby allowing for the inclusion of engineering judgment in the process.

With this toolbox, the sizing of one-dimensional elements can be easily performed. Additionally, an interface has been created to allow for the calculation of reserve factors. The reserve factor can be calculated for engine mount members with the desired thicknesses. As a result, the time required for the sizing of 1D structures such as the engine mount has been significantly reduced.

Material and Method

In this study, a comprehensive set of tools and methodologies was employed to design and optimize the engine mount structure for the nose propeller training aircraft. The primary design and analysis were conducted using Hypermesh, which facilitated the finite element modeling of the engine mount and surrounding structural components, including the frame, longeron, keel beam, and floor. These components were interconnected using connector modeling to simulate their interactions accurately. To model the engine mount members, 1D beam elements were utilized, and a mesh size of 10 millimeters was selected for precision in the analysis. Static analysis of the engine mount structure was performed using the MSC Nastran solver, providing critical data for stress distribution and load conditions across the structure. The force and moment pairs for each element from the analysis results were imported into Excel.

To determine the optimal thickness for the engine mount members, a custom MATLAB code was developed, incorporating safety factors derived from Von Mises stress, linear buckling, and local buckling criteria. The MATLAB program also considered the welding factor, accounting for reductions in material properties due to welding processes. Additionally, a graphical interface was designed to allow users to visualize and select the most appropriate radii for the engine mount members, enhancing the usability of the tool. The following equations were

employed for these calculations, σ_{11} is the normal stress in Equation 1, and σ_{12} is the shear stress in Equation 2. By using these two formula, Von Mises stress can be calculate as Equation 3 (Bruhn, 1973).

$$\sigma_{11} = \sigma_{axial} \pm \sigma_{bending} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 1)$$

$$\sigma_{12} = \sigma_{shear} \pm \sigma_{torsional} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 2)$$

$$\sigma_{vm} = \sqrt{\sigma_{11}^2 + 3\sigma_{12}^2} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 3)$$

$RF_{Von\ Mises}$ represents the reserve factor according to the Von Mises criteria, and it can be determined using Equation 4 where σ_{vm} is the Von Mises stress occurs on the beam elements. F_{tu} is the tension allowable for the selected material. There are four solutions for the Von Mises stress calculation due to the signs of bending and torsional stresses. The maximum Von Mises stress solution was selected for the calculations.

$$RF_{Von\ Mises} = \frac{F_{tu}}{\sigma_{vm}} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 4)$$

Equation 5 is used to determine the critical linear buckling axial loads, which must be compression forces. By comparing these with the axial loads on the engine mount members, the buckling reserve factor is calculated using this method. In Equation 5, E is the Young Modulus of selected material (Niu M. C., 1991). I is the moment of inertia. L is the length of the engine mount member. RF_{LiB} represents the reserve factor according to the linear buckling, and it can be determined using Equation 6, where P_{axial} is the axial load.

$$P_{cr} = \frac{\pi^2 EI}{L^2} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 5)$$

$$RF_{Linear\ Buckling} = \frac{P_{cr}}{P_{Axial}} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 6)$$

The local buckling equations are shown in Equation 7 to 10 (Yıldız K., 2018). For local buckling to occur, σ_{11} must be a compression load. σ_{cr} represents the critical stress for wall buckling, and it can be determined using Equation 7. γ is the correlation coefficient in Equation 8, where r_o and r_i are the outer and inner radii, respectively. RF_{LoB} is the reserve factor of local buckling as shown in Equation 10, where σ_{11} is the normal stress.

$$\sigma_{cr} = \frac{E}{\sqrt{3(1-\nu^2)}} \frac{r_o - r_i}{r_o} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 7)$$

$$\gamma = 1 - 0.901\left(1 - e^{-\phi}\right) \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 8)$$

$$\phi = \frac{1}{16}\sqrt{\frac{r_o}{r_o - r_i}} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 9)$$

$$RF_{Local\ Buckling} = \frac{\sigma_{cr}}{\sigma_{11}} \quad \#(SEQ\ Equation \setminus *\ ARABIC\ 10)$$

The engine mount members need to be welded together to ensure their connections. Due to welding, a decrease in the material's allowable properties may occur; thus, the reduction factor, which called as welding factor, was used for the calculations. Welding factor was added as 1.2 to the toolbox and MATLAB code (Bruhn, 1973).

Findings

- **Engine Mount Load Case Calculations**

Initially, similar aircraft within the scope of training aircraft were examined. The Super-Tucano training aircraft was selected as a comparable model for this project due to its recognition for its design and mission capabilities. The engine used in the Super-Tucano and the compatible propeller types were researched to calculate the engine loads. For the nose propeller training aircraft, the design and analysis of which will be conducted within the scope of this project, the PT6A-67AF engine has been chosen. This engine, offering higher performance compared to others in the same series as the Super-Tucano, is still in production and features a high Thrust-to-Weight ratio. After investigating the propeller types compatible with the PT6A-67 engine series, it was determined that the Socata TBM700 propeller was suitable for both this engine and the type of aircraft on which the work will be carried out.

Based on the selected engine and propeller types, four load conditions were calculated to satisfy aviation certification requirements, following the guidelines in CS23 (European Aviation Safety Agency, 2012). In this phase, the calculations were based on the study by Olejnik et al., which focused on the design optimization of a very light aircraft engine mount, accounting for external flight loads (Olejnik et al., 2016). The parameters of the engine and propeller required for thrust and torque calculations were obtained from the PT6A-67AF and TBM700 documents (Pratt and Whitney Canada Corp., 2022; Hartzell Propeller., n.d.). The engine mount load cases were calculated, as shown in Table 1, using data from the engine and propeller documents.

4	Spin	0	-4015.96	0	0	0	0

- **Concept Analysis**

In the following stage, the coordinates for the connections of the engine mount structure were calculated based on the dimensions of the propeller engine. Five connection points were defined for the connection between the engine and the mount structure. Furthermore, four connection points were identified between the engine mount and the aircraft's front fuselage structure. Once the connection concept was finalized, the dimensions of the Super-Tucano aircraft were validated, and the positions of the frame and longeron stations were calculated. Subsequently, the master geometry design of the front fuselage was completed. At this stage, the coordinates for the connection points between the mount structure and the fuselage structure were fully determined.

The engine mount structure was designed based on five different concepts within the defined coordinates. Four previously calculated load conditions were applied to the structure at the propeller location using the Hypermesh program. The forces and moments for each beam element were obtained from the Hypermesh. The preliminary cross-sectional type and radii of the engine mount members were determined. The most suitable design concept was selected based on the Von Mises stress criterion. The selected engine mount concept design is shown in Figure 1.

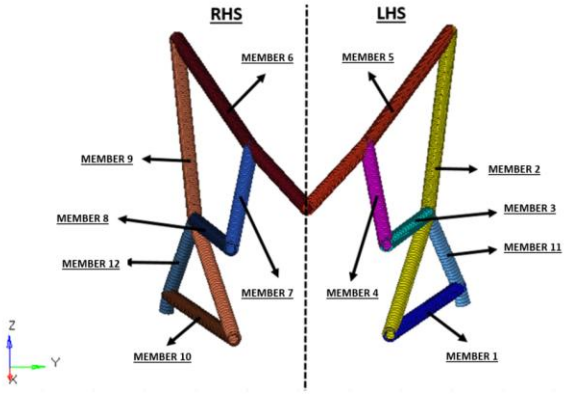

Figure 1. Engine Mount Concept.

- **Material**

The selection of materials for the engine mount members is critical, as these elements are subjected to vibration, temperature variations, and high levels of stress. Therefore, selecting a material capable of effectively withstanding these conditions is essential. A variety of materials were evaluated using MMPDS-23, and, among these, 4340 steel was selected due to its mechanical strength, insensitivity to temperature variations, excellent resistance to vibration-induced crack formation and propagation, and high tensile strength (Battelle Memorial Institute, 2013). Simultaneously, to proceed with the design of the front fuselage structure, AL7050 T7451 material, widely used in aviation, was selected for the front fuselage components.

- **Calculation and Results**

Using the software, the user can select the most suitable radii for the engine mount structure members from the graphical interface. Figure 2 shows an example of the graphical representation that allows for the selection of the radius for engine mount member 1.

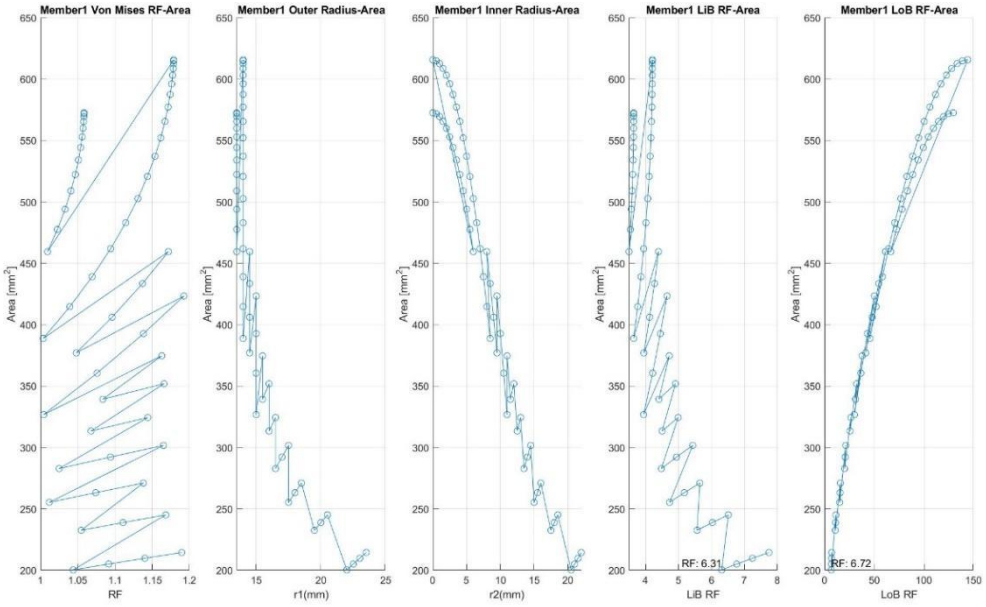

Figure 2. Output of software to select the suitable radii for Member 1.

A software toolbox has been developed that provides all relevant information about the engine mount members. The user can check the lowest reserve factor for each member. Additionally, the beam element number with the lowest reserve factor in each member, as well as the load condition number and weight parameters, can also be checked.

The engine mount members, for which the thicknesses were determined, were imported into the front fuselage finite element model previously prepared in the Hypermesh program, and another static analysis was performed. Comparisons were made between the results obtained from the engine mount members in this static analysis and the model previously created with only the engine mount members, and it was observed that differences in the boundary conditions used significantly affected the stresses on the engine mount members. Therefore, the force and moment pairs for the beam elements, exported from the Hypermesh program, were imported into Excel, and new thicknesses were calculated using MATLAB code. In this way, the most suitable thickness for the engine mount elements was determined.

Conclusion

As a result of this study, the process, from engine selection to determining the thicknesses of the members for the engine mount structure of a nose propeller training aircraft, was developed. Throughout this process, software tools and an interface were developed to facilitate the design of engine mount members with the optimal thickness.

Comparing Fractional Calculus And LSTM For Greenhouse Gas Emission Forecasting: Insights For Policy And Strategy

Gizem Göktaş Balkır[a], Nisa Özge Önal Tuğrul[a]

[a] Istanbul Technical University/Informatics Institute, Applied Informatics, Information and Communications Engineering, Istanbul, Türkiye
goktasg17@itu.edu.tr

Keywords: Climate Change, Fractional Calculus, Greenhouse Gas Forecasting, LSTM, Time Series Modeling.

Aim

Climate change has evolved into one of the most urgent environmental issues of our time, especially since the Industrial Revolution. The rise in global temperatures, sea level increases, more frequent extreme weather events, and the loss of biodiversity all pose significant threats to the sustainability of both societies and economies (Üstün, 2023). The World Economic Forum's Global Risks Report 2025 emphasizes the growing importance of environmental risks, highlighting climate change as a long-term threat to global economic stability and social cohesion (World Economic Forum, 2025).

Greenhouse gas (GHG) emissions, which are the leading cause of global warming due to their heat-trapping properties, originate primarily from energy production but also from agriculture, industry, and waste management. In response to this challenge, governments worldwide are developing policies aimed at reducing emissions to mitigate the impact of climate change and secure a more livable, stable future.

The Paris Agreement, adopted at COP21 (21st Conference of Parties) in 2015 and entered into force in 2016, aims to limit global warming to well below 2°C above pre-industrial levels, ideally keeping it to 1.5°C (United Nations, 2015). Türkiye ratified the agreement in 2021 and initially submitted an Intended Nationally Determined Contribution (INDC) to reduce its emissions by 21% by 2030 (Republic of Türkiye, 2022). Recognizing that this target may fall short amid rising energy demand, industrialization, and urbanization, Türkiye revised its pledge in 2023, increasing its reduction target to 41% and identifying 2038 as the peak year for national emissions (Republic of Türkiye, 2023). The updated plan includes strategies across key sectors—energy, industry, transportation, agriculture, and waste—and aims for net zero emissions by 2053.

These ambitions require reliable forecasting and modeling methods to assess progress, anticipate trends, and guide long-term planning efforts. In this context, accurate and comparative emission modeling has become an essential component of climate governance and scientific decision-making.

The aim of this study is to explore advanced modeling techniques to estimate and forecast GHG emissions in Türkiye. It compares two approaches: the Deep Assessment Methodology (DAM), based on fractional calculus, and the Long Short-Term Memory (LSTM) model, a deep learning method well-known for time series forecasting. By evaluating the performance of both models up to 2030, the study not only assesses forecast accuracy but also considers the practical applicability of fractional calculus to environmental modeling. Additionally, the study examines the impact of the COVID-19 pandemic on emissions, particularly the slowdown in industry and transportation.

Material and Method

The analysis uses national GHG emissions data published by the Turkish Statistical Institute (TÜİK), covering the years 1990 to 2022. The LSTM model was implemented in Python, using TensorFlow and Keras for training, while the DAM model was developed in MATLAB with customized algorithms using the Caputo fractional derivative (Önal Tuğrul et al., 2024). Model parameters were optimized to ensure best performance, and both models were evaluated using the Mean Absolute Percentage Error (MAPE), a widely used metric for assessing forecast accuracy.

The dual-model framework offers comparative insight into the strengths and limitations of machine learning and fractional calculus in emissions forecasting. This hybrid perspective provides a strong basis for understanding how these methods may complement each other in future integrated modeling strategies.

Findings

The main results are presented in Table 1. Model Fitting (1990–2022) and Table 2. Model Prediction Values (2023–2030). These tables include historical emissions data, model outputs for the same period, and projections for 2023–2030. Both DAM and LSTM predictions are presented separately to enable comparison.

Table 1. Model Fitting Values(1990-2022).

Year	GHG Values	LSTM Fitting GHG Values	DAM Fitting GHG Values

2025	626.23	622.12
2026	637.82	641.95
2027	665.59	659.12
2028	693.33	677.68
2029	723.21	681.32
2030	755.17	718.03

Figure 1. Model Values and Predicted GHG Emissions visualizes these results, contrasting actual emissions with model outputs.

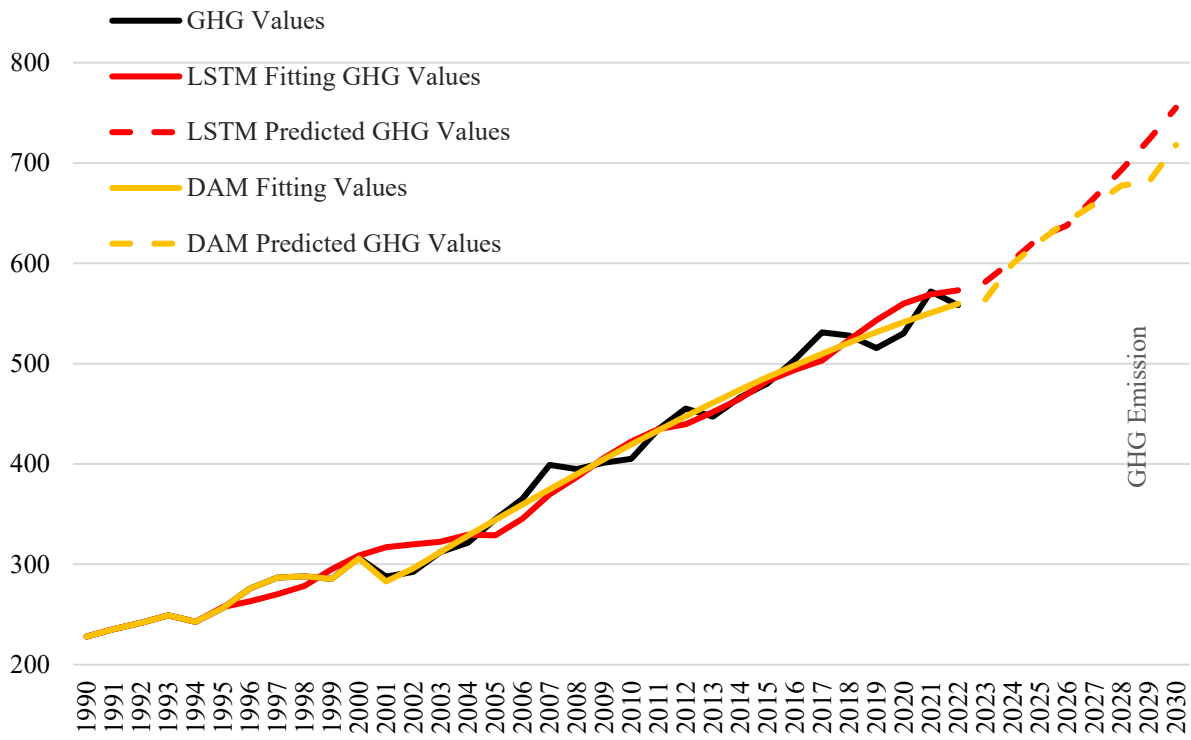

Figure 1. Model Values and Predicted GHG Emissions.

DAM achieved higher accuracy, outperforming LSTM with a MAPE of 1.8%, compared to 3.8% for LSTM. While LSTM is known for its strength in handling large datasets, DAM performed remarkably well even with limited data, benefiting from its transparent and interpretable structure. For 2030, DAM predicted emissions of 718.02 Mt CO_2e, while LSTM forecasted 755.2 Mt CO_2e.

The year 2030 was chosen as a benchmark because Türkiye has officially pledged to reduce its emissions to 695 Mt CO_2e by then under the Paris Agreement. Both models' forecasts exceed this target, highlighting the need for enhanced policy measures to meet climate commitments.

Energy production remains the dominant emissions source in Türkiye, contributing 71.8% of total GHG emissions—primarily due to coal-based electricity generation (Ministry of Energy and Natural Resources, 2024). This emphasizes the urgency of transitioning to renewable energy, enhancing efficiency, and investing in low-carbon technologies.

The study also analyzes the impact of the COVID-19 pandemic. Table 3. Model Fitting (1990–2018 – Pre-COVID) and Table 4. Model Prediction Values (2019–2030) show forecasts based on data excluding the pandemic years. This method allows an isolated evaluation of the pandemic's impact.

Table 3. Model Fitting Values(1990-2018-Pre COVID).

Year	GHG Values	LSTM Fitting GHG Values	DAM Fitting GHG Values
1990	228.00	228.00	228.00

2027	749.61	711.20
2028	777.27	734.04
2029	804.54	760.77
2030	832.01	780.47

Figure 2. Visualization of COVID-Adjusted Model Values and Predicted GHG Emissions compares model outcomes based on pre-pandemic data. In this scenario, DAM predicted 780.46 Mt CO_2e, and LSTM forecasted 876.89 Mt CO_2e for 2030. However, when models include pandemic years, both project significantly lower emissions, illustrating the temporary reductions caused by COVID-19 restrictions.

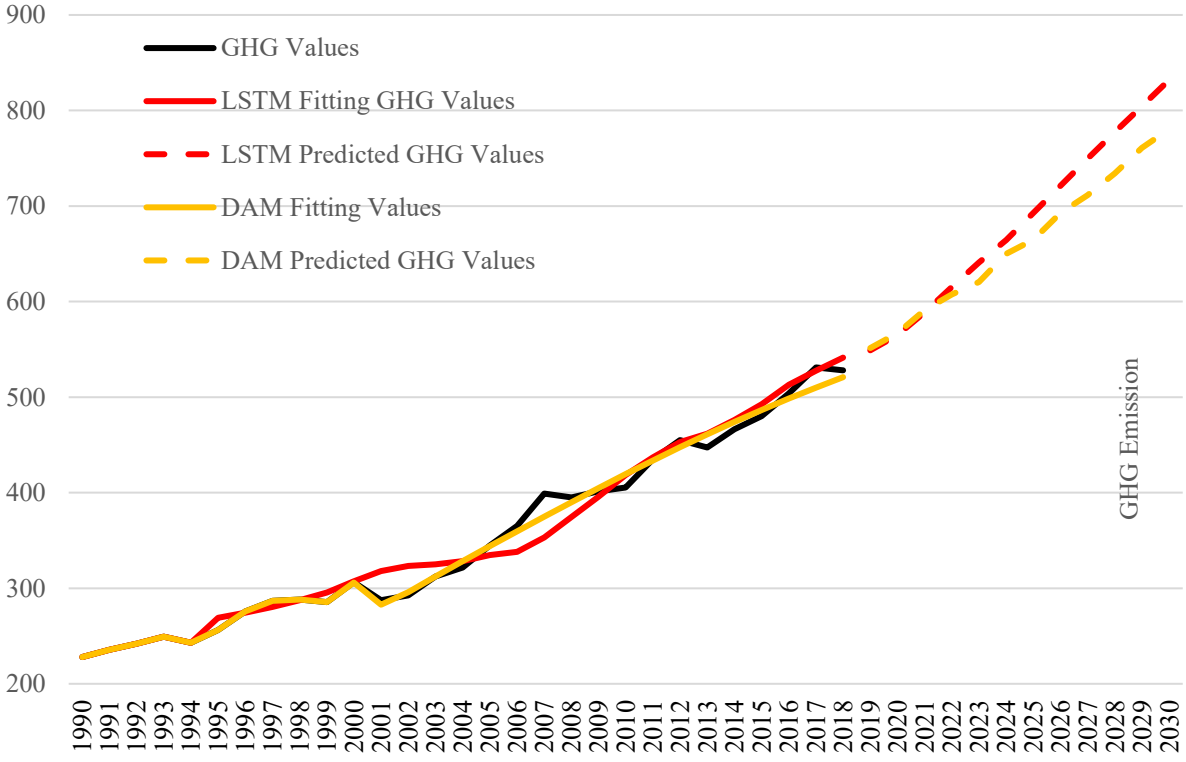

Figure 2. Visualization of COVID Adjusted Model Values and Predicted GHG Emissions.

These results confirm that model predictions are highly sensitive to training data and highlight the importance of including historical anomalies in long-term emission projections.

Similarly, a study conducted in Samsun Province found a 17.3 Gg CO_2e reduction in emissions from heating and transport during lockdown (Aykaç Özen, 2022). These insights underline the value of sustained structural change, rather than reliance on short-term disruptions.

Conclusion

This study demonstrates that the DAM model, with its fractional calculus-based structure, is a highly accurate and policy-relevant tool for modeling greenhouse gas (GHG) emissions. Compared to the LSTM model, DAM delivered more reliable forecasts and better captured long-term dependencies in emission trends.

The findings also suggest that reaching Türkiye's 2030 GHG target of 695 Mt may be challenging under current policy trajectories. This highlights the importance of strengthening mitigation efforts and considering additional measures. Moreover, the study examines the effects of reduced industrial and transportation activity during the COVID-19 period. When pandemic-related effects are excluded, it becomes clear that emissions would have been significantly higher. This underscores the fact that strong and targeted climate actions can lead to meaningful and measurable reductions in GHG emissions.

In conclusion, while current policies alone may not be sufficient, timely and science-based strategies can help close the gap. Beyond forecasting, the DAM model offers a novel analytical perspective for guiding future climate strategies.

Civil Architecture in Pieter Coecke van Aelst's Depictions from His Journey to Istanbul

Emre Can Yılmaz[a]

[a]İstanbul Technical University, Graduate School, Architectural History, Türkiye

yilmazemre@itu.edu.tr

Keywords: 16th century Istanbul, Civil Architecture, Pieter Coecke van Aelst, Turkish House.

Aim

This abstract has been prepared using data obtained from studies conducted as part of the doctoral dissertation titled *"A Perspective on the Civil Architecture of the Period through the Ayasofya Foundations Tahrir Register,"* which is carried out within the Architectural History program at ITU and examines 16th-century Istanbul's civil architecture from multiple aspects.

The doctoral dissertation aims to explore the origins of a highly picturesque form of civil architecture: the Istanbul-based Turkish House. The research primarily focuses on 15th- and 16th-century Istanbul to identify the characteristics of what may be considered as a proto-Turkish House model.

Two main source types serve as the foundation for this investigation: visual and textual traces. The dissertation is based on a particularly valuable register, the Ayasofya Vakıfları Tahrir Defteri, which provides detailed architectural insights. Additionally, numerous visual documents from the period have been examined, among which the drawings of Pieter Coecke van Aelst stand out. Although well-known among researchers, their remarkable potential for documenting civil architecture has been somewhat overlooked. This study seeks to highlight that potential.

Material and Method

The woodblock print engravings of Aelst, titled "Ces moeurs & fachons de faire de Turcz avecq' les Regions y appartenantes" (The Morals and Customs of the Turks and Their Territories) [1], were posthumously published in Antwerp in 1553 by his wife. Created during his visit to Istanbul in 1533, these engravings have long been recognized as a widely referenced source among researchers, with numerous studies dedicated to them.

However, the specific examination of civil architectural elements within these depictions has the potential to shed new light on previous research concerning the subject. Therefore, it is crucial to first explain the significance of this engraving series as a visual source within its chronological context, assess its degree of consistency as a documentary record, and focus on the author himself as a key figure in its production. For this reason, Aelst is studied as a polymath whose activities spanned painting, linguistics, and beyond.

Aelst (1502–1550) was a highly versatile artist. While his depictions of Istanbul may have been disproportionately highlighted by Turkish researchers, he was, more broadly, one of the leading figures of early 16th-century Flemish art. A noteworthy aspect of Aelst, particularly relevant for architectural historians, is that, in addition to being a painter and a designer of tapestries and woodblock prints, he was also an architect proficient in multiple languages. As a manifestation of this, he translated architectural treatises by Vitruvius and his contemporary Serlio into Dutch. [2] His translations of Serlio, in particular, were published almost simultaneously with the original editions. In fact, even the later English translations of these works were based on Aelst's publications. These books also included numerous woodblock illustrations that Aelst reinterpreted, contributing significantly to the dissemination of Renaissance architectural ideas in Northern Europe and the revival of classical proportions and styles.

When examining Aelst from this perspective, it is essential to recognize that he was not merely a scribe in a diplomatic delegation, a cleric, a diplomat, or a sailor producing sketches out of casual observation. Instead, he was a highly trained professional with a solid architectural and artistic background. For researchers studying Istanbul and the Ottoman Empire, his works present a unique visual documentation opportunity. Until Melchior Lorck's depictions in 1559, no other 16th-century Western source provided visual records of such documentary value. It is widely accepted that Aelst traveled to Istanbul as part of the Habsburg diplomatic delegation led by Cornelis de Schepper. The most prominent reason for his visit appears to be his plan to sell tapestries in Istanbul. In this sense, beyond his artistic identity, his role also had a commercial aspect. [3] Given Aelst's commercial position, it is likely that his role provided him with an opportunity to make more objective observations before creating his depictions.

Findings

Pieter Coecke van Aelst's seven-scene engraving series can be analyzed under various headings in terms of its documentary value, historical accuracy, and realism.

First, it is important to note that realistic perspective was not a primary concern in urban depictions produced during the century of its creation and in the following centuries. However, Aelst's drawings exhibit a certain consistency in perspective and a deliberate effort toward mimesis. While it would be an overstatement to claim that the scenes adhere to a photographic level of perspective accuracy, it is evident that the author approached them with an editorial intent, shaping the composition according to what he wished to highlight. The original sketches, which later served as the basis for woodblock prints published posthumously, were likely created with the intention of being developed into tapestries.

This compositional approach explains why the drawings feature numerous dynamic figures engaged in various actions, lending them an extraordinary sense of movement and liveliness. Nevertheless, the proportional scaling of figures based on their vantage points, as well as the perspective precision in the placement of background landscapes, settlements, and buildings, contribute to the documentary quality of the work.

Another key aspect of evaluation is the historical accuracy of the figures' attire, tools, and weaponry. When cross-referenced with contemporary sources, such as Western-produced Ottoman costume albums, these details demonstrate remarkable consistency. The weapons, shields, and even the intricate details of sword hilts and guards align with the period's stylistic characteristics. Furthermore, an extensive array of objects, from musical instruments and horse harnesses to tableware, spoons, and water flasks, provides valuable insights into material culture. Such attention to detail makes it possible to detect any potential historical anachronisms, yet no significant inconsistencies emerge. The series also incorporates behavioral themes, depicting religious rituals, communal dining practices (such as eating from a shared dish on the floor), funeral ceremonies, celebratory events, and the Friday procession. All these rich details suggest that the author conducted serious, on-site observations and documented them with remarkable objectivity. Supporting the interpretation of these scenes, the British Museum's surviving copies of the engravings contain short explanatory texts. Additionally, the series features two decorative plates—one at the beginning and one at the end—providing contextual information. While the final plate includes the publication date, the opening plate bears the series title and a statement affirming that Aelst personally sketched these scenes "true to nature" in Turkiye in 1533 in preparation for print. This evidence indicates that Aelst's field sketches were not merely adapted into woodblock prints after his death; rather, he himself composed the final woodblock print designs. This direct authorship further enhances the documentary credibility of the final work.

Not all seven pieces in the "Ces moeurs & fachons de faire de Turcz avecq' les Regions y appartenantes" series contain explicit location information. However, it is evident that Aelst depicted places he encountered on his journey to Istanbul. The first engraving is explicitly labeled as Slavonia, while the fourth piece has been identified as Plovdiv (Philippopolis) based on geographical markers. The final two engravings, however, are unmistakably from Istanbul.

In the sixth scene (Figure 1), the view is from the Kasımpaşa hills, looking towards Cibali. The ease with which the neighborhoods depicted in the scene can be identified is a result of the consistent urban perspective. Several public architectural landmarks, such as the Galata Tower, Fatih Mosque, Yavuz Selim Mosque, Zeyrek, Eski İmaret, and the Haliç Walls, are depicted with realistic proportions, aligning well with their actual placements. In fact, this depiction represents an extremely exciting example of urban realism for a time as early as 1533, offering an unprecedented level of perspective accuracy. There is, in fact, no earlier drawing of this quality with such an urban realistic perspective.

Figure 1. 6th Scene from "Ces moeurs & fachons de faire de Turcz avecq' les Regions y appartenantes".

The layering progresses from the Golden Horn to Suriçi. Just behind the crowd in transition, due to the perspective, there is a building group that is depicted with remarkable detail and size, as it appears to be in the foreground. This building group, except for the areas obscured by the people in the foreground, can actually be considered a perfectly depicted example of a 16th-century Istanbul residence (Figure 2).

Figure 2. Detail from the 6th Scene, 16th century Istanbul Residence.

This residence consists of courtyard walls, a courtyard gate, several single-story masses, and a unit with a lower floor containing a "*sofa"*, an upper floor, and a smaller upper unit above that. If observed carefully, even the building materials can be discerned. Based on the figures standing by the door, watching the outdoor entertainment, it can be inferred that this residence likely belonged to a Muslim family.

Although this residence may not closely resemble the picturesque "Turkish House" often depicted, it actually describes a composition that can be easily traced in the foundation deeds (vakfiye) of the period. For instance, the walls surrounding the house evoke the concept of "muhavvata", which frequently appears in the period's vakfiyes. In these documents, the term was used to refer to the courtyard, though the word "courtyard" itself is rarely mentioned. Etymologically, muhavvata means an enclosed or walled area. In fact, on the left side of the aforementioned residence, there seems to be an enclosed plot. Such areas are also marked as "menzils" (property plots) in vakfiyes. For example, in the Ayasofya Vakfiyeleri Tahrir Defteri [4], under a record for the Molla Hüsrev Mosque District, it states: "formerly a horse mill, now a walled plot of land" (p.147b).

The structure resembling a "cihannüma" on the upper floor of the residence is strongly likely to be a "gurfe". It is apparent that the building material is wood, which is consistent with records found in the foundation deeds. For instance, in the Ayasofya Vakfiyeleri Tahrir Defteri, there is a record from the Sultan Bayezid Mosque District that states: "beyt-i süfli (lower house) and a small gurfe made of wood above it" (p.226b). In fact, there are numerous records in the period's vakfiyes that indicate the use of wooden panels as building materials (for example, AVTD p.206a: "made from wooden planks" – "masnu' min el elvah").

Conclusion

As a result, after much discussion on the documentary nature of the depictions, one might ask: why is there not a single pictorial "Turkish House" with eaves, overhangs, projecting upper floors, numerous windows, bay windows, and top windows among the civil architectural examples depicted by Aelst on Ottoman soil, despite his work's emphasis on realism? In fact, the absence of such a housing type in the drawings is, in itself, a form of evidence. The residential settlement at the center of one of the most famous scenes from his well-known work, though not

prominently highlighted due to its nature, likely depicts a 16th-century "Turkish House" in a clear and unambiguous manner. Its consistency with other contemporary visual and written sources, as well as its historical coherence within the broader context of the artwork, strongly suggests that it represents a typical 16th-century "Turkish House", in contrast to the ambiguous depictions often found in other records. Thus, these depictions make a significant contribution to understanding the position of the "Turkish House" in the early 16th century's architectural evolution.

Fiction And Reality In Architectural Representation: Spatial Readings In Graphic Novels

Cigdem Akifoglu[a], Pelin Dursun Cebi[a]

[a] Istanbul Technical University/Graduate School, Department of Architecture, Architectural Design Program, Türkiye
akifoglu22@itu.edu.tr

Keywords: Architectural Representation, Fiction, Graphic Novel, Reality, User-Space Relationship.

Aim

According to Umberto Eco (1994), fiction and reality interact reciprocally; while fiction can be inspired by reality, reality can be reshaped by fiction. Similarly, Paul Ricoeur (1979) explored the blurred boundaries between fiction and reality, arguing that fiction is not merely a mirror reflecting reality but also a lens through which new possibilities and meanings can be imagined. How, then, can Eco and Ricoeur's fiction and reality dialectic be reflected in architectural representation?

The dialogue between fiction and reality exhibits a dialectical structure in architecture as well. Depending on the circumstances, these two concepts mutually influence and transform one another. For instance, throughout the design process, the data and constraints of the physical context play a significant role in shaping fictional narratives of space. Conversely, fiction, through the possibilities and scenarios it presents, enables the reinterpretation and transformation of real spaces. In this context, the focus of this study is on how the dialogue between fiction and real space is represented in architectural design.

Pérez-Gómez (2007) states that traditional architectural representations operate within a geometrized and homogeneous framework, relying on unquestioned sets of descriptive projections. Similarly, As and Schodek (2008) describe architectural representations as mechanical productions based on geometric algorithms, presenting a clear and definite reality. At this point, it can be stated that real space in architectural representation is conveyed through representational tools such as plans, sections, models, and three-dimensional renderings, utilizing a reductive language governed by specific rules. In this regard, As and Schodek (2008) note that architectural representations tend to reduce users' ability to perceive and experience space to a secondary place within the design process. This research examines the transmission of reality in architectural representation through the depiction of tangible and measurable spatial features that assert a definitive reality. Accordingly, it will be discussed how architectural representation frames space through specific rules and limited tools, thereby reducing reality and prioritizing only the tangible features of the space. Therefore, architectural representation will be examined from a critical perspective that mostly excludes user experience.

Kahvecioğlu (2008) states that the concept of space in architecture cannot be limited to objective definitions such as physical shell, frame, boundary, or surface; rather, space is a phenomenon built upon human life and experience and can be explained through different concepts of reality. This statement emphasizes that space should not be regarded merely as an object represented by tangible and measurable features but rather as part of a dynamic process that gains meaning through user experience. The genuine meaning and livability of space are formed by the user's involvement and experience. The user and space relationship is shaped by possibilities restructured in the individual's mind and ongoing experiences. Hence, this relationship is not a fixed and completed process but rather a dynamic structure in continuous transformation. Within this scope, the adequacy of conveying a space with architectural representation methods, the main goal of which is to represent concrete reality, is an issue worth considering.

Material and Method

This research examines that the discussions developed by Paul Ricoeur and Umberto Eco on fiction and reader experience provide an important theoretical framework for approaching the dynamic relationship between the user and space from a perspective that goes beyond the boundaries of concrete reality and for examining the role of

fiction in architectural representation. According to Paul Ricoeur (1979), fiction opens up a new world in front of us by shaking our perception of reality. In these worlds, the individual creates a unique space of existence under their assumptions and preferences. As Umberto Eco (1994) states that reading fictional narratives is playing a game in which we learn to give meaning to the boundless events that have happened, are happening, and will happen in the real world. Fiction introduces the individual to the unknown aspects of the real world. It enables the individual to encounter new possibilities, surpassing the limited experiences of the real world. Fictional narratives allow the individual to create a unique journey based on their personal preferences. Each choice opens up the possibility of new experiences and discoveries.

Fiction encourages the active participation of the individual in the process by providing opportunities for varied temporal and spatial experiences. This study initiates a discussion about the role and tools of fiction in architectural representation, questioning the efficacy of architectural representation that imposes a specific reading format within a limited and rule-bound framework, and investigating alternative methods of representation for conveying the fictional aspect in architectural representation. In this context, graphic novels, which make the dynamic relationship between fiction and real space visible and thus involve the reader in the spatial narrative, are considered an alternative tool for representing architectural space. To analyze how the representational potentials and formal characteristics of graphic novels are employed in the representation of architectural space, a deconstruction method has been applied to selected graphic novels (Figure 1.).

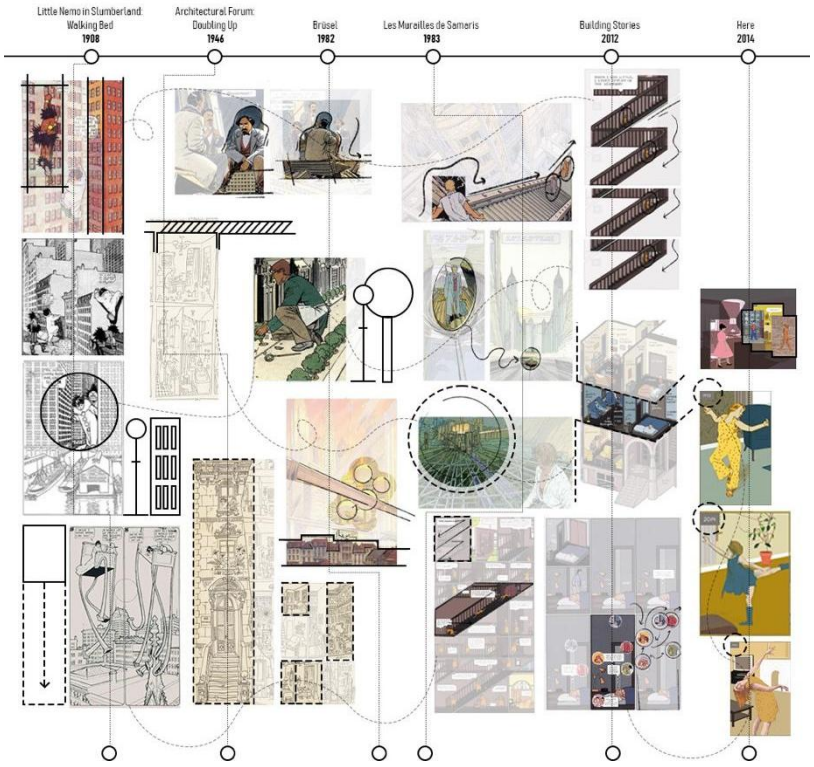

Figure 1. Deconstruction of selected graphic novels (Akifoglu, 2025).

Findings

Graphic novels are well-structured visual narratives that convey information, evoke sensory responses, and involve the reader into the narrative. Unlike architectural representation methods, in graphic novels, space is not presented within a limited framework; rather, it possesses a dynamic character shaped by the reader's involvement. Instead of representing space as a direct, concrete reality, graphic novels make alternative scenarios and possibilities related to space visible, encouraging the reader to reconsider space. Rather than positioning the reader as a mere observer, graphic novels place them as individuals actively participating in the narrative and constructing their

own spatial experience. Through graphic novels, fiction becomes visible, allowing the reader to engage with the space.

This research suggests the representational potentials of graphic novels as an alternative representation tool. In this regard, works such as Winsor McCay's *Little Nemo in Slumberland: Walking Bed,* Saul Steinberg's *Architectural Forum: Doubling Up,* Benoit Peeters and François Schuiten's *Brüsel* and *Les Murailles de Samaris,* Chris Ware's *Building Stories* and Richard Mcquire's *Here* have been selected as examples that highlight the visibility of fictional narratives in space by considering space not merely as a simple background but as an integral part of the narrative. The selected examples are analyzed through a deconstruction method, exploring how the boundaries of concrete reality are transcended by specific representation strategies, how fictional narratives containing alternative temporal and spatial scenarios become visible in spatial representation through these strategies, and how the reader becomes involved in space throughout this process.

Based on this framework, a cross-reading of selected graphic novels has been conducted based on the representation strategies identified through deconstruction method. This analysis enabled a comparative evaluation of how these strategies construct space within the interplay between fiction and reality across different narrative structures. For instance, the strategies employed to represent the temporal dimension of space in the graphic novel *Here* exhibit similarities to the representational techniques used in *Building Stories*. In both works, the temporal dimension of space is made visible through the representational potentials and formal characteristics of the graphic novels, incorporating time segments into the depiction of space. Rather than offering the reader a linear spatio-temporal structure, as typically encountered in real space, both graphic novels construct spatial narratives that encourage the reader to assemble their own interpretive framework. Within this non-linear spatio-temporal context, *Building Stories* centers on life unfolding within an apartment building, whereas *Here* explores the domestic structure of home life across multiple temporal layers (Figure 2.). In both cases, the shared representation strategies render the temporal scenarios of space visible and, significantly, shift narrative control to the reader, who actively participates in constructing the spatial narrative.

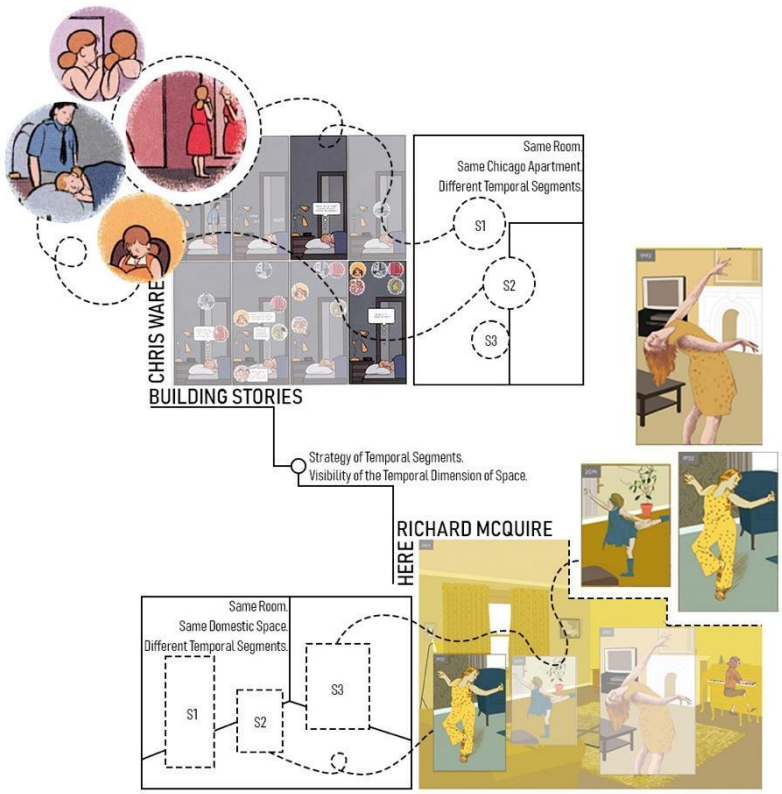

Figure 2. Visibility of temporal dimension of space (Akifoglu, 2025).

Conclusion

This research challenges the fixed and completed user-space relationship presented by traditional architectural representations, proposing graphic novels as an alternative representation tool that makes the fiction visible in spatial representation and emphasizes the dynamic relationship between the user and space. The findings reveal that graphic novels, through their representational strategies, distort and reconfigure reality, constructing multi-layered and dynamic spatial narratives on a spatio-temporal plane. These narratives make the dialectical relationship between fiction and reality visible, and most significantly, they highlight the reader (the user) as the primary agent who interprets, navigates, and reconstructs meaning within the spatial narrative.

As a result, the research offers a new perspective on real space, challenging the limits of traditional architectural representations and providing a conceptual foundation for architects seeking to explore the dynamic relationship between user and space through imaginative thinking. In this regard, by emphasizing the need for architects to have alternative tools for thinking, creating, and representing, the study argues that graphic novels and their representation strategies play a critical and mind-opening role in the representation of space, enabling the construction of user-centered spatial narratives within a spatio-temporal and interpretive framework.

Deconstruction of Clothing: Clothing as a Spatial and Embodied Medium

Zeynep Özlem Dündar[a], Pelin Dursun Çebi[b]

[a] Istanbul Technical University, Graduate School, Architectural Design Program, Türkiye
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Türkiye
dundar23@itu.edu.tr

Keywords: Body and Space Relationship, Clothed Body, Affordance.

Aim

From a normative perspective, the ideal body is determined within the context of architectural design and static spatial configuration is constructed in accordance with the predefined norms on how the ideal form integrates into the space. Yet, the body is not sole and ideal; it is constantly open to manipulation and transformation in its relationship with bodies, its surroundings, or non-human actors. The existence of a disembodied space is as meaningless as the creation of a stable spatiality by the dynamic and changing body. These manipulations can physically shape the body through attachments that form a second skin, or perceptually through actions resulting from the affordances of the attachments. In the network of relationships the body establishes with space, the actors mediating this manipulation can be considered as a whole, consisting of both humans and non-human objects. According to Huyse (2024), some of the strategies that manipulate the body are abating, attaching, bonding, broadening, caging, campering, covering, deforming, dramatizing, elongating, encasing, enfolding, enveloping, exaggerating, excepting, expanding, fragmenting, freeing, gapping, hiding, insulating, isolating, masking, mocking, shaping, swelling, uncovering, wrapping etc. The aim of the research is to explore the transformative effects on the relationship between the body and space by thoroughly examining non-human actors that manipulate the body. Transformative effects contain both the transformation of the body, space and the perception. In this context, the effects of non-human actors, which may initially seem ineffective, can be more clearly revealed in the body-space experience, and perception.

The research begins with considering clothing which is an actor in the body-space dialectic, as a design object. It attempts to interpret the perception created by clothing on the body within a semantic framework. There is a connection between human-centered thinking and object-centered thinking. The design of every object is shaped towards a purpose. As mentioned by Gibson (2015), "The different objects of the environment have different affordances for manipulation" (p. 120). Objects are designed with all their potential possibilities -with their affordance; however, apart from the designer's intention, implicit potentialities can be discovered in different ecologies and users. As noted by Gibson (2015), "The affordances of the environment are what it offers the animal, what it provides or furnishes, either good or ill" (p. 119). Clothing is suitable for manipulating the body's potential for action as a second skin. According to what Spurrett and Brancazio said, "When we wear certain clothing, it enables us to change our appearance or abilities, shaping our capacities as agents, either supporting or constraining our possibilities for action" (Spurrett and Brancazio, 2024, p. 1901). When it comes to clothing, a design that is proper with the body is brought to mind as a result of socially acquired judgments, and efficiency is essential in this design. Questioning the design principles, usage areas, and affordances of objects like garments, which are associated with the body but considered ordinary, can enable the creative destruction of the judgments attributed to them. Here, the phrase "creative destruction" refers to deconstructing clothing in order to explore its interaction with the body, thereby revealing its role in the body-space relation.

Material and Method

As noted by Spurrett and Brancazio (2024), "That the human body is typically clothed in ways that transform its capabilities seems important for thinking about human embodiment and cognition" (p. 1990). In the research, clothing is considered as an actor who transforms the body and space with a focus on experience. Schlemmer (1961), "The transformation of the human body, its metamorphosis, is made possible by the costume, the disguise" (p. 25). Clothing is considered as a tool to reinterpret the body and, consequently, to rethink spaces. The space

defined by the body in conjunction with clothing; as well as the body's perception, actions, and interactions through wearable technologies, can be manipulated. As a result, the organization and experience of space can be diversified. The theoretical framework of the research is discussed through Latour's Actor-Network Theory (ANT), exploring the manipulative power of clothing in the body-space relationship. As noted by Latour (2005), "It was at this point that non-humans -microbes, scallop, rocks and ships, presented themselves to social theory in a new way" (p. 10). The body is open to manipulation, and thus, space becomes a system that constantly forms and deforms with the body. Moreover, ANT does not represent a finite system and allows for the consideration of both human and non-human objects within the same system. The way the theory allows for the simultaneous consideration of human and non-human entities also shapes the methodology of the research.

Findings

In the continuation of the research, selected works of artists who have conducted experimental studies in clothing design are examined in terms of bodily, spatial, and social dimensions. As noted by Loschek (2009), "The three-dimensionality of clothing suggests a comparison to architecture, which is evident in deconstructivism" (p. 190). Martin Margiela is known for his innovative designs that demonstrate how deconstruction functions in fashion. By critically approaching traditional design concepts, he adds new meanings to garments. In doing so, he deconstructs the body, emphasizing its parts rather than presenting it as a whole. He reverses the inner and outer surfaces of garments, stitches parts in contrasting ways, or designs incomplete garments to evoke a sense of incompleteness, making the gaps visible. In a similar approach, Rei Kawakubo deforms the garment by breaking it into pieces in her "*Body Meets Dress, 1997*" collection. She offers a critique of the traditional aesthetic norms imposed on the body. In this context, the garment becomes a transitional object, serving as a tool that spans from the traditional to the innovative, and from the individual to the space. In the works of Donna Sgro, the impact of various factors, ranging from the material of the garment to its design, on both the body and the space, is traced and examined. In Sgro's "*Fractured Garment"* design, the garment responds to the moving body due to the soft and flexible fabric it is made from. The garment shapes itself according to the body's movements, expanding with the possibilities inherent in the fabric. This invites a reconsideration of the relationship between the body and its surroundings.

Fig. 1. Rei Kawakubo, *Body Meets Dress, 1997* (Url-1).

Fig. 2. Donna Sgro, *Fractured Garment* (Url-2).

A similar situation can be observed in Jana Sterbak's "*Remote Control II, 1989"* design. Sterbak discusses dualities such as body – machine, male – female, and freedom – captivity through her design. The design incorporates a mechanical system that enables the skirt to expand, contract, or transform into various shapes. In this way, the body redraws its boundaries each time through external control. The physical qualities that the skirt presents to the

body and its surroundings hold new potential for action for the wearer. The body, by breaking down its sensory-coded perception, re-discovers and re-creates the space. By lifting the body off the ground, it deprives it of its conscious movement. In this context, both human and non-human actors create a dynamic power politics on the body. Although the connections between humans and non-human objects may break and repeatedly re-form, spatial creation continues to sustain its existence within the system in different forms. The space now becomes an ongoing ambiguity, constantly deteriorating and re-forming, never disappearing, for the body integrated with the skirt. In her works, Sgro represents garments as transformative structures. In the "*Architectonic Exhibition* 2014", garments are approached as an architectural form, with new forms of design and structure emerging through different types of materials and structural design. As mentioned by Hodge (2006), " Vocabulary derived from architecture has been applied to garments ("architectonic,""constructed," "sculptural," etc.)" (p. 11). As an architectural form, the garment blurs the boundaries of the body, creating spatiality between the body and the garment.

Fig.3. Jana Sterbak, *Remote Control II,* 1989 (Url-3). **Fig.4.** Donna Sgro, *Architectonic Exhibition*, 2014 (Url-4).

A similar situation can be observed in the works of Lucy Orta. In her "*Refuge Wear, 1992-98"* designs, the garment transforms into a temporary shelter and architecture on the body, functioning as an architectural form.

Fig. 5: Lucy Orta, *Refuge Wear*, 1992-98 (Url-5).

Conclusion

As a result, the social, political, perceptual, experiential, and spatial effects of clothing are examined through the flexibility provided by Actor-Network Theory. In addition to the social effects of clothing as an actor on the body, the reflection of its limitation or expansion of the body's actions on architectural space is questioned. While exploring how clothing can manipulate the body both physically and perceptually, the study also traces how, beyond merely being a covering for the body, clothing becomes an active component in the creation of space through various designer approaches and changing environmental dynamics such as material and technology. In this direction, the research criticizes the static understanding of the body and space, while problematizing non-human actors in the body-space relationship through the lens of clothing, thereby opening new perspectives in design processes.

The Interpretation of the Metaverse through Rhizome Philosophy

Beril Deren Simsek[a], Meltem Aksoy[a]

[a] Istanbul Technical University/Graduate School, Department of Architecture, Architectural Design Program, Türkiye
simsekb22@itu.edu.tr

Keywords: Metaverse, Multispace, Rhizomatic Connections, Rhizome Philosophy, Virtual Space.

Aim

In this study, a discussion is carried out on the metaverse, where there are simultaneous interactions between virtual space and real space. Regardless of time and location, the metaverse allows for a variety of experiences by allowing transitions between different spaces. In this paper, these intertwined spaces are referred to as multispace. It can be stated that the complex and multi-layered structure of the multispace within the metaverse shares similarities with Deleuze and Guattari's rhizome philosophy. In the light of these similarities, it is aimed to read multispaces spatially and conceptually through rhizomatic connections. In the context of the characteristics of rhizome philosophy, which expresses non-hierarchical and infinite proliferation, can the metaverse form a rhizome?

Material and Method

The rhizome philosophy, described by Deleuze and Guattari in their book "A Thousand Plateaus" (1980), represents a way of thinking that contrasts with the tree metaphor, which stands for a fixed and hierarchical framework. It expresses a decentralized form of organization that is network-like, where multiple connections are established. Each connection is connected to any other point while constantly creating a new one. This approach offers a flexible and dynamic structure without being tied to a fixed root (Deleuze & Guattari, 1980/2023). Rhizome, which does not show a linear growth model, reproduces through underground trunks formed by additional shoots upwards, downwards or laterally, as in the botanical meaning. It has no beginning, end or specific direction of spread. (Adkins, 2015).

Deleuze and Guattari have detailed how rhizomatic connections are formed and multiplied with six principles: "connectivity", "heterogeneity", "multiplicity", "asignifying rupture", "cartography" and "decalcomania". In this study, it is argued that the metaverse can be associated with the rhizome in that it does not have a certain boundary indicating where the connections will end, creates a decentralized communication network instead of a single authority and has a multi-layered structure. Within the framework of the rhizome philosophy, it has been discussed where multispaces are similar to the principles of the rhizome and a narrative has been created in this direction.

When looking at various metaverse platforms, it is seen that exhibition space and showroom designs are mostly prominent in the use of metaverse. Therefore, in the last stage of the study, the virtual gallery project called "NFTism" designed by Zaha Hadid Architects in the metaverse was selected as a case study and analysis was made over multispaces.

The metaverse transforms today's online experiences into interconnected and immersive virtual spaces where one can interact with others regardless of location (Levine, 2022). It can be said that the disappearance of physical and environmental boundaries in traditional architectural practice in these areas has created differences in spatial experiences. According to the definitions of Mantegna and Rinesi, while in "augmented reality (AR)" technology, a variety of spatial perceptions can be achieved by adding a new digital layer to the real world, with "virtual reality (VR)" technology, users can have a realistic experience. "Mixed reality (MR)", which is at the intersection of AR and VR applications, is defined as hybrid environments where real and virtual spaces can react to each other at the same time (Mantegna & Rinesi, 2023). The metaverse brings all these technologies together and enables transitions between spaces. These different technologies are gathered under the title of "extended reality (XR)" and form the interaction area of the metaverse (Image-1).

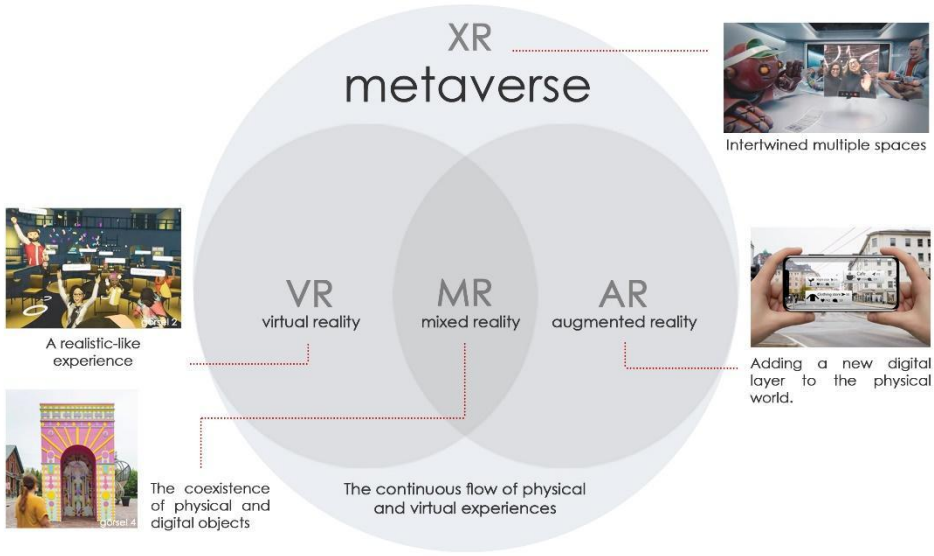

Image 1. The Scope of extended reality (Simsek, 2024).

XR technologies allow architects to redesign and experience spatial environments by transcending traditional boundaries. In this way, virtual spaces can be perceived at various scales and with different sensory organs. For instance, by incorporating XR technologies into a project designed for a real space, the space gains dimension and richness. Thus, instead of passive viewing, a transition is made to a multispace where users can explore the works from different scales. According to Hopkins (2023), multispace emerges at the intersection of the real and the virtual and it does not indicate a singular space. In this multispace, where the boundaries are constantly changing, the individual has the situation of being both alone and together at the same time. Therefore, it points to an open and pluralistic structure actively nourished by various experiences, identities and cultures.

Findings

Rhizome, unlike tree roots, refers to any point being connected to any other point. Connections are not fixed and specific, they are constantly reshaped. In this network of relationships, a heterogeneous structure is formed by the coming together of various interaction areas. At this point, the "connectivity" and "heterogeneity" principles of the rhizome philosophy can be associated with the metaverse. According to Ponde's definition, the metaverse is based on the concepts of interoperability and interconnectedness (Ponde, 2022). When switching between different spaces, the system can work interconnected, both within itself and with new additions, in harmony and interaction, as in the rhizome. In addition, the concept of accessibility in the metaverse can be interpreted with these principles of the rhizome. Depending on the level of integration of XR technologies into multispaces, there are differences in the spatial experience. For example, switching to a virtual space with VR tools can be perceived as more realistic than connecting to that space via a phone or computer. Dynamic, unstaid virtual spaces can be created with real-time updates. Similarly, the rhizome philosophy defines a constantly renewed, developing and dynamic organizational structure.

In the "multiplicity" principle of the rhizome philosophy, the rhizome multiplies connections, transforms them and creates innovations. Deleuze and Guattari have explained this principle with the concept of "lines of flight". Lines of flight encourage the formation of a different connection and create multiplicity. In other words, it can be said that these are effective in bringing different contexts together creatively. Similarly, the transitions between multispaces and the new intersections that emerge also show a rhizomatic growth. It can be thought that a system open to continuous expansion, without a specific beginning or end, is formed by the design and collective coming together of virtual spaces.

Moreover, new identities and bodies are formed through rhizomatic connections (Ballatyne, 2012). When virtually included in a space, areas and objects can be explored in three-dimensional and real-time experiences through

virtual bodies known as avatars, and multispace can be freely navigated. For instance, by pressing a direction button designed near the object, it can be instantly transformed to a different space and these spaces can be observed from different angles. This situation can be associated with the "lines of flight" in the rhizome philosophy. Thanks to new connections, a constant state of flow occurs between real and virtual spaces or within completely virtual spaces. This allows the perception of time and space to change.

According to the principle of "cartography", a rhizome acts like a map, as opposed to a template, it does not have a single entry point, and it has multiple entries. The map builds new connections. It can be disassembled, reversed, changed, reconnected and adapted to any kind of modification (Deleuze & Guattari, 1980/2023). From the perspective of the principle of "cartography", virtual spaces, unlike real spaces, can be designed by expanding the boundaries. When the physical boundaries brought by factors such as gravity, climatic conditions and materials are eliminated, multispaces can exhibit a rhizomatic structure; they can disperse, recombine and produce different variations by diversifying user experiences. For example, when evaluated in the context of an exhibition space, it may be possible to reconsider the artwork from different angles, switch to a new flow of information or open a different layer in the space through a QR code. In this way, while spatial features are enriched, it bears traces of the multidimensional structure of the rhizome.

Today, the concept of art has found a new medium in the metaverse through multispaces. This environment, which enables the active participation of the audience, adds flexibility to the ways in which works of art are exhibited. Traditional forms of representation have gained an interactive dimension with the innovations brought by digitalization. In the exhibition techniques of architecture, painting, design, music and performance arts, an experiential environment that transcends the boundaries of physical spaces is created thanks to the opportunities offered by the metaverse. Considering this, Zaha Hadid Architects' "NFTism" project offers a dynamic and multi-layered space design where various NFT (Non-Fungible Token) artworks are exhibited (Image-2). There is no fixed direction or specific roadmap while visiting the works in this multispace, and this allows visitors to have various experiences. Beyond being an exhibition space, the "NFTism" project highlights the flexible, multi-layered and network-like structure of architecture. This feature can be an example of how the basic principles of the rhizome philosophy can be transformed into a spatial experience. One of the important parts of the exhibition space, the "Z-Car One" vehicle designed by Zaha Hadid Architects, is an object that moves within the virtual exhibition space and whose parts can be examined separately (Image-3). Therefore, the representational power is increased and the transfer of information is taken to a different dimension, and an interaction area is created by establishing new connections between the artist and the visitor. NFT works placed on different surfaces and volumes create a more impressive environment by bringing together sound and image. In addition, the fact that visitors interact with each other in this multi-layered space also emphasizes the social power of the space.

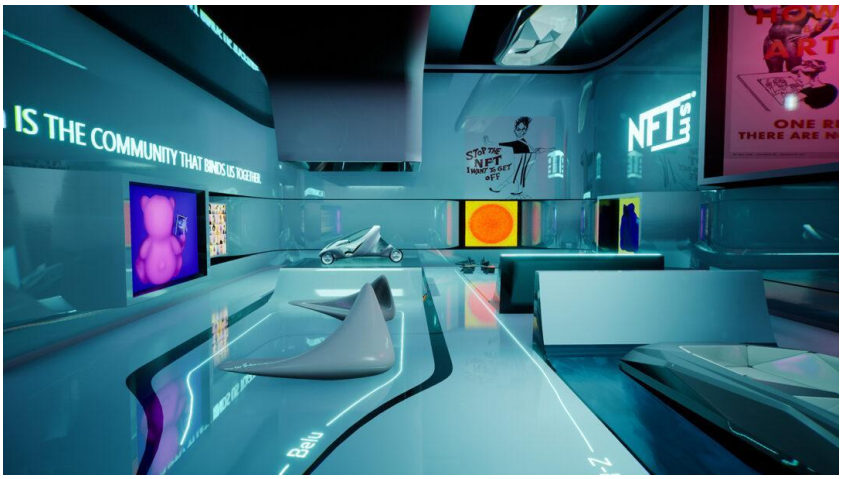

Image 2. "NFTism" at Art Basel Miami Beach, Zaha Hadid Architects, 2021.

Image 3. "NFTism" at Art Basel Miami Beach, Zaha Hadid Architects, 2021.

Conclusion

The dynamic and interconnected structure of the multispaces that make up the metaverse has significant parallels with Deleuze and Guattari's rhizome philosophy. In this study, the metaverse is examined through the principles of the rhizome. Multispaces that go beyond physical boundaries and constantly expand, reshape, and transform with user interactions make a network-like structure possible. Due to the nature of the rhizome, these connections have an unlimited growth potential and allow different relationships to emerge with the addition of new "lines of flight". Especially thanks to the opportunities provided by XR technologies, users can freely navigate, interact, and reshape the space itself in multispaces. From this perspective, it can be said that the metaverse forms a rhizome with its non-hierarchical, decentralized, and constantly changing structure. In the future, with the development of metaverse technologies, it is likely that virtual space experiences will diversify further and rhizomatic connections will become more apparent.

Evaluation of Social Performance in Public Squares Through Social Media Images : A Case Study of Taksim Square and Beyazıt Square

Muhammed Eker[a], Mehmet Emin Şalgamcığlu[a]

[a] Istanbul Technical University, Departmant of Architecture, Architectural Design Program, Türkiye
ekerm22@itu.edu.tr

Keywords: Social Performance, Space Syntax, Socio-Spatial Image, Isovist.

Aim

With the proliferation of social media, digital images have become an important source for reflecting the social construction of the city and everyday behaviour. Images, which are a partial product of the individual's perception of the city, contain important potential information to reveal the impact of the built environment on social constructs and social behaviour.

Research Question : **Can social media images that contain information about the social construction and behaviour of the city be used to evaluate the social performance of the urban area?**

The answer to this question has been investigated through two distinct urban squares in Istanbul (Taksim Square, Beyazıt Square), reflecting the community's different behavioural practices through their lifestyles and social structures. Various qualitative research and evaluation methods have been employed to assess the social content of images. Quantitative evaluation method has been employed for the syntactic assessment of images through the concept of isovist.(Benedikt, 1979) The syntactic evaluation of images utilized metrics such as Digital Space Interaction (DSI) and Digital Space Visibility (DSV) (Maldonado-Gil & Psarra, 2022).The DSI and DSV data generated from social media images were compared with the configurational Visibility Graph Analysis parameters of the space. The research aims to present a comprehensive assessment of the place by integrating observation, spatial syntax, digital data, with the goal of visualizing the socio-performance of the space.

This paper utilizes analysis methods developed by Psarra to examine Instagram images through the isovist tool developed by Benedikt. The research is developed within the context of Beyazıt Square and Taksim Square, which are believed to reflect distinct characters in terms of their social pattern, behavioral practices and are considered to possess contrasting features. Beyazıt and Taksim Squares, including their surrounding contexts, landmarks, functional diversity, and social patterns, exhibit distinct social performance character.

The aim of the study is to conduct research in order to comparatively evaluate the perceived social performances of Beyazıt Square and Taksim Square in Istanbul, which are thought to be distinct from each other. The analysis employs Digital Space Intelligibility tools (Maldonado-Gil & Psarra, 2022) to evaluate the social and spatial characteristics of these environments, both in Instagram photographs and real space. Isovists, developed by Michael Benedikt and utilized in various studies treat each Instagram photo of a space as an isovist. When collectively examined, all Instagram photos of the same space offer a comprehensive representation of the spatial characteristics, activities, and behavioral patterns occurring in that space.

Material and Method

The research utilized Instagram photographs as the prominent representation platform of visual media.The images shared publicly on the Instagram platform in the locations identified for the research, namely Taksim and Beyazıt, between November 2023 and January 2024, were scanned. One hundred images that met the specified criteria were selected for evaluation. The origin and vision field of the selected photos were manually geolocated in QGIS.

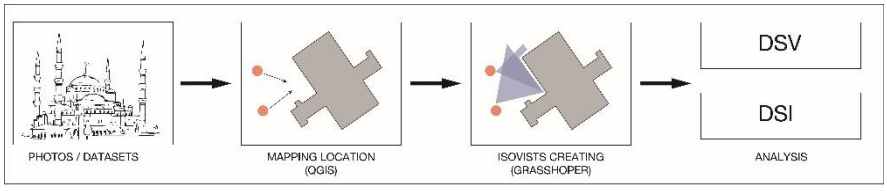

Figure 1. Method Diagram.

After completing the mapping process, the resulting dataset was exported to Grasshopper. Subsequently, a custom algorithm script was utilized within this program to compute two novel spatial measures: Digital Space Interaction (DSI) and Digital Space Visibility (DSV). Digital Space Interaction (DSI) assesses the spatial location attributes of the images. Digital Space Visibility (DSV) evaluates the connectivity characteristics of the depicted space.
To visualize and assess the distribution of the in the researched squares the Shannon-Weaver Diversity Index's entropy formula (Yoshimura vd., 2022) employed.
In order to compare this approach to Visibility Graph Analysis (VGA) (Turner, et al., 2001) measures, it was used DepthmapX software (Varoudis, 2015) to analyse each public space, calculating the values of integration and connectivity. For this study, a 150 m radius model from both public spaces was drawn, considering all spaces that are visible (eye-level). Consequently, it was quantified the measure of intelligibility (Hillier, 1996)for both cases.
The last part of the research measures the social indicators of a place through an observational study of the same places featured in the dataset, i.e. the Instagram photographs used in the analysis. Two categories were selected to measure the social indicators of a place, both of which are based on the framework developed by the Jan Gehl (Gehl & Svarre, 2013) : sociability and uses & activities

Figure 2. Instagram Photos.

Findings

Social Indicator Findings

The social performance of both squares has been calculated, taking into account the specified indicators. In Beyazıt Square, 35% of the photos depict scenes without any individuals. Social activities represent the most prevalent content, accounting for 32% of the images. Furthermore, 89% of the photos were taken during the daytime, with limited night time usage observed. The most common activity captured in photos is posing, constituting 28%, followed by political and activist gatherings as the second most prevalent activity at 28%. (Figure 3)
In Taksim Square, 30% of the photos depict scenes with 1-5 people. Landmark elements dominate the content of 32% of the photos. Posed activities are featured in 55% of the images. Additionally, 12% of the photos reflect the square's involvement in recent New Year's Eve events as a special activity. The observation of night time use in 35% of the photos indicates that the square hosts diverse activities throughout different times of the day (Figure 3).

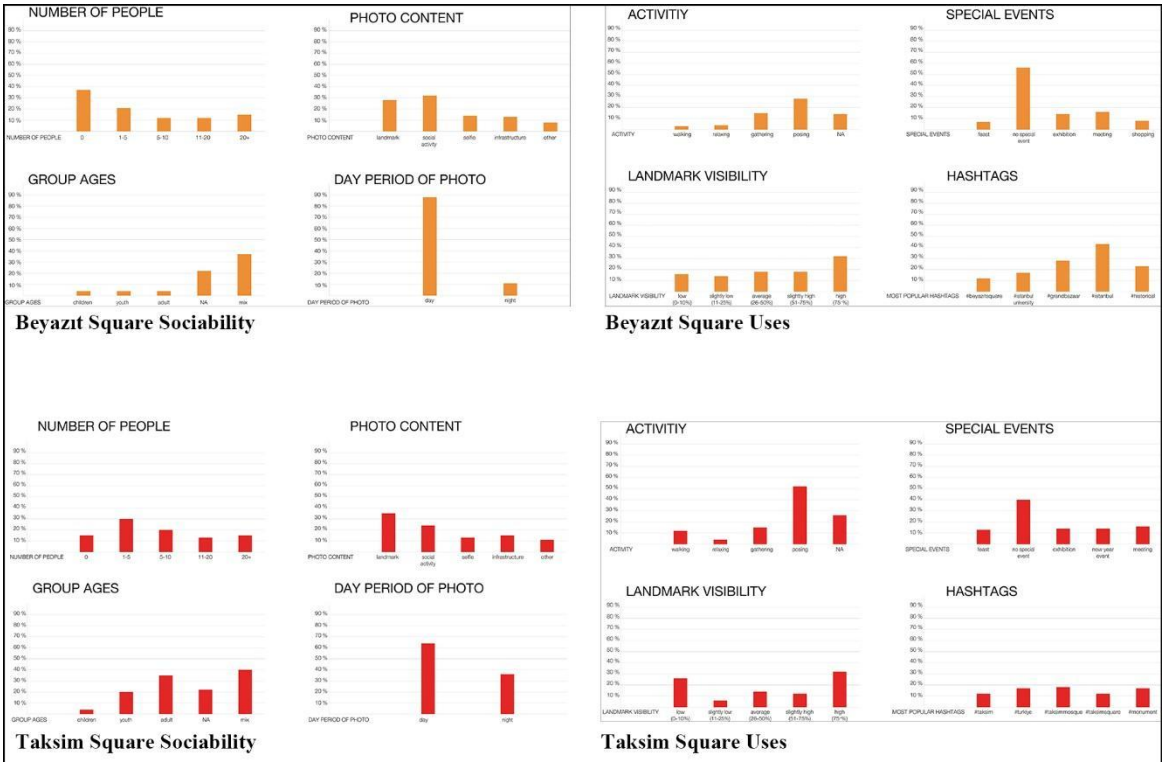

Figure 3. Sociability & Uses Analysis.

Physical Visual Syntactic Findings

The Visibility Graph Analysis and Axial Maps methods were employed for the physical visual syntactic analysis of the two spaces. Evaluations were conducted by calculating visual integration, connectivity, and intelligibility values. The DepthmapX (Varouidis, 2012) software was utilized to generate the analyses, and calculations were performed based on the obtained data.
In Beyazıt Square, the highest integration value is observed in the area around Beyazıt Mosque, Kapalıçarşı (Grand Bazaar), and the intersection of Ordu Avenue. Due to the three main landmark elements, Islamic Arts Museum, Beyazıt Mosque, and Istanbul University Entrance Structure, which disrupt the overall visual composition of the square, a heterogeneous and low integration value is observed throughout the square.(Figure 4)
In Taksim Square, the highest integration value is observed in the connection between Tarlabaşı Boulevard and Taksim Mosque. The area between the Republic Monument, Gezi Park, and Atatürk Cultural Center exhibits a homogeneous and lower integration distribution. In the area connecting Atatürk Cultural Center and İnönü Avenue, higher values are observed compared to the homogeneous integration in the square. (Figure 4)

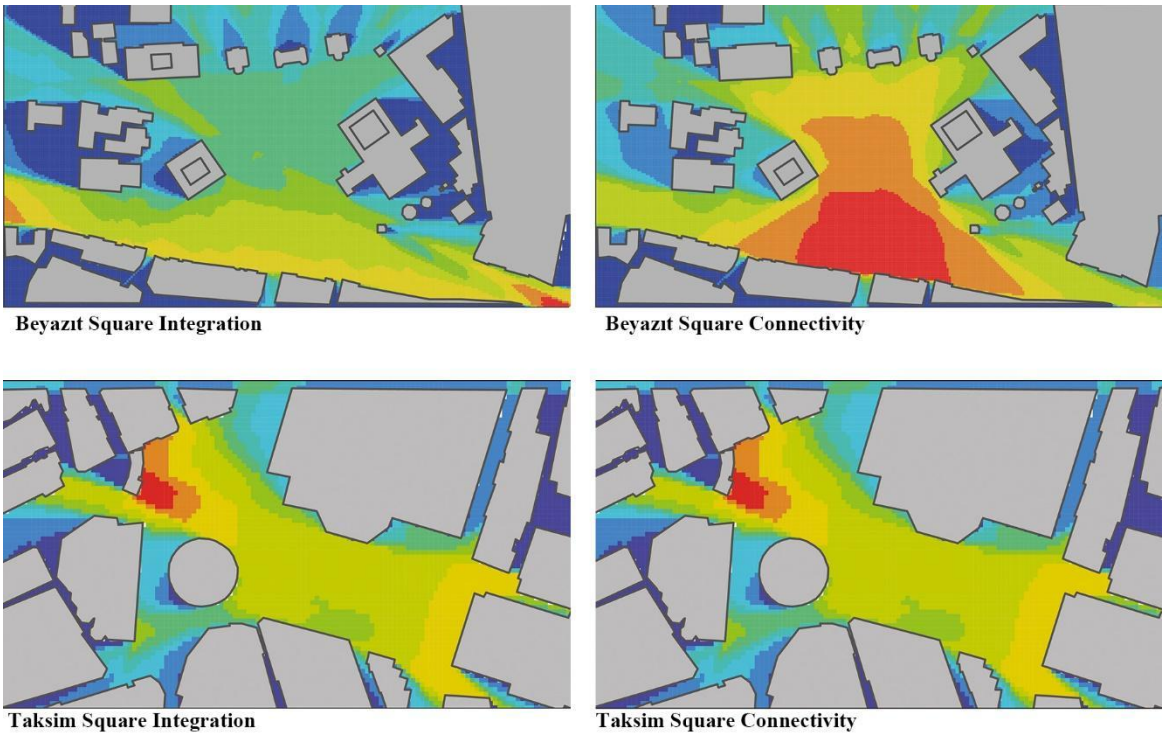

Figure 4. Physical Visual Syntactic Findings.

For both squares, R2 visual intelligibility values were calculated. In Taksim Square, the intelligibility value according to R2 is 0.696, indicating both a high integration value and ease of orientation, landmark visibility, and navigation. In Beyazıt Square, the intelligibility value according to R2 is 0.593, and although visually strong integration is observed, it is noted that orientation, landmark visibility, and navigation are not as easy as in Taksim.

Table 1. Physical Visual Intelligibility.

	Beyazıt Square	Taksim Square
Physical Visual Intelligibility	6.96	5.93

Digital Visual Syntactic Findings

As a result of the evaluations of Digital Space Interaction (DSI) derived from the Shannon-Weaver entropy formula, analyses reveal the formation of hotspots in Beyazıt Square, specifically in front of the Museum of Islamic Calligraphy Arts and between the Beyazıt Mosque and the Entrance Structure of Istanbul University.
In Taksim Square, a singular and homogeneous hotspot area has been identified, concentrated around the Monument of Republic. DSI index value of 9.02 in Taksim Square confirms a more homogeneous and centralized distribution around the Republic Monument.(Figure 5) In Beyazıt Square, a DSI value of 6.93 confirms a more concentrated distribution at two different points, with an overall more scattered and heterogeneous distribution throughout the square.(Table 2)
When the analyses of the Digital Space Visibility Index are evaluated, high values are observed in the area between the Entrance Structure of Istanbul University and Beyazıt Mosque in Beyazıt Square; this area indicates a location where social activities and events predominantly occur. In Taksim Square, high values are observed around the Republic Monument due to landmarks focusing on Taksim Mosque and the Monument of Republic.(Figure 5) In DSV assessments, Taksim exhibits a more homogeneous and centralized distribution in its visual field with a value of 8.92 compared to Beyazıt. However, it does not show as strong a homogeneous distribution as the DSI value; there is a more heterogeneous texture in the digital visuals of the space. In Beyazıt Square, it is observed that the collision of isovists concentrated in two different focal points demonstrates a more homogeneous distribution character compared to DSI with 7.02 value.(Table 2)

Table 2. DSI and DSV Index .

	Beyazıt Square	Taksim Square
Digital Space Integration (DSI)	6.93	9.02
Digital Space Visibility (DSV)	7.04	8.92

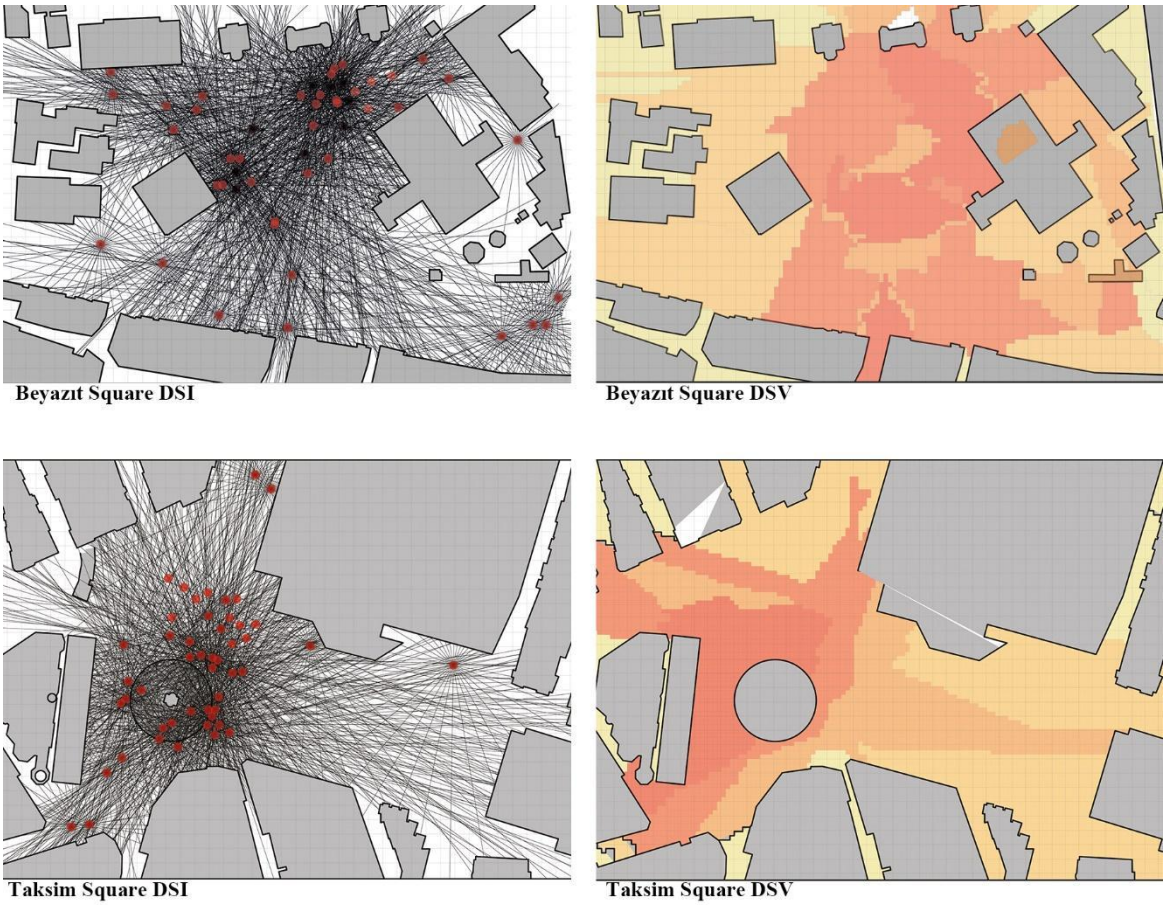

Figure 5. Digital Syntactic Findings.

Conclusion

The correlation between traditional space syntax methods and the visibility generated through digital images in the city has been tested. The statistical correlations were examined between the measure of physical space integration (VGA) and the digital measures of the Diversity Index of DSI and DSV.

The assessments revealed a high correlation (0.620) between VGA and DSV for Taksim Square, whereas a weak correlation (0.389) was observed for Beyazıt Square. Additionally, when examining the social indicator values for Taksim Square, it is evident that dimensions such as activity, nighttime usage, social usage density, and user diversity show higher correlation compared to Beyazıt Square.

This study aims to uncover the potentials and limitations inherent in each space. It is premised on the idea that visual data extracted from Instagram can serve as a valuable tool in deciphering the appeal spaces have for individuals, shedding light on their real-life usage and digital behavioral patterns. By examining how physical spaces are portrayed in digital media alongside spatial analysis of the physical environment, it provides insights into the notion of place. Here, 'place' is defined by individuals' preferences for specific environments, documented and communicated through photographs. Such analyses serve as valuable complements to traditional observational techniques and configuration analyses.However, the selected images represent a narrow sample and demographic,

shared through a single social media platform, meeting specific criteria within only a three-month period. While providing a significant assessment of the space's social performance, the sample has been limited.
The findings give rise to reflections on the role of digital media and their integration into spatial behaviors within urban and architectural environments. It is important to note that this research does not claim the faithful representation of real physical experiences of public spaces in digital photos. However, it does provide valuable information regarding social usage patterns.

Architectural Representation in the New Media Era and Lateness

Hasan Aydın[a,b], Ozan Önder Özener[a]

[a] İstanbul Technical University, Graduate School, Architectural Design Program, Turkiye
[b] Yıldız Technical University, Department of Architecture, Architectural Design Program, Turkiye
aydinhas18@itu.edu.tr

Keywords: Architectural Representation, Artistic Practices, Design Tools, Digital Design Media, Lateness.

Aim

Architectural representation has served as a bridge between ideas and reality through its various tools throughout history. Since the 16th century, evolving representational techniques — such as axonometric projection— have been among the factors influencing architectural discourse. However, the design tools that emerged in the last quarter of the 20th century and into the 21st century have led to a profound transformation in architectural representation. Computer aided design (CAD), building information modeling (BIM) and 3D modeling softwares are among the prominent examples of these tools. Vroman and Cannaerts (2022) argue that technological advancements have enabled a form of human-computer hybridization, allowing for translation and integration between analog and digital drawing practices. For instance, the proliferation of new tectonics in the 1990s parallels the simultaneous development of spline technology (Carpo, M. (ed.), 2013). Within the axis of this transformation, the transmission of architectural ideas has become increasingly complex, multilayered, and blurred. How is lateness, a concept that resists clarity, positioned in architectural representations that are the visual projection of these transfers?

The concept of 'lateness,' borrowed from Theodor Adorno's discussion of the late style, offers a critical lens for analyzing representations undergoing radical transformation. Adorno originally examined this concept in the context of music, identifying it in the fragmented and dissonant compositions of Beethoven's late works. In Peter Eisenman's interpretation, lateness signifies an architecture that resists stability, subverts conventional meaning-making methods, and engages in self-referential critique within the form-history framework. Lateness has no ties to any particular style, nor does lateness operate as a style in itself. It manifests itself as an interruption to linear time…(Eisenman, P. Iturbe, E. 2020). Eisenman approaches lateness as an aesthetic condition embedded with contradiction, resisting both unity and clarity in the architectural works he analyzes. At this point, the limitation of lateness to completed buildings becomes a subject that calls for critical scrutiny. Could lateness be inherent in contemporary architectural representations? In the age of new media, can architectural representations be read as a form of lateness, one that resists linear/deterministic closure and challenges established architectural narratives? The paper explores how hybrid drawings and collages embody the unresolved nature of lateness. As a methodological lens, it focuses on hybrid representations and bricolages. Hybrid representations facilitate novel design trajectories by synthesizing the controlled, constraint-driven logic of digital tools with the creative indeterminacy and freedom inherent in analog techniques. Instead of striving for pseudo-photo-realism, this new cult of the drawing explores and exploits its artificiality, making us as viewers aware that we are looking at space as a fictional form of representation (Jacob, 2017). Bricolages are created by bringing together fragments -such as images and materials- taken from different contexts in an eclectic and sometimes coincidental way. In this context, the representations in question are evaluated by considering their capacity to resist clarity, incorporate anachronistic elements, and engage in a fragmented visual logic.

Eisenman argues that the notion of lateness he brings into architectural practice is not a bridge between past and future, but rather something formally and temporally ambiguous. According to Bell (2021), lateness is the experience of forms tangentially dislocated from the social forces (sources) that limited them. Building on this, when translated into architectural representation, lateness can be observed in the disruption of traditional visual order, the displacement of temporal fragments, and the emergence of blurred spatial readings. Such instances of lateness may be found in hybrid representations and bricolages that combine techniques from different historical periods. As discussed above, these representations resist singular interpretations and challenge linear narratives.

Material and Method

Several architectural firms have employed unconventional representation strategies in competitions, contributing to more compelling narratives, with some even achieving recognition or awards. This conceptual potential of representation has also been emphasized by Scheer (2014), who argues that the manipulation of formal rules within a representation can generate new knowledge about phenomena. Strategies such as anachronism, fragmentation, and superimposition align closely with the notion of lateness. These strategies can be defined, respectively, as the use of concepts and objects outside their temporal context, the subdivision of visual elements into separate elements, and the emergence of distinct components within a single system. Moreover, successful representational strategies may become widespread among architects. In this context, award-winning projects offer a valuable area of inquiry for understanding the influence of representations associated with lateness in architectural competitions and practice.

The research focuses on the digital collages, conceptual representations, and experimental visual works produced by Openact Architecture and Le Erreria Office of Architecture, both of which have received recognition in housing and urban planning competitions. Axonometric projections, bricolages, and hybrid drawings are examined in detail.

This study employs a typological reading method to analyze selected architectural representations. In this approach, the observed representational techniques are categorized based on the extent to which they reflect the criteria associated with lateness. The analysis goes beyond the projected building and explores how representation becomes an act of critical resistance. This case study investigates the criteria of fragmentation, ambiguity, and incongruity within architectural representations produced in the context of competition culture.The presence of disrupted forms, layered spatial readings, and non-continuous geometries indicate the emergence of fragmentation. Ambiguity, as inherent to representation, offers wide possibilities for creative expression (Scheer, 2014). It can be observed in the superimposition of conflicting visual elements that resist singular interpretation. Finally, dissonance can be found in non-hierarchical compositions, temporal disjunctions, and unresolved tectonic relationships.

Many architectural design offices employ anachronistic and fragmented representational strategies to challenge conventional notions of space and time. These methods are particularly evident in the following examples:

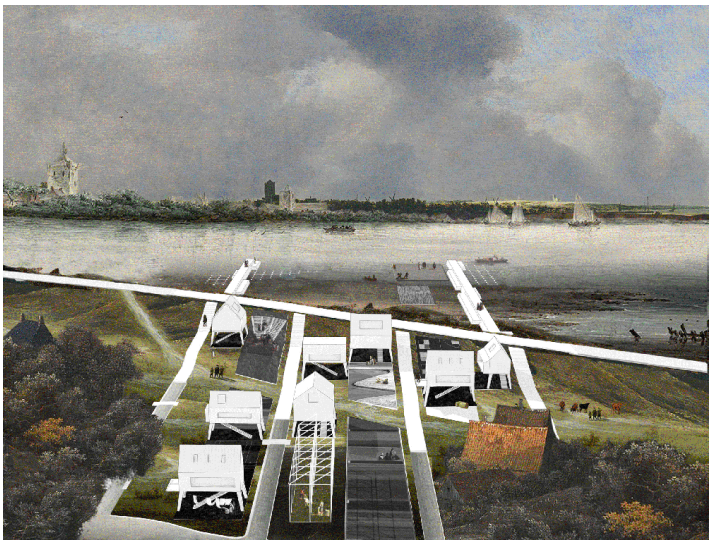

Image 1. Runner-up of EUROPAN13 - Streefkerk, Netherlands. Openact Architecture, 2015.

Architectural collages challenge conventional composition by bringing together historical references, speculative elements, and digital distortions. As seen in Image 1, the collage from Openact Architecture's second place proposal resists singular narrative through the superimposition of analog and digital elements while also expressing

ambiguity and disjunction. The colorless architectonics are seamlessly embedded into Streefkerk's landscape painting, creating a visual synthesis that further amplifies the composition's timeless and complex properties.

Image 2. Winner of EUROPAN15 - Vestre Toten, Norway. La Errería Office of Architecture, 2019.

As iconic as they are, axonometric projections resist perspectival dominance and allow for multiple, non-hierarchical readings of space. In contemporary practice, the resurgence of exploded and layered axonometric drawings signals a shift toward representations that embrace ambiguity and disjunction. As shown in Image 2, the award-winning Spanish architecture office La Errería generates disjunction by combining axonometric projection with the traditional plan. Moreover, the drawing incorporates multiple axonometric viewpoints within a single representation, whose arrangement conveys a sense of contingency.

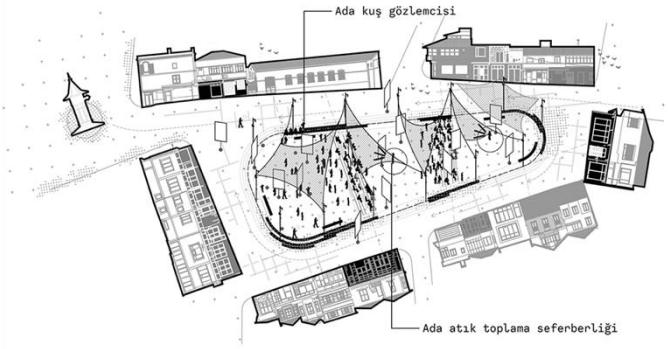

Image 3. Winner of Two-Phased Urban Design Competition - Istanbul, Turkiye. Openact Architecture, 2021.

In the example shown in Image 3, Openact Architecture creates a complex representation by combining axonometric drawing with façade views. The surrounding buildings are fragmented and detached from their perspectival depth. Incorporating multiple representational techniques, the drawing exhibits both fragmentation and disjunction.

Findings

It has been observed that architectural representations examined in the selected examples exhibit different aspects of lateness: fragmentation, anachronism, ambiguity, and contingency. The objects present in these representations must be reinterpreted in relation to their temporal and spatial positions. In all three cases, lateness is observed both through visual elements and through the use of alternative projection techniques. Based on these case studies, the research reveals that resistance to clarity in architectural representation has continuous dialogue with architectural practice.

This study reveals that lateness is not only a condition of built architecture but also an inherent characteristic of contemporary architectural representation. These findings demonstrate that hybrid representations offer a critical alternative to traditional architectural narrative. The use of elements that conflict in terms of time, scale and place makes these drawings more open to interpretation and distances them from linear narrative logic. Blurred spatial representations that reference the late style enables an architectural discourse that is deliberately left unresolved. Furthermore, with the increased emphasis on narrative in architectural competitions, representation surpasses its conventional functions and becomes a critical medium.

Conclusion

Lateness positions the representation it inhabits not merely as a tool for resolution, but as a site of resistance.This positioning offers a critical perspective on the trajectory of architectural representation in the age of new media. In doing so, it contributes to the ongoing discourse on the role of digital and hybrid representational techniques in architecture. This pictorial tale can be read as a theoretical guide to confront the architectural presentations of the last decade.

As architectural representation continues to evolve in the digital era, the embrace of lateness in hybrid drawings and collages suggests a paradigm shift toward representations that resist closure, challenge traditional spatial logic, and engage in ongoing critique. The use of layered, fragmented, and ambiguous imagery reflects a broader tendency in architectural discourse to question the clarity of form and meaning. This study argues that lateness is not only a theoretical construct but also an active representational approach that shapes contemporary architectural practice. Moving forward, architectural competitions and design methodologies will likely continue to prioritize representations that embody uncertainty, contradiction, and unresolved spatial conditions.

The Mask as an Instrument of Spatial Construction

Naz Üstündağ[a], Pelin Dursun Çebi[b]

[a] Istanbul Technical University, Graduate School, Architectural Design Program, Türkiye
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Türkiye
ustundag22@itu.edu.tr

Keywords: Bauhaus Theatre, Body, Costume, Mask, Spatial Perception.

Aim

Grounded in the idea that bodily experience is essential to spatial understanding, this study approaches the mask as a bodily supplement. Beyond being a mere object, the mask can be seen as an interface that defines the boundaries of the body, transforms identity, and redefines the body's relationship to space. While it delineates the limits of both the space and the body that wears it, it also creates an experiential space that enables the audience to transcend these boundaries. The meaning that emerges is shaped not only by the movement of the body but also by the performer's role on stage, the function of the mask within the performance context, and the perspective of the audience. This study explores the mask as an experiential tool that shapes both the performer's body and influences the audience's relationship to space on stage.

Material and Method

In order to examine these dynamics, this research focuses on the Bauhaus Theatre, a significant example of modern theatre, and the works of Oskar Schlemmer. These works are approached with the perspective that they shaped an innovative and experimental research domain of their time, replacing traditional narrative structures with more abstract and dynamic forms of expression. In this regard, performance recordings and relevant written sources are utilized to map how the mask transforms bodily and spatial perception. Through this approach, the study investigates how the mask redefines spatial experience for both the performer and the audience, and how it generates multilayered narrative fields beyond physical structures.

Findings

While the mask may initially appear as a passive object on stage, once integrated with the body, it surpasses this passivity and becomes an active element. In its passive state, the mask exists merely as a shape or form; however, upon its integration with the performer's body, it acquires a dynamic structure, transforming into a force that drives the narrative on stage. According to Vartolioğlu (2022), the mask imposes instructions on the performer, who complies without hesitation. Although this authority may appear to restrict the performer, it actually fosters bodily exploration and facilitates the emergence of new forms of expression. The mask limits gestures and facial expressions, allowing the body to express itself solely through movement, thus transforming the body into the primary means of expression. This process, according to Meyerhold, develops bodily control and enhances movement sensitivity (Karaboğa, 2014). Furthermore, the mask plays a crucial role in transforming the performer's identity and presence on stage. As İspirli (2021) states, the integration of the mask with the performer's body leads to an identity transformation, detaching the performer from everyday movements and elevating them to an alternative plane. Therefore, rather than its mere existence, it is important to consider the purpose for which the mask is made, how it functions on stage, and the effects it produces.

The transformative power of the mask induces a continuous shift in the relationship between the performer and the mask. Güçbilmez (2014) states that the mask's dynamic structure, with its openness to change and transformation, constantly reshapes the relationship the performer establishes with it. This prevents the audience from forming a fixed perception of the mask, thereby transforming not only its physical manifestation on stage but also the audience's experience of space. The mask redefines the boundaries of the stage by creating a distance between itself and the audience that observes it. By concealing the underlying reality, it constructs a new domain of meaning within the audience's mind, shifting their role from a passive observer to an active interpreter. Thus, the interaction between the mask and the body alters the stage space from a fixed to a dynamic state.

The mask's influence on transforming spatial perception arises from its capacity to transcend its physical boundaries, thereby inducing change on both symbolic and imaginary levels. On the symbolic plane, the mask's visible surface evokes multilayered meanings for the audience. On the imaginary plane, its concealed side constructs an alternative reality in the audience's mind. This duality shifts the audience from a passive observer to an active participant in the meaning-making process. Lacan (1973) states that there is a gaze behind the mask and defines the audience's process of meaning-making in the gap of desire between the subject of representation and the observing gaze. The underlying ambiguity creates a desired gap for the audience, which is interpreted by the subject with each encounter. In this context, the mask functions not only as an element that transforms the wearer's body but also as a tool that directs the audience's gaze, alters their perception, and consequently reshapes the space itself. The surface of the mask is shaped by the audience's gaze, while its unseen side—the void behind it—acts as a gap or object of desire, invoking an image in the audience's mind that requires completion. The atmosphere created by the mask, combined with bodily movement, constructs a continuously evolving, multi-layered narrative on stage that unfolds for the audience in a dynamic process.

In the context of the Bauhaus, the transformative role of the mask becomes particularly evident in Schlemmer's designs, which seek to transcend the restrictive limitations imposed by organic bodies through stage costumes often associated with masks, exploring the potential of mechanical bodies capable of unrestricted movement within space. The synthesis of space and body, mediated through masks and costumes, redefines the body's relationship with movement. Schlemmer's designs aim to liberate the body, thereby facilitating freedom of movement (Schlemmer, 1961). They alter the performer's perception of space, disrupt habitual routines by restricting everyday movements on stage, and lead the audience to perceive the performers' bodies as both concealed and distorted (Figures 1, 2, 3). The concealed and distorted bodies, shaped by circularities, curvatures, diagonals, and lines, generate new spatial boundaries with each movement. Through the mask, each boundary dynamically activates the stage space, illustrating that architectural environments can be perceived as fluid, transformable, and open to interpretation, rather than as fixed structures. Thus, the mask, functioning both as a physical object and a symbolic agent, becomes central to the transformation of both body and space.

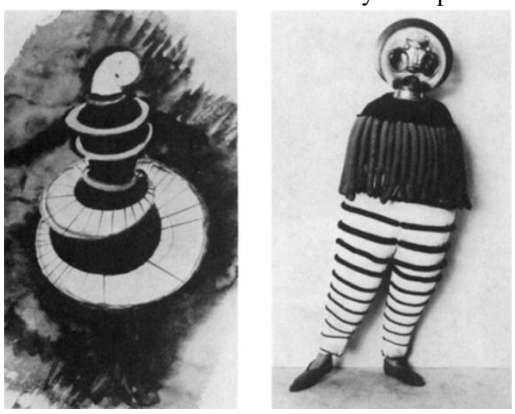

Figure 1. Triadic Ballet. (Schlemmer, 1961, p. 34).

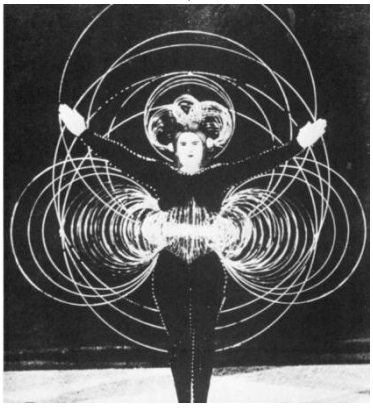

Figure 2. Triadic Ballet. (Schlemmer, 1961, p. 36).

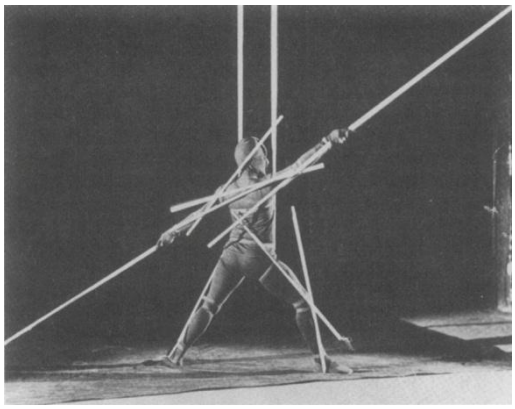

Figure 3. Pole Dance. (Lahusen, 1986, p. 75).

Conclusion

This study demonstrates that the mask, far from being a static theatrical prop, operates as a dynamic mediator between body and space. By transforming the performer's bodily expression and altering the audience's spatial perception, the mask emerges as a critical agent in constructing a fluid and mutable stage environment. The Bauhaus Theatre and Schlemmer's experimental designs exemplify how masks and costumes can extend bodily boundaries, restructure spatial relationships, and generate immersive, multilayered performative experiences. As both a physical object and symbolic interface, the mask challenges fixed notions of identity and spatiality, inviting continual reinterpretation. Ultimately, this research reveals that the mask is not merely worn but enacted—an instrument that shapes, disrupts, and redefines the architecture of performance space itself.

Tracing a Cultural Heritage from the Ottoman Era to the Present: A Study on the Conservation of Kepenekçi Sinan Mosque

Emrullah Ekinci[a], Yegân Kâhya Sayar[a]

[a] Istanbul Technical University, Restoration Program, Türkiye
ekincie22@itu.edu.tr

Keywords: 16th-century Classical Ottoman Architecture, Conservation, Historic Peninsula of Istanbul, Kepenekçi Sinan Mosque, Restoration.

Aim

Reflecting the layered legacy of Roman, Byzantine, and Ottoman civilizations, the Historic Peninsula has served as a significant cultural center throughout history (Kuban, 2010). Following the conquest of Istanbul, numerous buildings were constructed in the area. Among these, neighborhood mosques emerged as some of the most distinctive elements of the Ottoman urban fabric. These small-scale mosques functioned not only as places of worship but also as focal points of social life. Kepenekçi Sinan Mosque, situated at the intersection of historic streets leading to the Marmara Sea and embedded within the traditional neighborhood layout, is located at the junction of the Byzantine Mese Street and the Ottoman Uzunçarşı and Tahtakale routes (Eyice, 2021). The mosque is integrated into an urban circulation network that has remained uninterrupted from past to present. Mosques on the Historic Peninsula are generally constructed from stone and brick. Their roofs typically consist of domes or wooden coverings. According to Öz (1997), wooden roofs were commonly used in smaller, local mosques, while larger mosques featured brick domes. These architectural characteristics have enabled neighborhood mosques to serve as visual landmarks within the cityscape and have played a key role in shaping the distinctive urban fabric of the Historic Peninsula. In recognition of its rich cultural and historical heritage, the Historic Peninsula was declared an 'Urban and Historical Conservation Area' under the protection of the decision issued by the Istanbul Cultural and Natural Heritage Conservation Board No. I, dated July 12, 1995 and numbered 6848 (Archive of the Istanbul Number IV, the Regional Commitee for the Conservation of Cultural Assets) Reflecting the architectural character of 16th-century classical Ottoman design and serving as a significant example, Kepenekçi Sinan Mosque is today a valuable component of the cultural heritage that needs to be protected. This building was registered by the decision of the High Council of Real Estate Antiquities and Monuments (dated April 9, 1977, and numbered 9776) and was designated as a Group I conservation asset by the decision of the Istanbul Regional Board for the Protection of Cultural and Natural Assets in Renewal Areas (dated April 16, 2009, and numbered 713).

However, like many other historical buildings, Kepenekçi Sinan Mosque has been subjected to various interventions over the centuries and has partially lost its original architectural integrity. Particularly during the 20th century, unqualified repairs and reinforced concrete additions significantly damaged the building's original fabric and architectural coherence. This situation not only hinders a proper understanding of the building's historical and cultural significance but also poses a threat to its physical preservation. The aim of this study is to systematically document the current condition of Kepenekçi Sinan Mosque and to propose a restoration strategy in accordance with contemporary conservation principles.

Material and Method

The study employed historical research, detailed architectural documentation, and comparative analysis. The research was conducted in three main phases. In the first phase, the existing condition of the mosque was comprehensively documented using a combination of traditional and advanced measurement techniques (Figure 5). In this documentation process, the plans, sections, elevations, material usage, and damage assessment of the building were prepared in detail. In the second phase, archival documents, historical maps foundation records, and historical photographswere analyzed to understand the building's historical development (Figures 1, 2, 3 and 4).

Figure 1. Extract from the Pervititich map showing the Kepenekçi Sinan Mosque and its vicinity in the urban fabric of early 20th-century Istanbul.

Figure 2. The elevation of the mosque and its minaret as documented in a 1940s photograph (Istanbul Archaeological Museums Directorate).

Figure 3. The elevation of the mosque and its minaret as documented in a 1950s photograph. (Istanbul Regional Board No. IV for the Conservation of Cultural Assets**).**

Figure 4. Southwest facade of the mosque (Ekinci, 2025).

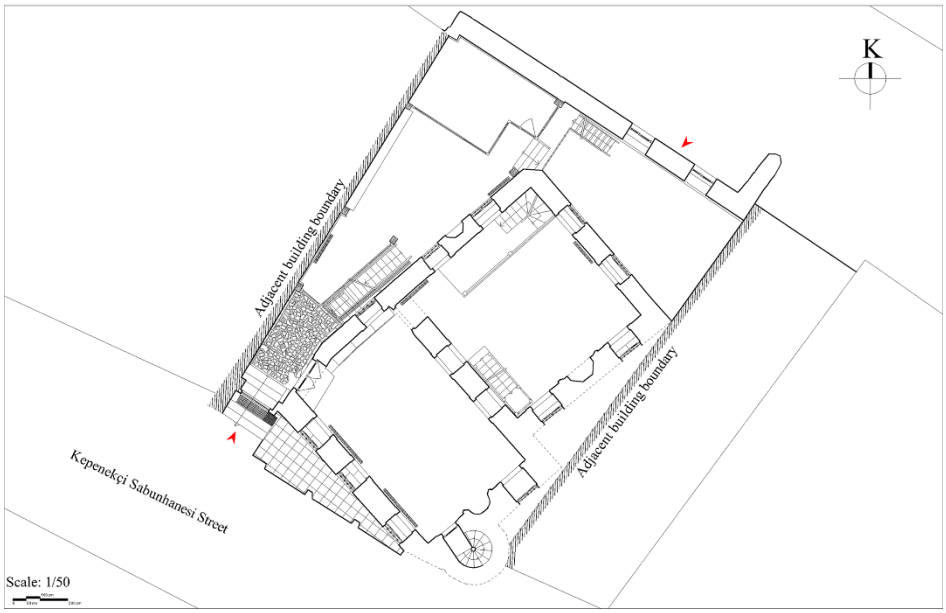

Figure 5. Ground floor plan based on the measured survey of the Kepenekçi Sinan Mosque (Ekinci, 2025).

The data obtained from these historical sources serve as reliable primary information for understanding the building's original state (Kâhya Sayar and Kahraman, 2017). In the third phase, a comparative analysis method was applied. To understand the original features and the characteristics of different periods of the building—which has undergone significant alterations to its original fabric due to restoration works carried out in the mid-20th century—a comparative study was conducted with other classical-period structures possessing similar characteristics within the Historic Peninsula.

Findings

When the construction material and techniques of Kepenekçi Sinan Mosque were analyzed, it was determined that the primary building material is limestone, and the walls were constructed using this material. While the base of the minaret was built with masonry stone, bricks were used in the shaft and were supported with stone bands at regular intervals, whereas the muqarnas section rising from the balcony was entirely constructed with bricks. The mosque has a rectangular plan, featuring two mihrabs and various arch types. A flat arch is used at the entrance, while pointed arches are employed in the window openings and in certain parts of the basement level (Figure 6). In the lower row of windows, a flat lintel system is observed on the interior, whereas both pointed arches and flat lintels are present on the exterior. The upper covering consists of a wooden framework system and is formed as a

hipped roof, covered with Marseille-type tiles.Within the scope of the documentation studies, the deterioration patterns and user interventions that have occurred in the building over time were analyzed in detail and categorized. This categorization includes damages such as element loss, material degradation, surface erosion, joint loss, surface pollution, vegetation growth, as well as user-induced repairs and interventions. Surface loss on the molding at the lower part of the minaret base on the south façade, as well as joint loss on the stone surfaces, was observed. On the northwest and northeast façades, layers of paint were found to partially cover the stone surfaces, and over time, color variations have appeared due to the removal of this paint using inappropriate cleaning methods. On the minaret, widespread soiling and brick loss were documented on the shaft, missing elements were observed on the balustrade, and moss growth was identified on the lower molding of the balustrade. In contrast, the muqarnas molding exhibited less surface contamination compared to the shaft. The most critical issue concerning the building is the interventions it underwent, particularly during the 20th century. While early photographs from the first half of the 20th century depict the building in good condition, reinforced concrete additions were introduced during restoration works in the 1960s, including the insertion of beams and columns along the northwest wall. On the northeast façade, the original masonry wall has recently been subjected to unauthorized alterations involving steel reinforcements. These interventions have significantly disrupted the building's original fabric, adversely affected its architectural integrity, and hindered the ability to accurately interpret the structure of the other façades from the exterior.

Conclusion

As a result of the analytical documentation and historical research conducted on Kepenekçi Sinan Mosque—which has undergone various interventions over time and experienced a significant loss of architectural integrity, particularly due to alterations made in the 20th century—it has been determined that the building has experienced both physical and structural changes, and its original fabric has been substantially compromised. In particular, reinforced concrete and steel additions have adversely affected the architectural integrity of the mosque, hindering the perception of its historical character and compromising its architectural identity.
In light of these findings, a comprehensive restoration proposal was developed, addressing the mosque's structural components, including the roof system, minaret, spatial organization, and stone masonry. The removal of inappropriate reinforced concrete interventions should be evaluated from a structural perspective, taking into account the load impact they exert on the building. If found appropriate in terms of structural safety based on technical calculations, their removal is recommended. The original materials should be restored in accordance with their historical characteristics, and surface cleaning, reintegration, and localized repairs should be carried out using traditional techniques.
This restoration approach aims to reestablish the architectural identity of Kepenekçi Sinan Mosque and highlight its historical significance within the urban fabric. The study presents a conservation framework that may serve as a reference not only for Kepenekçi Sinan Mosque but also for other Ottoman-era neighborhood mosques. The proposed restoration will extend the lifespan of this significant example of Ottoman architectural heritage and ensure its transmission to future generations with its original values preserved.

Documentation and Conservation Proposalofa 19th Century Ottoman Heritage: Kececizade Fuat Pasha Mosque

Filiz Avcı[1], Umut Almaç[2]

[1]Istanbul Technical University, Restoration Graduate Program, Türkiye
[2]Istanbul Technical University, Faculty of Architecture, Department of Architecture, Türkiye
avcif22@itu.edu.tr

Keywords: Architectural Conservation, Kececizade Fuat Pasha Mosque, Orientalism, Ottoman Architecture, Restoration.

Aim

This study aims to identify the conservation issues of Keçecizade Fuat Paşa Mosque, a notable example of Ottoman architecture built under Orientalist influences in the 19th century, through architectural documentation studies and to develop conservation recommendations to ensure the building's preservation for future generations. Within the scope of the study, the development of the building in the historical context was investigated and analysed comparatively with similar period buildings. Plan features, architectural features, and ornamental elements were discussed in detail. To ensure the sustainability of the building through the restoration project, necessary cleaning, consolidation, renovation, and intervention proposals for its use have been developed.

Material and Method

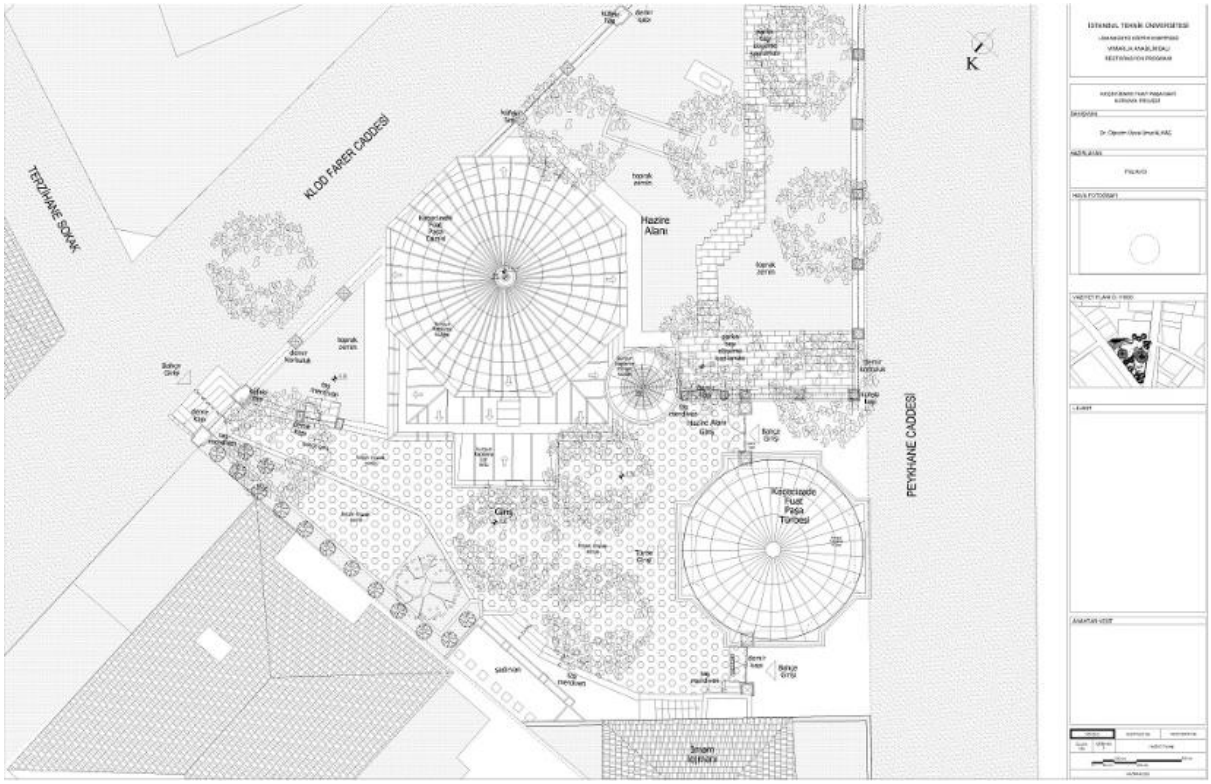
Archival research, photogrammetry, laser scanning and detailed measurement techniques were applied to document the building. The current condition of the building was expressed in scaled drawings (plan, section, facade, detail, etc.) prepared with the dataobtained during the architectural documentation process. Material analyses were conducted by determining the use of traditional building materials, such as stone, wood, plaster, and metal, in the building. The observed deterioration and damage have been classified and indicated on the scaled drawings.

With the help of archival research and on-site observations, the repairs the building has undergone in the past were evaluated, and the practices that damaged its integrity were identified. Research on the original condition of the mosque was conducted in accordance with the General Directorate of Foundations Archive, Ottoman archive documents, old maps and photographs, as well as other written and visual sources from the period,and comparisons with period buildings.

The restoration proposals for the building have been developed within the framework of international conservation principles (the Venice Charter, ICOMOS Principles and Regulations, and UNESCO Cultural Heritage Conservation Principles, etc.) as well as local legislation. Priority has been given to preserving the original materials and construction techniques.

Findings

The Kececizade Fuat Pasha Mosque was built within a complex that includes a mosque, mausoleum, graveyard area, entail, and ablution areas (Drawing 1: Site plan). There is different information about the construction date of the mosque in various sources. Semavi Eyice, in his article "Notes from Historical Graves," published in the Journal of the Institute of History, drew inferences about the mosque's construction date based on various publications and engravings. As a result of these inferences, it is assumed that the mosque was built after Fuat Pasha's death in 1869.



Drawing 1 : Site plan (Avcı, 2024).

The mosque was built in an orientalist style. The primary feature that enables the mosque to be treated in this style is the use of arched doors and windows with horseshoe arches. The tripartite arrangement with the addition of round windows is reminiscent of some Mamluk facades in Egypt. The capital soft the columns in the center of the double windows bear the motif of lotus leaves with outwardly curved tips, which is found in the lower parts of the floral decorated Moorish capitals. The interior is dominated by decorations in yellow, red, and blue colors, as recommended and applied to various European buildings of the same quality, in accordance with the fashion of Orientalism with a Maghreb component (Saner, 1998, p. 92).

Built with masonry construction technique, the building features an octagonal plan and is topped with a single dome. The dome is covered with lead sheets, devoid of windows or openings, and a copper finial (alem) is positioned on top (Figure 1).The minaret sits on a cut stone base with a plan scheme close to square and is built entirely of limestone(Figure 2).

Figure 1: Photo showing the mosque (Avcı, 2024).

Figure 2: Southwest facade photo (Avcı, 2024).

The minbar, mihrab, and pulpit are the architectural elements that have survived to the present day, preserving their originality. While the minbar draws attention with its intense use of geometric elements and floral motifs, it is decorated with fine marble artistry(Figure 3). The mihrab is arranged as a niche in the southeastern wall of the building and is construct edentirely of marble. The pulpit has an octagonal plan scheme and is designed in a more straight forward style. The building receives natural light through four horseshoe arched windows. The windows are positioned in a rectangular niche framed by moldings (Figure 4). The main walls and dome in the interior space are adorned with rich compositions featuring yellow, red, and blue tones (Figure 5). In the center of the dome, a decorative ornamental element made of plaster features relief floral ornamentation. The types of deterioration detected in the mosque include repairs made using inadequate materials, dirt on stone surfaces resulting from air pollution, improper additions to the building, and biological formations caused by moisture. The prevalence of cement-based pointings on the exterior facades of the building and the minaret shaft was

observed, and it was determined that this intervention caused deterioration on the stone surfaces. Due to air pollution, dark layers of dirt have accumulated on the stone surfaces of the building, resulting in significant discoloration, particularly at the base of the minaret. Various biological formations are observed in the pedestal section of the building due to the increased humidity. Corrosion was evident on the lead coatings on the central dome and minaret cone, and detachments were detected at the joints of the lead plates. The presence of different-coloured lead plates near the dome skirt indicates previous repair interventions in these areas. Similar deterioration was observed on the minaret cone.

Figure 3: Pulpit photo (Avcı, 2024).

Figure 4: Northeastern side photo (Avcı, 2024).

Figure 5: Dome decoration photo (Avcı, 2024).

The decorations on the interior facades of the building are generally in good condition; however, plaster and paint losses can be observed in limited areas. Traces of earlier period decoration were visible in some places where plaster detachment was present. In addition, historic photographs of the building uncovered during research carried out in the Archive of the Council revealed the presence of marble imitation plaster and various decorative patterns on the walls. Detailed research, including non-destructive testing (NDT) methods, is recommended in these areas to understand the extent and condition of any possible original architectural and decorative elements.

Critical or evident structural issues were not detected; however, documentation using accurate laser scanning tools revealed that the minaret deviated from the vertical by approximately 14 cm in the east ward direction. According to archival documents, the shaft on the balcony and the balustrades of the minaret were repaired in

1970 under the supervision of the Pious Foundation Directorate. Dirt on the surfaces, cracks and material losses were observed on the minaret's balcony railings due to environmental factors, precipitation and atmospheric conditions. These critical areas should be handled meticulously during the restoration process. To evaluate the structural condition of the mosque, the characteristics of the building's foundations should be determined through inspection pits opened during the restoration process. Additionally, the ground properties on which the building is located should be assessed using ground surveys.

Conclusion

Kececizade Fuat Pasha Mosque is one of the most important historical buildings of 19th-century Ottoman architecture, characterised by its interior and exterior ornaments, plan scheme, and construction materials. The building, which has maintained its original function to this day, has undergone various interventions and inadequate repairs at different times.

Within the scope of this study, it was determined that the mosque's function should be continued by preserving its authenticity, historic and aesthetic values. Conservation proposals aimto eliminate or prevent the damages caused by unqualified repairs, careless use and the physical conditions in which it is located. Accordingly, in light of contemporary conservation approaches and principles, the original materials should be conserved with minimum intervention as possible.

This research has documented the current condition of the building on a scientific basis and developed comprehensive conservation recommendations within the frame work of restoration theory, thereby ensuring the building's sustainability. The proposed interventions aim to preserve the original architectural character of the building while adapting it for the future, in accordance with current conservation principles. At the same time, the analyses and proposed restoration approach aim to establish a precedent for the conservation of similar historic buildings.

The Role of System Sections in Architectural Competitions: From Conceptual Design to Construction

Fulya Kılıç[a], Fatih Yazıcıoğlu[b]

[a] Istanbul Technical University, Graduate School, Environmental Control and Construction Technologies Program

kilicf23@itu.edu.tr

Keywords: Detail, System Section, Architectural Competitions, Detail Sustainability.

Aim

Architectural competitions serve as a significant tool for fostering critical thinking and advancing innovative production processes in the fields of architecture and urban design. (Chupin, 2011) In these competitions, architects typically present their projects using three-dimensional visualizations and two-dimensional drawings. Although three-dimensional visuals dominate competition presentation boards, jury members also meticulously evaluate two-dimensional drawings. Given that the selected project has the potential for construction, competition briefs often require 1/50 and 1/20 scale system section details to support the project's feasibility.

This study examines the significance of system sections in architectural competitions in Türkiye and investigates their impact on the transition from conceptual design to construction. The primary objective is to evaluate the influence of system sections on jury evaluations, project constructability, and the transition from competition to construction. Additionally, the study explores how different architectural competition regulations shape the role of system details and how they affect the likelihood of winning projects being constructed.

Material and Method

This study adopts a mixed-method research approach incorporating literature review, case analysis, and future interviews with professional architects. The research examines 292 architectural competitions conducted in Türkiye, analyzing the presence and role of system section details. Among these, 92 competitions included system detail drawings, which were evaluated in detail. Competitions were categorized based on whether system sections were explicitly required, and the relationship between the inclusion of these details and project construction rates was examined. Furthermore, 45 system sections from 15 selected competitions underwent a two-stage evaluation process:

Visual Analysis: Assessment of drawing techniques, material representation, dimensioning, and technical scope. This phase evaluates the quality of technical drawings and their ability to communicate material and structural information effectively.

Performance Analysis: Examination of the impact of system details on the performance of building elements. This phase assesses the extent to which proposed system sections align with practical construction requirements and effectively convey buildability information to both jury members and future contractors.

In architectural design, the integration of building elements can be evaluated under three main categories: physical, visual, and performative. This tripartite classification enables a comprehensive assessment of system details, not only in terms of their technical functionality but also regarding spatial efficiency, aesthetic coherence, and multifunctional performance. For instance, a shear wall simultaneously serves as a load-bearing structure and partitioning shell, embodying all three forms of integration. Although not all designs exhibit these three types equally, analyzing system details through this framework allows for a more holistic understanding of their architectural significance and their role within competition projects. (Bachman, 2003; Yazıcıoğlu, 2007) Therefore, the performance analysis has been examined under seven subheadings:

1. Foundation-Floor on Ground- Ground Integration
2. Foundation-Floor on Ground-Wall Integration
3. Beam-Column-Floor-Exterior Wall Integration

4. Beam-Column-Floor-Interior Wall Integration
5. Beam-Column-Floor-Roof Integration
6. Roof-Exterior Wall-Column Integration
7. Roof-Interior Wall-Column Integration

Findings

The detail sustainability refers to the extent to which system details specified during the competition phase are maintained in the construction process in terms of long-term functionality, aesthetic integrity, and structural integration. The findings reveal that design-phase details can be altered during construction due to factors such as material availability, technical constraints, and budget considerations. Furthermore, the client's expectations and engagement are critical to the overall success of the project.

Architectural competition regulations in Türkiye are established by the Union of Chambers of Turkish Engineers and Architects (TMMOB), which defines competition types, specifications, jury responsibilities, required documents, and prize allocations in the 2003 Competition Regulation (TMMOB Mimarlar Odası, 2003). In contrast, international regulations, such as those from the Australian Institute of Architects and the Royal Institute of British Architects, often include additional requirements, such as material specifications, average budget estimations, and system detail drawings (Australian Institute of Architects, 2016; RIBA, 2019). In Türkiye, however, system details, material specifications, and budget information are not mandatory in all competitions, which contributes to lower construction rates.

An analysis of 292 architectural competitions in Türkiye revealed that the inclusion of system details in competition briefs began in 2010. Among the 168 system detail drawings obtained from the 92 analyzed competitions, only 23 belonged to competitions where system details were not explicitly required. The collected data indicate that only 45% of analyzed competitions progressed to the construction phase, while the remaining 55% were not built.

In this context, system sections obtained from competitions were analyzed in detail, comparing system sections from the competition phase with those in application projects. Due to the limited preparation time in architectural competitions and the conceptual nature of most projects, system details are often developed at a conceptual level or presented with varying degrees of detail and information. A total of 45 system details from 15 competitions were analyzed. The findings indicate that among the examined competitions, 10 had participants with high evaluation scores ranking at the top, while 5 competitions featured participants ranking lower. These results suggest that the clarity of system details in terms of drawing technique and their contribution to jury evaluations of project feasibility and cost perception positively influenced jury decision-making. Among the evaluation criteria, drawing technique emerged as the strongest area, whereas dimensioning information was found to be insufficiently emphasized. In terms of performance analysis, the integration of "Beam-Floor-Interior Wall-Column" was the most frequently overlooked system detail. Architects predominantly used system details to convey façade information, leading to the most common examples being "Beam-Floor-Exterior Wall-Column" integrations.

In the later stages of the research, the indirect impact of system details on jury evaluations will be examined in greater depth through professional interviews and analysis results. Additionally, the influence of limited preparation time on the depth and quality of system details will be investigated, aiming to gain a more comprehensive understanding of the representativeness and practical significance of system details across different project types.

The findings suggest that architectural competitions prioritize conceptual design over technical resolutions. However, the presence of system sections plays a crucial role in the transition of projects to the construction phase. Given the recent inclusion of system sections in Turkish competition requirements, policy changes should be considered to integrate technical drawings into the competition framework further.

Conclusion

This study highlights the critical role of system sections in architectural competitions, emphasizing their impact on jury evaluations and project construction rates. While system sections often remain at a conceptual level during competitions, their systematic integration can enhance project feasibility and constructability. The purpose of this study is to contribute to the literature on the significance of system details in architectural competitions, to investigate the influence of precise design on outcomes, and to give light on practical constructions and future research. In conclusion, the study demonstrates that addressing system details in architectural competitions within a holistic and systematic approach can enhance the constructability of projects and contribute to making jury evaluation processes more objective.

Valorizing Cultural Heritage through Art and Movement: Spatial and Bodily Experience in a Promenade Performance

İpek Çakmak[a], Zeynep Kuban Tokgöz[b]

Keywords: Bodily Experience, Cultural Heritage, Performative Art, Spatial Experience, Valorization.

Aim

The re-signification of cultural heritage structures within collective memory and their perpetuation through intergenerational experiences can be achieved not only through physical preservation but also via artistic and performative interventions. In the process of 'valorization' of historical buildings and spaces, it is argued that inviting individuals to these sites through cultural and artistic events allows the collective judgment to determine the value of the place (Lorusso et al., 2016). When performative arts are chosen as a means of valorization, art is summoned into the historical structure through the artist and their body. Unlike other forms of art, in performative arts, the artist does not bring a completed artwork into the space; rather, they are physically present, creating their art in real-time and in a live manner. In this case, the audience experiencing the art in the space is referred to as 'spectators' rather than 'visitors'. The repetitive production process of performance art gains significance through the simultaneous presence of both the artist's and the spectator's bodies within the same space. As a subcategory of performative arts, promenade performances allow spectators to become part of the performative narrative, moving within the space and following the artist from one point to another. In this context, the spectators' perception of the artist's body, as well as their spatial experience in promenade performances, becomes an essential aspect of the performative encounter.

This study focuses on the spectators' experience in historical sites where performative arts are used as a tool for valorization. How can performative arts shape spectators' spatial perception? Can the artist's spatial experience influence that of the spectators? In this regard, *Dignità Autonome di Prostituzione (D.A.d.P.)* a show by Luciano Melchionna has been selected as a case study. It is a show format created in 2007 by Luciano Melchionna and Betta Cianchini, and it has been staged at Sant'Elmo Castle in Naples, Italy since 2022. This study aims to conduct a theoretical discussion on the perception of space and the body, as well as critically examine the movement and dramaturgical structure of the chosen performance.

Material and Method

This study uses a qualitative research approach to examine how performative arts shape the spatial experience of spectators in the valorization of historical sites. The movement dramaturgy and spatial relations of the selected case study, *Dignità Autonome di Prostituzione*, are analyzed through the bodily presence of spectators and their observations. The research employs cognitive and phenomenological approaches alongside participant observation to explore the relationship between space, body, and performance.

According to Çelebi (2020), value fundamentally requires a judgment formed in consciousness, which is directly linked to experience. In the valorization of historical buildings and sites, prioritizing artistic and experiential approaches aligns with Çelebi's proposed relationship between value, judgment, and experience. The spectators' spatial experience directly influences their perception of the space and, consequently, their judgment of its value. While performative arts provide an immersive and multi-sensory experience, this study specifically focuses on spectators' spatial and bodily perception.

The perception of space and body is examined in two aspects. The first concerns the spatial relations perceived directly through the spectators' own bodies. In this regard, the research investigates the consequences of the spectators' forced movement within the performance's dramaturgical structure, as opposed to the movement patterns of an ordinary visitor in the castle. The distinctive architecture of Sant'Elmo Castle, combined with the

expansive spatial movement design of the *D.A.d.P.* performance, aligns with Mark Johnson's (2005) image schemas of center-periphery, container, verticality, and source-path-goal. Johnson grounds these image schemas in fundamental sensory-motor experiences and links spatial perception to bodily cognition.

The second dimension of spatial and bodily perception focuses on the artist's body, which assumes the most active role within the space. However, this analysis is conducted from the spectators' perspective. In this context, the study questions how the artist's bodily experience becomes part of the spectators' experience, drawing upon mirror neuron theories. Sinigaglia and Rizzolatti (2019) conducted experiments following the discovery of mirror neurons, concluding that observing actions such as grasping, holding, or clutching in another body triggers similar motor responses in the observer's neurons. When applied to the spectator-artist relationship in performative arts, this framework suggests that the artist's embodied interactions with space, objects, and their own body may trigger analogous motor responses in spectators. From a cognitive perspective, observed actions are expected to contribute to the spectators' spatial experience and the judgments they form about it.

This study is conducted within the context of a single performance and a specific site. Therefore, the findings are not intended to be generalized; rather, the research aims to provide a conceptual discussion on the impact of performances in historical sites on spectator experience. While individual interviews were conducted with participants, the study primarily focuses on observational data and theoretical analysis.

Findings

Performative art practises in historical spaces transforms the way audiences experience the space. Additionally, in the selected performance example, the fact that the audience's movement is an integral part of the narrative makes this experience mandatory while also diversifying and reinforcing it.

The theater-based performance *Dignità Autonome di Prostituzione* employs an expansive spatial design where it is staged. In its editions at Naples' Sant'Elmo Castle, the performance primarily occupied the uppermost level of the castle, while various other indoor and outdoor areas were also integrated into the production. The performance begins with the audience moving up from the entrance of the castle to the top level, while performers initiate their acts on that ramp. This initial movement of the audience exemplifies the verticality and source-path-goal image schemas, as they both ascend and move toward a specific destination. By the time the sun sets, the audience is seated in the main performance area, where they begin to enjoy the music and dance performances. The actors, positioned at different elevations surrounding the audience, first perform dance choreographies and then recite their lines. (Figure 1.) This initial spatial arrangement, where the audience is encircled by performers at different heights, corresponds to the center-periphery image schema. Following this introduction and an explanation of the narrative, around thirty different performers are sequentially introduced. This leads to the part where the audience selects an actor whose solo performance they wish to watch. The actors, gathering an audience of twenty to fifty people around them, then lead them to predetermined spaces for their performances. (Figure 2.) These spaces can sometimes be offices, meeting rooms, or storage areas within the castle, or enclosed spaces such as chapels, cells, and dungeons, while they include also some open-air areas at different elevations of the castle. After selecting a performer in the main area, the audience moves toward the solo performance location and returns to the main space at the end, corresponding again to the source-path-goal image schema. Upon reaching the destination, if the space is an enclosed room, storage area, dungeon, or church (Figure 3.), this is perceived through a container image schema, climbing the stairs to different levels follows the image schema of verticality. Each audience member typically has time to watch three solo performances in one evening, or at most four if they manage their time well. This means that throughout the night, each spectator repeatedly engages with multiple source-path-goal schemas while also participating in various spatial interactions that activate the verticality and container image schemas.

Figure 1. Opening coreography around the main space, Author, 2024.

Figure 2. Actress is walking to her solo performing space with a group of audiences, Anna Abet, 2022.

Figure 3. A group of audience members is about to enter a room from the castle's outdoor space, Author, 2024.

In the movements of the performers, who are the main focus for the audience, we observe interactions with space, objects, and other bodies. The performer's body does not move alone; it responds to space and others. These interactions can influence the audience's experience and contribute to spatial memory, which can be discussed through mirror neuron theories. As the audience's spatial experience is shaped by movement, observing other bodies also affects their perception. Especially movements that may activate motor responses in the observer's brain are seen in the performers, who remain central throughout the performance. In this study, movements such as grasping, holding, and gripping—observed in the artist's body—are categorized into space-body, object-body, and body-body interactions. In space-body interactions, the performers engage with elements beyond the audience's immediate and potential spatial experience, incorporating the ramps, elevations, structures, and railings of the castle into their choreography and performance. During these moments, bodily actions such as grasping, holding, and gripping activate the mirror neurons of audience members in the observer position, according to Sinigaglia and Rizzolatti's (2019) mirror neuron experiments. (Figure 4.)

Figure 4. Hands grasping the added structure (foreground) and the castle's parapet (background), Anna Abet, 2022.

Regarding object-body interactions, the primary object forming the core of the performance's structure is the 'dollarini', small, colorful, printed representations of dollar banknote. Before every monologue performance starts, audience members need to "pay" the actors with these symbolic dollars for their art. (Figure 5.) After reaching an agreement on the price with the audience group, the actors collect the symbolic money from them. In this scenario, while the audience directly engages in an object-body interaction, they simultaneously observe the grasping and holding movements occurring both in the artist and in other audience members.

Figure 5. An audience member paying to the actress for her performance, with 'dollarini', The screen capture is taken from Rai News' video report titled "Dignità Autonome di Prostituzione: un inno alla vita" (Rai News, 2024).

The interaction between performers and the audience is not only established through dialogues or objects; physical contact also emerges as a form of body-to-body interaction. In such situations, the audience members touched by

the performers experience the contact directly, while other spectators in the same room observe both their fellow audience members and the actors engaging with them. Besides individual interactions during monologue performances, performers also re-engage with the audience in the main area at the end of the evening. Accompanied by music, they invite audience members to dance, linking arms with them in collective movements and concluding the event with shared bodily engagement.

Conclusion

In this study, by discussing the body-space experience related to spatial perception and the experience gained through observation within a theoretical framework. The performative structure of a promenade performance staged in a historical building has been analyzed from spatial and bodily perspectives; the findings have been grouped and exemplified. It is indicated that the movement structure of the performance, which also involves the audience, deepens their interaction with the space. At the same time, instead of performing on a designed or confined stage, the artist presents the performance in various areas of a medieval castle. This process, influenced by the unique architecture of the space, enhances the audience's spatial perception through both bodily and visual sensory experiences. This, at a conscious level, is directly reflected in the judgment mechanism that attributes value.

Performances not only highlight the physical dimensions of the space but also contribute to the audience's attribution of new meanings to the space through sensory and cognitive processes. The absence of a boundary between the artist and the audience, and even the physical contact established, allows the audience to perceive the space not merely as a spectator but as a direct participant in the experience. In this regard, performative art should be considered an effective tool among various art forms in the process of valorizing historical spaces.

In conclusion, performative arts staged in historical spaces enrich the sensory dimensions of the space, ensuring a strong place in the audience's memory and transforming the quality of their connection with the site. In the valorization process, the diversity of spatial experience, the multi-layered structure of the performance, and the integration of the movement design with the unique architecture of the space stand out as crucial elements that can contribute to the sustainable valorization of heritage sites.

sadiksoz23@itu.edu.tr

Keywords: Aquivion, Proton Conductivity, Proton Exchange Membrane, Sulfonated Polysulfone

Aim

Proton Exchange Membrane Fuel Cells (PEMFC) are crucial for renewable energy, offering high efficiency and low emissions. Proton exchange membranes (PEMs) enable proton transport while blocking electrons and gases, ensuring controlled reactions and electrical insulation (Sharaf & Orhan, 2014). Their high chemical durability and low electrical resistance improve fuel cell longevity and reliability. Perfluorosulfonic acid (PFSA) membranes, such as Nafion and Aquivion, are commonly used but face challenges due to high costs and performance decline at elevated temperatures. Developing cost-effective membranes with higher conductivity and broader operational temperature ranges is a key research focus. For PEMFC applications, membranes must prevent gas permeability while maintaining proton conductivity (Tellez-Cruz et al., 2021).

In this study, proton exchange membranes were produced using the solution casting method. Sulfonated polysulfone (SPSU), sulfonated polyethersulfone (SPES), and Aquivion® PW79S were used as polymers, while graphene oxide (GO) was incorporated as an additive. The effects of different material combinations on proton conductivity were evaluated to develop alternatives to Nafion.

Material and Method

Polysulfone (PSU, Udel® P-1700) was provided by Solvay, while another PSU with a molecular weight of 30.000 was synthesized in the ITU chemistry lab (D102). Polyethersulfone (PES, Ultrason® E6020P) was supplied by BASF. Aquivion® PW79S, N,N-dimethylacetamide (DMAc), N,N-dimethylformamide (DMF), 1-methyl-2-pyrrolidone (NMP), methanol, trimethylsilyl chlorosulfonate (TMSCS), chlorosulfonic acid, and toluene were all obtained from Sigma-Aldrich. Acetone, dichloromethane (DCM), bisphenol A (BPA), and sodium hydroxide (NaOH) were purchased from Merck. Additionally, Graphene Oxide (UGOX™) was bought from United Nano Tech Innovations Pvt Ltd. All chemicals were used as received without further purification.

PSU was synthesized by first mixing DMAc and toluene, followed by the addition of bis(p-chlorophenyl sulfone), BPA, and potassium carbonate. The reaction mixture was stirred and heated at 150°C for 4 hours. After completion, the mixture was cooled to room temperature and filtered. The polymer was then precipitated using a methanol-water solution, washed with methanol, and finally dried in a vacuum oven at 60°C for 12 hours.

Two different sulfonation methods were used, and in Sulfonation Method-1 (SM-1), the synthesized PSU and commercial PES were sulfonated separately using chlorosulfonic acid and dichloromethane. Initially, the polymers were dried at 80°C, then dispersed in DCM and stirred. Chlorosulfonic acid was gradually added, and the reaction proceeded under stirring. The resulting SPES and SPSU were washed in an ice-water bath and dried in a vacuum oven at 60°C (Shirvani et al., 2023).

In Sulfonation Method-2 (SM-2), commercial PSU was dissolved in DCM at 35°C under stirring. After achieving a homogeneous solution, TMSCS diluted in DCM was added dropwise, and the reaction was allowed to proceed. The sulfonated PSU was then precipitated using alcohol, filtered, washed, and dried. The required amount of TMSCS was determined by calculating the moles of repeating units in the polysulfone sample and applying a targeted sulfonation ratio, considering the molecular weight of TMSCS to obtain the corresponding mass.

The sulfonation degree (DS) of the polymers was determined using a titration method widely referenced in the literature (Devrim et al., 2009; Guan et al., 2005; Zhao et al., 2018). For 16% DS SPES and 35.2% DS SPSU from the first method (SM-1), and 30% DS SPSU from the second method (SM-2), the polymers were dissolved in DMF solvent, and the released H^+ ions were quantified by titration with 0.1 M NaOH using phenolphthalein as an indicator.

The repeating unit's molecular weight was 232 g/mol for SPES (coefficient: 0.232) and 442 g/mol for SPSU (coefficient: 0.442), with DS calculated using the following formulas.

For PES:

$$DS\% = \frac{(0.232 \times M \times V)}{(W - 0.08 \times V)} \times 100 \qquad (1)$$

For PSU:

$$DS\% = \frac{(0.442 \times M \times V)}{(W - 0.08 \times V)} \times 100 \qquad (2)$$

where M represents the NaOH concentration (M), V is the volume of NaOH added at the equivalence point (mL), and W is the weight of SPES (g).

The final calculations confirmed that the sulfonation degrees were 16% for SPES (sulfonated using SM-1), 35.2% for SPSU (sulfonated using SM-1), and 30% for SPSU (sulfonated using SM-2).

Membrane preparation involved stirring polymer solutions with different concentrations in dimethylacetamide (DMAc), N-methyl-2-pyrrolidone (NMP), or isopropyl alcohol (IPA) for 24 hours using a magnetic stirrer. The prepared solutions were then poured into glass petri dishes and placed in an oven at 70°C for 24 hours. After complete evaporation of the solvent, membranes were obtained for proton conductivity analysis.

The membrane conductivity test was performed using a cell where the membrane was placed in direct contact with platinum electrodes, and a voltage difference of 0-100 mV was applied across the two central electrodes.

$$H_2 \rightarrow H^+ + 2e^- \qquad (3)$$

Reaction (3) takes place, where the generated protons (H^+) pass through the membrane and are converted back into hydrogen on the other platinum electrode. During this process, the resulting current is measured from the outer electrodes.

$$\sigma = \frac{L}{R * A} = \frac{L}{R * W * T} \qquad (4)$$

where σ is the conductivity (mS/cm), L is the distance between the voltage-applied probes (0.425 cm), W is the width (cm), T is the membrane thickness (cm), and R is the resistance (Ohm-Ω).

The resistance (R) is determined from the slope (dV/dI) of the voltage (V) versus current (I) graph. Subsequently, the conductivity is calculated using the formula (4) mentioned above.

During the measurement, hydrogen gas (100% relative humidity - RH) was supplied while maintaining the cell temperature at 80°C. In the presence of conductivity, the current is expected to vary linearly with voltage. The resistance (R) value obtained from the slope of the dV/dI graph is then used to calculate the conductivity (σ).

Findings

The membrane produced with Aquivion achieved a proton conductivity of 615.46 mS/cm, which is higher than the general values in the literature. In contrast, for the PEMs prepared by mixing SPSU and PES polymers sulfonated using SM-2, conductivity values of 1.3 mS/cm and 1.08 mS/cm were recorded, respectively. On the other hand, no conductivity was obtained from the SPSU PEMs sulfonated using SM-1.

Conclusion

Based on the studies mentioned above, conductivity was obtained from the membranes produced using Sulfonation Method-2. However, the membranes derived from sulfonated polymers exhibited lower conductivity compared to the general literature, and the addition of Graphene Oxide did not affect their conductivity. In contrast, the membrane produced with Aquivion ionomer showed higher conductivity compared to the literature. In the continuation of our studies, new proton exchange membranes were developed by combining Aquivion ionomer, SPSUs obtained via both methods, GO, and Fe_3O_4@SiO_2@NH_2-SO_3H. Proton conductivity analyses will be conducted.

Aim

The growing emphasis on environmental awareness and tightening regulations have led the chemical industry to move towards "Sustainable Business Models," favoring fossil resource minimization and waste prevention practices. Increased adoption and utilization of renewable resources lies at the core of this transition (Karuppiah et al., 2023). Conventional biotechnological processes (in short, bioprocesses), such as corn wet milling (CWM), offer an ideal platform for testing the utility of modern tools and approaches, such as synthetic biology, machine learning, and process integration/intensification (Amado et al., 2017; Byanju et al., 2023; Shih, 2018; Wang et al., 2017) . Along these lines, as being already profitable and highly widespread, we argue that CWM is arguably one of the most strategic targets for speeding up this transition. Nevertheless, we inevitably need to establish a solid basis for analyzing the potential of implementing these new developments as industrial processes, which is hard to realize without taking advantage of computational simulation platforms such as SuperPro Designer and Aspen Plus, to name a few (Cecílio et al., 2023; Cortes-Peña et al., 2020; Ramirez et al., 2008; Wooley & Putsche, 1996). Aspen Plus is undoubtedly the leading process simulation software as it covers a comprehensive set of theoretical models that enable accurate analyses (Al-Malah, n.d.). Also, recent progress made in ASPEN Plus, such as Biocomponent definition or enhanced thermodynamic modeling, improves its suitability for bioprocesses. Plus, CWM is an utterly complex process impacted by several factors, such as grain moisture content, SO2 concentration in steep water, temperature, and pH. On top, CWM involves multiphase unit operations, including not only liquid but also a solid phase, necessitating the use of a comprehensive platform for performing reliable simulations. Thus, we decided to test the capabilities of Aspen Plus in simulating CWM, synthesizing the open literature information on CWM with the expertise of Sigma Process Technologies. By doing so, here, we aim to adequately transfer our accumulated knowledge to Aspen Plus environment as faithfully as possible to pave the road for future process integration and intensification efforts.

Material and Method

We opted for Aspen Plus primarily due to the availability of an extensive database and reference studies for simulating conversion reactions involving lignocellulosic biomass (Cecílio et al., 2023) and the recent introduction of a physical property database for biocomponents (Wooley & Putsche, 1996). The CWM process, which is based on the separation of corn kernels into fractions, serves as a strong reference point in the integration of different processes (Figure 1). As a starting point, we focus on obtaining starch as the main product and gluten, germ, fiber, and corn steep liquor as by-products from corn grain by wet milling process.

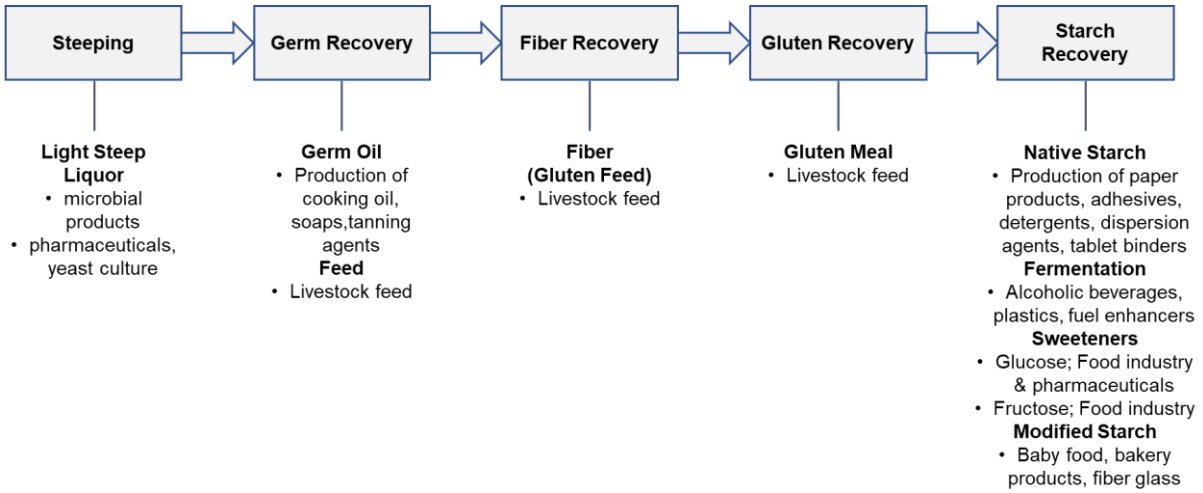

Figure 1. Schematic diagram of CWM-based products with usage areas of end-products (Amado et al., 2017; Rausch & Eckhoff, 2015; Serna-Saldivar, 2019).

Since it is a bioprocess involving multiphase unit operations, simulation studies are necessary to facilitate improvements within the process and to enable the integration of different processes into wet milling. We have specifically employed Aspen Plus V14 equipped with Properties and Simulation modules. The modeling of the wet milling process is based on the know-how of Sigma Process Technologies and several studies available in open literature. The process typically involves steeping, germ recovery, fiber recovery, gluten recovery, and starch washing steps, respectively (Eckhoff & Watson, 2009; Rausch & Eckhoff, 2015). Steeping, the step that includes the conversion of soluble monosaccharides in the structure of corn into lactic acid and the dispersion of the protein matrix by sulfur dioxide added to the system with steep water, is the most critical step that determines the efficiency of the process(Hull et al., 1996). The step that aims to soften the corn and obtain the components without damaging them in other steps is followed by the steps of milling and obtaining germ, fiber, gluten, and starch. The germ is collected from the overflow of the hydrocyclones based on the density differences. Subsequently, fiber recovery is achieved through a pressure screen that exploits differences in particle size. Finally, the separation of gluten and starch is performed using centrifuges that take advantage of density differences, and then the process is continued with washing, dewatering, and drying steps for all products (Rausch & Eckhoff, 2015). The process flow diagrams of the CWM process are represented as Corn cleaning and steeping steps (Figure 2), Germ recovery step (Figure 3), Fiber recovery step (Figure 4), Gluten recovery step (Figure 5), and Starch recovery step (Figure 6), respectively. Several basic properties required for simulating the CWM process, particularly those concerning solids handling, such as particle size distribution (PSD), density, and moisture content, have been collected from the literature (Serna-Saldivar, 2019).

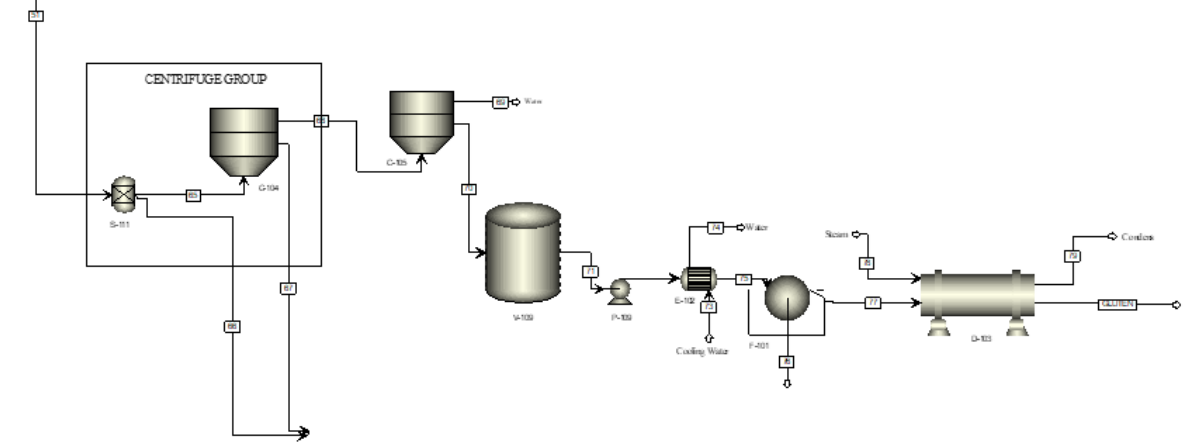

Figure 5. Gluten recovery step.

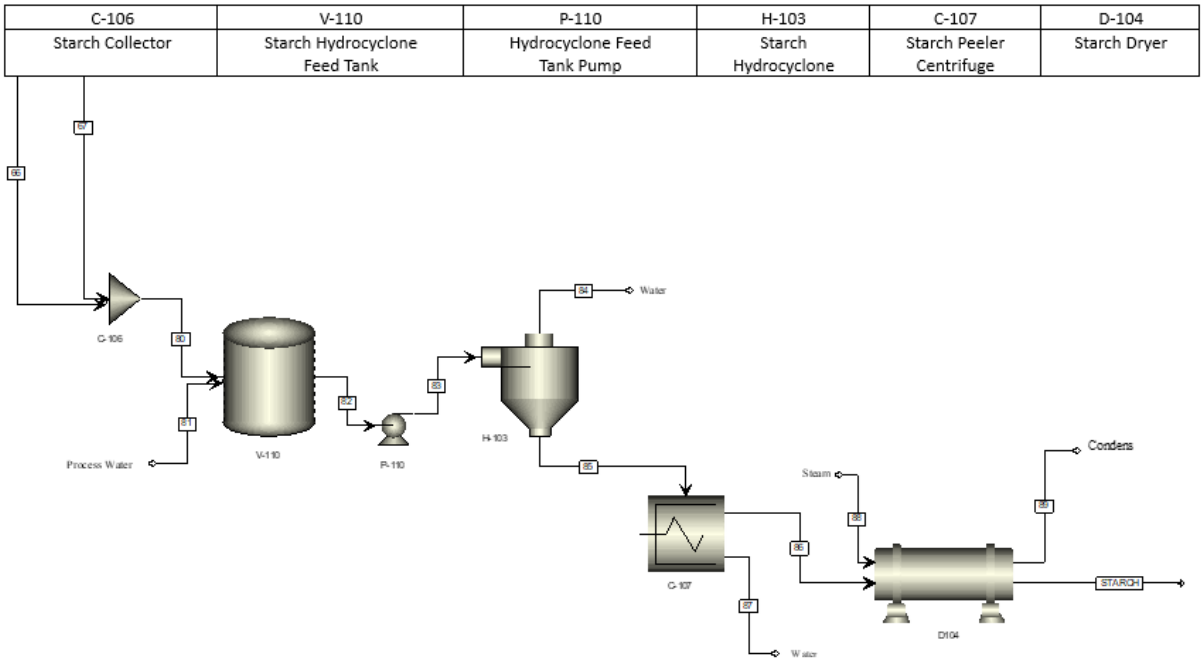

Figure 6. Starch recovery step.

One of the key challenges of simulating CWM process is that none of the corn components (e.g., germ, fiber, gluten, and starch) are included in the Aspen database by default. As the hemicellulosic fractions and protein structures have already completed their polymerization reactions, defining these components as a polymer is not a suitable approach. It is rather fair to register those as their monomers in the simulation environment (Serna-Saldivar, 2019). It is, on the other hand, common practice to consider starch and lignin as nonconventional solids due to their extremely long chain lengths and the challenges associated with defining their chemical formulas (Serna-Saldivar, 2019).

One of the critical steps that impact the overall efficiency of CWM is the steeping phase. During this phase, six tanks operate in a semi-continuous manner, allowing for continuous input and output to the general steeping system. In contrast, the batch scenario pertains only to the specifics of individual tanks. Consequently, only the general steeping system has been modeled in Aspen Plus, including the transportation of corn using sluice water and the reaction step of corn with mill water. Identifying the conversion of glucose to lactic acid in the reaction step (Hull et al., 1996) is deemed important due to the function of lactic acid in softening the corn kernels and enhancing the diffusion rate of sulfur dioxide (SO2) into the endosperm, dissolving endosperm proteins, and weakening the cell walls (Eckhoff & Watson, 2009; Rausch & Eckhoff, 2015). Notably, since the protein content of the kernel is classified within the amino acids, the identification of the dissolving endosperm proteins step is eliminated.

Findings

Corn kernels, the primary raw material input for the process, have a complex and heterogeneous structure that makes it impossible to characterize the feed stream in Aspen Plus as a straightforward conventional solid. When proximate and ultimate analysis results of those are known, different biomass materials can be classified as nonconventional solids in Aspen Plus. As no ultimate analysis data was not available in the literature for corn grains, we estimated the corn kernel composition by backcalculating from the composition of end products in CWM (basically starch, germ, gluten, fiber, and water-soluble compounds). The yields of the main products and byproducts obtained as a result of CWM are compared with the values reported in the literature. As seen in Table 1, our simulation results are close to literature values. It is important to remember that during this comparison, the yield will vary depending on the corn type and features such as moisture content value, which reinforces that our approach proved to be a good starting point.

Table 1. The comparison of main and side product yields compared to literature (Eckhoff & Watson, 2009).

	Reported Yield (Eckhoff & Watson, 2009)	Our Simulation Yield
Germ	6.78 ± 0.13	6.35
Fiber	13.37 ± 0.42	14.89
Gluten	10.91 ± 0.21	4.85
Starch	65.29 ± 0.16	73.91

Another challenge in that study is the inability to achieve effective separation in equipment, where separation is carried out according to density differences such as hydrocyclones or centrifuges. The light product, oil rich germ, should be separated from high dense products using a hydrocyclone model in Aspen Plus, by taking into account density differences (Eckhoff & Watson, 2009). However, in Aspen Plus, hydrocyclones are operated by focusing on particle size distribution without directly considering the density differences. During the wet milling simulation phase, the particle size distribution was established for the combined streams of CI Solid and NC Solid. However, it was not possible to delineate particle size characteristics based on individual components such as germ, gluten, and fiber. To operate the hydrocyclones effectively, a separator is placed before the hydrocyclone block to achieve the separation of light and heavy fractions, allowing the light stream to be fed into the hydrocyclone (Dickey et al., 1997). The separator and hydrocyclone block are evaluated as a system and with this assumption, germ recovery efficiency from the first hydro cyclone group is enhanced to 54.523% from 0.668%.

Conclusion

We argue that there is huge potential in revisiting the design aspects of conventional bioprocesses to implement modern biotechnological approaches down the line. As a start, here we focused on simulating CWM process, as it will probably maintain its pivotal role in starch industry in the future. However, we found out that the limited availability of open literature on this subject presents a substantial challenge. However, despite those limitations, our initial progress proved that Aspen Plus offers sample opportunities for simulating CWM, enabling further research and development.

Unlike the vast majority of existing studies that use starch as its monomer (glucose), we attempted to adopt a different approach: introducing starch as a nonconventional component. When starch was defined with the glucose monomer in the Aspen Plus, as in other references, it gave errors due to the lack of some thermophysical properties such as vapor pressure, heat capacity, density and enthalpy, and this required correct definitions in Aspen for these missing properties. On the other hand, the nonconventional definition neglects phase and chemical equilibrium calculations and is based on density and enthalpy modeling. Since starch, which we defined as NC in Aspen Plus, does not undergo any physical separation or chemical reaction during the CWM, our NC approach is sufficient for a study in the early-stage analysis.

This study reveals that Aspen needs further development in the biocomponent area and solid module. The assumptions made were aimed at filling these gaps in the program, and improvements will be made in these assumptions to enhance the reliability of Aspen Plus simulations.

Aim

The skin is the largest organ, protecting the body from the environment. In the case of trauma, surgery, burns, or chronic diseases, the skin's barrier is disrupted, and the skin's normal function is impaired. This can lead to more severe health problems in overall health. Therefore, it is quite important to cover and protect the wound to provide the proper environment for wound healing. Many traditional and innovative wound dressings are available to support wound healing stages (hemostasis, inflammation, proliferation, and remodeling). Even though traditional wound dressings such as gauze or bandages are cost-effective, their functions are insufficient to promote the healing of complex wounds. To provide a better environment to meet the needs of the wound area, innovative wound dressings, including hydrogels, nanoparticles, micelles, microspheres, sponges, scaffolds, films, and nanofibers, have been standing out [1]. Nanofibers having a diameter in the nanometer range are polymeric materials containing many superior properties like a high surface-to-volume ratio leading to a large surface area, high porosity, good mass transport ability, light-weight, and excellent mechanical properties. Among the fabrication methods of nanofibers, electrospinning is considered one of the most practical ways due to its simple equipment requirements, cost-effectiveness, and the ability to obtain continuous nanofibers with outstanding features [2, 3].

To meet the particular application area, synthetic and natural polymers can be combined in the fabrication of polymeric nanofibers. Even though natural polymers are a great candidate for tissue engineering by having superior biocompatibility and decreased immunogenicity in contrast to synthetic polymers, synthetic polymers have superior mechanical properties such as strength, viscoelasticity, and a higher rate of degradation. Therefore, combining synthetic and natural polymers to prepare nanofibers can be an effective way in terms of obtaining good biological characteristics, adjustable mechanical strength, and better performance. To eliminate the possibility of wound infection which can lead retardation of wound healing and bring about severe health problems, functionalized nanofibers with antibacterial agents such as antibiotics, metal nanoparticles, plant extracts, and antimicrobial peptides have been preparing by the researchers [1].

Especially medicinal plants are quite rich in terms of diverse bioactive compounds such as volatile oils, alkaloids, flavonoids, phenolic alcohols, quinones, saponins, and glycosides showing great antibacterial activity. Medicinal plants have been standing out for their effectiveness and fewer side effects compared to most other synthetic modern drugs [4]. Therefore, there are various studies on electrospun plant extract-loaded nanofiber wound dressing with antibacterial activity for promoting wound healing [1].

The plant species Cedrus deodara, planned to be used as a wound dressing plant extract, is a member of the Pinaceae family, conifers, and includes many of the commonly known conifers of commercial importance, such as cedar, fir, hemlock, larch, pine, and spruce. It is found throughout most of the Northern Hemisphere and generally in temperate climates, but occurs in species ranging from arctic to tropical [5]. Cedrus deodara, commonly known as deodar, is a species of western Himalayan cypress tree belonging to the Pinaceae family. It grows locally in eastern Afghanistan, northern Pakistan, northwestern India, southwestern Tibet, and western Nepal [6]. It is abundant in coniferous forests [7]. Commonly known as Himalayan cedar, C. deodara is widely used in Chinese beverages and herbal medicines for its nutritional and medicinal properties. C. deodara pine needles are considered as nutritious food source rich in protein, vitamins, and minerals [8]. Different parts of the

plant have been traditionally used to treat various diseases such as arthritis, asthma, stomach upsets, inflammation, microbial infections, neurological and skin disorders. The leaf and resin paste of the plant are used topically for wound healing [6].

In summary, this study aims to obtain plant extract (PE) added bilayered nanofiber wound dressings by using the electrospinning technique to utilize the mentioned therapeutic effects of the cedar wood extract. The cedar wood extract obtained from the plant waste was used in the polymer blend containing synthetic and natural polymers to promote wound healing by utilizing its antioxidant, antibacterial, and anti-inflammatory properties. Therefore, this study is also contribute to sustainability in terms of recycling woody waste and reintroducing it to the consumption chain.

Material and Method

Polycaprolactone (PCL), gelatin (Ge), cedar wood extract (0.5–5% w/w, from plant waste), acetic acid (AA), formic acid (FA), and deionized water were used as materials in this study. Among different types of electrospinning techniques, the blending electrospinning technique was chosen to form a nanofiber bilayer structure since it is the simplest and most effective method. Polymer blends with varying PCL: Ge ratios (30:70 to 70:30) were prepared by using AA: FA (1:1 v/v) as the solvent mixture and polymer blend electrospun into bilayered nanofiber nanocomposites. This process involved the blending of natural and synthetic polymers, which were prepared as a uniform solution and then electrospun through a single nozzle. In this study, polycaprolactone was used as a synthetic polymer due to its biodegradability, high processability, durability, and high solubility at room temperature conditions; gelatin was used as a natural polymer due to its high hydrophobicity, high biodegradability, and biocompatibility. The electrospinning process involved blending PCL and gelatin in various volume ratios, ranging from 30:70 to 70:30, to create a uniform solution. Cedarwood extract, obtained from plant waste, was incorporated into the polymer blend to enhance the healing properties of the wound dressing. The cedar wood extract concentration ranged from 0.5% to 5% by weight. In this bilayered structure, one of the nanofiber layers was made from PCL as a reinforcement layer, and the other layer was prepared from a blend polymer including PCL and gelatin. The combination of PCL and gelatin aimed to enhance the hydrophilicity of synthetic polymers, thereby promoting cell adhesion and growth. The effects of varying polymer blend concentrations and cedar wood extract concentrations were investigated on the samples. The morphological assessments (such as fiber diameter and uniformity) and chemical structure were investigated by Scanning Electron Microscopy (SEM) and Fourier transform infrared (FTIR), respectively to determine the properties of the obtained wound dressings.

Findings

The blend of the polymers in different ratios were electrospun into nanofibers under the relevant process conditions (i.e., solution concentration, applied voltage, tip-to-collector distance, flow rate, etc.). Figure 1 shows the chemical structure of the samples.

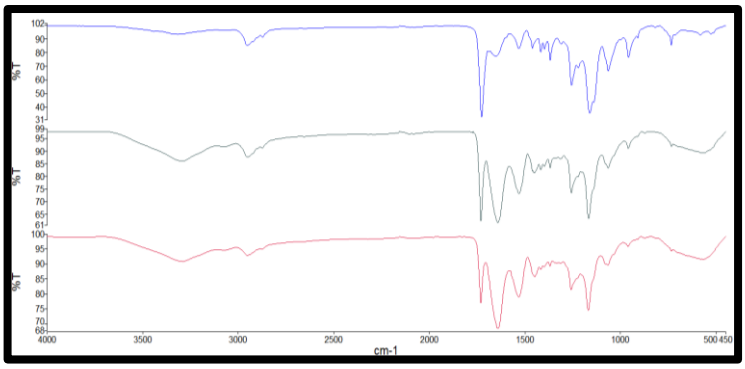

Figure 1. FTIR spectra of samples A (Pure PCL), B (PCL-Ge blend), and C (PCL-Ge with 5% extract). The top, middle, and bottom curves correspond to samples A, B, and C, respectively.

According to the FTIR spectra of the electrospun membranes, the gelatin characteristic peaks amide I (1650 cm^{-1}) and amide II (1540 cm^{-1}) were observed in (b) and (c), indicating that gelatin was successfully incorporated into these samples. The asymmetric CH_2 stretching (2943cm^{-1}) and symmetric CH_2 stretching (2866 cm^{-1}) appeared in all samples, representing the characteristic peaks of PCL. Strong peak at 1725 cm−1 belongs to the C=O double bond, peaks at 1293 and 1240 cm^{-1} are belong to the C–O, C–C stretching. The FITR results showed that PCL/gelatin hybrid nanofibers were successfully fabricated [8,9].

The morphological structure of the samples can be seen from Figure 2. According to the SEM images, it was seen that obtaineed GE:PCL samples without the plant extract showed nanofiber structures. However, 70:30 Ge:PCL sample indicated better nanofiber structure with homogeneous and bead-free based on both SEM observations and through the electrospinning process. Therefore, it was decided to add the plant extract into 70:30 Ge:PCL sample. The nanofiber mats maintained almost its homogeneous, bead-free structure after the inclusion of the plant extract. Furthermore, it was also detected that higher concentrations of plant extracts lead to thicker fibers due to increased viscosity. The electrospun Ge:PCL:PE nanofiber mats have fiber sizes in the range of 120-155 nm (Table 1), which closely mimic the collagen fibrils (50-500 nm) that compose typical human extracellular matrix, making them ideal for wound dressing material [10,11]. The visual inspection of the obtained samples by hand (Figure 3) indicated that the samples had enough hardness and dense structure for possible wound dressing applications.

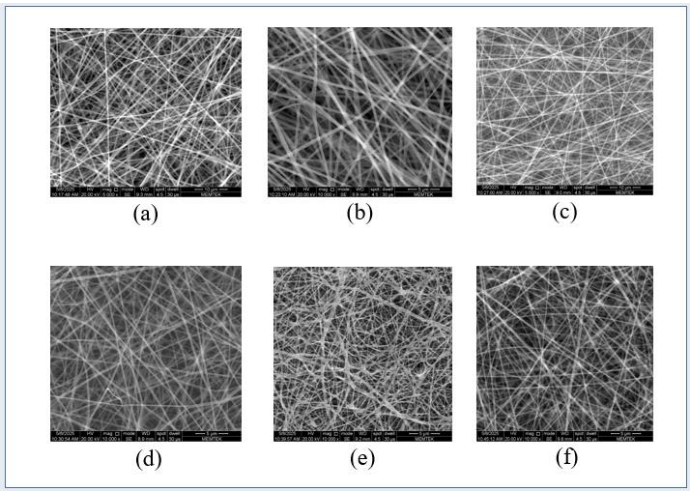

Figure 2. SEM images of the nanocomposite samples. (a) 70:30 Ge: PCL with 0.5 % extract, (b) 70:30 Ge: PCL with 2.5 % extract, (c) 70:30 Ge: PCL with 5% extract, (d) 70:30 Ge: PCL with % 0 extract, (e) 50:50 Ge: PCL with % 0 extract, (f) 60:40 Ge: PCL % 0 extract.

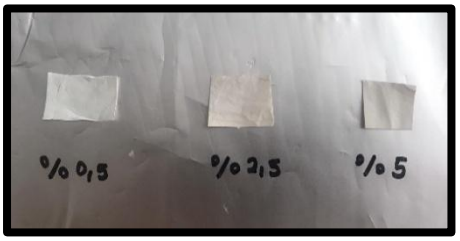

Figure 3. Nanocomposite samples containing %0.5 , %2.5, %5 extract respectively

Table 1. Average fiber diameter of samples in nanometers

Sample	**Average Fiber Diameter (nm)**
70:30 Ge: PCL (% 0.5 extract)	149.594 ± 31.845
70:30 Ge: PCL (% 2.5 extract)	120.798 ± 28.485
70:30 Ge: PCL (% 5 extract)	154.798 ± 30.137
70:30 Ge: PCL (% 0 extract)	116.814 ± 22.688
60:40 Ge: PCL (% 0 extract)	107.203 ± 27.264
50:50 Ge: PCL (% 0 extract)	139.777 ± 24.292

Conclusion

This study provided a substantial insight into the bilayered nanocomposites, including synthetic and natural polymers, and highlights their potential as a wound healing material. This study resulted in the fabrication of a sustainable and effective bilayered nanofiber wound dressing with cedar wood extract for advanced wound healing. The combination of both synthetic and natural polymers, taking advantage of the properties of medicinal plant extracts, provides the wound dressing with antibacterial, antioxidant, and anti-inflammatory properties. The electrospinning technique was used to fabricate nanofibers, offering a simple, cost-effective, and efficient method to obtain these wound dressings. The morphological analysis of the electrospun nanofiber structures revealed a homogeneous and bead-free fiber formation, which is a critical indicator of successful electrospinning. Notably, this uniform morphology was maintained even after the incorporation of cedar wood extract, indicating that the addition of the extract did not compromise the structural integrity of the fibers. Furthermore, the measured fiber diameters were found to be within the optimal range for wound dressing applications, offering a balance between porosity and mechanical strength that can support cell attachment and proliferation. These findings suggest that the developed nanofiber bilayer composites not only possess the desirable physical characteristics for wound healing but also maintain their structural consistency upon bioactive agent incorporation, highlighting their potential as effective and stable wound dressing materials.

Keywords : Analytical Method, GC-MS/MS Headspace, N-nitrosamines, Pharmaceutical Dosage Forms.

Aim

Drug substances, which are used in drug products, are obtained via organic synthesis including reaction mechanisms. Reactive chemicals, reagents, solvents, catalysts and other excipients are used in the synthesis of drug substances. Due to degradation reactions during or after chemical synthesis result of using these ingredients, impurities can occur in all drug substances and related drug products. Qualification and quantification of these impurities has great importance to provide safety and efficacy of the drug products. The Threshold of Toxicological Concern (TTC) has been developed to identify a common exposure concentration for any chemical that does not have any information about its carcinogenicity or other toxic effects. However, some structural groups have been determined to have a theoretically significant carcinogenic risk potential even at intakes below the TTC (ICH M7, 2023). N-nitrosamines, members of "cohort of concern", are also classified as probable human carcinogens by the International Agency for Research on Cancer (IARC) (Wu et al, 2015). These compounds can originate from sources such as environmental water, food, textiles, tobacco, pesticides, plastics, cosmetics or veterinary drugs and human medicines. The presence of nitrosamines in drug substances and drug products may be caused by solvents, starting materials, processing water, excipients and degradation of substances or cross-contamination in multi-purpose facilities (Witkowska, Giebułtowicz, Dabrowska and Stolarczyk, 2022). The aim of this study is development and validation, an analytical method which can be used for determination of N-nitrosamines (NDMA, NDEA, NEIPA, NDIPA, NMPA, NDBA) in different pharmaceutical dosage forms without any matrix effect.

Material and Method

In this study, three pharmaceutical dosage forms used as suspension, emulsion and film coated tablet. The analytical method was developed by GC-MS/MS instrument equipped with Headspace module. An Agilent VF-WAXMS column is a high-performance polyethylene glycol column designed for GC/MS applications especially where trace analyses are required was used during analysis, which has 30 m length, 0.25 mm diameter and 1µm pore size. Helium was used as carrier gas. Water, Methanol and Sodium Carbonate were used as diluent and reagent during analysis.

For MSMS method parameters, dMRM (dynamic Multiple Reaction Monitoring) mode was selected to scan a wide range of m/z for providing detection of N-nitrosamines with the same chromatographic conditions.

Nitrosamine standards were supplied in solid form, including NDMA, NDEA, NEIPA, NDIPA, NMPA and NDBA. Individual stock standard solutions were prepared in Methanol in 250 µg/mL concentration from each nitrosamine standard. Internal standards (isotope-labelled nitrosamines) were supplied as liquid form in Methanol in 1000 ppm concentration, including NDMA-D6, NDEA-D10, NDIPA-D14, NMPA-D5 and NDBA-D18. Stock internal standard solution was prepared diluting from internal standards in 500 ng/mL concentration and diluted internal standard solution was prepared by diluting from stock internal standard solution in 50 ng/mL concentration with water. Final solution concentrations were adjusted as 1.92 ng/mL for NDMA, 0.53 ng/mL for NDEA, 8.0 ng/mL for NEIPA, 30.0 ng/mL for NDIPA, 2.0 ng/mL for NMPA, 0.53 ng/mL for NDBA and 2.0 ng/mL for each internal standard.

Three different pharmaceutical dosage forms were used for the analytical method development and validation studies. Product A is a suspension, Product B is an emulsion and Product C is a film coated tablet form. Placebos

were used for each pharmaceutical dosage form which were formulated without active ingredients. Sample solutions were prepared in 0.08 mg/mL concentration for Product A, 0.002 mg/mL concentration for Product B and 3.2 mg/mL concentration for Product C and, placebo solutions were prepared same as products. Internal standard solution was added into all solutions in 2.0 ng/mL concentration for each internal standard. Nitrosamines spiked sample solutions were prepared by adding stock standard mixture solution into the product solutions including internal standards. Blank solution, placebo solutions for each pharmaceutical product, standard solutions, sample solutions and nitrosamines spiked sample solutions were injected respectively.

In order to determine optimized method parameters, design of experiment (DoE) was applied by Minitab program. Scope of experimental design, oven temperature, vial equilibration time and vial pressure parameters were selected as factors. Full factorial design was applied, and peak areas and RSD values of nitrosamines were compared individually and cross-relatedly.

Method validation was performed with the parameters of specificity, limit of detection and limit of quantification, linearity and range, system precision, repeatability, intermediate precision, accuracy and recovery, robustness as changes in chromatographic method parameters and solution stability.

Findings

Nitrosamines were not detected in blank, placebo and sample solutions for Product A, B and C for batch analysis. Therefore, nitrosamines spiked sample solutions were used during method validation study for all parameters.

In the specificity study, it was seen that there was no interfering peak in blank and placebo solutions which had same m/z value with nitrosamine and internal standard peaks in standard, sample and nitrosamines spiked sample solutions. For LOD and LOQ determination, six consecutive injections were applied, concentrations were calculated via s/n, and RSD% (relative standard deviation) obtained less than 15.0% for six nitrosamines. According to obtained linearity results, the method was found linear in the concentration range of LOQ-150% level with a correlation coefficient more than 0.99 for all nitrosamines. System precision, repeatability and intermediate precision were evaluated according to RSD% values with the limit as not more than 15.0%. Accuracy results were found between 70.0-130.0% at LOQ, 100% and 150% levels. For robustness parameter, nitrosamine results obtained from changes in method parameters were compared to repeatability results and absolute differences were calculated and it was shown that analytical method is robust against to changes. And solution stability was shown for six nitrosamines during 68 hours for standard, placebo, sample and nitrosamine spiked sample solutions for three tested pharmaceutical finished products.

Conclusion

GC-MS/MS equipped with Headspace (HS) module provides significant advantages in terms of efficient analytical method for determination of nitrosamines because of avoiding matrix effect for various dosage forms of pharmaceutical drug products. Suitable HS parameters make it possible to analyze six nitrosamines simultaneously in drug products even for trace levels.

This study aimed to obtain effective results in less time by adapting more dosage forms to the same analytical method, with common linearity and LOD & LOQ parameters and applied successfully according to the results obtained from all validation parameters for six nitrosamines.

Preparation of Peptide-GelMA Composite Hydrogel-Based Wound Dressing with 3D Printer and Its Physical Characterization

Keywords: 3D Bioprinting, DLP, GelMA, Peptide-Based Hydrogels, Wound Dressings.

Wound healing requires a wound dressing that protects the wound bed to support skin regeneration and accelerate healing (Obagi et al., 2019). Wound dressing is a sterile compress acting as a barrier to protect the injured epidermal tissues from the outside and promote healing (Fahimirad & Ajalloueian, 2019). These dressings ideally should keep the wound moist to support wound healing, provide oxygen permeability, be biocompatible with the skin and be antibacterial to prevent infection (Liang et al., 2022).

Traditional wound dressings, such as gauzes, plasters, and bandages, remain widely used today due to their affordability and easy accessibility. However, they come with several drawbacks, including inadequate adhesion, insufficient absorption of wound exudate, and the need for frequent changes, which can cause discomfort and pain. More importantly, they often fail to provide adequate wound drainage (Brumberg et al., 2021). Therefore, there is a growing need for novel wound dressings.

Hydrogels are the current choice for the development of modern wound dressings. They can be described as intricate three-dimensional structures composed of hydrophilic polymer chains, exhibiting a quick swelling response upon contact with water. More than 90% of the hydrogel framework consists of water, forming a partially solid material that enables it to maintain a moist environment at the wound surface and facilitate tissue repair. Hydrogels possess numerous properties that make them ideal for wound dressings, including firm adhesion, shape adaptability, and mechanical protection, ensuring sufficient wound coverage. Additionally, hydrogel-based dressings are highly tuneable, allowing the incorporation of antibacterial and antimicrobial agents, cells, biomolecules, and growth factors (Gounden & Singh, 2024).

Some other polymers such as chitosan, alginate, and cellulose are frequently integrated in hydrogels. However, these materials suffer from certain setbacks. As such, they require covalent cross-linking agents for gelation, which can damage biocompatibility and biodegradability. Some of them have very low mechanical strength, lower porous structure, poor cell adhesion, deficient oxygen vapour permeability, poor stability and very poor water solubility. They are also not prone to controlled variability due to their complex and variable composition. These limitations can hinder the effectiveness of those polymers in hydrogel applications (Elango et al., 2023).

To overcome this problem, the most suitable biopolymer to be preferred as the main component of hydrogels is peptides. By changing peptide sequences, concentration and external stimuli, the stiffness, flexibility and durability of the hydrogel can be tuned (Clarke et al., 2018). Compared to conventional polymeric hydrogels, peptide hydrogels have several advantages, such as controllable structure and assembly, stimuli responsivity, biocompatibility, biodegradability, ease of modification, and specific biological activity (Liu et al., 2019; Sedighi et al., 2023) Peptide hydrogels can be combined with antimicrobial agents to reduce the risk of infection and support the healing process. Additionally, hydrogels with antimicrobial properties can be synthesized by incorporating antimicrobial peptides (Zhu et al., 2024).

Aim

The use of peptide hydrogels as a base material for wound dressings is a relatively recent development in the literature. Leveraging the advantages of peptides, our goal is to design a highly biocompatible GelMA-based composite hydrogel with antimicrobial properties and to fabricate it using Digital Light Processing (DLP) 3D printing. DLP was selected for its high resolution, rapid printing capabilities, and ability to produce intricate

structures with fine details while maintaining a biocompatible and cell-friendly environment. To enable photocrosslinking essential for DLP printing, improve mechanical strength, and enhance stability, gelatin methacryloyl (GelMA) was incorporated into the hydrogel formulation.

Material and Method

In this hydrogel, Ac-Ile-Val-Phe-Lys-NH_2 (IVFK) peptide, originally reported by Alshehri et al. (2021) was of choice because of its self-assembly ability in solution and high hydrogelation property. This peptide was synthesized by solid phase peptide synthesis (SPPS) method on Rink Amide resin. Initially, 150 mg Rink Amide resin was added to the column, swollen in DMF and then washed. The Fmoc protecting group was removed using 20% (v/v) piperidine/DMF. Subsequently, each amino acid (Lysine, Phenylalanine, Valine, Isoleucine) was dissolved in DMF, activated with HBTU, and basified with DIPEA. The amino acids were sequentially coupled to the resin. After each step, the resin was capped with acetic anhydride, pyridine, and DMF to block unreacted sites. Once the final amino acid was attached, the Fmoc group was removed, and the resin was washed with DMF and DCM, then dried under vacuum. The peptide was cleaved from the resin by using TFA (95%), TIPS (2.5%), and H_2O (2.5%) mixture. The crude product was collected, and residual solvents were removed under reduced pressure. The synthesized peptide was purified using reverse-phase preparative High-Performance Liquid Chromatography (HPLC) to achieve high purity. Following purification, the peptide was characterized using Mass Spectrometry (MS) to confirm its molecular weight.

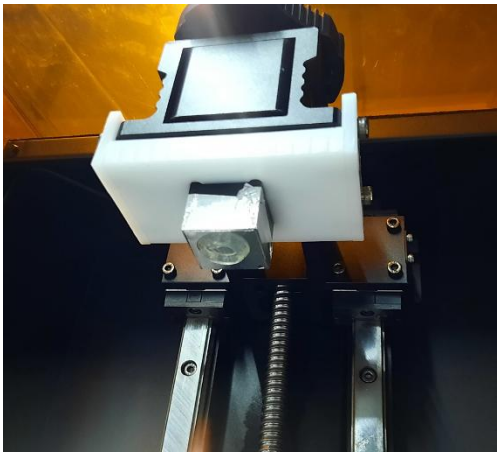
Then GelMA, which has the acrylate-tipped structure required for printing on a DLP 3D printer and increases the mechanical strength of the hydrogel when combined with the peptide, was synthesized through the reaction of gelatin with methacrylic anhydride (MAA) under carefully regulated alkaline conditions, which allowed for an accurate degree of functionalization. The reaction was conducted at a constant temperature with continuous stirring to promote homogeneous modification. Then, extensive dialysis against deionized water was performed to eliminate unreacted MAA and byproducts. The resulting purified GelMA was then lyophilized, yielding a stable hydrogel precursor that is photo-cross-linkable and possesses improved mechanical strength with adjustable viscoelastic characteristics.

The bioink was formulated by initially dissolving the IVFK peptide in ultrapure water. Then, a few drops of 0.5 M NaOH solution were added, and the mixture was titrated with 0.1 M HCl solution until the pH reached ~7.4. The total volume was then adjusted to 1 mL using 0.1 M PBS. Separately, 200 mg of GelMA was dissolved in 2 mL of PBS, with stirring conducted at 60°C and 100 rpm, while the beaker was entirely covered with aluminium foil. Once the GelMA was fully dissolved, the previously prepared peptide solution was incorporated. Finally, 10 mg of LAP (photoinitiator) was added to improve the printability and stability of the hydrogel after the temperature was reduced to 40°C. The mixture was then stirred at 40°C and 100 rpm, thereby completing the preparation of the hydrogel.

The prepared hydrogel was transferred into the vat of the 3D DLP printer (Phrozen Sonic Mighty 14K Revo), and a design file in .ctb format was selected. Multiple printing trials were conducted under 405 nm UV light to optimize

the exposure time. Once the optimal exposure time was determined, ensuring the ideal hydrogel structure, printing was repeated using this parameter (Figure 1).

The printed hydrogel was then stored at 4°C. The printing parameters were carefully optimized to ensure compatibility with DLP technology, which provides precision in 3D printing. Finally, the printed hydrogels were



characterized using Fourier Transform Infrared Spectroscopy (FTIR) and Scanning Electron Microscopy (SEM).

Findings

The IVFK peptide was successfully purified using reverse-phase preparative HPLC. The purified peptide was then analyzed by LC-MS, confirming that its molecular weight matched the expected value (Figure 2). This result verifies the success of both the peptide synthesis and purification processes.

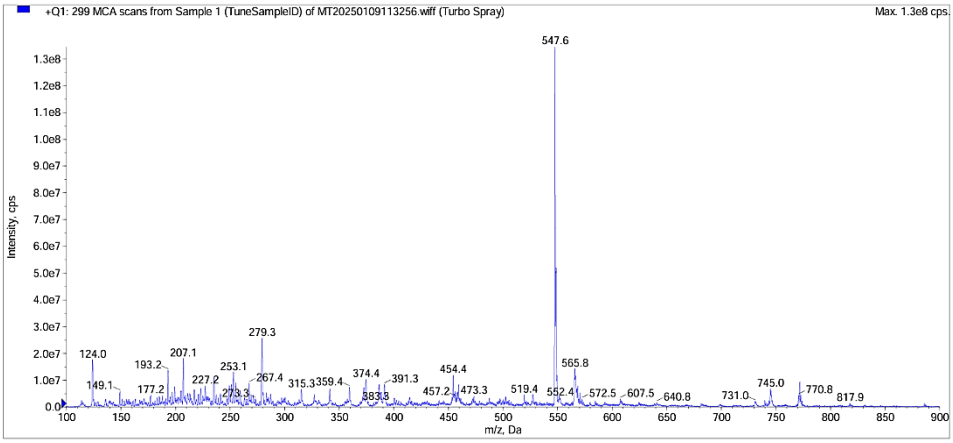


Figure 2. LC-MS spectrum of IVFK peptide.

The successful synthesis of GelMA enabled the formation of a hydrogel suitable for bioprinting, exhibiting structural integrity and maintaining its intended geometry after printing. The incorporation of the peptide/GelMA composition in the bioink contributed to the hydrogel's structural stability. The 3D-printed hydrogel demonstrated

stability and precise shape fidelity, indicating the appropriateness of the selected bioprinting parameters (Figure 3).

Figure 3. The printed peptide/GelMA composite hydrogel.

FTIR spectra of the IVFK/GelMA composite hydrogel, as shown in Figure 4, exhibited a broad absorption band at 3334 cm^{-1}, corresponding to the O–H and N–H stretching vibrations, indicative of hydrogen bonding interactions in the solid state. The strong peak at 1631 cm^{-1} is attributed to the amide I (C=O stretching), while the bands at 1546 cm^{-1} and 1463 cm^{-1} correspond to amide II and C–H bending vibrations, respectively. Notably, the amide I peak at 1631 cm^{-1} suggests β-sheet formation, a characteristic secondary structure of self-assembling peptides, which plays a crucial role in hydrogel stability. Additionally, the peak at 1245 cm^{-1} corresponds to C–N stretching and N–H bending (amide III), consistent with the presence of GelMA. These findings confirm the successful formation of a structurally integrated hydrogel.

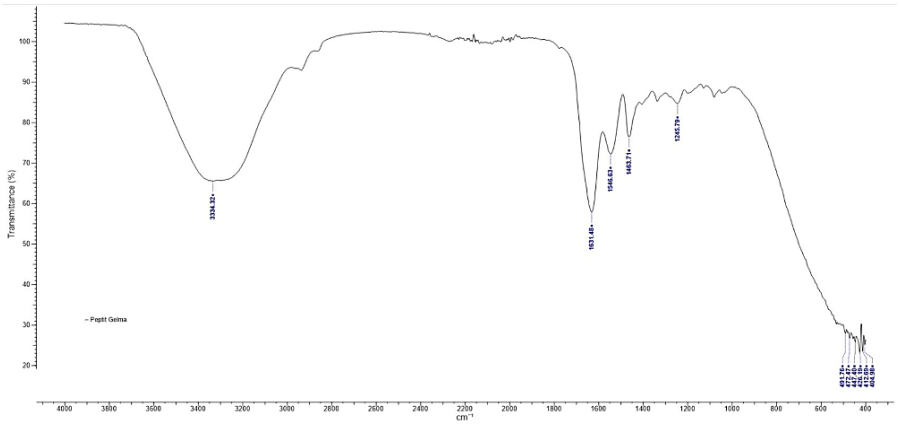

Figure 4. FTIR spectrum of the hydrogel.

SEM image, as seen in Figure 5, reveal a smooth, uniform and well-integrated hydrogel structure with preserved interlayer integrity and a compact surface, indicating successful polymerization under optimal crosslinking and curing conditions. Also, the porosity of wound dressing is relatively low, indicating dense, highly crosslinked structures. This well-defined morphology, minimal surface defects, and absence of phase separations confirm the homogeneous distribution of the polymer network and the structural stability of the hydrogel.

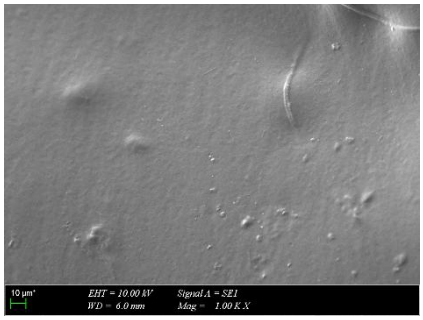

Figure 5. SEM image of the hydrogel.

Conclusion

The hydrogel was successfully printed using DLP 3D printing technology, allowing precise control over its structure and mechanical characteristics. The printed hydrogel exhibited an interconnected porous structure, likely stabilized by the combination of peptide self-assembly and cross-linking interactions.

In conclusion, preliminary results indicate that the development of peptide-based hydrogels in combination with GelMA presents significant advantages in biomaterial design by providing enhanced mechanical stability and tunable degradation rates. The integration of DLP 3D printing technology enables the fabrication of customized structures with precision and reproducibility, while also maintaining biocompability. The ability to fine-tune porosity, alongside the antimicrobial potential of peptide/GelMA hydrogels, underscores their promise as innovative modern wound dressing materials.

In the later stages of the study, the optimized methodology will be applied to another peptide with antimicrobial properties to expand its potential biomedical applications further.

Keywords: 3D Bioprinting, Peptide-Based Bioinks, Chronic Wound Healing, Peptide-Based Hydrogel Wound Dressings, GHK-Cu.

Wound healing is a complex and dynamic process requiring an optimal tissue regeneration environment. An ideal wound dressing should maintain moisture, allow gas exchange, promote angiogenesis, prevent infections, and be biocompatible (Dhivya et al., 2015). Traditional wound dressings, such as gauze and foams, primarily serve as passive barriers, whereas modern wound dressings, including hydrogels, hydrocolloids, and bioactive dressings, actively contribute to the healing process. Hydrogels, in particular, provide a moist environment, support tissue regeneration, and enable controlled drug delivery. Functionalizing hydrogels with bioactive molecules, such as peptides, further enhances their therapeutic potential in wound healing (Koehler et al., 2018).

In recent years, peptides, including self-assembling and bioactive sequences, offer several advantages over conventional biopolymers and they are widely used in wound dressings. Their well-defined molecular structures allow precise tuning of their biochemical properties, while their ability to interact with cellular receptors makes them highly effective in modulating wound healing pathways. Self-assembling peptides can form nanofibrous hydrogels that provide structural support for cell attachment and migration (Alshehri et al., 2021). Compared to larger biopolymers, peptides offer superior control over degradation rates, reduced immunogenicity, and enhanced bioactivity at lower concentrations (Dong & Guo, 2021).

The major challenge in wound care is the limited effectiveness of conventional dressings in treating chronic wounds. Chronic wounds impose a significant burden on healthcare systems due to their prolonged healing process, high susceptibility to infections, and limited treatment options. In addition to providing a protective barrier, wound dressings are essential for maintaining an optimal environment that supports tissue regeneration. Among various wound dressing materials, hydrogels have emerged as promising candidates due to their high water content, excellent biocompatibility, and ability to mimic the extracellular matrix (ECM), thereby supporting cellular adhesion, proliferation, and differentiation (Liang et al., 2021).

A promising approach to addressing this challenge is the development of peptide-based wound dressings, incorporating bioactive peptides like GHK (Gly-His-Lys). GHK is a bioactive tripeptide with strong regenerative properties, making it an ideal candidate for wound healing applications (Pickart, 2008). It has been shown to enhance cell proliferation, stimulate angiogenesis, and regulate inflammation, all of which contribute to efficient tissue regeneration. Additionally, GHK plays a crucial role in ECM remodelling by promoting collagen synthesis and fibroblast activation. Studies have demonstrated that GHK also exhibits antioxidant properties, reducing oxidative stress and improving cellular resilience in damaged tissues (Lee et al., 2023). Furthermore, the copper-complexed form of GHK, known as GHK-Cu, has been identified as a potent wound-healing agent with enhanced biological activity. GHK-Cu plays a critical role in tissue repair by stimulating the production of collagen, elastin, and glycosaminoglycans while also upregulating genes associated with skin regeneration. Additionally, GHK-Cu enhances angiogenesis through vascular endothelial growth factor (VEGF) activation and contributes to reducing inflammation by modulating cytokine activity, thereby improving fibroblast proliferation and promoting collagen remodelling (Pickart & Margolina, 2018). These properties make GHK-Cu an attractive candidate for integration into bioactive wound dressings for the effective treatment of chronic wounds.

To fully harness the therapeutic potential of peptide-functionalized hydrogels, advanced fabrication techniques such as digital light processing (DLP) bioprinting are required to achieve precise structural control and optimize their biological performance. DLP is a high-precision 3D printing technique that offers significant advantages for fabricating wound dressings. Unlike conventional hydrogel preparation methods, DLP enables the rapid and accurate fabrication of complex structures with fine resolution and tunable mechanical properties (Zhou et al., 2024). One of the major advantages of DLP over other 3D printing techniques is its ability to create highly customized wound dressings with intricate geometries, ensuring precise fitting for irregular wound surfaces (Hu et al., 2024). Also, one of the advantages of this technique over its traditional counterparts is the ability to integrate multiple functional materials such as bioactive peptides into a single construct (Joshi et al., 2023).

Aim

In this study, we aim to prepare a wound dressing from peptide-GelMA composite hydrogel for the treatment of chronic wounds. For this, the peptide IVFK was chosen as it spontaneously self-assembles to a stable hydrogel in the aqueous milieu. The wound dressing made of IVFK peptide and GelMA was printed using a DLP 3D printer. Subsequently, GHK-Cu peptide was encapsulated into PLA microparticles and electrosprayed onto the printed hydrogel wound dressing. The chronic wound healing potential of the fabricated GHK-Cu encapsulated wound dressing was evaluated through biological assessments.

Material and Method

The IVFK peptide was synthesized according to the Fmoc-based solid-phase peptide synthesis (SPPS) technique with Rink Amide resin. The peptide was then purified via reverse-phase preparative high-performance liquid chromatography (HPLC) and characterized through mass spectrometry (MS).
GelMA was prepared by reacting gelatin with methacrylic anhydride (MAA) under controlled alkaline conditions, ensuring a precise degree of functionalization. The reaction was maintained at a constant temperature with continuous stirring to facilitate homogeneous modification, followed by extensive dialysis against deionized water to remove unreacted MAA and byproducts. The purified GelMA was then lyophilized to obtain a stable, photo-cross-linkable hydrogel precursor with enhanced mechanical integrity and tunable viscoelastic properties. When GelMA and the synthesised IVFK peptide were combined, a targeted hydrogel formulation was obtained. Then, this was loaded into a 3D printer (Phrozen 14K REVO) for DLP printing, resulting in the fabrication of peptide-based wound dressings (Figure 1).

Figure 1. 3D printing process of the peptide-based hydrogel wound dressing.

The encapsulation process of GHK-Cu into the fabricated hydrogel wound dressings was performed using an electrospraying technique (Figure 2), based on the methodology described by Taşcı et al. (2021). First, a polyvinyl alcohol (PVA) solution was prepared in 20 mL of dichloromethane (DCM) following the parameters optimized in the referenced study. Separately, a GHK-Cu solution was prepared by dissolving the peptide in ethanol before mixing it into the PVA solution. The resulting mixture was drawn into a 10 mL syringe and loaded into the

electrospraying pump (IPS-12, Inovenso). The electrospraying was performed at an applied voltage of 18 kV, a nozzle-to-substrate distance of 15 cm, and a flow rate of 20 µL/min. A previously fabricated 3D-printed GelMA-IVFK composite hydrogel wound dressing was positioned beneath the nozzle to facilitate uniform deposition. The electrospraying process was carried out for 30 minutes to ensure effective encapsulation of GHK-Cu onto the hydrogel surface (Figure 3). The results were evaluated through an optical microscope. (Olympus - Colorview) In addition to this approach, an alternative encapsulation method was also employed. Using the same electrospraying parameters, GHK-Cu was first dissolved in ethanol and then mixed into a PLA solution prepared in DCM. This mixture was electrosprayed directly onto an empty petri dish to generate microcapsules. Following the electrospraying process, the microcapsules were collected and dissolved in PBS. The resulting suspension was then incorporated into the bioink formulation alongside the GelMA-IVFK hydrogel during the 3D printing process. This method aimed to enhance the integration of encapsulated GHK-Cu within the hydrogel matrix, ensuring more effective and sustained release of the peptide within the wound dressing.

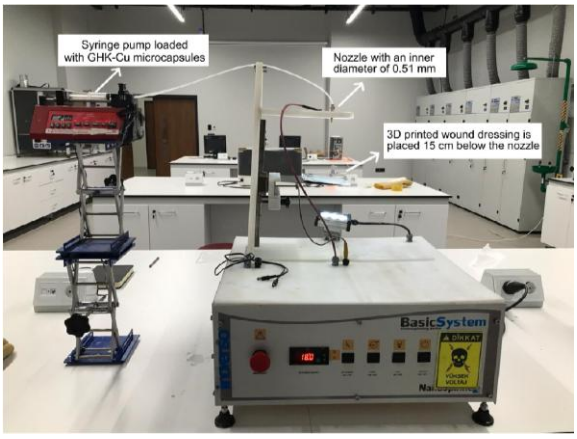

Figure 2. Electrospraying setup.

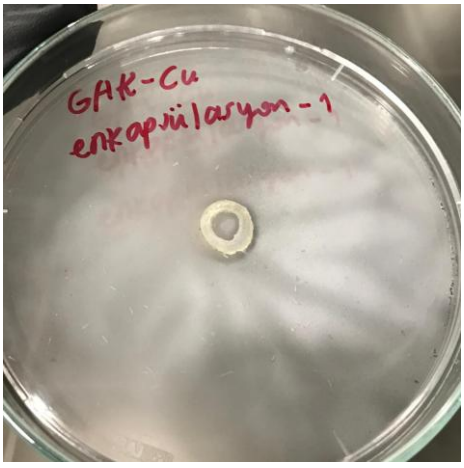

Figure 3. Encapsulated GHK-Cu onto the peptide-based hydrogel wound dressing.

The cytocompatibility of the produced GHK-Cu encapsulated GelMA-IVFK composite hydrogel wound dressings was evaluated using human dermal fibroblasts (HDF). Cell viability and attachment were assessed through MTT assays and fluorescence microscopy. The scaffolds were seeded with HDFs and incubated under standard culture conditions. Following incubation, MTT assays were performed to quantify cell metabolic activity, while fluorescence microscopy was used to visualize cell adhesion, morphology and proliferation on the hydrogel surface.

Findings

The IVFK peptide was efficiently synthesized and purified using reverse-phase preparative HPLC, with its identity confirmed by LC-MS characterization (Figure 4). GelMA was successfully synthesized and when combined with the peptide in solution, it formed a hydrogel with optimal viscosity for DLP-based 3D printing. This hydrogel was then effectively printed to fabricate hydrogel-based wound dressings, demonstrating its suitability for advanced wound healing applications (Figure 5).

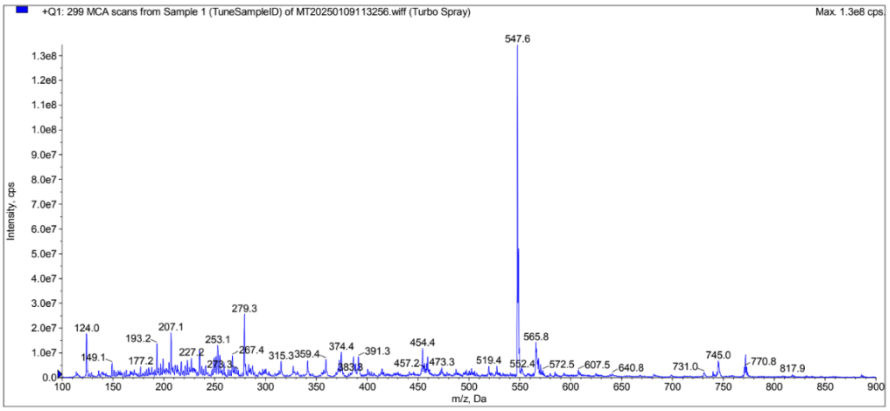

Figure 4. Mass spectrum of the synthesised IVFK peptide.

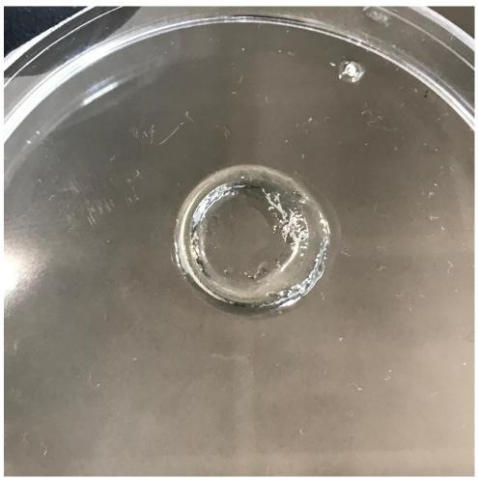

Figure 5. 3D printed peptide-based hydrogel wound dressing.

The encapsulation of GHK-Cu via electrospraying yielded successful results and the optimization of the process further enhanced the integration of encapsulated GHK-Cu into the produced wound dressing. Optical microscopy analyses confirmed uniform deposition without significant aggregation. Cytocompatibility studies demonstrated strong fibroblast attachment and proliferation, while MTT assays verified high cell viability. Additionally, fluorescence microscopy revealed that the cells maintained their normal morphology. These findings confirm the synthesis, fabrication, and functionalization of peptide-based wound dressing, highlighting their strong potential for chronic wound healing applications.

Conclusion

In light of the findings, this study successfully developed and characterized a novel peptide-functionalized hydrogel wound dressing from GelMA and IVFK, fabricated via DLP bioprinting. The incorporation of GHK-Cu through electrospraying enhanced the bioactivity of the hydrogel, making it a promising candidate for chronic wound healing applications. The efficient synthesis of the peptides, along with the fabrication of the hydrogel wound dressings, demonstrated excellent cytocompatibility, with favorable cell attachment and proliferation. Overall, the results highlight the potential of this peptide-functionalized hydrogel system in accelerating wound

healing, offering a customizable and bioactive solution for tissue regeneration. Further studies will focus on encapsulating other biologically active molecules into this 3D-printed hydrogel wound dressing.

Synthesis and Characterization of Liposomal Formulations of Biguanide Derivative Active Pharmaceutical Ingredient

Sevgi Demiröz[a], Kader Poturcu[b]

[a]Süleyman Demirel University, Department of Chemistry, Graduate School of Natural and Applied Sciences, Türkiye
[b] Suleyman Demirel University, Department of Chemistry, Faculty of Engineering and Natural Science, Türkiye
kaderpoturcu@sdu.edu.tr

Keywords: Liposome, Biguanide Derivative API, Thin Film Hydration Method, Drug Delivery System, CTEM.

Aim

Liposomes are spherical structures that serve as drug-delivery vehicles. They consist of one or more lipid bilayers that encase an aqueous core, allowing for the encapsulation of various therapeutic agents, which are hydrophilic and hydrophobic (Liu et al., 2022). Liposomes demonstrate remarkable properties, including the ability to protect encapsulated drugs from physiological degradation (Bautzová et al., 2012), prolong the drugs' half-life, and regulate the release of drug molecules (Wang et al., 2009). Their excellent biocompatibility and safety profiles further enhance their appeal (Liu et al., 2022).
In this study, we synthesized a liposomal drug delivery system containing a biguanide derivative active pharmaceutical ingredient (API) using the thin-film hydration method under reduced pressure. The importance of the study is related to the that the cholesterol is widely used component during liposome synthesis. In this study, we aimed to use cholesterol-like compounds instead of cholesterol to synthesize liposomal formulation and investigate morphological structures of materials with High Contrast Transmission Electron Microscopy (CTEM). Additionally, the EE% and DL% values based on the calibration graph of the standard solution of the API, which exhibited a correlation coefficient (R^2) of 0.999, were calculated. The EE% values for F1, F2 and F3 were as follows: %98.15, %99.49 and %74.52. The % DL values in the same order for formulations were %1.85, %0.507 and %25.5, respectively.

Material and Method

1-Materials

The chemicals were acquired from the specified chemical companies as follows: L-alpha lecithin (Merck, Darmstadt, Germany), cholesterol-like component (Abcr, Karlsruhe, Germany), Methanol (Isolab, Germany), Trichloromethane (Isolab, Germany), biguanide derivative API (Merck, Darmstadt, Germany), buffer solution (Wisent, Canada).

2-Thin-film hydration method

Liposomal drug delivery systems were synthesized with the thin-film hydration method under reduced pressure with minor modifications to the literature (Thabet et al., 2022). Cholesterol-like structure: lecithin mixtures were dissolved in trichloromethane: methanol (3:1, v/v) organic solvent mixtures at three different ratios. After solution preparation, the mixture was evaporated at two hours and then the evaporation continued under reduced pressure with a vacuum pump (DRVAC300, Taiwan) to remove the all traces of the solvent and thin films were prepared (Torres-Flores et al., 2020). The thin- film was hydrated with buffer solution (pH 7.4) which contains dissolved biguanide derivative API and stirred 150 rpm for an hour at 40˚C. The drug loaded liposomal suspension was stored at 4˚C for further analyses.

3-Entrapment Efficiency

Drug-loaded liposomal formulations were ultracentrifuged at 14.000 rpm for 40 min to calculate percentage of Entrapment Efficiency (EE%) and Drug leakage (%DL). The supernatant was removed, and 1 ml buffer solution

was added to the Eppendorf tube that contains the pelleted part of the liposomal formulations and centrifuged again. The centrifugation steps were repeated three times. The supernatant taken at every step proceeded in UV-Vis spectrophotometer at the fixed wavelength of 233 nm to determine un-entrapped drug molecule in liposomal formulation using the following EE% and DL% equations (Kesharwani et al., 2021).

$$EE\% = \frac{amount\ of\ API\ added\ in\ liposome - amount\ of\ unentrapped\ API}{amount\ of\ API\ added\ in\ liposome} \times 100 \text{ (Eq.1.)}$$

$$DL\% = \frac{amount\ of\ API\ added\ in\ liposome - amount\ of\ unentrapped\ API}{total\ amount\ of\ liposomal\ formulation\ (drug+excepients)} \times 100 \text{ (Eq.2.) (Waghule et al., 2021)}$$

4-Characterization analysis

High Contrast Transmission Electron Microscopy (CTEM, FEI, Tecnai G2 Spirit Biotwin) containing LaB6 electron gun with an accelerating voltage of 20–120 kV was conducted on GEM loaded liposomes for imaging F1, F2 and F3 formulations. Ethanol diluted nanoparticles were dropped on carbon coated copper grids and let air-dried before imaging.

Findings

The selected biguanide derivative API has issues with gastrointestinal tolerance, a short half-life, and low bioavailability. To address these challenges, we synthesized liposomal drug delivery systems for this API using a cholesterol-like compound instead of cholesterol as a component of the liposome structure, as shown in Figure 1. To achieve this, three different drug-loaded liposomal formulations were synthesized.

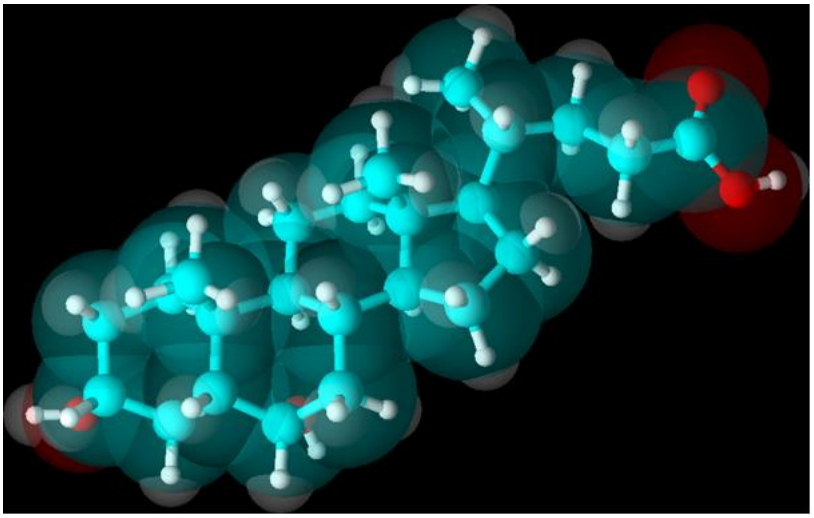

Figure 1. The three-dimensional optimized chemical structure of the cholesterol-like compound (HDCA) used in the synthesis of liposomes.

The physicochemical properties of the selected API were calculated using the ACD/Labs PhysChem Suite. At the studied pH, which simulates the physiological pH of the human body, the API has a net charge of +1 (see Figure 2 and Table 1). The -COOH functional group present in the cholesterol-like compound labeled as PS2 in the figure has a net charge of -1 at the analyzed pH, as illustrated in (Figure 2).

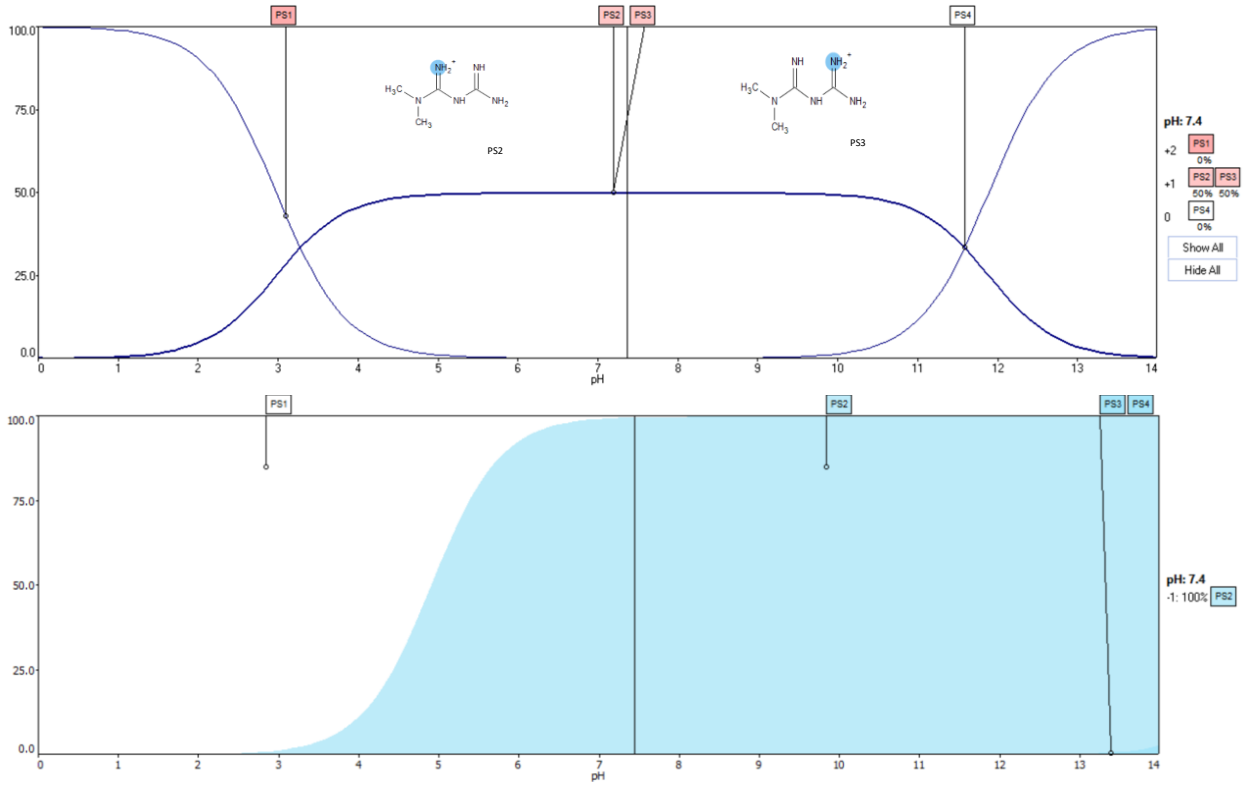

Figure 2. Protonation states (PS) vs pH graph of the biguanide derivative API (above) and the cholesterol-like compound (below) at the analyzed pH (pH 7.4).

Table 1. Net charge vs. pH of the biguanide derivative API.

Net charge/pH	1.7	2.0	3.0	4.0	4.6	5.0	6.0	6.5	7.0	7.4	8.0	9.0	10	11
q=0	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.01	0.11
q=+1	0.05	0.10	0.51	0.91	0.98	0.99	1.00	1.00	1.00	1.00	1.00	1.00	0.99	0.89
q=+2	0.95	0.90	0.49	0.09	0.02	0.01	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00

The calibration graph for a standard solution of a biguanide API displays seven different concentrations (Figure 3).

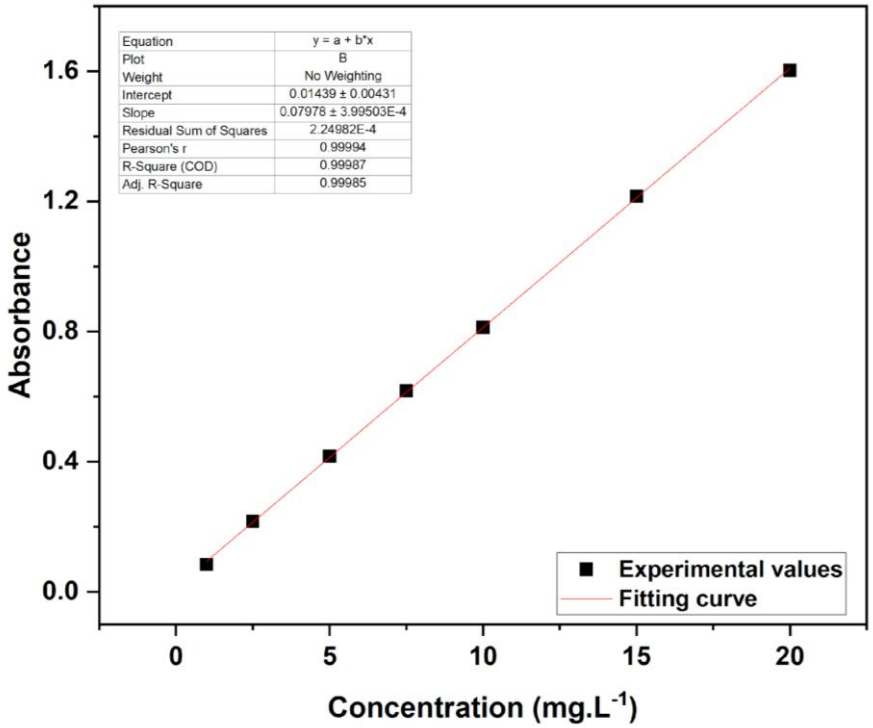

Figure 3. The calibration graph of standard solution of biguanide derivative API.

The regression equation is $y = 0.07978x\ (\pm 3.995 \times 10^{-4}) + 0.01439(\pm 0.00431)$ having a R^2 value of 0.9999 (Figure 3). This linear regression equation was used to calculate the EE% and DL% values of liposomal drug formulations.

EE% and DL% values

The ultracentrifugation process aims to determine the lowest absorbance value that indicates the absence of un-entrapped drug molecules in the supernatant. UV-Vis results for each centrifugation step are presented in Figure 4. Each step involves different dilution ratios, which must fall within the linear range of the calibration graph. To quantify the amount of entrapped drug molecules in the liposomal formulations, the pelleted structure remaining after the removal of the supernatant in the Eppendorf tube is lysed with isopropanol. This mixture is then centrifuged again, and the measurements are conducted using a UV-Vis spectrophotometer with the appropriate dilutions.

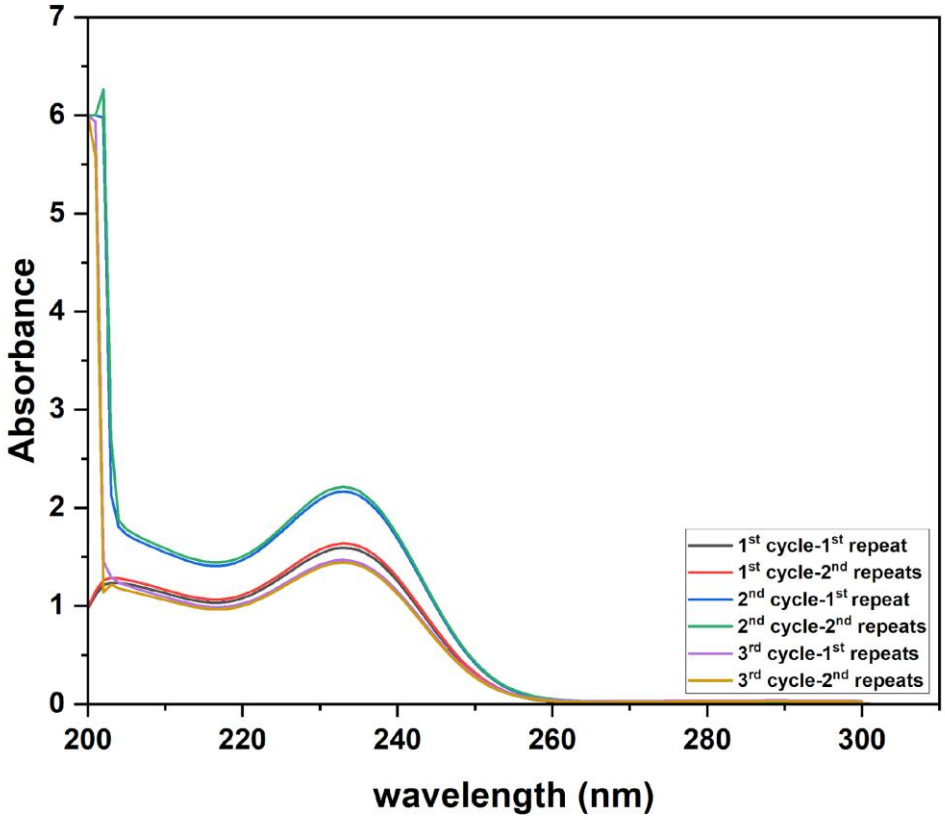

Figure 4. UV-Vis spectrum of drug-loaded formulations obtained after each centrifugation step.

The EE% values for three different drug-loaded liposomal formulations, designated F1, F2, and F3, were 98.2%, 99.5%, and 74.5%, respectively, calculated according to Equation 3. The DL% values for these formulations were 1.85%, 0.507%, and 25.5%, respectively. The highest EE% with the lowest DL% values were obtained with F2 formulations of the synthesized liposomal formulations.

CTEM analysis was performed to observe the morphology of MET loaded liposomes and confirm the particle size distribution results. High Contrast Transmission Electron Microscopy images of MET loaded liposomes prepared by ultrasonication for F2 formulations were given in the Figure 5. The liposomes generally exhibit spherical shape which agreed with the study of Dag and Oztop (2017). The particle size were between 500 nm to 100 nm were given in the Figure 5. The morphology of liposomes containing MET was partially bound to large or small drops (Gibis et al., 2012). Small liposomes tend to merge to decrease their curvature.

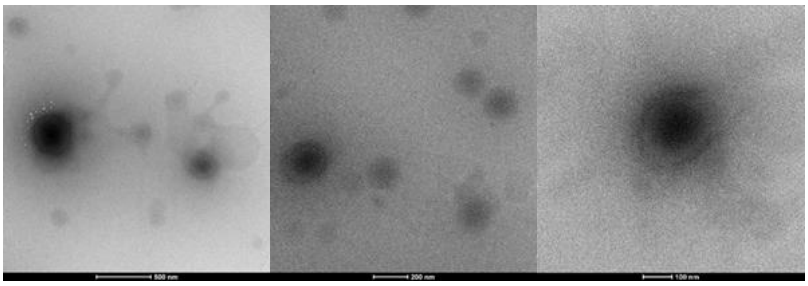

Figure 5. Morphology and size of F2 formulations ((A) 500 nm (B) 200nm (C) 100 nm) visualized by High Contrast Transmission Electron Microscopy (CTEM).

Conclusion

The thin-film hydration method is a widely used technique for preparing liposomal formulations. In these drug delivery systems, cholesterol is a widely used component, often combined with different phosphatidylcholine derivatives substances. The difference of this study is to increase of the short half-life and the oral bioavailability of the biguanide derivative API, metformin, using cholesterol-like structure instead of cholesterol for the synthesis of the liposomal drug delivery systems. Three different cholesterol-like structure-to-drug ratios were employed during liposome synthesis, while keeping the amount of the drug molecule constant. The plotted calibration graph of the API has a R^2 value of 0.9999. Using linear regression of this calibration graph, we calculated the amounts of un-trapped and entrapped drugs and subsequently determined the entrapment efficiency (EE%) and drug leakage percentages (DL%) for the synthesized formulations. The EE% values for formulations F1, F2, and F3 were as follows: 98.15%, 99.49%, and 74.52%, respectively. The corresponding drug leakage values were 1.85%, 0.507%, and 25.5%. The Metformin loaded liposomes generally exhibit spherical shape which is confirmed by CTEM analyses.

Immobilization of Cobalt Wastes in Ceramics for The Long-Term Storage in Deep Radioactive Waste Repository

Esra Varbil[a], Sema Akyil Erenturk[a]

[a] Istanbul Technical University, Energy Institute, Türkiye
varbil@itu.edu.tr

Keywords: Cobalt Waste, Feldspar, Immobilization, Chemical Durability, Leaching Rate.

Aim

High-level radioactive waste can be immobilized in glass, ceramics, glass-ceramics and glass composite materials and stored in geological final waste storage areas (Bernardo et.al., 2003). Vitrification is one of the first methods developed for the immobilization of high-level radioactive waste (Boccaccini et.al., 2004; Shelby, 2005; Lee et., al., 2006). Although waste can be reduced to smaller volumes with the vitrification method and products with high chemical and mechanical strength can be obtained, the waste intake capacity in the glass matrix is limited to 20-35% (wt). In ceramics, glass-ceramics and glass composite materials developed later, the waste intake capacity can increase to 50-70% (wt) and at the same time, high-strength materials can be obtained (Yanikomer and Erenturk, 2025; Jakkula and Deshpande, 2013). The aim of this study is to prepare ceramics with high chemical and mechanical strength, high waste absorption capacity and as low processing temperature as possible. In ceramics prepared with suitable composition, immobilization of ^{60}Co, one of the important fission products, was carried out. Then, the suitability of the main matrix and matrix compositions containing waste for long-term storage conditions underground was examined with detailed tests. The leaching of cobalt ions from ceramic products containing waste was found in terms of average dissolution rates (g cm^{-2} min) of the elements forming each ceramic composition based on unit mass losses after waiting in the oven at 90 ^oC for 7 days. Structural analysis of ceramics was performed by FTIR and XRD. The obtained results showed that the ceramic structure was a suitable matrix for the immobilization of ^{60}Co.

Material and Method

Feldspar was used as a ceramic raw material. Cobalt, a radioactive fission product, was immobilized in feldspar. Cobalt was added to the main matrix in certain proportions and the mixture was mixed homogeneously in an agate mortar and then pressed in a 33 mm mold with a 40-ton press. The mixture, which turned into pellets, was placed on a graphite block and turned into ceramics by applying heat treatment with controlled heat increases between 900 ^oC and 1200 ^oC in a high-temperature furnace. The product obtained was left to cool in the furnace until it reached room temperature.

The weights of the ceramics that were ready for the chemical resistance test were determined first. Then, the samples were subjected to the chemical resistance test by hanging them on a thin thread in 50 mL of bidistilled water in polyethylene containers and waiting in an oven at 90^oC for 1 week. The weights of the samples were weighed at certain time intervals and the pH value of the water was measured. Then, the time-dependent unit mass losses were calculated by considering the mass losses and surface areas of the samples. Based on the unit mass losses, the average dissolution rates of each ceramic composition were calculated in terms of (g cm^{-2} min) (Buelt et al., 1987; Komatsu et al., 1990; Bengisu et al., 2006).

Based on unit mass losses, the average dissolution rates of the elements forming each ceramic composition were found in terms of (g cm^{-2} min). The volume of the samples was measured using the Archimedes principle and their specific gravities were calculated from the sample weight and volume. The leaching rates of the elements found in the structure of the obtained glasses from the glass structure were calculated.

Structural investigation of all ceramic compositions examined was carried out by X-ray diffraction (XRD) and Fourier Transform Infrared Spectroscopy (FTIR) analyses.

Findings

Ceramic compositions have been used for years. Prepared ceramics have the desired properties for immobilization of radioactive waste. Feldspar was used as ceramic raw material. The results obtained showed that crystalline phases formed in feldspar main matrix ceramic structures play an important role in the immobilization of cobalt. In addition, it was observed that cobalt was immobilized in the feldspar matrix.
As a result of chemical durability tests, the average dissolution rate of cobalt-containing waste ceramics is very low and did not differ significantly depending on the waste rate.

Conclusion

Considering all the results, it was determined that ceramic structures prepared using feldspar, which is the preferred barrier material in radioactive waste management, can also be used in the immobilization of nuclear waste. Some changes to be made in the composition of such materials can increase their chemical and physical durability.
Different new compositions are still being studied for nuclear and radioactive waste immobilization. Especially ceramics are promising for waste immobilization. Within the scope of this study, the immobilization of cobalt, one of the important fission products, in ceramic matrices, one of the newly developed solidification materials in nuclear waste management, was investigated.

Stimuli-Responsive Polymers Based on Calix[4]pyrrole and Pillar[5]arene Molecular Recognition

Deniz Memis[a], Necla Bektas[a], Abdullah Aydogan[a]

[a] Istanbul Technical University, Department of Chemistry, Türkiye
memisd@itu.edu.tr

Keywords: Calix[4]Pyrrole , Host−Guest Interaction , Pillar[5]Arene , Supramolecular Polymers.

Aim

Supramolecular polymers (SPs) are polymeric systems characterized by the ability of monomeric units to be connected through non-covalent reversible interactions (Wei et al., 2015). The behavior and conformation of these polymers are directly influenced by these interactions. SPs, which are synthesized by combining monomers with interaction motifs, hold significant importance in the production of materials with hybrid properties. The dynamic bonds between the monomers of SPs enable them to possess the properties of conventional polymers, as well as those of smart materials such as self-healing and responsiveness to external stimuli (Yan et al., 2013). The responsiveness of these materials is provided by means of dynamic bonds based on various intermolecular reversible interactions, such as π−π stacking, hydrophobic interactions, metal−ligand coordination, hydrogen bonding, anion recognition, and host−guest interactions (Li et al., 2012). The pyrroles units of calix[4]pyrroles provide a hydrogen-bonding array capable of binding anions selectively in organic media (Gale et al., 1996). By virtue of this, calix[4]pyrroles have become widely utilized in various applications, including supramolecular polymers (Bektas & Aydogan, 2023). Pillar[5]arenes are suitable hosts for electron-deficient molecules such as pyridinium and imidazolium cationic species and neutral molecules such as dibromoalkanes, alkanediamines, and alkylnitriles in the construction of supramolecular polymers (Li et al., 2019). The primary objective of this study is to synthesize alternating supramolecular polymers responsive to external stimuli from alkylnitrile functionalized calix[4]pyrrole and pillar[5]arenes bearing carboxylate units.

Material and Method

We report the synthesis and characterization of an alkylnitrile-functionalized calix[4]pyrrole (CPN) and two distinct pillar[5]arenes tethered with carboxylate units (P1 and P2). These compatible supramolecular monomers were subsequently utilized to synthesize two different supramolecular assemblies (designated as CPN + P1 and CPN + P2) based on orthogonal neutral nitrile and carboxylate ion recognition motifs in chloroform (Figure 1). The characterization of SAPs was conducted through a combination of ^{1}H NMR and two-dimensional diffusion-ordered ^{1}H NMR (DOSY) techniques, along with viscosity measurements. Furthermore, the linker chain length differences between pillar[5]arene cores and carboxylate units of P1 and P2 were investigated in relation to the SAP formation performance. Additionally, we conducted studies on the stimuli-responsive properties of SAPs against temperature, pH, and competing guest species.

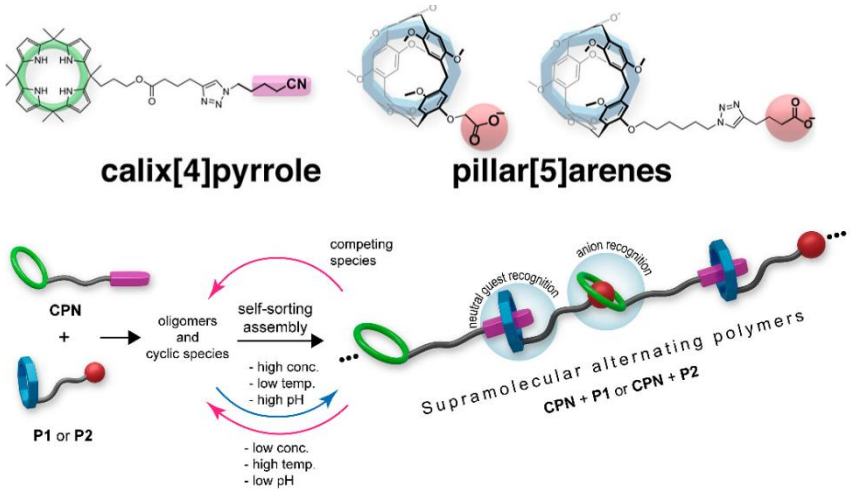

Figure 1. Cartoon representations depicting the supramolecular polymerization.

Findings

CPN + P1 and CPN + P2 SAP systems comprise calix[4]pyrrole and pillar[5]arene macrocycles capable of binding carboxylate units and forming inclusion complexes with alkylnitrile units, respectively. These noncovalent interactions are inherently dynamic due to hydrogen bonding and host-guest interactions, which can be modulated by external stimuli. Consequently, we subjected CPN + P1 and CPN + P2 to various stimuli, including temperature, acid-base, and competing species. SAPs of the aforementioned systems exhibited reversible disassembly and reassembly upon application of one of the aforementioned stimuli sources.

We commenced by investigating the temperature dependence of SAPs in chloroform through inverted vial tests. Notably, SAPs of CPN + P1 (434 mM) and CPN + P2 (387 mM) exhibited self-standing high-molecular-weight polymers at 25 °C (Figure 2). However, they were observed to transition to less-viscous states when the temperature of the supramolecular polymers was elevated to 50 °C. These findings demonstrated the thermoresponsive properties of CPN + P1 and CPN + P2.

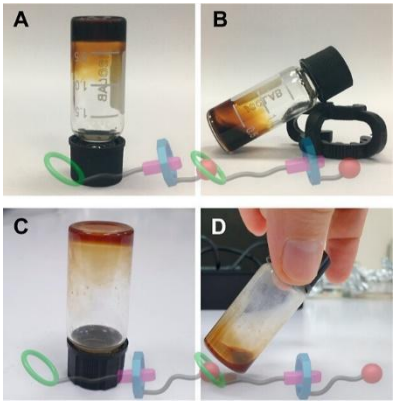

Figure 2. Responses of SAPs to temperature changes. Inverted vial tests of equimolar (A,B) CPN + P1, (C,D) CPN + P2 at (A,C) 25 °C and (B,D) 50 °C.

The pH-responsive behavior of supramolecular polymers was investigated using a sequential acid-base treatment method. The calix[4]pyrrole and alkylnitrile ^{1}H NMR resonance signals of CPN + P1 and CPN + P2 were monitored. The underlying principle of these experiments is the protonation and deprotonation of carboxylate units in P1 and P2 components, which disrupt their complexation with the calix[4]pyrrole units of CPN. Consequently, the sizes of SAPs could be controlled by pH changes. To achieve this objective, $CDCl_3$ solutions of SAPs (14 mM) were sequentially treated with equimolar methanesulfonic acid (MSA) and tetramethyl guanidine (TMG). When CPN + P1 or CPN + P2 was treated with MSA, the pyrrole NH resonance signals of SAPs exhibited upfield shifts,

indicating the destruction of calix[4]pyrrole-carboxylate complexation. Upon the introduction of TMG, the original chemical shifts of pyrrole NHs were restored, suggesting the reconstruction of calix[4]pyrrole-carboxylate interactions. The pH-responsive behavior of SAPs was further confirmed by DOSY experiments. After treatment with MSA, the increased D values were attributed to the destruction of supramolecular polymers and their subsequent reconstruction after treatment with TMG.

The responses of CPN + P1 and CPN + P2 against competing guest species were also investigated using ^{1}H NMR and DOSY experiments under the same conditions as those applied for pH-responsiveness. Tetrabutylammonium fluoride (TBAF) and 5-bromovaleronitrile (BVN) were selected as competing guests due to their frequent use in calix[4]pyrrole- and pillar[5]arene based supramolecular polymer systems (Ünlü & Aydogan, 2022). The calix[4]pyrrole core of CPN exhibits a stronger affinity for fluoride anion compared to carboxylate. Therefore, the addition of equimolar TBAF to SAP solutions disrupted the linear chains of CPN + P1 and CPN + P2. This was corroborated by the ^{1}H NMR spectra. pyrrole NH resonance signals, which exhibited a shift to >12 ppm. Additionally, the complete complexation of calix[4]pyrrole units was deduced from the sharper and completely upfield shifted pyrrole CH peaks around 5.6 ppm. The pillar[5]arene cores of P1 and P2 were also targeted using BVN as a competing guest. The responses of CPN + P1 and CPN + P2 were investigated. When equimolar BVN was added to the $CDCl_3$ solutions of supramolecular polymers, significant changes in the pillar[5]arene and calix[4]pyrrole-related peaks were observed. These results enabled us to propose that alternating linear supramolecular polymers of CPN + P1 and CPN + P2 were transformed into smaller aggregates in solution upon interactions with BVN. Support for this hypothesis was provided by additional DOSY experiments, revealing D values of 5.11×10^{-10} and 4.06×10^{-10} m^2 s^{-1} for CPN + P1 and CPN + P2, respectively, after treatment with BVN in $CDCl_3$. These values correspond to 1.68 and 2.00 times increases in D values and support the aforementioned results obtained from ^{1}H NMR experiments.

Conclusion

In conclusion, we have successfully designed, synthesized, and fully characterized complementary calix[4]pyrrole (CPN) and pillar[5]arene (P1 and P2) supramolecular monomers. These monomers are tethered with carboxylate and alkylnitrile functional groups and utilized to obtain SAPs (CPN + P1 and CPN + P2) in chloroform via. concurrent anion recognition and host-guest interactions. The formation and characterization of SAPs were monitored using a combination of techniques, including viscosity measurements and DOSY analyses. Additionally, the thermo-, pH-responsive properties of the SAPs of CPN + P1 and CPN + P2 and the influence of anionic and neutral competing species were elucidated through a series of viscosity, ^{1}H-, and DOSY-NMR experiments. To the best of our knowledge, this study presents the first instance of SAPs based on the simultaneous utilization of calix[4]pyrrole and pillar[5]arene molecular recognition, followed by their application in the formation of stimuli responsive systems. The ease of monomer synthesis, coupled with the facile preparation of the materials, is anticipated to pave the way for the production of advanced, multicomponent synthetic self-assembled systems.

Keywords: Solubility, P-Amino Benzoic Acid Derivative API, XRD.

Aim

The solubility of drugs and drug candidates is a critical physicochemical parameter in pharmaceutical analysis. Approximately 40% of marketed compounds are poorly soluble, and around 90% of drug candidates have soluble properties (Jouyban-Gharamaleki et al., 2020; Martínez et al., 2017). Various solubility enhancement techniques have been reported in the literature, including micronization, solid dispersion, the use of surfactants, co-solvency, pH adjustment, and more (Savjani et al., 2012).

In the present study, the solubility behavior of a p-aminobenzoic acid derivative active pharmaceutical ingredient was investigated in a propylene glycol+2-propanol non-aqueous binary mixture using the co-solvency method at 310.15K. The experimental solubility values were determined using at least three experiments conducted with diluted solutions. The minimum solubility was found to be 9.10 (± 0.44)$\times 10^{-3}$ mol.L^{-1} in neat 2-propanol, while the maximum solubility was 2.34 (± 0.06)$\times 10^{-1}$ mol.L^{-1} in neat propylene glycol at the studied temperature. Additionally, density measurements were determined in this binary mixture for saturated systems. Characterization tests of the saturated drug solutions were performed using X-ray diffraction (XRPD) analysis across 2theta values from 10°C to 90°C. According to the XRPD results, the crystallinity of the drug molecule remained unchanged, indicating no polymorphic transformation occurred during the dissolution process in the studied binary mixtures.

This study aims to determine the solubility values of p-aminobenzoic acid derivatives' active pharmaceutical ingredient (API) in propylene glycol+2-propanol non-aqueous binary mixtures using the co-solvency method. The density values of saturated API were also determined experimentally. The characterization tests were performed using XRPD analysis. Until now, no solubility data on selected non-aqueous binary mixtures has been available for this API in the literature.

This study was supported by TUBITAK 2209-A University Students Research Projects Support Program with the Project number of 1919B012320617, 2023/2nd term.

Materials and Method

Table 1 lists the chemicals used during experiments. The supplier provided the purities of the chemicals shown in the Table, and they were used without any purification.

Table 1. The list of chemicals used in this study.

Chemicals	Purity*	Supplier
p-amino benzoic acid derivative API (Procaine HCl)	0.99% (mass fraction)	Sigma Aldrich, China
Propylene glycol	≥99.5%	Carlo Erba, Germany
2-Propanol	≥99.5%	Supelco, Darmstadt, Germany

Absolute ethanol	≥0.999%	Supelco, Darmstadt, Germany
HPLC grade water	Conductivity: 0.55 µS/cm	Milli-Q water, Millipore

Solubility Analysis

A standard shake-flask method (Martínez et al., 2017) was employed to analyze the solubility of p-aminobenzoic acid derivative active pharmaceutical ingredient (API) in binary mixtures of propylene glycol (PG) and 2-propanol at 310.15 K. Excess amounts of the API were added to volumetric flasks containing 10 g of neat solvents or various solvent mixtures with different mass ratios (w_1=0.1–0.9). The flasks were then tightly sealed and placed on an orbital shaker (Heidolph, Germany) within an incubator system (MhmtGhsm Company, Dublin, Ireland). The drug solutions were shaken for 72 hours at the specified temperature.

After shaking, the saturated mixtures were centrifuged and diluted with a mixture of ethanol and water (30:70% v/v). Spectrophotometric measurements were conducted using a UV–Vis spectrophotometer (UV 1800 Perkin Elmer Inc., USA) at a fixed wavelength of 299 nm. A calibration curve was constructed using stock solutions of p-aminobenzoic acid derivative API within a concentration range of 2.5 $mg.L^{-1}$ to 25 $mg.L^{-1}$. This involved diluting the drug solutions from the stock solutions to create the calibration curve. The resulting calibration curve showed an R^2 value of 0.9996 within the studied concentration range.

The density values of the saturated API mixtures were determined using a 5 mL pycnometer, with an uncertainty of 0.001 g/cm^3. The solubility data and density values reported are averages of at least three replicate measurements.

X-ray Powder Diffraction (XRPD) Analysis

The characterization tests of p-aminobenzoic acid derivative API equilibrated in the saturated solutions were performed by XRD analyses (Rigaku Ultima IV, Tokyo, Japan) from 10° to 90°. The voltage and current applied were 40 kV and 15 mA, respectively using CuKa radiation. The scan speed was 5.00°.min^{-1} with a step width of 0.02°. All samples were dried in an oven at 100 °C before XRD analysis. XRD analyses were performed at the R&D Training and Measurement Center, X-Ray Diffraction Laboratory (METU, Türkiye).

Findings

The p-aminobenzoic acid derivative compounds that contain both amino and carboxyl groups at their structure are the commonly used building blocks in pharmaceuticals (Haroon et al., 2023). The p-aminobenzoic acid is a non-toxic compound, easily absorbed in the intestine, and they have broad biological activities (Al-Rubaie et al., 2021; Haroon et al., 2023). More than 184 drugs in the database of commercial drugs are p-aminobenzoic acid derivative synthetic compounds which have local anesthetic, anti-tuberculosis, anti-convulsant, and antineoplastic effects in therapeutic applications (Tang et al., 2020).

In the present study, the p-aminobenzoic acid -based local anesthetic drug (Figure 1) was selected for solubility analyses in PG+2-propanol non-aqueous binary mixtures. The density values of saturated API were determined experimentally. The raw API and saturated API characterization tests in non-aqueous binary mixtures were conducted using XRPD analyses.

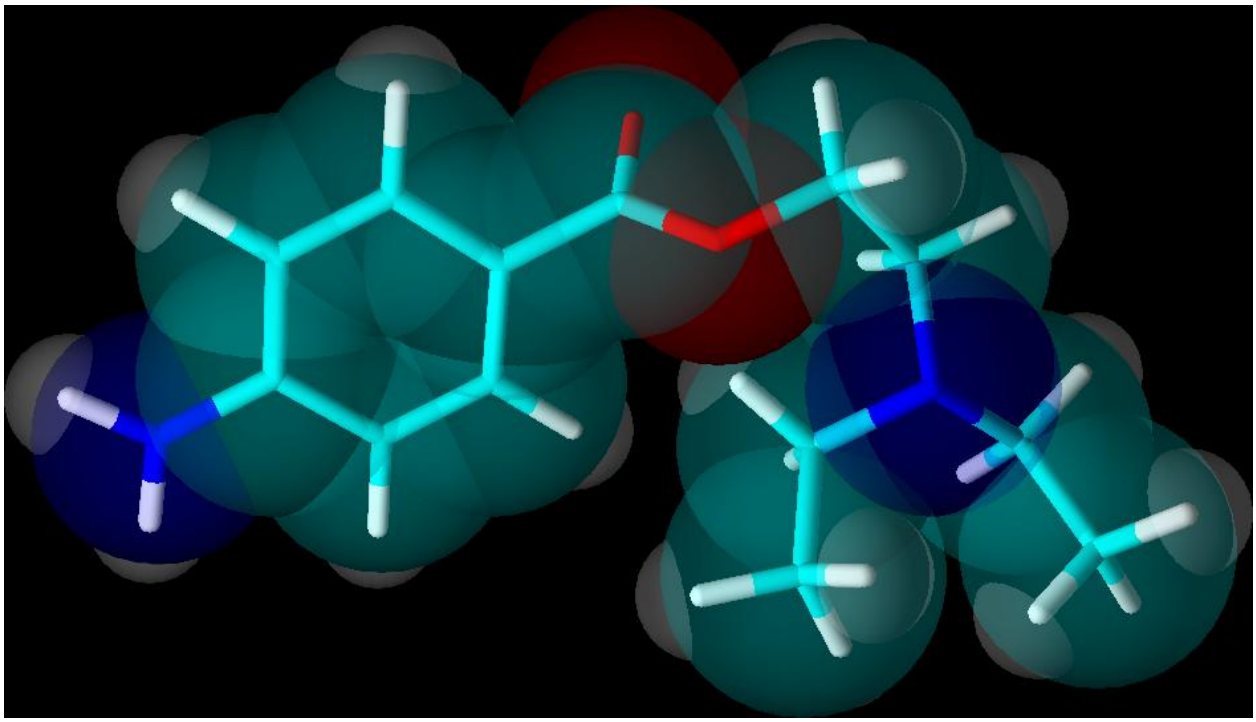

Figure 1. The 3D-optimized chemical structure of the p-aminobenzoic acid derivative API.

A standard stock drug solution was prepared and appropriately diluted to plot the calibration curve. The R^2 value obtained was 0.9996 within the studied concentration range, which included seven points on the calibration graph, as shown in Figure 2.

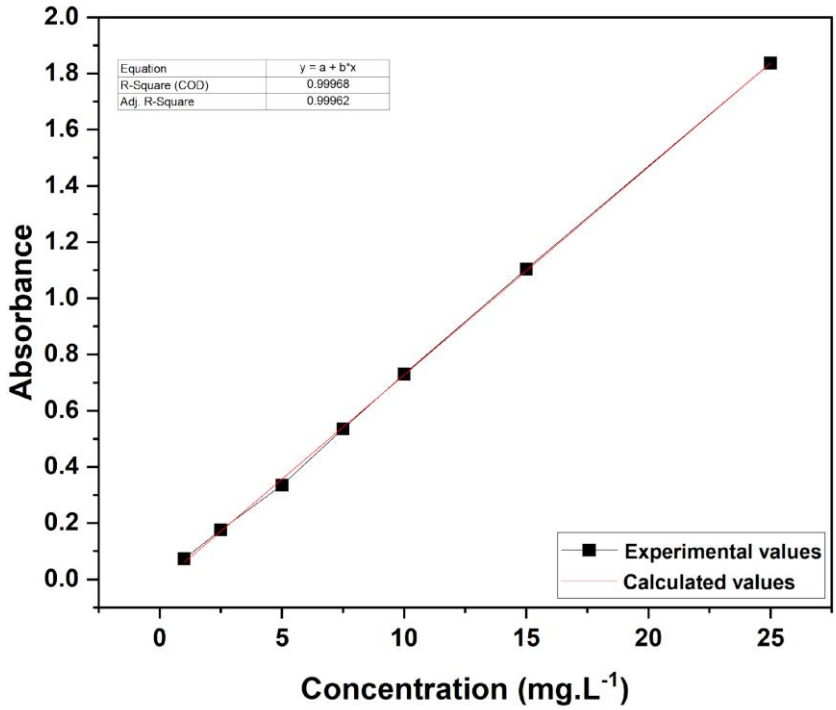

Figure 2. The calibration graph of the p-aminobenzoic acid derivative API.

The absorbance value of the saturated drug solutions at different mass fractions of PG in the PG+2-propanol non-aqueous binary mixtures were measured with UV-Vis spectrophotometer. Each mass fraction was prepared with

different dilution ratios and given in Figure 3. The UV-Vis maximum of saturated drug solutions was obtained at 299 nm as shown in spectrum.

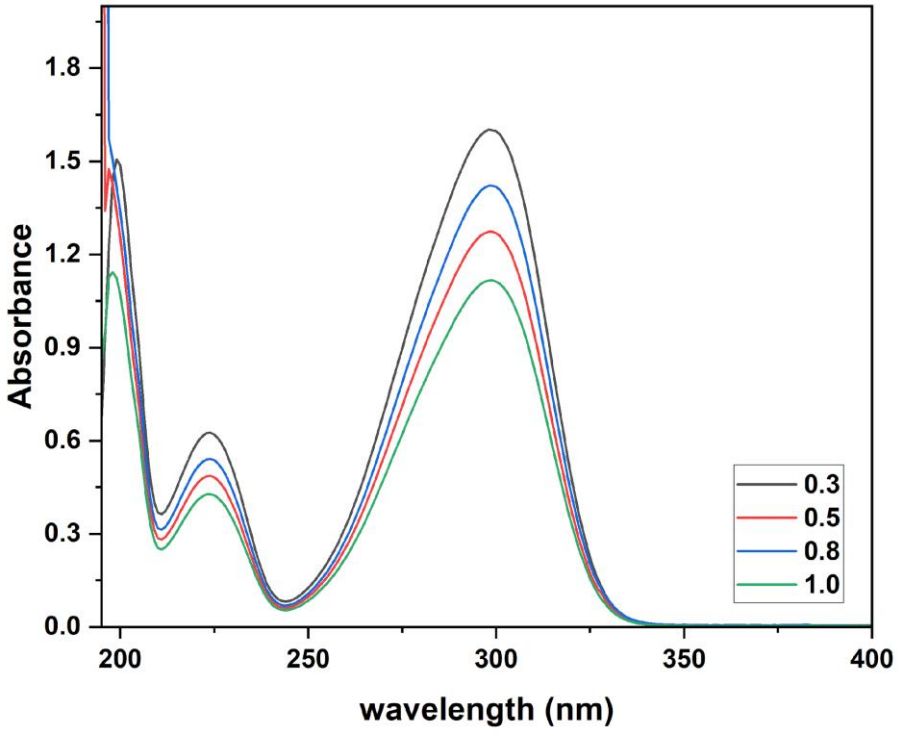

Figure 3. UV-Vis spectrum of saturated drug solutions in the PG+2-propanol non-aqueous binary mixtures.

The results of experimentally determined solubility values of p-aminobenzoic acid derivative API in molarity scale are given in Table 2.

XRPD Analysis

The characterization tests of the p-aminobenzoic acid derivative API equilibrated in saturated solutions were conducted using XRPD analyses, as detailed in the literature by Foroughi et al. (Foroughi et al., 2023). The XRD patterns for both the raw and equilibrated p-aminobenzoic acid derivative API in PG and 2-propanol non-aqueous binary mixtures are presented in Figures 4 and 5. The XRPD analysis indicated that the characteristic peaks for the raw drug material and the residuals from the PG and 2-propanol binary solvent mixtures were similar. These results suggest that the crystallinity of the API remained unchanged, with no evidence of polymorphic transformation occurring during the dissolution process in the investigated binary mixture system.

Figure 5. XRPD pattern of equilibrated p-aminobenzoic acid derivative in PG+2-propanol non-aqueous binary mixtures.

Conclusion

The solubility analysis of the selected p-amino benzoic acid derivative API was conducted for the first time in non-aqueous binary mixtures at a temperature of 310.15 K. The minimum solubility value was found to be 9.10 (±0.44)×10^{-3} mol/L in neat 2-propanol, while the maximum solubility value was 2.34 (±0.06)×10^{-1} mol/L in neat PG at the studied temperature. XRPD characterization tests of both the raw API and the saturated API in PG+2-propanol binary mixtures showed that the crystallinity of the API remained unchanged. There was no polymorphic transformation occurring during the dissolution process in the PG + 2-propanol non-aqueous binary mixtures. Additionally, the density of the saturated drug solution was determined experimentally.

Keywords: Melamine Urea Formaldehyde, Wood Adhesive, Particleboard, Low Formaldehyde Emission.

Aim

The wood-based panel industry extensively utilizes resins such as urea formaldehyde (UF), melamine formaldehyde (MF), phenol formaldehyde(PF) and melamine urea formaldehyde (MUF) due to their excellent adhesive properties and cost-effectiveness. However, these resins are well-known sources of formaldehyde emissions, which pose significant environmental and health concerns. This study aims to investigate the modification of MUF resin with silane compounds to reduce formaldehyde emissions from wood-based panels without compromising their mechanical and thermal properties. Specifically, the study focuses on evaluating the effects of silane incorporation at varying concentrations on the properties rheological and termal of MUF resin. Besides performance of particleboards produced with these modified resins.

Material and Method

In this study, control MUF resin was synthesized using melamine, urea, and formaldehyde chemicals, following established industrial procedures. Silane modification was performed by adding bis(trimethoxysilylpropyl)amine (BTMSPA) at three different weight ratios: 1%, 3%, and 5%. The modified and unmodified resins were then used to manufacture three-layer particleboards with a thickness of 8 mm. The pressing process was conducted at 200 °C for 4 minutes to ensure proper curing and bonding.
Physicochemical characterization of the resins included density measurements and rheological analyses. Viscosity and gelation time were determined using a rheometer under controlled temperature conditions. Thermal properties were assessed by differential scanning calorimetry (DSC) and thermogravimetric analysis (TGA). Mechanical properties of the particleboards were evaluated through internal bond strength (IB), modulus of elasticity (MOE), and modulus of rupture (MOR) tests, following relevant standards.
Formaldehyde emissions from the particleboards were quantified using the perforator method in compliance with TS EN 120 standard. In this method, samples were heated in toluene to release formaldehyde, which was then absorbed in distilled water and measured by photometric analysis(Popović et al., 2020).

Findings

The incorporation of silane compounds at 1%, 3%, and 5% ratios into Melamine Urea Formaldehyde (MUF) resin resulted in measurable changes in resin characteristics. Among these changes, rheological behavior was particularly influenced by the presence of silane, providing insight into the interactions between the silane compounds and the resin matrix. The rheological analysis of MUF resins modified with bis(trimethoxysilylpropyl)amine (BTMSPA) revealed a clear trend of increasing viscosity as the silane content increased from 1% to 5%. This increase in viscosity suggests that silane molecules interact with the resin matrix, possibly through the formation of siloxane bonds or hydrogen bonding with urea and melamine functional groups. Such interactions reduce the mobility of polymer chains, leading to a more viscous resin system. This behavior is consistent with previous studies that report silane compounds acting as coupling agents, enhancing cross-link density and molecular entanglement in thermosetting resins (Lee et al., 2022; Kumar et al., 2023). The higher viscosity may also influence the resin's flow during pressing, potentially affecting the impregnation of wood particles and ultimately the panel's mechanical properties.

Gelation time measurements showed a progressive extension with increasing silane content. This indicates that silane modification slows down the curing kinetics of MUF resin. The delay in gelation may be attributed to the steric hindrance introduced by silane groups or the alteration of reactive sites available for cross-linking. DSC thermograms supported this interpretation by exhibiting shifts in the exothermic curing peaks toward higher temperatures and broader peak profiles as silane concentration increased. These changes reflect a modified polymerization pathway, possibly involving the formation of siloxane networks that compete or cooperate with traditional formaldehyde-based cross-links. Such modification of curing behavior can be advantageous by providing a more controlled curing process, reducing internal stresses and defects in the final particleboard (Zhang et al., 2021).

Thermogravimetric analysis (TGA) demonstrated that the thermal stability of MUF resins was maintained after silane incorporation. The mass loss profiles exhibited typical multi-step degradation patterns corresponding to the decomposition of organic resin components. Importantly, no significant reduction in the onset decomposition temperature was observed, indicating that silane modification does not compromise the thermal resistance of the resin. This is critical for industrial applications, where particleboards are exposed to elevated temperatures during both pressing and service life. Furthermore, differential scanning calorimetry (DSC) results confirmed that the incorporation of silane did not negatively impact the curing kinetics of the resin, supporting the suitability of this modification for practical processing conditions.

Mechanical testing of particleboards bonded with silane-modified MUF resins revealed that internal bond strength (IB), modulus of elasticity (MOE), and modulus of rupture (MOR) values were comparable to those of boards produced with unmodified resin. This indicates that the structural integrity of the panels was preserved despite the chemical modification. The preservation of mechanical properties is essential to ensure that environmental benefits from reduced formaldehyde emissions do not come at the cost of product performance. The slight increase in viscosity and extended curing time did not negatively impact resin penetration or bonding quality. Similar findings have been reported in recent literature, where silane-modified adhesives maintained or improved mechanical properties in wood composites (Kumar et al., 2023).

The most significant outcome of this study is the reduction in formaldehyde emissions from particleboards bonded with silane-modified MUF resins. Formaldehyde release decreased progressively with increasing silane content, with even 1% silane addition producing measurable emission reductions. This effect is likely due to the chemical interaction between silane groups and free formaldehyde molecules, possibly through the formation of stable bonds that immobilize formaldehyde within the resin matrix. Additionally, silane-induced changes in curing kinetics and cross-link density may reduce the availability of free formaldehyde by promoting more complete polymerization. The perforator method results align with growing research emphasizing the role of resin modification in mitigating indoor air pollution and health risks associated with formaldehyde exposure (Zhang et al., 2021).

Conclusion

In conclusion, modification of Melamine Urea Formaldehyde (MUF) resin with silane compounds offers a very promising strategy to effectively reduce formaldehyde emissions from wood-based particleboards while preserving critical resin and panel properties. The study showed that silane addition increased resin viscosity and extended gelation time, indicating modified curing dynamics that remained compatible with industrial processing requirements. Thermal analyses confirmed that these modified resins maintained their thermal stability and ensured their suitability for high-temperature pressing used in particleboard production. Formaldehyde emission measurements show further reductions in emissions with increasing silane addition amounts. Considering the classification of formaldehyde as a human carcinogen and its role as a major indoor air pollutant, reducing its emissions is essential for consumer safety and regulatory compliance. This silane modification approach not only addresses these environmental and health concerns, but also aligns with global trends toward sustainable materials and green chemistry in the wood panel industry, providing a scalable and effective solution to meet increasingly stringent environmental standards and improve indoor air quality.

Keywords: Acinetobacter Baumannii, adeRS, Docking, Drug Target, Efflux Pump.

Aim

The objective of study is to identify novel inhibitors targeted to the two-component regulatory system in Acinetobacter baumannii called adeRS that regulate gene expression of adeABC efflux pump. AdeS is a transmembrane histidine kinase that senses signal and transmits to the adeR response regulator that initiates the transcription of adeABC efflux pump (Figure 1) (Wimalasekara, White, & Kumar, 2025). The adeABC plays a critical role in reducing antibiotic susceptibility to multiple type of drugs including aminoglycoside, β-lactam, tetracycline, fluoroquinolone, chloramphenicol, trimethoprim and tigecycline (Ciftci & Asik, 2011). Thus, our study targets the adeABC regulators to inhibit antibiotic resistance in A. baumannii. To achieve this, molecular docking and molecular dynamics (MD) simulations were performed to screen and evaluate potential inhibitors.

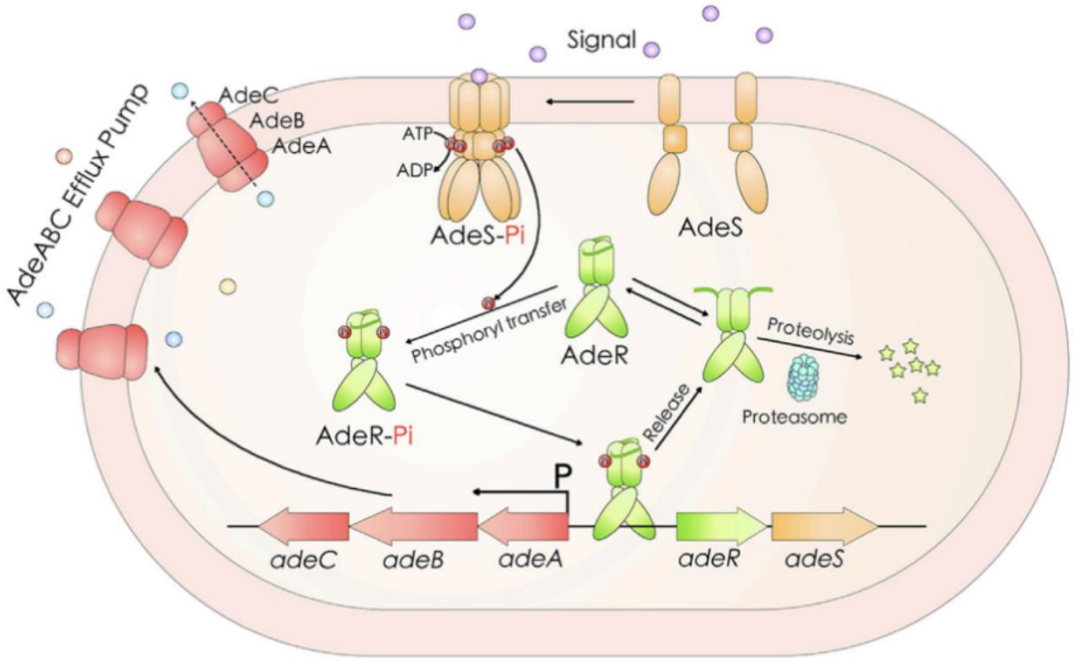

Figure 1. Schematic representation of the regulation of AdeABC gene expression. A signal from the environment causes autophosphorylation of the AdeS histidine kinase, and then AdeR becomes phosphorylated. Phosphorylated AdeR binds to a specific DNA sequence between the adeA and adeR promoter regions and initiates gene transcription (Ouyang et al., 2021).

Material and Method

To address this objective, ATP-binding domain of adeS (residue 204-357) and DNA binding domain of adeR (residue 139-247) were selected as receptor through in-silico studies. Both structure of adeS and adeR were solved (7CCH.PDB and 5X5L.PDB, respectively); however, some of the regions are missing (residue 298, 299, 307-319 in adeS and residue 159,199, 240-247 in adeR) (Wen et al., 2017, Ouyang et al., 2021). Therefore, we used

AlphaFold3 web server to model kinase domain of adeS (residue 139-357) with ATP and DNA-binding domain of adeR (residue 139-247) with HOLO state. Before virtual screening, we performed 1μs MD simulations of adeS to check its dynamics and stability with ATP and of adeR itself to obtain its APO state. There are studies in the literature showing that adeR mutations increase the expression of adeABC. The position of the mutations reported in these studies within the adeR protein have been examined. Among the reported mutations, only L192R and E291A are in the DNA-binding region targeted in this project (Yoon, Courvalin, & Grillot-Courvalin, 2013, Lari, Ardebili, & Hashemi, 2018). Therefore, these two mutations will be included in the molecular screening calculations. To understand whether there are structural changes in adeR due to these two mutations, 1 μs simulations were performed for each mutation. All systems were prepared in CHARMM-GUI web server (Jo, Kim, Iyer, & Im, 2008). Their atom parameters were generated with CHARMM36m force-field (Huang et al., 2016). All systems were run with NAMD3.0 simulation package (Phillips et al., 2020). Then, we clustered the trajectories from each system to obtain dominant structure to be used in molecular docking simulation. For virtaul screening, we applied a high-throughput screening of 3.3 million molecules retrieved from the ZINC20 database using GNINA, which is a deep learning-enhanced version of AutoDock VINA, where binding poses are generated similarly to AutoDock VINA, but scored using a CNN-based deep learning framework (McNutt et al., 2021). Molecules that are ranked in top-10K for GNINA pose score results were selected and redocked with GlideXP (Friesner et al., 2006). The top 200 molecules were clustered using the 'fingerprint clustering' method with the RDKit module, and a single representative molecule was selected for each cluster. In the final step, their ADME properties were assessed using QikProp. Among the ADME properties, molecules having higher bioavailability were selected and their dynamics in the binding site were tested performing 100ns MD simulation with Desmond. In the final stage, binding affinities were evaluated with thermal_mmgbsa.py on the last 20ns trajectories of the MD simulations.

Findings

In the first stage of our study, the structures of AdeS and AdeR were refined using molecular dynamics (MD) simulations. Each system was initiated with three different initial velocities. To analyze the simulation results, root mean squared deviation (RMSD) analysis was performed. Additionally, the RMSD of the ATP molecule was also calculated. In ATP-bound AdeS simulations, the ATP molecule remained stable in all systems. The RMSD value of the protein stabilized after deviating approximately 3.5 Å from the initial state (Figure 2). In wild-type and mutant AdeR simulations, the RMSD value stabilized after deviating around 1.5 Å from the initial position (Figure 3). In the clustering analysis, frames from AdeS simulations were divided into 100 clusters, while frames from AdeR simulations were grouped into 10 clusters. The conformation of AdeR in aqueous solution was compared with its DNA-bound conformation. In the AdeR crystal study, both the DNA-bound and unbound forms of the AdeR protein were resolved and structurally aligned. When we aligned the most dominant cluster we obtained for AdeR with the initial structure, we observed similar results to the conformationally changing regions suggested by the reference (Figure 4A-B). Normally, clustering calculations were planned to be done for 10 clusters. However, since the loop structure in the ATP binding region is very flexible, 10 clusters did not provide sufficient resolution. Therefore, clustering was performed for 100 clusters. To determine the protein structure to be used in docking calculations, not only the most dominant cluster was considered, but also the structure with the best potential for molecule binding was selected. For this, the representative structures of each cluster were docked with a randomly selected set of 5000 small molecules using the AutoDock Vina docking program. Based on the docking results, the structure that showed the highest average binding affinity and represented the cluster with the most frames was selected for docking calculations with 3.7 million molecules. As a result of these processes, 97 molecules in the AdeS ligand set and 84 molecules in the AdeR ligand set were tested using molecular dynamics simulations to evaluate their stability in the binding site. The binding affinities of molecules that remained stable in the binding site throughout the simulation were calculated. Finally, the 20 molecules with the highest binding affinities for AdeS and AdeR were suggested for experimental testing.

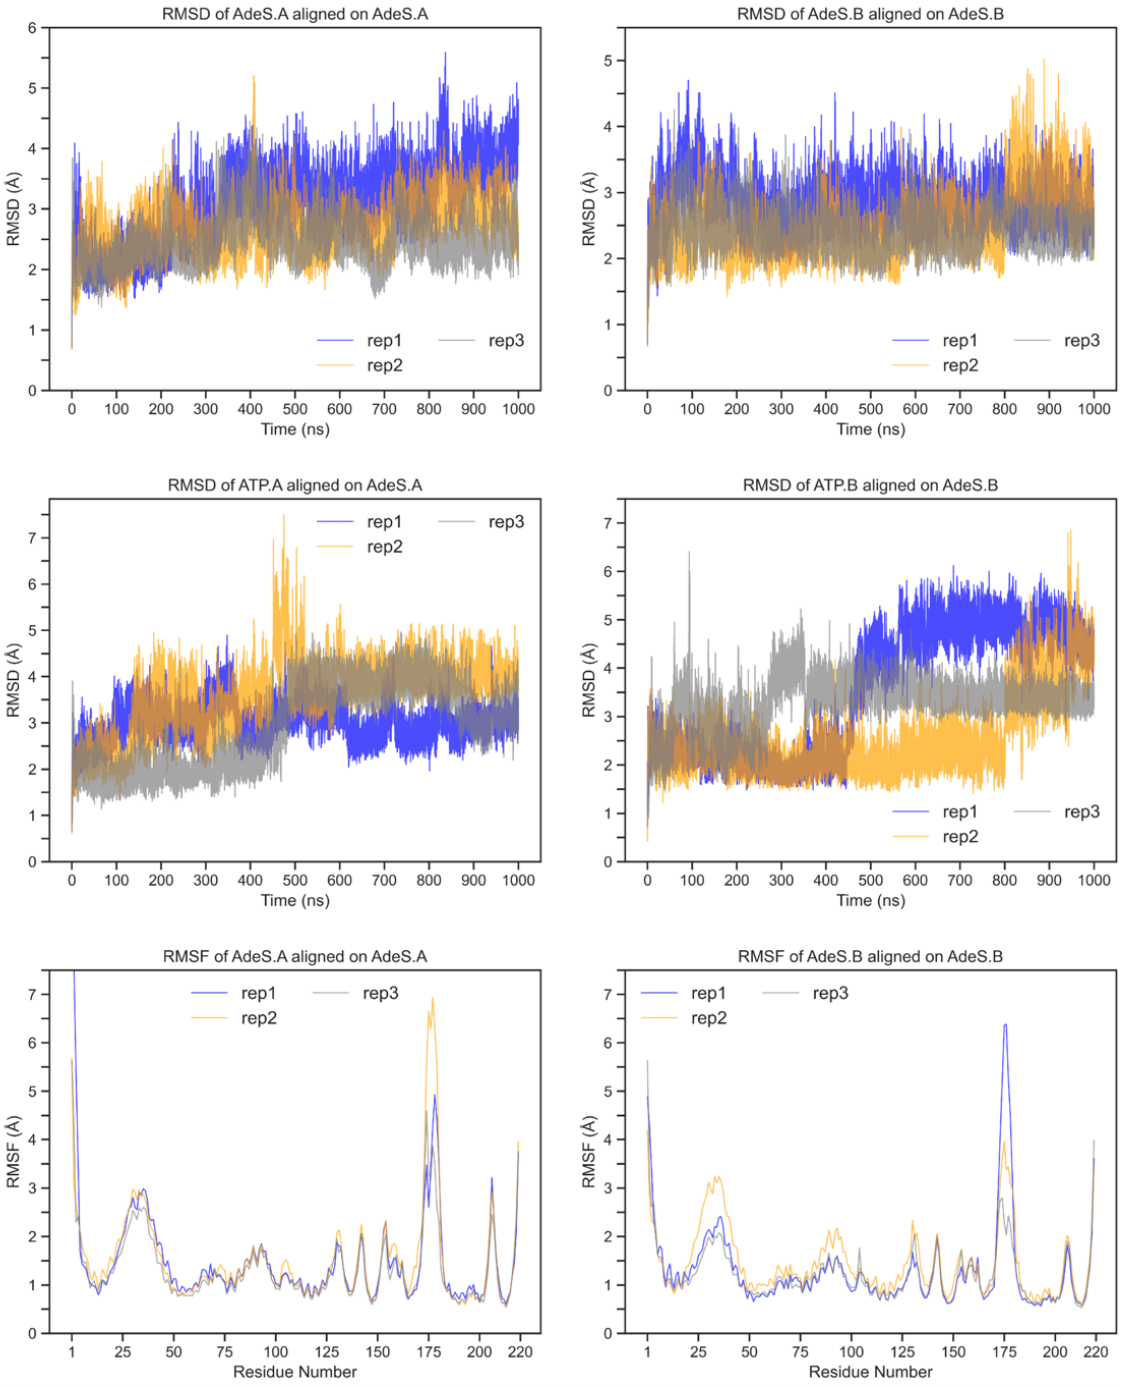

Figure 2. Frame Analysis of ATP-Bound AdeS Histidine Kinase.

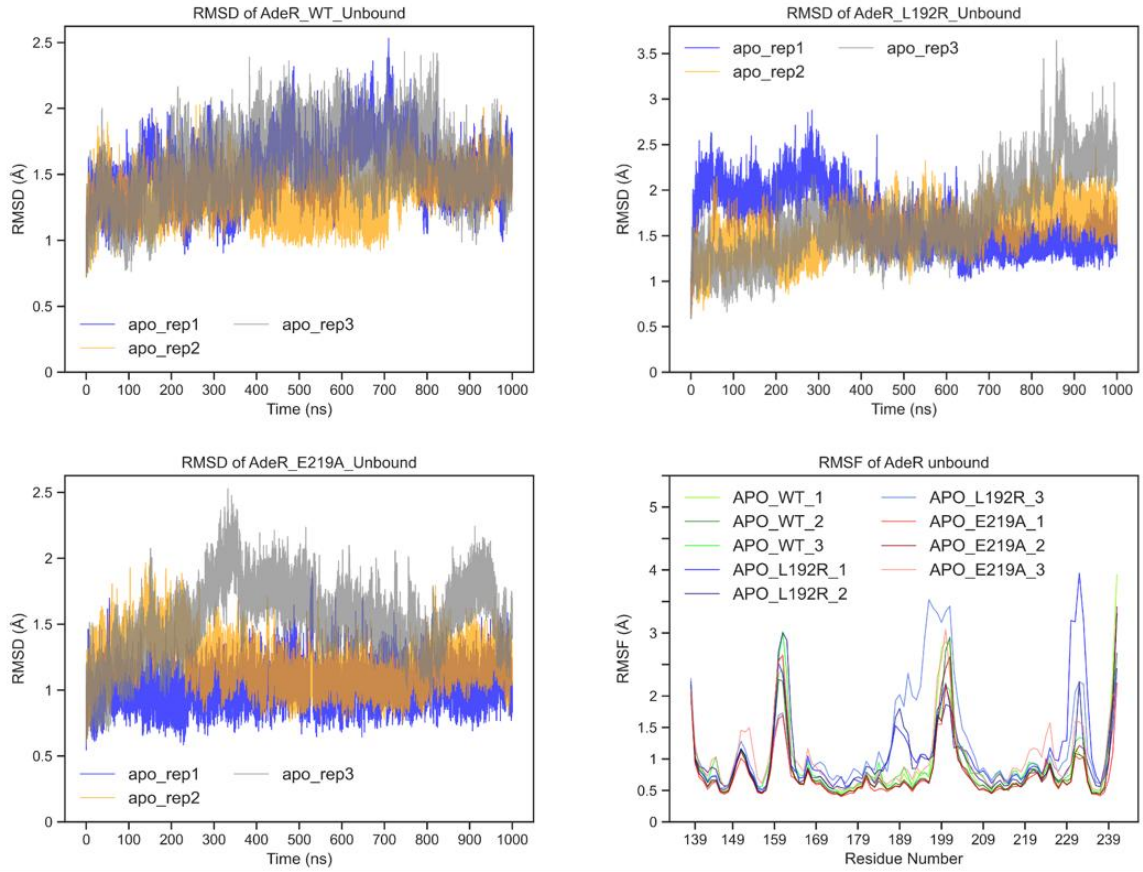

Figure 3. Frame Analysis of ATP-Bound AdeR Response Regulator.

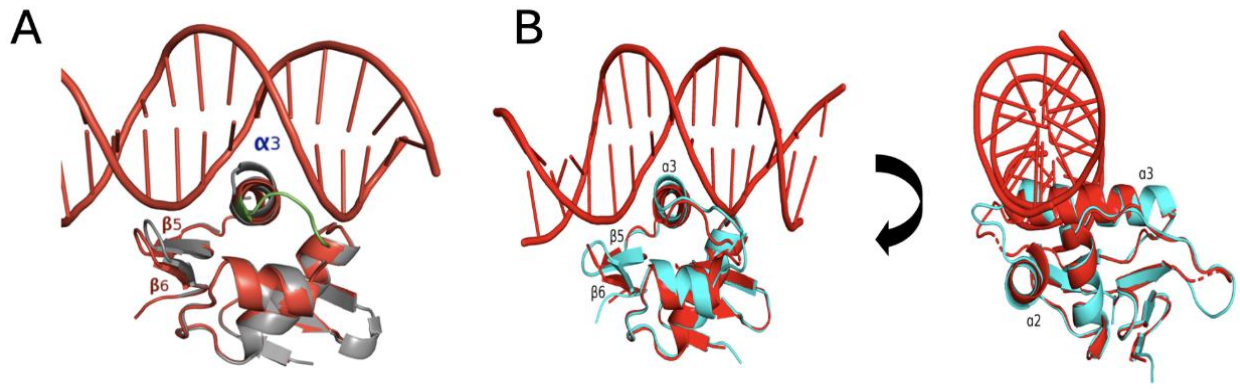

Figure 4. A) Structural Alignment of DNA-Bound and Unbound Forms of AdeR DBD Protein Red: DNA-bound structure, Grey: DNA-unbound structure (Wen et al., 2017). B) Structural Alignment of DNA-Bound AdeR DBD Crystal Structure (Red) with the First Cluster Representative Structure (Cyan).

Conclusion

Two-component regulatory systems play a crucial role in bacterial resistance to antibiotics (Scoffone et al., 2025). In this study, we identified potential molecules that can inhibit the AdeRS two-component proteins, which regulate the expression of the adeABC efflux pump, using in-silico methods. The approach aims to inhibit adeABC expression, allowing existing antibiotics to be used more effectively. As a result of our study, we identified potential

inhibitors against both proteins. As a future direction, our collaborators will conduct experimental testing on the suggested molecules.

Keywords : CHK2, DNA Repair, Molecular Dynamics Simulations, Mutations, Tumor-Suppressing Gene.

Aim

Cancer remains a significant global cause of mortality, highlighting the importance of understanding the complex molecular mechanisms that drive its development. The Checkpoint kinase 2 (CHEK2) gene is a critical target in cancer prevention, as it plays a pivotal role in maintaining genomic stability by regulating DNA repair processes and cell cycle checkpoints. Although mutations in CHK2 protein have been linked to a variety of cancers, many details of its catalytic cycle are still unclear and require further investigation. Understanding the molecular details of CHK2's function and dysregulation could lead to novel targeted therapeutic interventions and enhanced cancer management strategies.

As a key tumor-suppressing gene, CHEK2 encodes the vital serine/threonine kinase protein CHK2, essential for cell cycle checkpoint control and DNA repair pathways. Its role is crucial in preserving genomic stability and protecting against DNA damage. Key structural components of CHK2 include the N-terminal SQ/TQ cluster domain (SCD), a central forkhead-associated (FHA) domain, and the C-terminal serine/threonine kinase domain (KD). The SCD contains phosphorylation sites important for CHK2's substrate recognition. The FHA domain enables CHK2 to sense and respond to DNA damage signals, while the KD is responsible for phosphorylating target proteins (Ung, 2018).

Mutations in CHK2 have been linked to various cancers, such as breast cancer, underscoring its significant role across multiple cancer types. Such mutations or losses can impair CHK2's normal function, diminishing the cell's capacity to respond effectively to DNA damage, which can lead to uncontrolled cell growth and cancer development (Zhou, 2000). Understanding how CHK2 dysfunction contributes to cancer is important for developing targeted therapies and strategies to fight tumorigenesis.

This study investigates a set of CHEK2 gene variants in the KD to assess their potential mutational impact on CHK2 protein structure and dynamics through all-atom molecular dynamics simulations. Five mutations, namely G306A (Boonen, 2022), E351D (Richards, 2015), S356L (Lim, 2023), D409V (Branco, 2018), and V415I (White, 2022), were selected for in silico analysis. The primary aim was to determine how these mutations influence CHK2 dynamics and structural integrity, as disruptions in CHK2 function could impair DNA repair and cell cycle control, ultimately increasing breast cancer susceptibility. By investigating these mutations, this work seeks to deepen our understanding of CHK2's role in tumor suppression and provide insights into potential targeted therapies for individuals carrying CHEK2 mutations.

Material and Method

To obtain active wild type (WT) CHK2, starting structural model was constructed by combining structural information derived from the crystal structures with PDB IDs 3I6U (Cai Z. C., 2009) and 2CN5 (Oliver, 2006). Residues S379, T383, T387, and T389 within the CHK2 activation loop were phosphorylated. Additionally, the ADP molecule, two Mg^{2+} ions, and crystal water molecules derived from the 2CN5 structure were included in the system. Mutant structures containing G306A, E351D, S356L, D409V, and V415I were prepared using the Mutator plugin in VMD. All structures were subsequently solvated in a TIP3P water box, applying padding dimensions of 28 Å along the x-axis, 20 Å along the y-axis, and 28 Å along the z-axis. Systems were neutralized, and ion concentrations were adjusted to 210 mM KCl and 20 mM NaCl. All system preparation steps were performed using VMD (Humphrey W, 1996).

To evaluate the structural dynamics of CHK2 and the effects of the selected mutations, MD simulations were performed using NAMD 3.0 (Phillips JC, 2020)and the CHARMM36 all-atom force fields (Best, 2012). Two femtosecond time step was employed, and the SHAKE algorithm was applied to constrain bonds involving hydrogen atoms. Long-range electrostatic interactions were treated using the Particle Mesh Ewald (PME) method. All simulations were conducted under NPT ensemble conditions, with temperature and pressure held constant using a Langevin Nosé-Hoover approach.

Prior to production runs, systems were minimized and equilibrated in multiple steps. Initially, harmonic restraints were applied to the C_α, ADP, and Mg^{2+} atoms, allowing only water molecules to move freely. Following an initial unconstrained minimization, the heavy atoms of the protein, ADP, and Mg^{2+} were fixed, and the water molecules were equilibrated for 2 ns. Subsequent equilibration involved gradually releasing harmonic restraints on the C_α, ADP, and Mg^{2+} atoms. A final equilibration with no restraints was carried out before initiating production runs of 300 ns for each system.

To assess protein structural deformations throughout MD simulations, Root Mean Square Deviation (RMSD) (Phillips J. C., 2005) analysis was performed. RMSD quantitatively measures the average displacement of atoms between the structure at a given simulation time point and a reference structure. The starting structural model was used as reference structure. It is calculated as:

$$\mathrm{RMSD}(t) = \sqrt{\frac{1}{N}\sum_{i=1}^{N} \left(r_i(t) - r_i(0)\right)^2}$$

where N is the total number of atoms, $\mathbf{r}_i(t)$ is the position of atom i at time t, and $\mathbf{r}_i^{ref}$ is the position of atom i in the reference structure.

The flexibility of individual residues was probed via Root Mean Square Fluctuation (RMSF) (Karplus, 2002) analysis. RMSF provides a measure of residue-wise flexibility by quantifying fluctuations of atomic positions around their average positions throughout the simulation. It is calculated using the following formula:

$$\mathrm{RMSF} = \sqrt{\frac{1}{T}\sum_{t=1}^{T} \left\| r_i(t) - \langle r_i \rangle \right\|^2}$$

where T is the total number of trajectory frames, $\mathbf{r}_i(t)$ represents the position of residue i at time t, and $\langle \mathbf{r}_i \rangle$ is the average position of residue i across the entire trajectory.

In RMSD and RMSF calculations, only the coordinates of alpha carbon (C_α) atoms were used.

Findings

For each mutant, two 300 ns long MD simulation runs were carried out. Each simulation trajectory was independently analyzed for RMSD and RMSF values. RMSD analysis indicated that three mutants, G306A, D409V, and V415I, exhibited higher RMSD values relative to the WT, as shown in Figure 1. In these trajectories, the mutants remained above the WT RMSD curve, suggesting increased conformational mobility and structural instability.

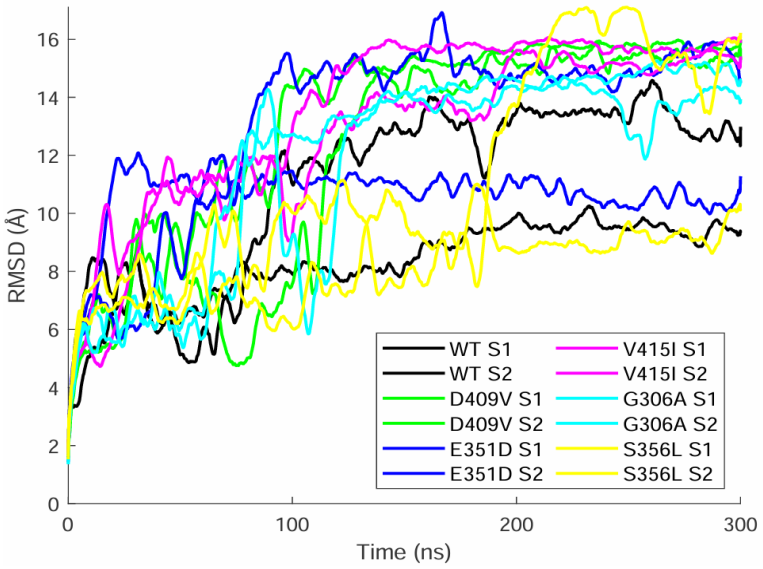

Figure 1. RMSD Comparison of Wild-Type and Mutant CHK2 Proteins.

In the 205-270 amino acid range, all mutations exhibit lower RMSF values compared to the WT (Figure 2). This region includes the Gly-rich region (residues 227–232), which is considered structurally significant. Additionally, in the 370-405 amino acid range, our analysis shows that the RMSF values of all mutations are noticeably higher than those of the WT. This region contains the A-loop (residues 368–394), which plays a crucial role in the protein's. Visual representations generated with VMD were added to the figure to highlight these critical regions.

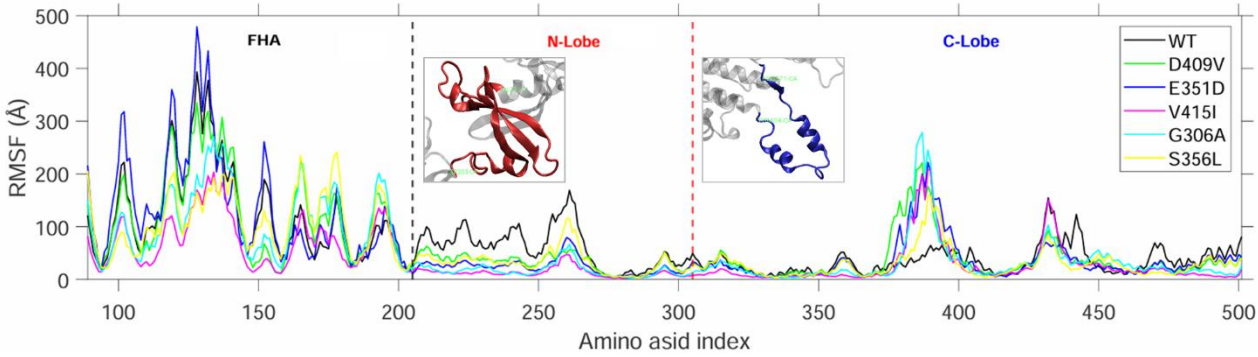

Figure 2. RMSF Values for Mutants and Wild Type by Amino Acid Index.

Conclusion

In summary, MD simulations of CHK2 revealed noteworthy structural and dynamic alterations resulting from five specific mutations within the kinase domain. RMSD analysis demonstrated that mutations G306A, D409V, and V415I induce notable conformational changes, potentially leading to structural deviations compared to the WT protein. These structural changes could compromise the stability required for CHK2's tumor suppressor functions. In addition to those structural changes shown by RMSD analysis, RMSF analysis further showed that these mutations affect protein dynamics, highlighting distinct fluctuations in the residues 205–270 and residues 370–405, both critical areas for CHK2's catalytic activity and regulatory role.

Collectively, these findings predict that the studied mutations could impact both the structural integrity and dynamic behavior of CHK2, potentially impairing its ability to regulate cell cycle checkpoints and respond effectively to DNA damage. Consequently, these mutations may increase susceptibility to cancer. This study

provides valuable insights into the functional consequences of CHEK2 variants and lays groundwork for future research into targeted therapies aimed at restoring CHK2's tumor-suppressive activities in affected individuals.

Keywords: Energy Saving, RPL, Topology, Wireless Sensor Networks, Cooja.

Aim

Wireless Sensor Networks (WSN) have been a very fast-growing practice. WSNs installed in difficult-to-access locations feature many sensors. Sensors in WSNs are expected to be able to set up their network, route packets, maintain network continuity, and self-repair the network against a change. The RPL protocol has been developed to perform these operations under the constraints of limited memory and processing power, a lossy wireless environment, most importantly, a limited energy supply. The battery life of the sensors determines the life of the network. The ability to save battery regardless of the source is a significant and critical issue in wireless sensor networks. What effect does topology formation have on energy consumption; we investigated this with Contiki Cooja Simulation. We studied energy consumption over different topics.

Material and Method

Wireless sensor networks are one of the most important structures of IoT systems. With the RPL protocol, sensors reach the main sensor directly or through neighboring sensors, automatically forming a network.A working group has been established by the IETF organization on the connection and transport of wireless sensor networks to the Internet. The goal of this working group, called 6LoWPAN, was to make low-power personal wireless area networks compatible with the IPv6 architecture. The 6LoWPAN structure is built on the 802.15.4 protocol previously standardized by the IEEE.With the features brought to the standard and stack structure, IEEE 802.15.4 compatible wireless sensor structures can communicate with the internet. IEEE 802.15.4 When verifying physical and data link layers, which are the first and second layers in the OSI architecture, the 6LoWPAN adaptation layer also acts as an interface between these two layers and the network layer. Wireless sensor nodes are by their very nature unlikely to work with existing routing protocols. For this reason, the IETF has adopted the IPv6 Routing Protocol for Low-Power and Lossy Networks (RPL) standards for low-power and lossy networks with another working group called ROLL (Routing over Low Power and Lossy Links) developed for IoT systems.
The main function of the RPL protocol is to enable the routing of data traffic between wireless sensors and the Internet cloud. In doing so, it also considers the features of wireless sensors such as low power consumption and loss. In RPL architecture, Objective Function (OF) methodology determines how RPL nodes translate one or more metrics into ranks, and how to optimize and select routes in a network. In the literature, there are objective functions considering several metrics like OF_0 with hop count, Minimum Rank with Hysteresis Objective Function (MRHOF) with Expected Number of Transmission (ETX) (known, OF_1).
The most critical issue in Wireless Sensor Networks is energy restriction. The battery life of the sensors determines the life of the network. It seems impossible to interfere with the many sensors installed in difficult geographies. Therefore, applications that will reduce energy consumption independently of the battery become important. The first step in networking is topology formation. In our study, we considered topology to examine its effect on energy consumption. For each sensor, the average power and energy consumption of the CPU, LMP, Rx, and Tx operating modes were calculated separately. Both single-hopping and multi-hopping topologies of the sensors trying to reach the main sensor were evaluated. The random and circular topologies were examined under the same conditions

and their average power and energy consumption were obtained by the Cooja Simulation, which we ran on Contiki-3.0, which we ran on.

Findings

In the figures, the main sensor (UDP-sink) is depicted in dark green, while the surrounding sensors (UDP-senders) are shown in yellow. The same number of sensors were arranged to form two distinct network topologies, and their energy consumption was analyzed during topology formation.
Each figure illustrates the spatial distribution of the main sensor and the other sensors. Additionally, the coverage area for each sensor is indicated in green. Accompanying tables present the average power consumption and calculated energy usage for each numbered sensor.
The average power and operational time values were derived from simulations conducted in Cooja, using Contiki OS version 3.0. Energy consumption was calculated by multiplying the average power by the corresponding active time. To ensure consistency across comparisons, sensor numbering remained identical between the two topologies, and each simulation ran for a duration of 20 minutes. The simulation parameters are summarized in Table 1.

Simulation Time	20 Minute

Circular Topology and Random Topology

A total of sixteen sensors (UDP-senders) were successfully deployed around a central main sensor (UDP-sink) without clustering too closely to one another. These sixteen sensors were arranged in two distinct configurations: one with a circular layout and the other with a random distribution within the coverage area of the main sensor. These two resulting topologies are illustrated in Figure 1 and Figure 2, respectively.

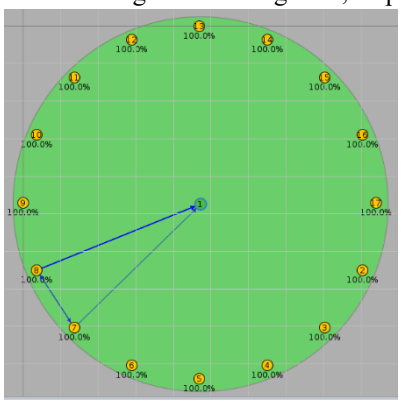

Figure 1. Circular Topology.

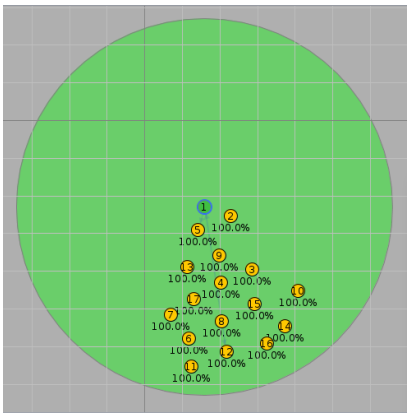

Figure 2. Random Topology.

The average power consumption in the CPU, LPM (low-power mode), Rx (receive), and Tx (transmit) modes, along with the time spent in each mode, was obtained from the Cooja simulation. Energy consumption was calculated individually for each operating mode, and the total energy consumption per sensor was determined by summing these values. This approach allowed for the total energy expenditure of each topology to be quantified. As presented in Table 2 and Table 3, the total energy consumed in the random topology was 2832.07 mJ, whereas the circular topology consumed 2603.28 mJ.

Table 2. Random topology power-energy consumption.

Sensor	CPU Power	LMP Power	Rx Power	Tx Power	Power	Energy

17	0.459	0.150	0.504	0.053	1.167	183.03
				Total	**19.18**	**2832.07**

Since sensors constantly communicate to establish and maintain the network, as well as to detect changes, sensors positioned very close to each other experience increased communication, which leads to higher energy consumption.

Circular Wide Topology and Random Wide Topology

In the initial circular and random topologies examined, the network was established without requiring multi-hop communication between sensors within the main sensor's range. In this study, the coverage area was expanded, and the network was designed to require four or more communication hops. The corresponding topologies are shown in Figures 3 and 4. As in the previous section, energy consumption was calculated for these configurations. As shown in Tables 4 and 5, the energy consumption for the random wide-area topology was 4101.35 mJ, whereas the circular wide-area topology consumed 3911.24 mJ.

Conclusion

Randomly sequenced sensors tend to increase energy consumption. In contrast, organizing sensors at relatively uniform, non-overlapping distances without placing them too close can reduce energy usage during network setup. This principle holds for both single-hop and multi-hop networks. Overall, circular topologies generally yield more favorable results in terms of energy efficiency. Carefully planning the deployment area and selecting the most suitable topology based on these findings can lead to significant energy savings. Future work could involve testing these configurations in real-world environments, as well as conducting a similar analysis for sensors equipped with additional security features.

Keywords: Predictive Error Compensation, Overfitting, Stock Price Forecasting, Time Series.

Aim

Finance is one these industries that through the improvement of predictive abilities machine learning has impacted many industries. An important financial application, stock price forecasting, is still challenging because market data is dynamic, unpredictable, and non-linear. The Predictive Error Compensation Neural Network (PECNET) is feature extraction and fusion model for deep learning applications. PECNET combines iterative error compensation with wavelet-based feature extraction to deal with these kinds of issues. Considering stock market example, in non-linear and time-varying systems, no matter how good the method is, performance goes towards a convergence (Wolpert & Macready, 1997). That means it cannot exceed a certain level. The data used in train does not represent the model in its current state (Gama et al., 2014). Either the number of data according to time or the number of parameters needs to be increased (John, 2010). However, this time, for both cases, the number of parameters to be calculated, the total weight internal hyperparameter number leads to overfitting (Goodfellow et al., 2010). To use data without causing overfitting, PECNET works as a feature extractor for time series in different windows and as a fusion in increasing the number of different variables.

TSMixer, TimeGPT and Prophet models are among the prominent methods in financial time series forecasting. TimeGPT is effective in modelling long-term dependencies inspired by the transformer architecture and offers successful results in predicting volatile financial markets (Garza et al., 2023). On the other hand, TSMixer captures complex patterns with its multi-layer perceptron-based architecture, it is reported to achieve high accuracy rates in financial data sets (Ekambaram et al., 2023). Prophet maintains its resilience to irregularities in data sets thanks to its flexible modular, additive regression model structure developed by Facebook. It can explicitly model seasonal components and holiday effects (Taylor & Letham, 2018). Each of these models provides significant advantages in understanding the dynamic properties of financial time series thanks to their different methodological approaches. Comparative performance analysis reveals that model selection varies depending on the application context. In the study, their comparative performance is evaluated.

Material and Method

In this study we used stock market dataset for four major technology companies, Apple (AAPL), Microsoft (MSFT), Facebook (META), and Google (GOOGL). Each dataset consists of four different features. These are daily closing prices, trading volume, index values and price-to-earning (P/E) ratios. Three of these features obtained from Yahoo Finance (Yahoo, 2025) are closing price, volume, and index values. The fourth feature, price-to-earnings ratio is obtained from MacroTrends.net (Macrotrends, 2025). The dataset consists of approximately 8 years of data from January 2017 to December 2024.

Adding previous prediction errors as extra inputs or using recurrency in neural networks (NNs) is a traditional way of reducing prediction errors (Bao et al., 2017) (Montgomery et al., 2015). This increases training's weights size and needs to utilize extra training dataset for not being overfitted (Ustundag and Kulaglic, 2020). PECNET architecture includes this structure in an efficient way, and it gives better results when even the simplest ANN is used inside its structure. ANNs generally underperform when compared to LSTM in capturing temporal dependencies (Macit & Ustundag, 2023). But using ANN with PECNET approach substantially improves forecasting accuracy. It is evidenced by its significantly lower RMSE in drought forecasting experiment compared to LSTM (Ustundag and Kulaglic, 2020). It is also possible to apply PECNET to more advanced models instead of a standard ANN (Ustundag and Kulaglic, 2020).

The PECNET model architecture consists of multiple neural networks connected in a hierarchical manner to refine predictions iteratively. The first NN is our main predictor, which is named as primary network. It uses the closing price to make predictions for the next day. Based on this prediction, in our second neural network, we predict the closing price error of the next day. In this way, the second NN corrects the error of the first NN by removing the misleading of the first NN's predictions. PECNET can contain additional neural networks if information from other features is needed to be fused together. All predictions which are generated by the primary network and other subsequent networks lastly through compensated through an additional error compensation network. In Figure 1, the PECNET model's architecture is displayed.

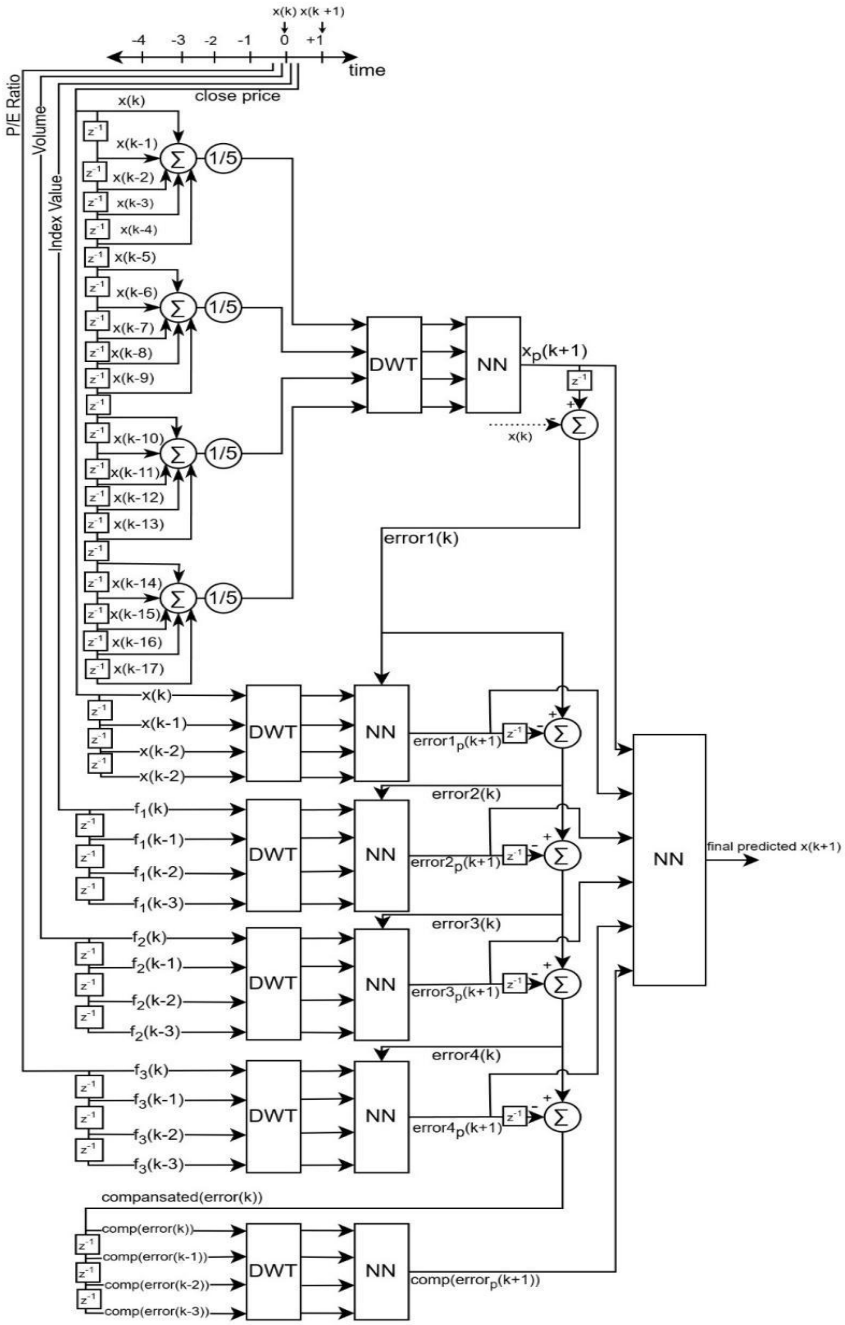

Figure 1. PECNET Model's Architecture.

In order to achieve the optimal feature extraction performance, each individual input variable undergoes their own preprocessing techniques that would consist of wavelet decomposition, successive windowing, and moving average smoothing. It also uses multiple error compensation at different stages, and features formed by fusing a number of stock indicators. The error compensation process also improves generalization since it systematically eliminates residual errors from previous predictions. This way minimizes the accumulation of noise and reduces overfitting.

Findings

The findings of several companies' closing price estimates were examined and, four separate models TimeGPT, TSMixer, Prophet, and PECNET were implemented using various input datasets. We used three distinct data sets. The first batch of data consists of the closing stock prices of four days in a row. The second batch of data consists of the closing stock prices of eight days in a row. The third dataset consists of four subsequent days and four weekly data. The models' outputs are the closing price for the following day.

In this experiment TimeGPT was overfitted, which remains a significant drawback, especially when trained on complex, high-dimensional financial data. TSMixer, in contrast, did not exhibit overfitting and demonstrated more generalization ability. Prophet was the closest model to PECNET in terms of evaluation metrics, but it demonstrated lower accuracy, with higher RMSE and MAE values. Through various techniques such as wavelet-based feature extraction, multi-stage error correction, and dropout regularization, PECNET successfully bridges the gap between statistical and deep learning models using neural network-based iterative compensation, multivariate financial indicators, discrete wavelet transform, and a supportive feature network. This ensures high prediction accuracy while addressing the modelling constraints and computational limitations of existing approaches. As seen in Table 1, PECNET achieves the lowest RMSE and an R^2 score of 0.96 demonstrating its superior generalization capabilities. When compared to TimeGPT, Prophet, and TSMixer, PECNET performs better.

Table 1. Test results for Microsoft Stock.

Model	Window Size	RMSE	MAE	R2
TimeGPT (19)	4 days	24.83	21.32	0.23
	8 days	28.66	23.12	0.20
	4 daily + 4 weekly	22.91	21.23	0.18
TSMixer (20)	4 days	7.53	6.26	0.91
	8 days	7.54	6.33	0.91
	4 daily + 4 weekly	6.94	5.57	0.93
Prophet (18)	4 days	5.10	3.95	0.93
	8 days	5.39	4.19	0.92
	4 daily + 4 weekly	5.15	4.02	0.94
PECNET	4 days	4.10	2.87	0.96
	8 days	4.90	4.08	0.93
	4 daily + 4 weekly	2.81	2.01	0.96

Conclusion

PECNET showed better results than the compared models. The findings showed that while TimeGPT encounter significant overfitting issues, TSMixer and Prophet did not overfit and exhibit stable prediction performance. TimeGPT's prediction accuracy is reduced when applied to unseen data. This is highlighting its inability to generalize effectively. Although Prophet and TSMixer avoiding overfitting, their prediction performances are worse than PECNET, which shows higher RMSE and MAE values.

PECNET superior performance can be attributed its ability to capture both short-term price volatility and long-term market trends, with it is Discrete Wavelet Transform (DWT) and hierarchical feature extraction mechanisms. It combines multiple time windows, exogenous financial indicators, and error correction layers to produce more precise and reliable forecasts than common models, which only use sequential time series inputs. These results indicate that the potential of PECNET as a powerful alternative to existing stock price prediction models, especially in high volatility and non-linearity environments. The findings shows that PECNET provides better prediction performance compared to state-of-the-art models with achieving lower RMSE and MAE values and higher R^2 scores. Finally, in light of these findings, we can say that PECNET is more successful than the leading models in the financial world.

A Gamified Hybrid Application for Sports Club Fans: Development and Implementation

Ozan Ust[a], Robbert Oomens[b], Esma Güneş Kaya[a]

[a] Triodor R&D Center, Software Engineering, Türkiye
[b] Azerion, Sports, Netherlands
o.ust@azerion.com

Keywords: Digital Platform, Fan Engagement, Gamification, Monetization, Sports Clubs.

Aim

The aim of this study is to develop a digital platform that allows sports clubs to create a digital ecosystem that can be specifically tailored to the needs of their communities. This platform, which will strengthen the bond between sports clubs and their fans, gathers various functionalities in a single center. With a wide range of interaction features such as ticketing, news, live match center, and sports merchandise store, clubs can connect with their fans in a more personal and interactive way. With the developed platform, sports clubs can establish a closer relationship with their fans, increase their revenues through in-app purchases and improve the fan experience by using available historical data. With the digital platform that resulted from this project, an end-to-end integrated fan engagement tool and revenue model is offered to sports clubs.

Material and Method

Sports is a field that appeals to large audiences by becoming an indispensable part of daily life. The sports industry consists of components such as professional sports clubs, media, sponsorship and advertising, fan spending, etc. This industry is undergoing a significant transformation due to technological innovations and changing consumer behavior [1]. Sports clubs are increasingly emphasizing the use of digital platforms to increase their revenues and ensure their financial sustainability. By means through digitalization such as social media interaction, online product sales, digital subscription services, and blockchain-based assets, clubs are building stronger relationships with their fans, building loyalty and increasing revenue [2]. In the context of sports, fan engagement has been defined as a customer engagement behavior that focuses on the extra role behavior of the fan. [3]. The Consumers Online Brand Related Activities (COBRA) framework categorizes fan activities as consumption, contribution and creation [4]. When we look at the literature, there are studies investigating the ways in which sports clubs can increase their fan engagement levels [5].

With this innovative platform we have developed for sports clubs, we offer a wide range of services to fans, bringing together in one place functions such as playing games, purchasing tickets, and accessing sports content. In addition, it is designed with an integrated digital ad inventory and ad sales algorithm to maximize sponsorship and advertising revenues, which are a main source of income for clubs.

Findings

Studies were carried out in order to create different income channels for sports clubs and to increase the overall monetization rate from application users. To this end, the user experience of the platform was improved, ad slots were added for better monetization, and content and gamification layer operations were carried out. The Unity engine was used to develop a hybrid application framework with gamification features for the platform. For the ad slots operation, external structures for targeted ads were integrated using the supply chain of the company's main platform, the integrated digital ecosystem. To add monetization to the app, an in-house advertising SDK was integrated to the frontend and the Awin API was integrated to the backend. In order to integrate the advertising SDK, the necessary changes have been implemented to accommodate all ad format slots.

A gamification layer was designed to keep users coming back more often and thus increase engagement and time spent in the app. A mini-games feature has also been developed within the app that encourages competition and

rewards, providing additional interactive experiences to increase the users' time spent in the app. A new flow has been added to the app, which includes a number of different situations the mini-games can be found in. During the addition, separate scenarios were created for each situation to ensure clear communication to the user. Since not every mini-game can be included in every application, we separated them from the main application, designing them as features for the different applications we have. A communication layer was developed within the application to enable sports fans and sports clubs to communicate. Before, the only forms of communication available were sending push notifications or writing news articles. Communication/marketing pop-ups were added as a second communication layer. The ability to include a call to action here, either as a deep link or a direct URL, was added to further engage users.

A social layer was developed to increase interaction between users. The first version allows users to choose a background for the mini profile and change their avatar in a different menu structure than they are used to. These features are designed to work in conjunction with the gamification layer components, which will also be displayed in the mini-profile. Users can show their commitment to the club they support and the use of the app through this mini-profile, which can be viewed by others on the leaderboards. Since the gamification layer and social layer features were developed simultaneously, solutions were developed to some of the technical obstacles encountered in order to preserve the data structure.

The flow has been changed to allow users to link their existing ticketing accounts to their accounts in our app. By doing so, fans can now view their tickets or season passes within the app and also scan the QR code to enter the stadium. Following a request from existing clubs and subsequently the Football Association (FA), an Identity Based Access control for ticketing has been integrated within the app. This means that a user has to identify themselves with a driver's license, passport or ID card. This process uses NFC scanning of the chips inside these to link a user's profile to their identity. Additionally, a Consent Management Platform, a system that enables users to give and manage their explicit consent to the collection and processing of their personal data, was created for the app.

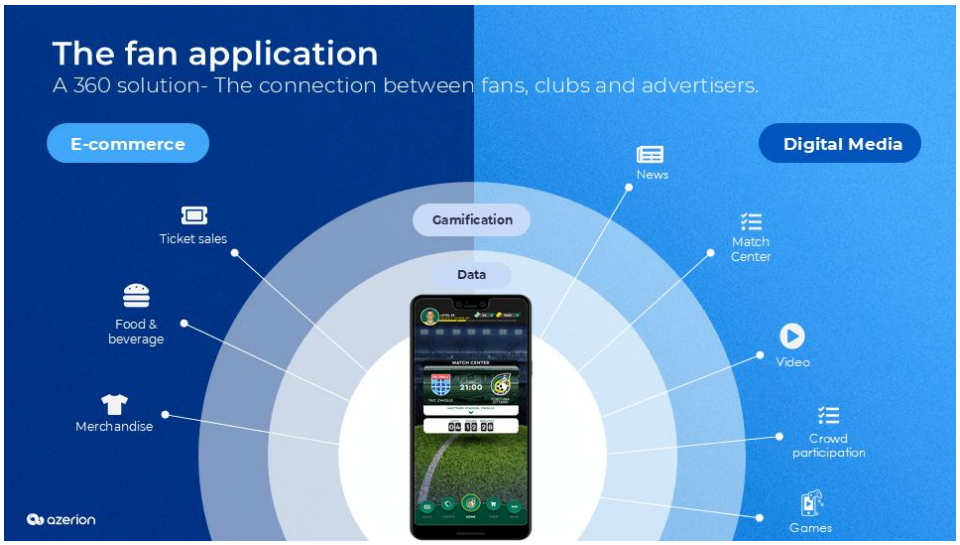

Figure 1. The fan application.

Conclusion

Digital transformation strategies for professional sports clubs support their long-term success by strengthening their economic structure. This platform eliminates the need for clubs to work with multiple service providers in different areas such as software development, content production and advertising technologies, and enables the management of processes in an integrated structure. Therefore, the innovative and competitive aspect of this project is that it brings together fans, sponsors, advertisers and content producers in a sports club's ecosystem on a single digital infrastructure, optimizing their interactions.

Comparative Analysis of Large Language Models for Natural Language to SQL and Visualization Code Generation

Baykal Mehmet Uçar[a], Sefer Baday[a,b]

Keywords: Data Visualization, Large Language Models, Natural Language to SQL, Semantic Kernel, Text-to-Code.

Aim

The aim of this study is to develop and evaluate a pipeline leveraging Large Language Models (LLMs) to convert natural language queries into SQL statements and Python visualization scripts. The research compares performance metrics across several advanced LLMs, including OpenAI GPT-4o, Anthropic Claude 3.5 Sonnet, Meta Llama 3.1 70B, Google Gemini 1.5 Flash, and DeepSeek Chat.

This work is motivated by the goal of improving data accessibility and democratization within organizations. Non-technical users often face challenges when trying to retrieve data from databases, as this typically requires SQL knowledge or assistance from technical staff. By enabling natural language interactions with databases, the pipeline increases efficiency, reduces costs, and empowers more timely, data-driven decision-making (Kim et al., 2020; Qin et al., 2022).

The primary rationale for selecting these models is their recency and relevance at the time the experiments were initiated. Each model represents the latest or one of the latest iterations from its respective organization, thereby ensuring that the comparison reflects the cutting-edge capabilities available in the field. Furthermore, all selected models offer accessible inference APIs, making them suitable for integration into a standardized evaluation pipeline without the need for specialized hardware or fine-tuning efforts, which supports reproducibility and practical applicability.

Beyond their availability and release timing, the models were chosen to represent a diverse set of development philosophies and architectural innovations. OpenAI, Anthropic, Meta, Google, and DeepSeek have distinct approaches to model training, instruction tuning, and optimization, offering a broad view of current trends in LLM development. Additionally, the selection includes both closed-weight (e.g., OpenAI, Anthropic, Google) and open-weight (e.g., Meta, DeepSeek) models, which allows analysis not only of model performance but also of practical considerations such as deployment flexibility and cost implications (OpenAI, 2025; Anthropic, 2024; Google AI, 2025; Meta AI, 2024; DeepSeek, 2024).

The proposed system addresses three main domain problems:

- Data Accessibility: Providing a natural language interface to databases enhances accessibility for non-technical users, supporting data democratization efforts (Kaoshik et al., 2021).
- AI Democratization: Allowing users to leverage AI capabilities without requiring technical expertise contributes to broader AI adoption and usability within organizations.
- LLM-Agnostic Architecture: Another goal was to design the framework in a flexible way, allowing for the rapid addition of new models, so that the system can easily keep up with the fast-paced developments in generative AI and LLM technologies.

Material and Method

We utilized Microsoft's Semantic Kernel SDK to abstract interactions with various LLMs. Semantic Kernel is an open-source development kit that enables developers to integrate AI services, such as OpenAI and Azure OpenAI, with conventional programming languages like C# and Python, facilitating the creation of AI applications that combine the strengths of both paradigms (Microsoft, 2025). By leveraging Semantic Kernel, we efficiently

orchestrated complex AI tasks, including prompt chaining, recursive reasoning, and summarization, thereby enhancing the functionality and responsiveness of our system (Figure 1).

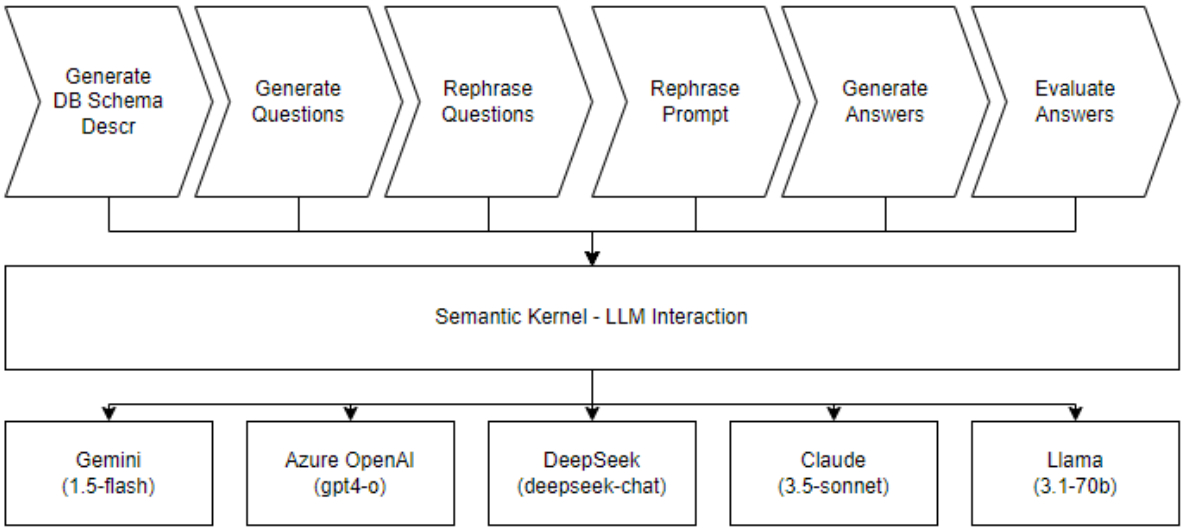

Figure 1. LLM-Based Pipeline Architecture for Natural Language to SQL and Visualization.

If a model (e.g., DeepSeek) is not supported by Semantic Kernel, developers can quickly integrate it by implementing interfaces like ChatCompletionClientBase or BaseModel, enabling compatibility with new APIs (Lagerkrans-Pandey and LaHaye, 2025).

The pipeline includes:

- Database Schema Description: Generated via LLMs with manual refinements.
- User Query Generation: LLM-generated queries categorized by complexity (simple, moderate, complex, very complex).
- User Query Handling: LLMs generate executable SQL and Python code based on user inputs and schema descriptions.
- Performance Evaluation:
    - Human Evaluation: Each query and code was manually scored based on the following rubric:
        - 100: Fully correct and executable
        - 75: Minor fixable issues (e.g., wrong column name)
        - 50: Structural issues requiring major edits
        - 25: Incorrect but partially relevant
        - 0: Irrelevant or completely incorrect
    - LLM-Based Evaluation: After identifying the most accurate model through human scoring, this model was used as an LLM-based evaluator. It reviewed the generated SQL and Python code for the remaining models and assigned scores accordingly, ensuring scalable and consistent benchmarking.

PromptToQueryResult is an asynchronous Python function designed to transform a user-provided natural language prompt into executable SQL and Python code through interaction with LLMs using the Semantic Kernel framework. The function enables query execution, result retrieval, and visualization generation in an end-to-end automated pipeline.

The pipeline consists of the following major steps:

- Kernel Initialization: The Semantic Kernel is initialized based on the selected LLM service, model name, and mode (e.g., chat).
- Prompt Handling: If no user prompt is provided, the user is interactively queried. Optionally, the prompt can be reformulated for clarity using the rephrase_prompt function, which invokes a dedicated rephraser plugin.

- Code Generation: The (rephrased) prompt and a predefined data schema are passed to an LLM through the execute_llm_prompt function. The model responds with structured text containing SQL and Python code enclosed within specific tags.
- Code Parsing: The generated result string is processed by parse_sql and parse_python_code functions to extract the respective code segments.
- SQL Execution: The extracted SQL query is executed against a configured database using the execute_sql function, which internally leverages the run_sql_query utility. If the execution fails, an automatic error correction mechanism is triggered through execute_fixed_query, which iteratively refines the SQL using the LLM.
- Python Code Execution: If Python visualization code is available, it is executed via the execute_python_code function within a controlled environment. Any execution errors invoke the execute_fixed_python_code function to attempt automatic code fixing through the LLM, with up to three retries.
- Output Handling: Upon successful query execution and visualization, outputs such as the DataFrame and generated plots are saved to specified directories. SQL queries, Python scripts, and user prompts are also optionally persisted to disk for traceability.

The core functionality of PromptToQueryResult is supported by several auxiliary asynchronous and synchronous functions:

- execute_llm_prompt: Sends structured requests to the LLM for code generation, SQL fixing, or Python code fixing, depending on the invoked plugin and function.
- rephrase_prompt: Rewrites the user prompt to enhance its clarity and precision using an LLM-powered rephraser.
- execute_sql: Executes SQL queries and returns results as pandas DataFrames.
- execute_python_code: Executes Python code snippets for visualization or post-processing tasks.
- execute_fixed_query: Attempts to automatically fix faulty SQL queries iteratively using LLM feedback.
- execute_fixed_python_code: Attempts to automatically fix faulty Python code iteratively using LLM feedback.
- parse_sql, parse_python_code: Parse and extract SQL and Python code from structured LLM responses.

The design implements robust error handling:

- SQL and Python code execution errors trigger automated retries with LLM-assisted correction.
- Each fixing function (execute_fixed_query, execute_fixed_python_code) performs up to three iterations before giving up and notifying the user.

Findings

The evaluation results show consistent yet distinct performance patterns across the tested models, based on both human-annotated and LLM-based scoring.

Human Evaluation: Among the initial models evaluated manually:

- Claude 3.5 Sonnet achieved the highest performance, with an average score of 99.36% (SQL: 99.26%, Python: 98.96%), demonstrating near-perfect accuracy and readability in both code types.
- GPT-4o followed with an average of 86.95%, performing slightly stronger in SQL than in Python visualization.
- Gemini 1.5 Flash scored 80.77% overall, with a relatively balanced performance across both outputs.
- These scores were manually assigned using a 5-level rubric, and reflect both correctness and required post-editing effort.

LLM-Based Evaluation: To scale the evaluation, the best-performing model (Claude 3.5) was also used as an LLM evaluator, scoring the generated SQL and Python code from all five models:

- Claude 3.5 Sonnet again led with an average score of 88.13%, supporting its consistency.
- GPT-4o and Gemini 1.5 Flash saw reduced overall scores (74.38% and 71.88%, respectively), especially in Python code quality.

- LLaMA 3.1 70B and DeepSeek Chat were included in the LLM-based phase and showed mixed results. While their SQL scores were competitive, Python outputs were generally weaker (e.g., DeepSeek's 35.00% in Python).
- These findings reveal that while multiple LLMs can handle SQL generation with reasonable success, generating correct and readable Python visualization code remains more challenging.

Tables 1 and 2 present detailed scores for both evaluation strategies.

Table 1. Human Evaluation Scores.

Model	Avg Score	SQL Score	Python Score
gpt-4o	86.95%	87.50%	79.27%
claude 3.5	99.36%	99.26%	98.96%
flash 1.5	80.77%	86.76%	81.82%

Table 2. LLM-Based Evaluation Scores.

Model	Avg Score	SQL Score	Python Score
gpt-4o	74,38%	97.50%	51.25%
claude 3.5	88.13%	98.75%	77.50%
flash 1.5	71.88%	80.00%	63.75%
deepseek-chat	66,25%	97,50%	35.00%
llama 3.1-70b	80.00%	92.50%	67.50%

Conclusion

Distinct strengths across LLMs were identified, with Claude 3.5 Sonnet consistently demonstrating superior performance in both human and LLM-based evaluations. These findings align with recent academic benchmarks, reinforcing Claude's strength in structured code generation tasks such as SQL and Python visualization.

While GPT-4o and Gemini Flash showed solid SQL generation capabilities, they were less consistent in producing high-quality Python visualizations. Models like LLaMA 3.1 70B and DeepSeek Chat exhibited promising SQL outputs but struggled with full visualization pipelines.

These results highlight the potential value of hybrid approaches, combining the complementary strengths of different models to improve robustness and accuracy. Future work will explore such model orchestration strategies to enhance overall pipeline effectiveness across diverse query types (Wang et al., 2024; Lieber et al., 2024).

Developing An Ontology For Artificial Intelligence Assisted Quality Control Systems In Mega Projects

Hasan Efekan Bilen[a], Onur Behzat Tokdemir[a]

[a] Istanbul Technical University, Civil Engineering Department, Construction Management Program, Türkiye
bilen23@itu.edu.tr

Keywords: Ontology, Artificial Intelligence, Quality Control.

Aim

Developing an ontology to improve AI-assisted quality control in mega construction projects, ensuring the meaning of data and the effective use of AI algorithms.

Introduction

The construction industry with its mega construction projects have come to require complex and large-scale operations. Such projects consist of a large number of stakeholders, materials, processes, and data. This complexity underlines the significance of an efficient and effective quality control system. The traditional quality control systems usually follow a reactive approach, intervening only after a defect has occurred (Priemus et al., 2013). Not only can this lead to cost increases and time losses, it can also pose safety risks. Artificial Intelligence (AI) has become more common use in construction processes to better detect errors and manage risks (Zhang et al., 2025). Recent years have shown that the technological advancements in AI has the potential to transform the quality control processes in the construction industry (Hire et al., 2022). In this regard, studies on quality control in large-scale projects highlight the significance of proactive approaches in the success of quality control systems (Aziz et al., 2019). Weighing in such various aspects as mentioned, AI-assisted quality control systems can increase productivity, decrease costs, and improve safety in construction projects. However, the effective and efficient use of AI in the construction industry is dependent on how meaningful and structured the relevant data is (Ayhan & Tokdemir, 2019). This is where ontologies come into play. An ontology is a knowledge model which explains the concepts of a particular subject or a field of study, describing the properties of the concepts and outlining the relationship between the concepts (Felicetti & Franco Niccolucci, 2024). Developing an ontology for the construction industry can help AI algorithms comprehend the data and facilitate assistance with effective decision support by defining key concepts such as risk, error, material, and the relationship among these concepts (e.g. risks leading to errors; materials being used in processes). This thesis focuses on developing an ontology for AI-assisted quality control systems in mega construction projects. Combining expert knowledge on construction industry and AI technologies, the ontology proves to help improve the quality control processes and ensure effective decision support. Within this scope, current quality control methods in the construction industry as well as AI applications have been analyzed. Following this, the methods and tools for developing the ontology have been determined. The resulting ontology has been in turn evaluated by experts and integrated with AI systems. Consequently, this study aims to contribute to more effective, efficient, and sustainable construction projects by presenting the potential use of AI in the construction industry.

Material and Method

This thesis study aims to develop an ontology for AI-assisted quality control in mega construction projects. In line with this aim listed below are the methodological steps which the study has followed:

A. Definition of Scope and Field

The preliminary step of the study is to identify the key concepts, processes, stakeholders, and data sources in large scale construction projects; experts of the construction industry have been consulted, a thorough literature review has been conducted, and current quality control systems have been analyzed. Consequently, the scope and the

focus of the study have been clearly identified. The scope can be further narrowed down by identifying critical areas in the mega construction projects such as material management, process monitoring, risk management, compliance assessment where AI applications are better suited for use to reduce the complex, intensely data-driven nature of such projects.

B. Establishing the Conceptual Model

Having identified the key concepts of quality control and their relationships with one another in mega construction projects in the preliminary step of the study, a conceptual model has been established (Figure 1). The model demonstrates the hierarchical and relational structure of the key concepts, laying the groundwork upon which the ontology is based.

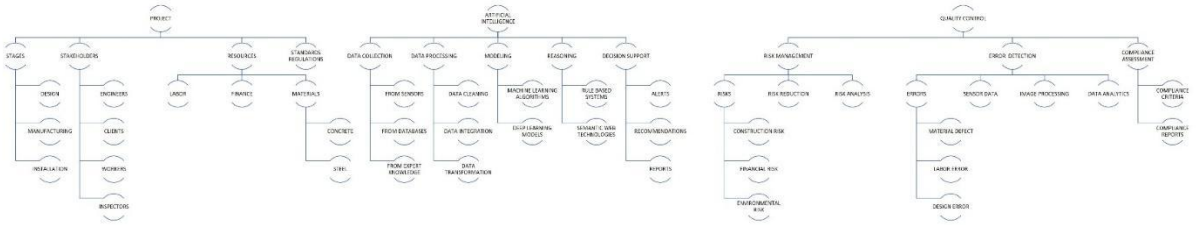

Figure 1. Conceptual model.

C. Developing the Ontology

Protégé is a comprehensive ontology editing software which produces ontological models in the OWL format (Musen, 2015). The ontology has been developed in Protégé with the conceptual model as the base. During the development, the hierarchical relationships between the concepts (e.g. quality control being a sub-category of project management; concrete and steel as sub-classes of material), their properties (e.g. material name, quality), constraints to regulate the relationships have been introduced. The form of expression for the ontology is the Web Ontology Language (OWL). Figure 2 below demonstrates the ontological model in OWL format, expressing the relationships between the concepts.

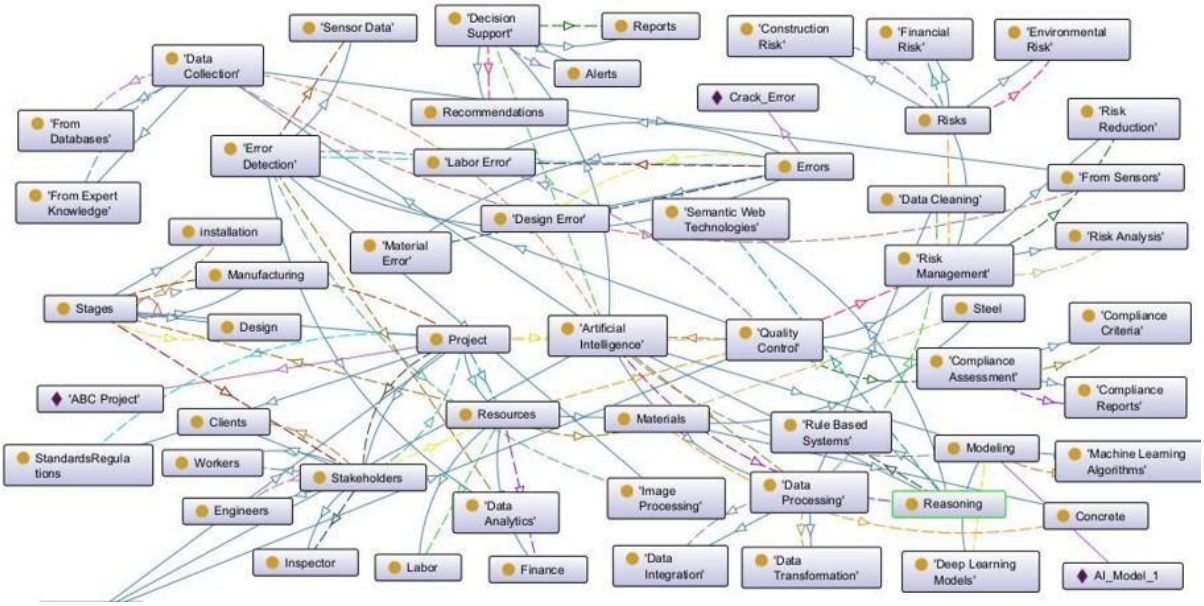

Figure 2. Ontological model.

D. Evaluation of the Ontology

The ontology thus far developed has been evaluated and tested by experts of the construction industry for reliability, accuracy and usability in the industry. The criteria used in the evaluation and testing of the ontology include how compatible the concepts and their relationships it details are with the real-world situations; how detailed and comprehensive it is; how suitable it is for AI use. The feedback received from the experts has been used to improve and update the ontology.

E. AI Integration

The main purpose of AI integration is making use of the developed ontology to assist with decision support in quality control processes. The integration step of the study determines how the ontology feeds information into AI systems and how the AI systems make use of the ontology (e.g. "Reasoning" on the ontology to derive conclusions). Furthermore, machine learning algorithms such as classification, clustering, prediction can be used in the integration of AI with the ontology.

Findings

Developed through Protégé, the ontology produces an extensive body of knowledge to provide AI algorithms with assistance during quality control processes. The main three constituents for the ontology have been determined as Project, Quality Control, and AI, modelling in detail their relationships with each other. The main findings obtained are as follows:

A. Constructing a Hierarchical and Relational Ontology

The ontology developed in Protégé is structured to demonstrate a hierarchical and relational structure: "Project"> "Resources" > "Material> "Concrete" (Figure 3). For instance, the "Project" class has "Design", "Manufacturing", "Installation" as subclasses; the "Stakeholder" class is sectioned by the subclasses of "Engineers", "Workers", "Clients", and "Inspectors". This hierarchical and relational structure clearly demonstrates the stakeholders and the processes in which they are involved in quality control processes.

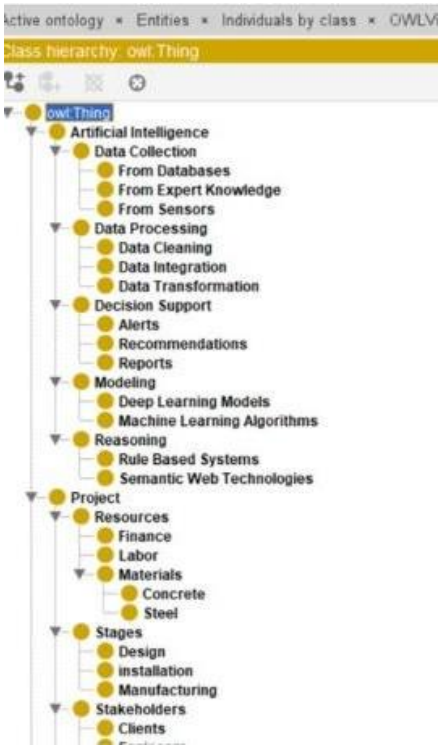

Figure 3. Class hierarchy.

B. Comprehensive Conceptual Model for Quality Control Processes

Developed in Protégé, the ontology has been designed to provide in detail the processes of quality control, e.g. Compliance Assessment, Risk Management, Error Detection. For instance, the subclasses of "Material Defect", "Labor Error" and "Design Error" are categorized and nested under the main class of "Error Detection". Risk Management class attributes "hasRiskType" (Figure 4) property to identify and define basic risks such as "Construction Risk", "Financial Risk", "Environmental Risk". The classifications as detailed help AI algorithms focus on certain types of risks when running analyses, helping reduce ambiguity in often complex and detailed construction projects (Salem et al., 2020).

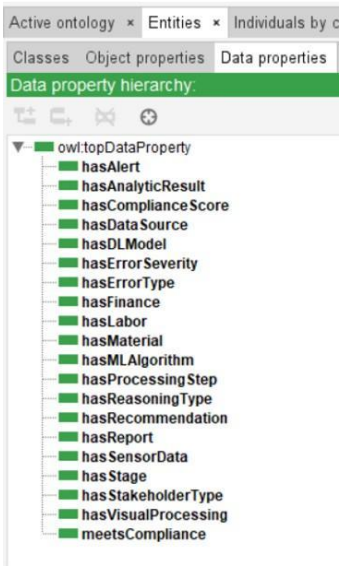

Figure 4. Data property hierarchy.

C. The Ontology Integrated with AI

The ontology contains data properties such as "hasSensorData" (Figure 4) which help to transfer information obtained from the database and sensors to AI algorithms in a meaningful way. The property "hasSensorData" is created to integrate sensory inputs into quality control processes. This property enables AI-assisted analyses of real-time sensory input. For instance, a sensor data stream to measure material quality such as concrete, generating automated alerts when below specified thresholds.

D. Testing Ontological Reliability using Reasoner

The ontology has been tested against its reliability in hierarchical structure, property attribution, and relationality using the Reasoner tool in Protégé. In accordance with the results of the testing, invalid concepts and relationships have been detected and removed. In one instance, it has been detected that a material was not only classified as an error type but also as a process type. This misclassification has been sorted out using the Reasoner tool in Protégé. Additionally, logical inconsistencies among certain concepts have been resolved by analyzing the relationship between risk levels and error types. Reasoner helped resolve conflicting properties where an error is classified as both "High" and "Low", ensuring logical consistency and coherency among classifications and properties.

E. Creating a Database for AI-assisted Decision Support Mechanisms

The ontology constitutes a database which helps AI-assisted decision-making mechanisms develop further. Properties such as "hasAlert", "hasRecommendation" and "hasReport" (Figure 4) help maintain data accuracy and reliability by enabling AI systems to make ontological inferences decision making processes (Horridge & Bechhofer, 2011). The AI systems for instance can create automated alerts for high-risk projects and offer suggestions on risk reduction. Properties such as "hasStandard" are created to help assure compliance with

standards and regulations (Figure 4), ensuring whether the quality control processes adhere to the industry standards and relevant regulatory requirements.

Conclusion

This study is aimed at developing an ontology to improve AI-assisted quality control in mega construction projects. The ontology has been designed to better comprehend the quality control processes in construction projects, structure the relevant data, and facilitate AI algorithms to work more efficiently and effectively. During the development of the ontology, the key concepts of quality control processes and their relations with each other have been determined through relevant literature review and consulting industry experts, rendering an ontological model in the Protégé software. The main three constituents for the ontology have been determined as Project, Quality Control, and AI. Project encompasses the stages, stakeholders, resources, standards, and regulations providing a structured body of subclasses. Quality Control introduces a systematic approach by defining risk detection, data analysis, compliance assessment and risk management. AI, on the other hand, facilitates artificial intelligence integration into quality control processes through data collection, data modelling, and focusing on decision support mechanisms. The hierarchical structure provided by the ontology facilitates the clarification of data from AI algorithms and enables better decision support in quality control processes in mega construction projects. Additionally, the ontology can be integrated with AI systems to help decision-making mechanisms in critical quality control processes such as optimized selection of material and compliance assessment. The contribution of this study is to assist with the decision support systems and mechanisms in AI-assisted quality control systems in the construction industry by providing an extensive and structured body of knowledge. It is suggested for the future that the ontology should be extended and tested in real-time in industrial projects. In this regard, the ontology can be populated with more data to be more comprehensive, efficient, and effective in the construction industry.

Usage of Large Language Models in the Construction Industry: A Literature Review and Evaluation

Şirin Şevval Uçak[a], Onur Behzat Tokdemir[a]

[a] Istanbul Technical University, Civil Engineering Departmant, Construction Management Program, Türkiye
ucak18@itu.edu.tr

Keywords: Large Language Models (LLMs), Construction Industry Applications, Automation and Efficiency in Construction.

Aim

The purpose of this study is to explore the contributions of large language models (LLMs) in various areas of the construction industry and highlight the advantages, challenges, and limitations associated with their use. Specific examples will be provided regarding how these technologies benefit fields such as project management, contract management, document management, and occupational health and safety. Additionally, the limitations encountered during these processes and potential challenges related to the technology will be discussed.

Material and Method

This study investigates the use of LLMs in the construction industry through a comprehensive literature review. Relevant academic sources were identified using keywords such as "large language models" and "construction industry." The objectives, methodologies, and findings of these studies were examined to determine the key application areas of LLMs, which include project management, contract management, document management, and occupational health and safety. The analysis highlights the benefits, challenges, and limitations associated with LLM adoption in these domains, aiming to offer a well-rounded evaluation of their effectiveness within the construction sector.

Findings

A. Project Management and Planning

Large Language Models (LLMs) offer notable advantages in the planning and management of construction projects. Prieto et al. (2023) investigated the use of ChatGPT in scheduling and resource allocation tasks, reporting high levels of accuracy, efficiency, clarity, and consistency. The study found that ChatGPT can streamline project management by automating time-intensive preparatory tasks, thereby accelerating overall workflow.
Similarly, research by He C. et al. (2024) reported that a GPT-based model was used to categorize meeting discussions into meaningful topics, followed by the training of a BERT-based model for constraint classification. The study found that the proposed model improved constraint classification accuracy by 8.8% compared to traditional methods.
LLMs support project managers not only in schedule development but also in the early identification of potential constraints, offering proactive solutions. This capability contributes to more efficient and timely project execution. By enhancing critical planning tasks such as time and resource optimization, LLMs enable more accurate outcomes. These applications improve key performance factors such as on-time delivery and budget control, thereby enhancing overall project efficiency.

B. Contract Management and Automated Contract Analysis

Contract management is a critical aspect of the construction industry, and the adoption of LLM-based technologies in this domain is expanding rapidly. Moon et al. (2022) developed a BERT-based classification model to associate clauses in construction specifications with contract-related risk categories. The model achieved an accuracy of 88.9% and an F1 score of 93.4%, with particularly strong performance in the safety category, underscoring the potential of LLMs in risk identification.
To enhance the analysis of lengthy contracts, Gao et al. (2024) introduced a text segmentation method that combines content summarization and intelligent question-answering, allowing users to quickly access relevant provisions. Their model demonstrated 93.3% user satisfaction when tested on the FIDIC Red Book.
He Y. et al. (2024) used LLMs to automatically identify risks in construction contracts. To address the long processing times and inconsistent results of traditional risk detection methods, contract clauses were vectorized,

indexed in a database, and evaluated using the Retrieval-Augmented Generation method. This approach achieved 76.7% accuracy compared to traditional expert evaluations.
Kim et al. (2025) developed an NLP-based framework for automated detection of risk statements in contracts using BERT and spaCy's dependency parser. Their model achieved 95.5% sentence parsing accuracy and 91.3% accuracy in identifying risk-related sentences.
Overall, LLMs enhance contract management by automating the extraction of key clauses and identifying critical terms, risks, and contradictions. This significantly reduces review time and error rates, supporting more accurate and efficient decision-making in construction projects.

C. Document Management and Information Extraction

LLMs have greatly improved access to project-related information by enabling rapid and accurate analysis of large and complex document sets, thereby enhancing overall productivity. Wang et al. (2022) developed a question-answering system for extracting information from Building Information Modeling data, allowing users to query BIM models in natural language. The system achieved 81.9% accuracy but struggled with complex sentence structures.
Kim et al. (2024) proposed a framework using pre-trained BERT models for multilingual construction documents, particularly FIDIC contracts, demonstrating improved retrieval speed and cost efficiency.
Similarly, Wei et al. (2024) evaluated embedding models for classifying documents related to construction delay disputes. Their findings showed that embedding techniques, especially with the K-Nearest Neighbors algorithm, effectively captured semantic similarities, supporting informed decision-making.
Park et al. (2024) further emphasized the use of domain-specific terminology dictionaries and Word2Vec representations to improve semantic understanding in construction documents, contributing to more precise and context-aware document analysis.
These studies highlight the significant potential of LLMs to transform information retrieval and document management in the construction industry.

D. Worker Health and Safety

LLMs play a vital role in enhancing construction safety by identifying risks, analyzing accidents, and supporting the implementation of preventive measures. Xu et al. (2023) developed a BERT-BiLSTM-CRF model to improve safety management in coal mine construction, which achieved high accuracy in automating safety information extraction and named entity recognition.
Ahmadi et al. (2024) analyzed construction accident reports using advanced LLMs. The study accurately classified the fundamental characteristics of accidents, contributing significantly to the improvement of safety measures.
Lee et al. (2024) employed the Retrieval-Augmented Generation model to optimize information access in construction safety management, enabling faster retrieval and more timely implementation of safety protocols.
These advancements demonstrate the growing potential of LLMs to support proactive and data-driven safety practices in the construction industry.

E. Project-Based Applications

LLMs are effectively applied not only in general construction fields but also in more specific projects, demonstrating their versatility.
Chen and Zhang (2024) explored the effects of LLM-based agents in bridge operation and maintenance processes. The findings revealed that LLMs can enhance data stability during bridge monitoring and improve the accuracy of fault diagnosis.
Yang et al. (2024) developed a methodology to increase information extraction accuracy in digital twin water conservation projects using LLMs. This methodology provided a significant improvement over traditional model.
Yi et al. (2024) utilized LLMs for data storage and rapid access in drilling operations. While the system enhanced operational efficiency, some concerns regarding its accuracy were raised.
Jang and Lee (2023) investigated the integration of BIM with LLMs and demonstrated that this integration improves the design process. LLMs play a significant role in collaborative design processes.

Table 1. Advantages of Using LLMs in the Construction Industry.

Advantage	Description
Automation and Increased Efficiency	LLMs automate time-consuming processes such as the analysis of construction specifications, review of contract clauses, and risk management, thus increasing efficiency (Moon et al., 2022; Prieto et al., 2023). These models, which are highly successful in extracting meaning from text-based data, text generation, and learning relationships within text, can provide significant benefits in processes such as document categorization, content analysis, information extraction, and risk assessment (Lee et al., 2024).
Risk Management and Safety Analysis	LLMs contribute to improving safety measures by analyzing construction accident reports (Ahmadi et al., 2024). Additionally, in interpreting construction safety regulations and compliance processes, LLMs assist in understanding complex legal texts (Tran et al., 2024).
Information Access and Management	LLMs facilitate access to information in systems such as BIM, allowing construction professionals to quickly and accurately access project data (Wang et al., 2022).
Decision Support Systems	LLMs assist in complex decision-making processes such as automatically identifying and analyzing constraints in construction planning meetings (He, C., et al., 2024). LLM-based agents provide high efficiency in tasks like real-time data analysis and automatic reporting (Chen and Zhang, 2024).
Cost and Time Savings	LLMs reduce manual workloads, leading to cost and time savings in construction projects (Pu et al., 2024; Kim et al., 2024).

Table 2. Disadvantages of Using LLMs in the Construction Industry.

Disadvantage	Description
Model Accuracy and Reliability	The application of language models like ChatGPT in construction engineering underscores the importance of expert oversight due to potential risks such as bias, incomplete information, and erroneous content generation (Aluga, 2023). Context loss in lengthy, complex documents may also lead to misinterpretations or failures in recalling prior content (Li et al., 2023). For instance, Wang et al. (2022) found that NLP-based QA systems often struggle with complex sentence structures. Furthermore, LLMs may produce hallucinations—contradictions, factual inaccuracies, or incoherent outputs—stemming from unreliable training data, ambiguous prompts, or logical gaps (Huang et al., 2024; Perković et al., 2024). Such issues pose notable challenges in technical domains like construction.
Scalability and Integration Challenges	Integrating LLMs with existing construction management systems can involve technical and operational challenges. Especially in large-scale projects, the performance and scalability of these models may be questioned (Fuchs et al., 2023).
Data Privacy and Security Concerns	LLMs require large amounts of data, raising concerns regarding the privacy and security of this data. The misapplication of model outputs, along with data privacy and user security issues, are important matters that need to be addressed and resolved (Linegar et al., 2023; Liang et al., 2023). In construction projects, the handling of sensitive data can increase the risk of data leaks or misuse.

Limitations of Training Data	Although LLMs are trained as general language models, they require domain-specific data to perform adequately in technical fields like construction. A lack of such data can limit the performance of these models. For example, Kim et al. (2024) mentioned that the lack of domain-specific data negatively affected model performance during the information extraction process from multilingual construction documents.
Limitations in Complex Tasks	LLMs may show limited performance, particularly in complex and multidisciplinary tasks (Yang et al., 2024). Additionally, the explainability and transparency of LLM-generated results can be a significant issue, especially in decision support systems.
Cost and Resource Requirements	Training and fine-tuning LLMs require substantial computational power and storage capacity, which can limit the widespread use of these models in terms of resource intensity (Aathilakshmi et al., 2024). This can be especially costly for small and medium-sized construction firms.

Conclusion

This study explored the potential applications of LLMs in the construction industry. The findings indicate that LLMs offer considerable benefits across various domains, including project management, contract analysis, document handling, occupational safety, and technical operations such as bridge monitoring and digital twin projects. In project management, LLMs enhance efficiency in scheduling, constraint detection, and resource planning. In contract and document management, they streamline information extraction and risk identification, improving accuracy and reducing time. They also contribute to safety management by analyzing accident data and supporting preventive measures. Integration with BIM further enhances access to project data and strengthens decision-support systems.

Despite these advantages —such as automation, improved efficiency, and better risk and safety management— LLMs face limitations in handling complex linguistic structures and performing domain-specific analyses. Addressing these challenges requires domain adaptation and targeted training.

In conclusion, LLMs hold significant transformative potential for the construction sector, and their continued development will improve their alignment with industry-specific needs, expanding their impact across the field.

Keywords: Artificial Intelligence, Construction Risk Management, Risk Visualization, Risk Assessment.

Aim

This study aims to classify and identify the various types of hazards that arise during building projects by analyzing the full spectrum of risks—technical, financial, legal, environmental, and human-related—and understanding their specific characteristics within the construction context. It also explores the use of artificial intelligence (AI) technologies, such as computer vision, natural language processing, deep learning, and machine learning, in enhancing risk management processes, particularly in data collection, risk assessment, and decision-making automation. Furthermore, the research critically evaluates existing literature to assess the effectiveness, maturity, benefits, and limitations of AI-based methods in real-world construction risk scenarios. Additionally, the study investigates risk visualization techniques, including Monte Carlo Simulation, Bayesian Networks, Fuzzy Logic, Risk Matrix, Bow-Tie Diagrams, and BIM-based visualizations, focusing on how these tools facilitate risk communication and aid stakeholders in interpreting complex data. Finally, by synthesizing the reviewed literature, the research identifies current gaps and proposes directions for future studies, particularly in integrating AI with visual analytics and practical project workflows.

Material and Method

This study employs a systematic literature review methodology to synthesize and analyze the current body of knowledge related to the integration of Artificial Intelligence in construction risk management. Scopus was chosen as the primary database due to its comprehensive coverage of peer-reviewed literature across engineering, technology, and applied sciences. The review followed a multi-stage protocol:
Keyword Development: Key terms such as "Artificial Intelligence," "Risk," "Construction Management," "Machine Learning," and "Building Site" were used in various combinations.
Inclusion Criteria: Only peer-reviewed journal articles and conference papers published between 2010 and 2024, in English, and with a clear focus on AI applications in construction risk management, were considered.
Screening Process: Abstracts and full texts were screened for relevance, quality, and methodological soundness. Duplicates and irrelevant studies were excluded.
Data from these studies were categorized based on AI technique, application domain (e.g., cost, schedule, safety), and type of visualization method used. In addition, keyword co-occurrence and cluster analysis were performed using VOSviewer software to identify dominant research themes and interconnections between subtopics.

Findings

A. Risk Types in the Construction Sector

Construction risks are typically categorized into several groups, including financial, technical, environmental, legal, contractual and administrative, occupational health and safety, and political risks. The dynamic and multi-layered nature of construction projects necessitates predictive approaches to risk management. For example, poor site conditions, delays in procurement, or miscommunication between subcontractors can lead to cascading risk effects throughout the project lifecycle (Sharma & Swain, 2011).

B. AI Applications in Risk Management

Design Optimization: AI-empowered Building Information Modeling (BIM) systems help detect clashes and identify potential hazards during early design stages (Gandhi, 2023).

Project Scheduling and Cost Estimation: Artificial Neural Networks (ANNs), support vector machines, and ensemble learning models are used to improve forecasting of budgets and timelines (Abioye et al., 2021).
Safety Monitoring: Real-time computer vision-based systems using drone imagery and wearable sensors detect safety violations and track worker behavior (Waqar et al., 2023).
Disaster Risk Simulation: Deep learning and digital twins simulate complex disaster scenarios (Kamari & Ham, 2022).
Quality Control: Image recognition and defect classification algorithms identify structural anomalies (Rafsanjani & Nabizadeh, 2023).

C. Risk Visualization Techniques

Risk visualization is not merely a supplementary tool but an essential component in translating technical risk assessments into intuitive, actionable formats for stakeholders at every level. The reviewed studies highlight the following techniques:
Monte Carlo Simulation (MCS): This technique generates thousands of possible outcomes based on probabilistic inputs, offering decision-makers a comprehensive understanding of the potential variation in cost, time, and resource-related risks. MCS is particularly useful for assessing financial uncertainties and scheduling deviations in large-scale projects where deterministic models fall short (Platon & Constantinescu, 2014).
Bayesian Networks: These probabilistic graphical models represent variables and their conditional dependencies via directed acyclic graphs. They allow dynamic risk updates as new evidence becomes available, making them ideal for risk analysis in project environments where uncertainty evolves over time (Charniak, 1991). They also facilitate scenario analysis by modeling the impact of one risk event on others.
Fuzzy Logic: This approach is beneficial in situations where inputs are vague, qualitative, or linguistic, such as expert judgments on project feasibility or safety. Fuzzy logic models interpret imprecise data and help create robust early-warning systems for hazard prediction (Dernoncourt, 2011).
Risk Matrices: These are commonly used tools to visually represent and prioritize risks based on their likelihood and impact. When integrated into digital dashboards, they can serve as real-time risk trackers across multiple project stages (Vicente, 2024).
Bow-Tie Diagrams: Bow-tie models map the relationship between causes, risk events, and consequences while identifying both preventive and mitigative controls. Their visual clarity makes them ideal for communicating high-level strategic risks to non-technical stakeholders (Turner et al., 2017).
BIM-Integrated Visualization: Building Information Modeling (BIM) platforms offer 3D and 4D simulations that help visualize physical construction elements along with associated risks. These visualizations allow the overlay of time-dependent data such as weather predictions or supply chain disruptions, thus enhancing proactive decision-making (Zhang et al., 2013; Zou et al., 2016).

D. Research Gaps and Future Directions

Despite the promise AI and visualization technologies hold, several areas remain underexplored or inadequately implemented:
Standardization and Data Interoperability: AI model training and scalability are hampered by disparate construction platforms' inconsistent data formats and structures. To increase consistency, shared data environments and standardized ontologies are required.
Explainability and Ethical AI Use: The majority of deep learning models used in the building industry are opaque systems that provide no insight into how they make decisions. Explainable AI (XAI) techniques must be used immediately to foster confidence, particularly in applications that are vital to public safety.
Cross-disciplinary Collaboration: It's still difficult to bridge the divide between legal professionals, construction engineers, project managers, and AI developers. In order to guarantee that AI technologies are not only technically sound but also operationally feasible and consistent with the law, collaborative frameworks are crucial.

Field Validation and Longitudinal Studies: A lot of AI models and visualization techniques are only tested in simulated settings. For evaluations of user acceptability, cost-effectiveness, and durability in actual construction projects, long-term empirical research is necessary.

Conclusion

This study has examined the role of Artificial Intelligence (AI) in enhancing risk management practices in construction projects and how visualization techniques can support these advancements. Recent literature indicates that AI applications are particularly effective in areas such as design optimization, cost and schedule forecasting, safety monitoring, disaster simulation, and quality control.

In addition, visualization techniques like Monte Carlo simulation, Bayesian networks, fuzzy logic, risk matrices, and BIM-based tools are essential for converting complicated risk data into understandable representations and enhancing decision-making during the course of a project.

However, the study also identifies several key limitations. The lack of standardized data formats, limited explainability of AI models, and the predominance of simulations over real-world applications restrict the broader adoption of these technologies. Furthermore, insufficient interdisciplinary collaboration poses challenges to the practical implementation of AI-based systems in construction workflows.

In conclusion, for AI-supported risk management approaches to be more effective and sustainable in the construction industry, efforts should focus on standardizing data structures, advancing explainable AI methods, and increasing field-based empirical studies.

CONTROL AND AUTOMATION ENGINEERING

Advances in Automatic Control Engineering

Applications of Control Engineering

Comparison Of Anti-Windup Methods for Fractional Order PI Controllers

Muhammed Ali Elaydın[a], Erhan Yumuk[a], Müjde Güzelkaya[a]

[a] Istanbul Technical University, Dept. of Control and Automation Engineering, Control and Automation Engineering Program, Türkiye
elaydin17@itu.edu.tr

Keywords: Fractional Order Controllers, Anti-Windup Methods, Integral Windup Mitigation.

Aim

Fractional-order control (FOC) is a specialized area in control theory that uses fractional-order integrators and derivatives to design control systems. Unlike traditional integer-order PID (IOPID) controllers, which have three parameters, fractional-order PID (FOPID) controllers include five parameters: proportional, integral, and derivative gains (K_p, K_i, K_d), as well as fractional orders of integration (α) and differentiation (μ). This provides greater flexibility and adaptability in controller design (Yumuk et. al.,2019).
However, like traditional PID controllers, FOPID controllers can experience integral windup, where the control signal saturates due to prolonged error accumulation, leading to overshoot and instability (Rahman et. al., 2018). Some methods proposed for integer order PID (IOPID) controllers, such as back calculation, conditional integration, and automatic reset configuration, can be adapted and used for anti-windup in fractional order PID (FOPID) controllers. In addition, some anti-windup methods have been specifically proposed for FOPID controllers. Examples of these include the fractional integrator reset method.
In this study, five anti-windup methods, i.e., conditional integration (clamping), back-calculation, automatic reset configuration (ARC), application of the ARC to fractional filtered PI configuration, and integrator order reset, are employed to design the Fractional Order PI Controller (FOPI). These five methods are compared on different order systems with different time delays to evaluate their effectiveness in preventing integral windup and improving system performance.

Material and Method

Integral windup is a common issue in control systems, occurring when the control signal exceeds the system's input range, leading to saturation and degraded performance. To address this problem, various anti-windup methods have been developed or adopted for fractional-order PID (FOPID) controllers. These methods aim to limit the integrator's effect during saturation, ensuring stability and improving system response. In this study, anti-windup methods were compared using the same fractional order PI (FOPI) controller for all methods. Figure 1 shows the block diagram of the control system and the FOPI controller.

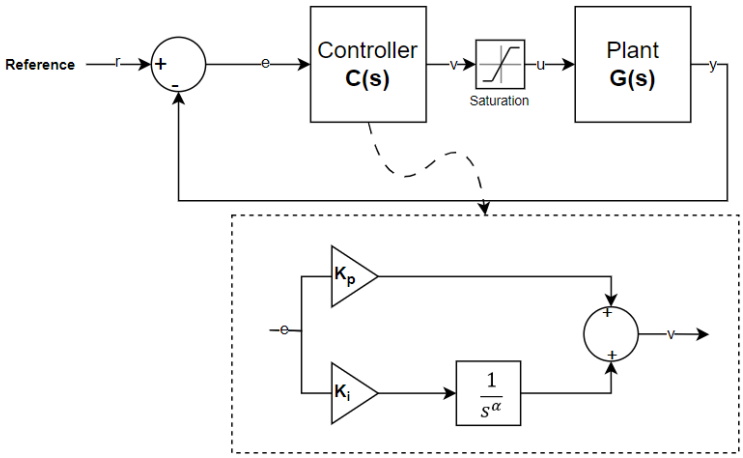

Figure 1: Control System and FOPI Controller Block Diagram.

In this section, the five anti-windup methods explained in detail below are used for designing FOPI:

(i) Conditional integration (clamping) method, disables the integral action when the control signal is saturated. Specifically, the integral coefficient (K_i) is set to zero during saturation, preventing further error accumulation. Once the control signal returns to the allowable range, the integral action is reactivated using the predefined integral coefficient. While simple, this method may result in slower recovery from saturation (Murad et. al., 2020). Figure 2 represents a block diagram of the conditional integration (clamping) method.

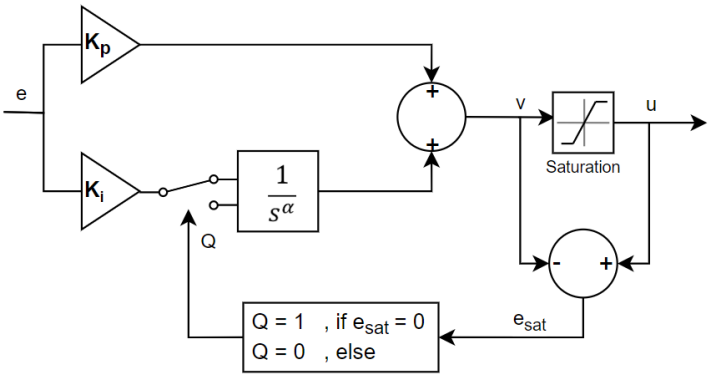

Figure 2: Conditional Integration Method.

(ii) The Back Calculation Method calculates the difference between the control signal before and after the saturation block. This difference is multiplied by a predefined anti-windup gain (k_{aw}) and fed back to the integrator. The feedback signal adjusts the integrator's output, preventing excessive error accumulation during saturation. For the classical back-calculation method, in FOPID controllers, k_{aw} is typically a fixed value (Ardjal et. al.,2022). Figure 3 illustrates the block diagram of the back calculation method.

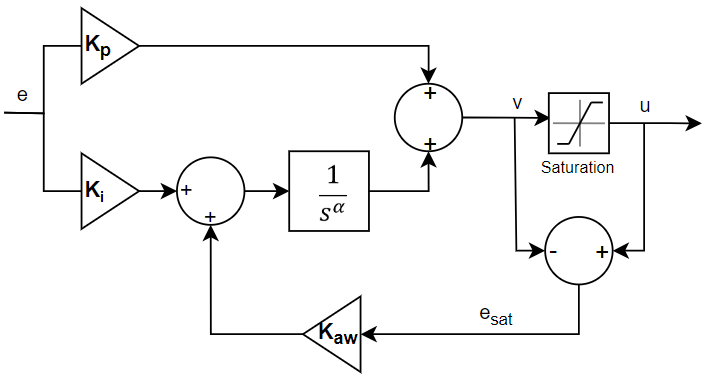

Figure 3: Back Calculation Method.

(iii) The automatic reset configuration (ARC) method modifies the control loop by placing the integrator terms in the feedback path rather than the forward path. Furthermore, an additional saturation block is placed in the forward path of the control loop. This method is expected to be effective in anti-windup because the FOPI controller predicts where the control signal will saturate in advance and generates a control signal that can adapt to saturation within itself. This configuration indirectly limits the integrator's output during saturation, reducing the risk of windup and improving system stability (Padula et. al., 2012). Figure 4 describes the block diagram of the automatic reset configuration method.

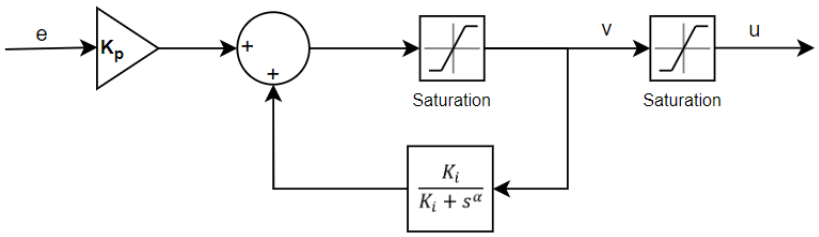

Figure 4: Automatic Reset Configuration (ARC) Method.

(iv) Application of the ARC to fractional filtered PI configuration builds upon the traditional approach of the automatic reset configuration method by maintaining the integrator terms in the feedback path and the saturation block in the forward path. However, this enhanced version introduces a fractional filter at the beginning of the controller. This fractional filter consists of two terms. The first one (α) is the integrator order of the FOPI controller. The second term is (λ) one of the requirement parameters in the controller design method. The fractional filter adds an additional layer of dynamic adjustment to the control loop, allowing for more precise tuning of the system's response. By incorporating this filter, the method further mitigates the effects of windup during saturation, enhances the controller's adaptability to varying system conditions, and provides better overall stability and performance (Meena et. al., 2024). Figure 5 pictures the block diagram of the automatic reset configuration method.

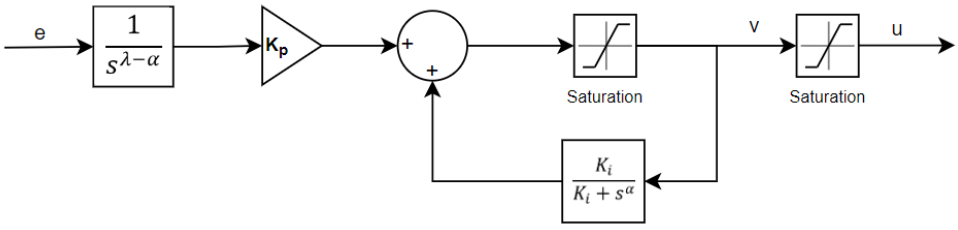

Figure 5: Application of the ARC to fractional filtered PI configuration.

(v) The fractional integrator order reset method is a unique approach for FOPID/FOPI controllers. This method leverages the flexibility of fractional-order controllers by dynamically adjusting the fractional integrator order (α) during saturation. When saturation is detected, the integrator order is reset to zero. This causes to reduction in the integrator's influence during saturation. Once the control signal returns to the allowable range, the integrator order is restored to its original design value. This method takes advantage of the additional degree of freedom provided by fractional-order controllers (Malezsa&Sierociuk, 2018). Figure 6 classifies the block diagram of the fractional integrator order reset method.

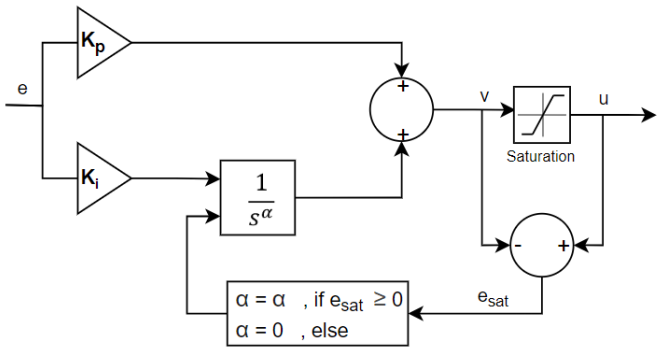

Figure 6: Fractional Integrator Reset Method.

These five methods were tested on different order systems with different time delays to evaluate their effectiveness in preventing integral windup and improving system performance. The fractional-order PI (PI^{α}) controller parameters (for some methods, just K_p and K_i; because of the configuration of the method) were kept constant across all tests to isolate the effects of the anti-windup methods.

Findings

The above-mentioned methods were tested on different order systems with different time delays for both step response and reference tracking. The methods were compared using first-order systems, second-order systems, and first-order plus time delay (FOPTD) systems. To generalize the study, different saturation limits and controller parameters were used during the comparisons.

As an example of the examined systems, a second-order system without time delay was considered for inclusion in the abstract. Saturation fundamentally affects two aspects of system behavior: it can cause overshoot and make the system respond more slowly. In the case study, the saturation limit was chosen with a particular focus on analyzing how much the system's response slows down. The G(s) system, whose transfer function is given in Equation 1, can be provided, where the saturation limit is ± 2.0.

$$G(s) = \frac{1}{s^2 + 3s + 2} \tag{1}$$

The controller parameters were specifically selected to analyze the benchmark system. Since the focus was on evaluating the speed of response, a set of parameters was chosen to ensure that the system would not exhibit overshoot, allowing for a fair comparison of response times. The parameters shown in Equation 2 are the fractional-order PI controller parameters, which are kept constant for all methods.

$$PI^{\alpha}:\ K_p = 1;\ K_i = 1;\ \alpha = 1.2 \tag{2}$$

For the example system, the comparison of reference tracking results for the examined anti-windup methods is shown in Figure 7.

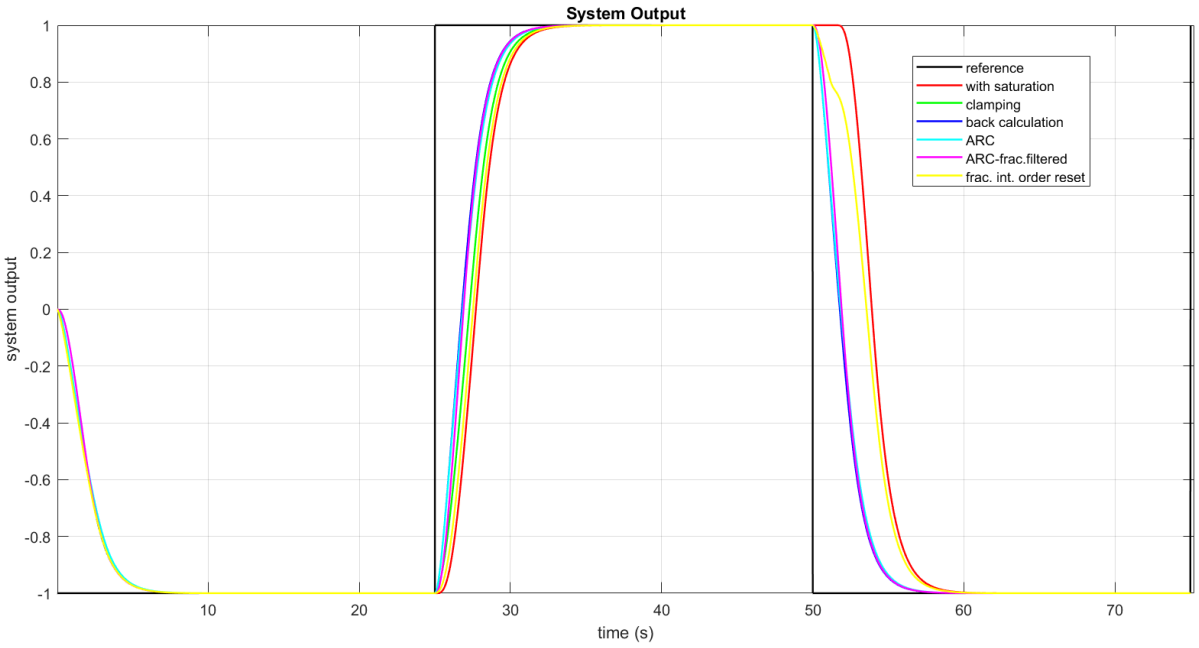

Figure 7: Reference Tracking Results for the Example System.

The system parameters and controller parameters were kept constant for all methods to ensure that only the effects of the anti-windup methods were compared. To allow for more comprehensive comparisons, simulations were repeated with different saturation limits. Although some classical methods produced similar results, the application of the ARC to fractional filtered PI configuration, which includes a fractional-order filter, was found to be one of

the most successful in reference tracking. Considering the phase with a reference of 1 applied at the 25th second in the system, the initial value is -1, and the reference value is 1. Under saturation, the system response reaches from -0.8 to 0.8 in 2.5 seconds. While the other methods rise within approximately 2.4 seconds, the ARC method achieves this in 2.2 seconds, and the fractional filtered ARC structure rises in 2.0 seconds. The analyses are being continued for different system models, different dead-time configurations, and different saturation limits.

Conclusion

Although fractional-order PID (FOPID) controllers are a relatively recent development in control theory, they require the same level of attention to issues like integral windup as traditional PID controllers. Various methods have been proposed to address integral windup in FOPID controllers, including adaptations of classical anti-windup methods and novel approaches that dynamically adjust the fractional integrator order. In this study, five anti-windup methods, i.e., conditional integration, automatic reset configuration, back-calculation, the application of the ARC to fractional filtered PI configuration, and integrator order reset, are employed to design Fractional Order PID Controllers (FOPID). The methods were tested on different order systems with different time delays by analyzing reference tracking and step responses.

The results indicate that while some classical methods provide reasonably good outcomes, others yield worse results in comparison. On the other hand, the results of methods specifically designed for fractional-order systems can vary under different systems and conditions. Nevertheless, it can be observed that the method applied using a fractional filter in the example system performs better than many of the classical methods.
In future studies, the effects of different system models, different dead-time configurations, and different saturation limits on the methods examined in this study will continue to be analyzed. The conditions under which the methods are relatively stronger or weaker will be investigated.

Applications of Control Engineering

DESIGN AND CONTROL OF A 120-TON CAPACITY TRANSPORTATION SYSTEM FOR INDUSTRIAL APPLICATIONS

Korel Dikmen[a], Lale T.Ergene[a]

Istanbul Technical University, Electrical Engineering, Turkey
dikmenk@itu.edu.tr

Keywords: Transportation System, Crane, PLC, HMI, Controller, Induction Motor

The main goal is to ensure the efficiency, safety, and automation of heavy load transportation systems used in large-scale manufacturing facilities, ports, mining sites, and steel plants.
Building automation systems are inevitable in every building in order to make life easier, decrease workload, and create safer and higher quality environments (Aydoğan, Özgün, & Karaaahmetoğlu, 2009; Özen & Şimşek, 2019). Today's automation technology generally makes use of computer-enhanced automation. PLC Systems are the most commonly preferred systems (Malik, Choudhry, Mehmood, & Hanif, 2010). With the developments in technology, various equipment and procedures are found to be in use in this field. With the increase in competition and consumer expectations worldwide, the need for smarter, faster, and more powerful technologies has been on the rise. Conventional industrial tasks were mainly controlled manually, which induced the risk of errors and proved to be more time-consuming and expensive. Automation resolves these issues by incorporating a variety of systems (process, machinery, software) that work together to achieve flexibility, better quality of products, and shorter production times in a cost-efficient manner. Automation reduces the probability of an error occurrence and provides energy and resource conservation. Therefore, the recent trend in industries is the shift towards faster and reliable automated systems over inefficient manual operations. Industrial automation has been the target of many studies that aim at increasing the performance level of the processes along with reducing their complexity (Nadgauda & Muthukumaraswamy, 2019; Waangping, 2023). Among the various automation techniques, PLC has been replacing the traditional relay controls due to its reliability, stability, flexibility, and ease of programming (Alzubaydy & Aziz, 2017). Asynchronous motors are widely used in industry due to their simple, economical, and robust structure, maintenance-free, and superior operating conditions. Various control techniques are used for the control of commonly used asynchronous motors (Çetinkaya & Kuşçu, 2018; Meshram et al., 2020; Terzioğlu et al., 2019). In this study, a transportation system is designed, programmed to control, and implemented in order to monitor and control the parameters of an automation system, which is a part of a harbor project.

Aim

This study focuses on the design and implementation of a 120-ton capacity transportation system for heavy load transportation in industrial applications and its control using PLC (Programmable Logic Controller).
PLC-Based control and automation to ensure the automatic and safe operation of the system, a PLC-based control mechanism has been developed. The PLC performs the following functions:

- Processing data from load sensors to prevent overloading,
- Providing precise speed and directional control for safe transportation,
- Integrating with the HMI system for real-time monitoring and fault monitoring,
- Implementing automatic stop and warning systems in emergency scenarios.

The transportation system consists of a high-strength steel structure, a hydraulic lifting mechanism, and motor systems with precise motion control. The movement and load balancing operations of the system are managed by using a PLC. The main goal is to ensure the efficiency, safety, and automation of heavy load transportation systems used in large-scale manufacturing facilities, ports, mining sites, and steel plants.

Material and Method

The system is designed based on the requirements, which specify the intended purpose and usage of the crane. Based on these requests, functional definitions and boundaries are determined for operations. The functional definitions include the crane's operating procedures, operational restrictions, and key safety considerations. The crane has four different operational modes required by the factory. To ensure the proper execution of these operational functions, software features are required, and their purposes are explained.

The system includes fourteen squirrel-cage induction motors. One lifting and two travel motors for 80-ton and one lifting and two travel motors for 40-ton and eight motors for the bridge are chosen and allocated for the complete system.

Two operation scenarios are designed. The first operation involves lifting and lowering a maximum load of 120 tons in synchronization using the 80-ton and 40-ton lifting groups. After lifting and lowering, the load is transported synchronously using both lifting groups or repositioned using the bridge group. The second operation consists of two steps. First step, the 40-ton lifting group remains stationary while the 80-ton lifting group lowers part of the sheet metal. During this process, the entire weight of the sheet metal rests on the 40-ton lifting group. Second step, the 80-ton lifting group moves. Once the movement is completed, the 80-ton lifting group lifts the lowered section of the sheet metal again, effectively flipping the front and back sides of the sheet. After the sheet orientation is changed, it is transported synchronously using both lifting groups or repositioned using the bridge group. The functional features of the transportation system are determined due to the application requirements. The design procedure includes functional descriptions that cover system operation procedures, operational restrictions, and key safety considerations.

Schneider TM241CEC24T PLC as a CPU, and Schneider HMIGTO3510 touchscreen was used in this system. The real-time monitoring and fault monitoring pages are designed on an HMI screen for this transportation system.

In lifting motor selection, a downward force occurs (or is generated). If we calculate this force correctly, we can determine the required mechanical power with the utmost accuracy. This downward force is, in turn, determined by the weights of the system.

In the calculation of the travel (or driving) motor power, load values, along with friction and wind values, are also taken into account. Differently from the lifting motor power calculation, moment values are calculated, and the travel (or driving) motor power is determined according to these moment values.

Induction motor drivers operate by rectifying the incoming AC voltage to a DC voltage, which is then supplied to an internal DC bus. Subsequently, this DC voltage is converted back (or inverted) to AC voltage at the desired frequency and voltage level. Using drivers in this system is primarily because the high power ratings of the motors prevent direct online starting. Furthermore, the customer's requirement for precise motor speed control also necessitated the use of drivers.

The lifting motor gearbox ratios, rotation speeds, and drum diameters of the lifting groups differ; a hook synchronization program is designed to ensure synchronized lifting and lowering operations. The detail of the designed hook synchronization layout is shown in Figure 1. This designed module captures the position information of the hooks, ensuring that the lifting or lowering operation ends at the same position where it started, thus maintaining the positional difference between the two hooks. By preserving the position difference between the two hooks during movement, the risk of load tipping is eliminated. To use this program, incremental encoders are installed on the lifting motors of both lifting groups. The positions of the hooks are determined by the encoders mounted on the rear of the motors.

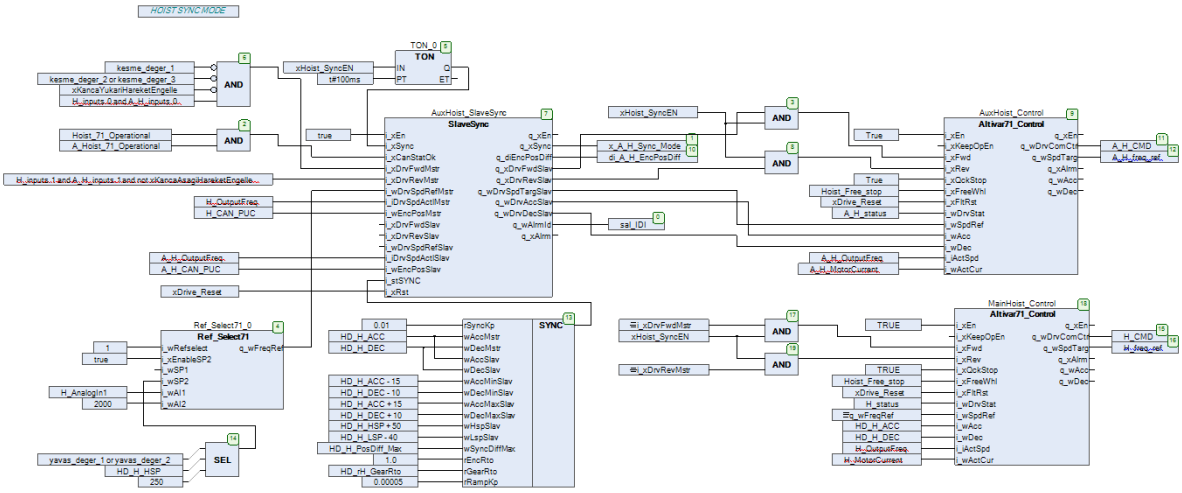

Figure 1. Hook synchronization program.

The travel synchronization program is designed to ensure synchronized load transportation using both lifting groups. The detail of the designed travel synchronization program is shown in Figure 2. Due to these differences, the linear speeds of the travel motors of the lifting groups are calculated to be different. The linear speeds can be equalized using the predefined gearbox ratios through the drive system. However, since the acceleration rates of the drives also vary, misalignments can occur during movement, leading to unbalanced load transportation. Therefore, the designed algorithm should also adjust the acceleration rates to ensure synchronized load transportation.

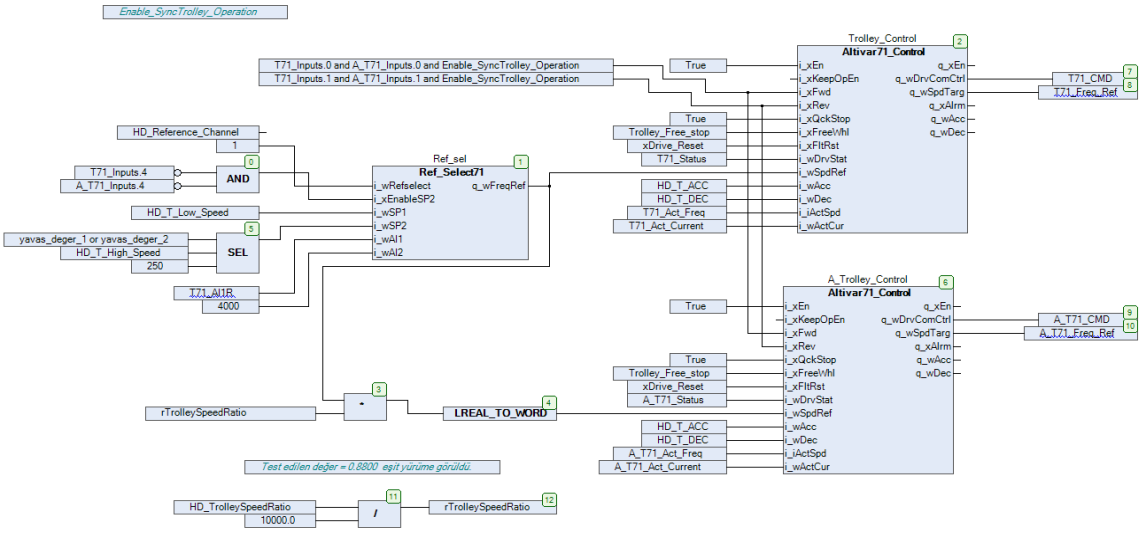

Figure 2. Travel synchronization program.

Overload protection for the lifting groups is ensured by pin-type load cells. To process the information received from the pin-type load cells, a load cell amplifier is used. The information obtained from the pin-type load cells is processed in the load cell amplifier after making the necessary adjustments and is then provided as an analog output signal. The analog signals from the load cell amplifier are directly transmitted to the PLC. These analog signals are evaluated within the PLC software, allowing modifications and restrictions in crane movements based on operational conditions. To enable these functions, one Schneider TM3TI4 analog input module was used in the system design. The loadcell scaling program is designed for overload protection, and detail of this program is shown in Figure 3.

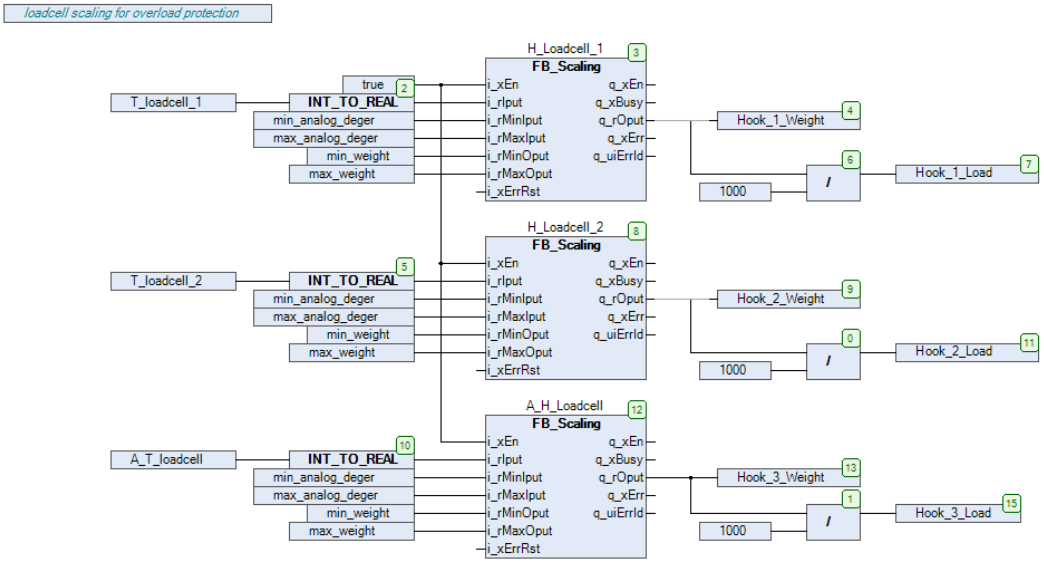

Figure 3. Loadcell scaling program.

Findings

The study covers the design and implementation of a PLC-based automation system for a 120-ton capacity transportation system. The performance of the system was evaluated based on key operational metrics and compared with traditional manual operation methods.

Key Observations:

- Synchronized Lifting Accuracy: The designed hook synchronization algorithm maintained a positional deviation within ±5 mm between the 80-ton and 40-ton lifting groups during lifting and lowering cycles, ensuring stable load handling.
- Load Transport Synchronization: The travel synchronization algorithm successfully equalized the linear speeds of different lifting groups, reducing misalignment occurrences by over 90% compared to manual control.
- Fault Monitoring & Safety: The PLC-based overload protection mechanism, integrating pin-type load cells and analog input modules, accurately detected simulated overloading conditions in 100% of test scenarios, triggering appropriate system responses.
- Operational Efficiency: Compared to conventional relay-based or contactor-based systems, the PLC-controlled automation system achieved a 20% reduction in load handling time and improved process repeatability, reducing operator-dependent variability.
- System Monitoring: The integration of HMI enabled real-time visualization of motor parameters (current, speed, torque) and temperature levels, enhancing diagnostics and reducing average fault detection time by an estimated 40%.

Overall, the system demonstrates measurable improvements in safety, reliability, and operational performance over traditional methods lacking automated synchronization and real-time monitoring.

Conclusion

In conclusion, the implementation of a PLC-controlled automation system in a 120-ton capacity transportation system has proven highly effective in improving operational efficiency, safety, and fault monitoring.

Performance evaluation using predefined metrics such as synchronization accuracy, overload detection reliability, and operational cycle time has shown that the system performs with high precision and consistency. For example, synchronized lifting was achieved within ±5 mm deviation, and overload protection was successfully triggered under all test conditions.

When compared to traditional systems based on manual control or simple contactor logic (without PLC, HMI, or drive systems), the proposed system offers significant advantages, including:

- Reduced operation time by 20%,
- Improved load handling stability,
- Enhanced fault monitoring and system visibility,
- Lower risk of operator-induced errors.

For future developments, the integration of a SCADA system is recommended to allow for remote monitoring, historical data logging, and advanced analytics, further enhancing system optimization. This study highlights that even in large-scale industrial applications, cost-efficient automation based on PLC and HMI technologies can substantially improve the precision and safety of transportation systems.

Keywords: Artificial Intelligence, Means-end Chain, Strategy, Value.

Aim

The Industry 4.0 process refers to a period in which radical changes are experienced in many sectors, along with the rapid development of technology and the spread of digitalization. In this process, innovative technologies such as AI, big data, the Internet of Things (IoT), and cyber-physical systems are integrated into business processes, enhancing efficiency, accelerating processes, and increasing flexibility. While Industry 4.0 symbolizes a new era that allows businesses to optimize their production and management processes, AI stands out as one of the technologies that stand out in this process. (Sarnıç and Acar, 2024)

AI has many different uses today. For instance, the use of AI applications in the field of HR management has increased by 300% in the last five years (Makers Consulting, n.d.). In the legal industry, AI can enhance efficiency and lower costs by automating repetitive tasks and streamlining workflows (Ultralytics, n.d.). In the e-commerce sector, AI can be used for chatbots, assistants, recommendations tools, visual and voice search, and customer relationship management (Fedorko, Kral and Bacik, 2022).

One of the most important areas of use is the IT sector. SAP Lean IX's AI survey of 226 global IT professionals in 2024 asked questions about the adoption of AI in the IT sector. 80% of survey participants said they currently use generative AI. 78% of participants said gen-AI enables them to finish their jobs faster, and 47% said it improves the quality of their work (SAP & LeanIX, 2024).

Although AI offers numerous advantages, the literature acknowledges that it also has certain drawbacks. This study explores the benefits and challenges of the growing use of AI in the IT sector and identifies core values that shape professionals' perceptions, adoption behaviors, and ethical considerations, based on individuals' responses. By integrating these core values with perceived benefits, potential drawbacks, and various sociodemographic characteristics, customized AI implementation strategies have been developed for different IT professionals.

In the literature review, several articles were identified that explored the underlying values associated with the use of Al. However, only a limited number of these studies employed Means-End Chain (MEC) analysis to uncover these values. Furthermore, no existing studies were found that directly investigate the motivations of employees in the IT sector concerning Al through MEC analysis. This gap in the literature highlights the unique contribution of our study, as it aims to address this underexplored area by employing MEC analysis to uncover the value-driven motivations of IT professionals in relation to Al technologies.

Material and Method

This study employs the MEC Theory, a value-based cognitive approach that helps us better understand individual behavior and decision-making. MEC establishes a connection between extremely abstract and intangible personal and emotional qualities (the ends) and the material characteristics of a product (the means) (Olson and Reynolds, 2001).

MEC Theory explains the underlying reason why certain outcomes are considered important by linking them to individuals' core values. To reveal these hierarchical value structures, a qualitative method known as laddering—developed by Gutman and Reynolds—is employed through in-depth interviews and analysis. The resulting ladders, which consist of interconnected attributes, consequences, and values, illustrate how individuals cognitively

associate an offering with their personal motivations. This structured linkage provides a clearer and more actionable understanding of people's perception and decision-making (Reynolds and Gutman, 1988).
The three hierarchical levels within this approach can be described as follows (Gutman, 1982):

- **Means:** The tangible features of the offering (product or service).
- **Consequences:** The functional or psychological effects that these features generate for the user.
- **End Values:** The individual's ultimate goals or personal values (e.g., happiness, success).

In this study, one-on-one in-depth interviews were conducted with 30 participants by applying the soft laddering method. The process began with demographic questions, followed by questions about the advantages and disadvantages of AI use. The interview, structured as a series of "why" questions, continued iteratively until each participant's underlying personal values were identified through their responses.
According to the soft laddering method, physical and online in-depth interviews lasting an average of 45 minutes were conducted. First, the following socio demographic questions were asked: Age, Gender, Seniority, Education Level. Then, starting with warm-up questions about AI, the following three questions were asked:

- Do you use AI in your daily workflow?
- How often do you use AI?
- For what purposes do you use AI the most?

Then, in the section about advantages, the following question was asked to find the attribute:

- What advantages might increasing or starting to use AI in your current workflows bring you?

Following the participant's response, the following question was asked to further explore the perceived advantages until a terminal value was reached:

- Why is this important to you?

Once the value was identified, the discussion shifted to the disadvantage section. The following question was then asked to identify the Attribute:

- What disadvantages might increasing or starting to use AI in your current workflows bring you?

After the participant responded to this question, additional questions were posed to explore the associated costs until a terminal value was reached.

- Why is this important to you?

While some participants were asked the question 'why is it important?' three times, some participants were asked up to six times.
In the light of the information provided by each participant in the interview, two separate matrices and hierarchical value maps (HVM) were prepared for the advantages and disadvantages that AI will create in the IT world. These maps contain attribute-consequence-value paths. Multiple correspondence analysis (MCA) was used to visualize the MEC components and demographic data from the interviews. Thus, the results are shown in a two-dimensional map. Based on the MCA analysis, an AI-implementation strategy was developed for the company.

Findings

All of the participants use AI in their daily workflows. While the vast majority use it for information retrieval, they do not place full confidence in the accuracy of the information AI provides.
While existing literature highlights key values underlying AI use, such as autonomy (Malouin, 2021), socialization (Rietz, 2021), self-actualization (Bankins & Formosa, 2023), and enjoyment (Rzepka, 2019), this study reveals that participants frequently emphasized additional values, including success, happiness, and dignity.
In some of the interviewees, the values obtained from the advantages map were the same as the values obtained from the disadvantages map. However, for most individuals, the value obtained as a result of advantage and disadvantage was different. For instance, while 'happiness' was found as a value in one interviewees advantages map, 'freedom' was found as a value in her disadvantages map.
Most participants emphasized productivity, time saving, and the opportunity for people to focus on more value-added work thanks to AI, as benefits and attributes. This output is consistent with the productivity increase (McKinsey & Company, 2020) argument that is frequently encountered in the literature under the advantages of using AI.

At almost every experience level, participants believe that they will have more diverse job opportunities as the use of AI increases.

Findings such as unemployment concerns (Rawashdeh, 2023) or remuneration changes (Ernst et al., 2019) due to AI, which are included as costs in the literature, were not frequently included in the study. In the interviews about disadvantages, it was frequently encountered that the quality of the work and people's creativity would decrease due to the intensive use of AI, as costs and attributes.

The results indicate that seniority within the sector, along with age, emerged as significant variables. At more junior levels, values such as staying in touch and freedom are more frequently repeated. As we approach the junior level, financial freedom concerns come to the fore as a cost.

As experience in the IT sector increases, core values such as self-actualization and dignity are more frequently repeated. More senior participants frequently stated that AI's hallucinations could cause problems in accessing accurate information, and therefore they had concerns about the scalability and sustainability of projects carried out with AI as costs.

Conclusion

In light of the findings provided above, it has been concluded that a single AI implementation strategy cannot be created within a company, and even if an umbrella strategy is created, sub-strategy clusters that appeal to the different values of employees with different socio-demographic features should be created.

A strategy proposal was presented for the senior and executive level with the theme of self-actualization and increasing their prestige in the sector in which they have been operating for many years. This strategy will not only strengthen the reputation of individuals, but will also strengthen the reputation of the company. Employees will increase their reputation and visibility by leading innovative AI projects. In this way, companies will be able to ensure that seniors and executives work willingly to become leaders in AI.

For employees close to the Gen-Z age group (junior and mid-level), a strategy has been developed to include them in projects that will result in them working more autonomously after using AI, emphasizing that the use of AI will make them more independent. Designing AI systems in a company that gives them control will motivate them to work. Giving them freedom to use AI tools and allowing them to choose the tools they will use will reinforce their sense of freedom. In order for them to progress successfully in their careers, they must be supported with technical training and be able to clearly see career opportunities within the organization.

Thus, two AI strategies produced for institutions will ultimately accelerate the institution's AI implementation. This structure separates strategies both horizontally (technical) and vertically (psychological/motivational), taking into account value-based differences within the institution. Thus, AI becomes not only a technological but also a human-centered and value-compatible transformation tool.

DISASTER AND EMERGENCY MANAGEMENT

Debris Management

Post-Disaster Debris Recycling: Mobile Recycling Units and On-Site Separation

Esra İmer [a], Abdullah Can Zülfikar [a], Didem Saloğlu Dertli [a]

[a] Istanbul Technical University, Disaster Management Institute, Disaster Management Programme, Türkiye
imere24@itu.edu.tr

Keywords: Debris Management, Mobile Recycling Units (MRUs), On-Site Separation.

Aim

Post-disaster debris management is not merely a waste disposal process but a complex procedure encompassing environmental, economic, and social dimensions. The destruction caused by disasters generates a substantial amount of construction and demolition (C&D) waste **(Figure 1)**. Inefficient management of this debris can lead to resource depletion, environmental pollution, and economic losses. Traditional disposal methods are not sustainable in the long run. In this context, mobile recycling units (MRUs) and on-site separation methods enable the rapid and efficient recycling of debris. This study aims to examine the effectiveness of mobile recycling units (MRUs) and on-site separation methods in post-disaster debris management, assess their economic and environmental contributions, and discuss their applicability in disaster-affected areas. Specifically, the research investigates the impact of MRUs on debris disposal costs, logistical advantages, and recycling rates.

Figure 1: February 6 earthquakes in Kahramanmaraş, Türkiye (*TÜRKONFED, 2023).*

Material and Method

This study includes a systematic review of previous research on post-disaster debris management and, based on these studies, develops a conceptual project focusing on identifying the areas with the highest debris accumulation and designing a temporary storage and recycling site model for recycling and other disposal alternatives. As part of the literature review, academic articles, government reports, and data from international organizations have been analyzed regarding construction and demolition (C&D) waste management**,** disaster waste recycling processes, and the use of mobile recycling systems**.** Additionally, the effectiveness of mobile recycling facilities and on-site

separation systems has been evaluated through an assessment of recycling methods implemented in disaster-affected areas and academic research reports.

Findings

1. The Importance of On-Site Separation of Debris

Construction and demolition (C&D) waste accounts for 30% of the total waste generated worldwide (EPA, 2019). In addition to the types and composition of debris, the sheer volume, often exceeding several times the daily solid waste generated under normal conditions, can quickly overwhelm traditional disposal systems ***(Table 1).***

Table 1. Waste Quantities Generated Due to Disasters (Brown et al., 2011).

Year	Event	Amount of waste
2010	Haiti Earthquake	23-60 million tons
2009	İtaly-L'Aguila Earthquake	1.5-3 million tons
2008	China-Sichuan Earthquake	20 million tons
2005	ABD-Hurricane	76 million m3
2004	ABD/Florida, Frances, and Jeanne Hurricane	3 million m3
2004	Indian Ocean Tsunami	10 million m3
2004	ABD-Charley Hurricane	2 million m3
1999	Turkiye-Marmara Earthquake	13 million tons
1995	Japan-Kobe, Big Hanshin Awaji Earthquake	15 million tons

Debris disposal accounts for more than 27% of the total disaster costs (Fetter & Rakes, 2012). On-site recycling through mobile units reduces the burden on waste disposal sites and contributes to the economy by lowering costs. Global disasters and related losses have been recorded since the 1980s with the advancement of technology ***(Figure 2).*** These records have shown that economic losses have increased over time. In light of these data, traditional debris management systems are becoming inadequate for the growing number of disasters and the debris they generate.

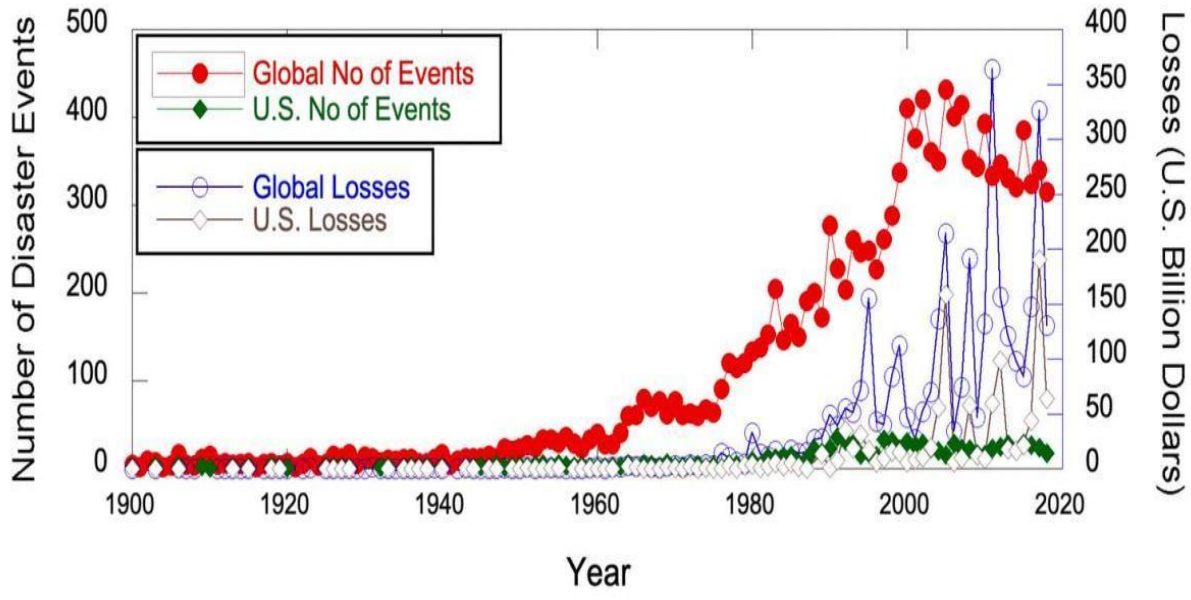

Figure 2. Global Disasters and Associated Losses After 1980, Emergency Events Database (EM-DAT) Data (Derrible, Choi, and Yeşiller, 2019).

2. Waste Types and Waste Disposal Options

The nature of debris or waste may vary depending on the type of disaster, but disaster debris is typically a mixture of one or more of the following categories (Table 2). Each of these waste categories presents unique challenges for disposal, even under normal conditions, and their disaster-related combinations often create new complex categories with increased challenges for separation, cleaning, and disposal.

- **Concrete and Mortar:** Constitutes the majority of demolished buildings.
- **Metals:** Includes recyclable materials such as steel and aluminum. Additionally, recycling steel consumes 75% less energy than producing new steel
- **Wood and Organic Materials:** Primarily sourced from rural buildings and furniture.
- **Plastic and Glass:** Obtained from interior furnishings and windows.
- **Hazardous Waste:** Includes materials such as asbestos, lead, paint, and chemicals that require special handling.

Table 2. Uses of Waste Generated from Disasters (Öztürk, 2017).

Waste material	Areas of Use
Metals	Steel, non-ferrous metals
Tiles	Clay production
Bricks	Clay production
Walls	Lime
Construction Timber	Lumber
Wood Waste	Compost, Energy production.
Green Waste	Compost, Energy production.
Electric Tools and Cable	Aluminum, copper
Plumbing Equipment and Copper Pipes	Brass, bronze

3. Debris Recycling Processes

The removal of debris from disaster zones is a difficult and costly process. Several methods exist for the proper management of disaster waste. The composition of disaster waste is similar to construction and demolition waste. Therefore, regular construction and demolition waste management methods can serve as a guide for disaster waste management. The most common way to manage construction waste is to collect all the waste from the site and transport it to landfills for final disposal; this method is the traditional approach to disaster waste. Another method involves transporting the collected waste to a recycling facility and sorting reusable and recyclable components either before or after transportation. However, this creates high costs due to the need for transporting the waste twice. One of the most environmentally friendly methods is sorting all materials at a temporary site according to their characteristics. This way, the disposal of untreated hazardous waste in landfills can be minimized (Onan, 2005). This method offers significant savings in logistics and time.

3.1. Mobile Recycling Units and On-Site Recycling

There are big differences between daily waste management and waste that occurs during a disaster. The large volume of disaster-related debris significantly strains existing storage capacities. The method focused on in this project is a study that enhances on-site separation through the previously mentioned temporary site sorting method. The study aims to identify the areas with the highest concentration of debris after a disaster and works on a model for temporary storage and recycling areas, considering recycling and other disposal alternatives ***(Figure 3).*** Mobile recycling units are modular systems equipped with portable equipment capable of processing various types of

debris and waste on-site ***(Figure 4).*** Compared to traditional fixed recycling facilities, they reduce logistical costs and offer the potential for rapid intervention.

Recycling Network

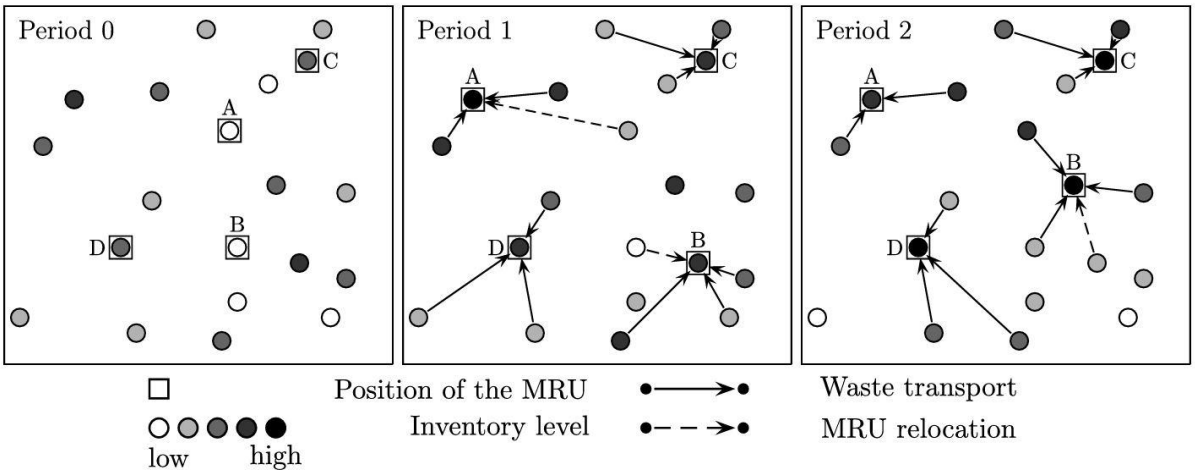

Figure 3. Graphical example of a recycling network (Alarcon-Gerbier and Buscher, 2024).

A network of 20 nodes is considered, where four MRUs can be relocated at the beginning of each period. A certain amount of waste is collected and stored at each node, graphically represented by different shades of gray for the nodes. Since storage capacity is limited, waste must be transported to another node or recycled on-site. As shown in Figure 3, the current inventory level and location of MRUs at each node are known. Based on this information and taking into account the amount of waste collected in subsequent periods, new locations of MRUs are defined to minimize total transportation costs. In this example, MRU B moves eastward at the beginning of period 1 due to the higher inventory level at that node. The same MRU moves north at the beginning of term 2. Some amount of waste still needs to be transported between nodes. If the MRU remains in its original position, the total distance traveled and therefore the total transportation costs are greater. It is important to emphasize that it is not necessary to transport waste from all nodes, as each node has some, albeit limited, storage capacity (Alarcon-Gerbier and Buscher, 2024).

4. Mobile Recycling Facility and On-Site Separation Concept Project

Within the scope of this study, a conceptual temporary social housing project was developed in the war-torn city of Marawi in the Philippines, using mobile recycling facilities and on-site segregation methods, with a focus on the reuse of debris. The project was designed theoretically to emphasize the reuse of rubble, the implementation of mobile recycling units, and on-site material separation. It originated from the question: *"Can a new city be built from the remnants of the old one?"* As an initial step, the method outlined in Figure 3 was applied at an urban scale. Following a rapid post-conflict site assessment, the most severely damaged areas of the city were mapped, and key nodal points were identified. A network was then established by installing mobile recycling systems at these nodes ***(Figure 4).*** A conceptual temporary social housing project was developed in the area with the highest concentration of debris, utilizing on-site recycling methods. Except for the primary structural framework, all other building components were designed using recycled debris materials ***(Figure 5).*** Following the mapping process, temporary mobile recycling facilities were installed at the designated nodes—i.e., the areas with the highest debris concentration—and the segregation and recycling process commenced ***(Figure 4).*** Debris sorted on the ground was lifted via a crane system for further processing and then stored in other units after being recycled.

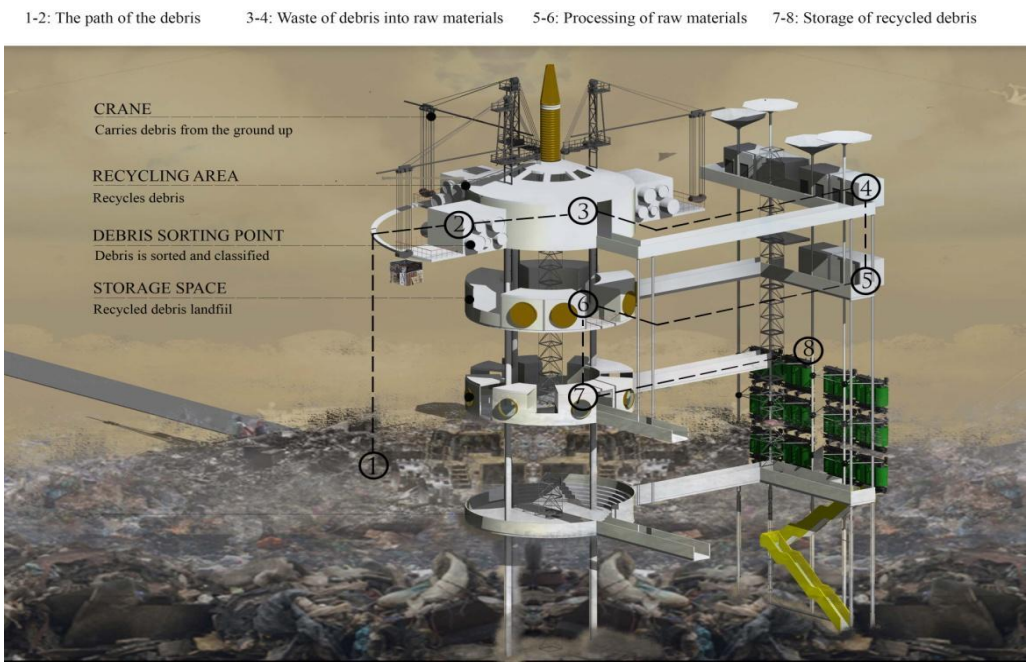

Figure 4. Concept Design of the Mobile Recycling Unit (MRU).

While the project's load-bearing structure was built using new materials, other structural elements (walls, windows, doors, flooring, etc.) were designed using recycled materials ***(Figure 5).*** After the project is completed, the removal of the mobile recycling facility from the site is planned.

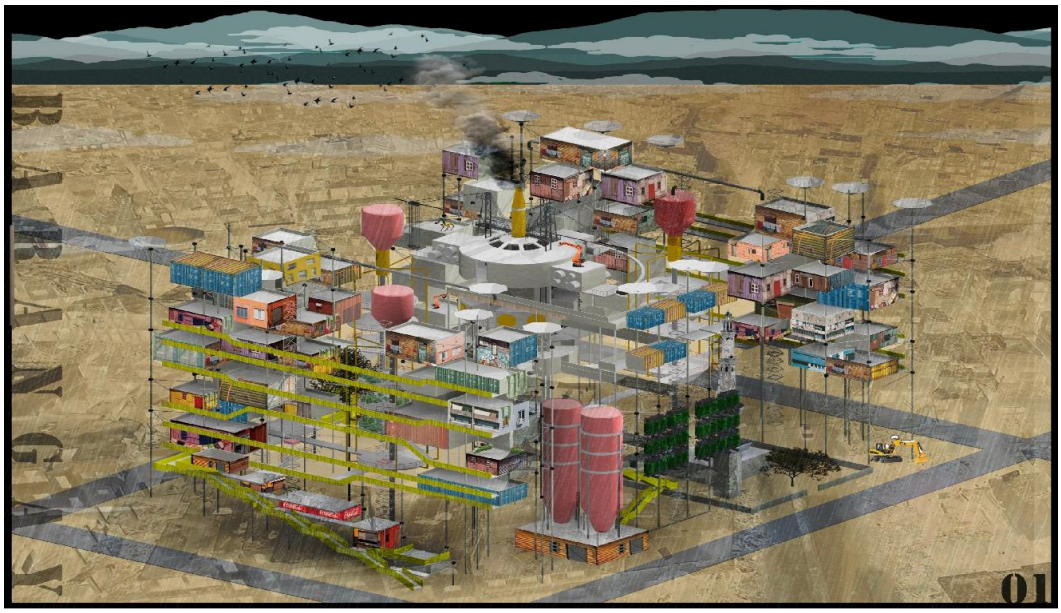

Figure 5. Concept Design of Social Housing Built Using Recycled Debris.

Conclusion

Disasters will continue to have devastating effects on both people and the environment in the future, just as they have in the past. While the loss of human lives is the most significant consequence of a disaster, the destruction of buildings and infrastructure also represents a major loss for both the economy and the ecosystem. The collapse of buildings and infrastructure during disasters generates large amounts of debris, such as concrete, bricks, and timber, adding an additional burden to communities. The disposal options for disaster-related waste and the

methods applied for its management play a crucial role in protecting both environmental and public health. As part of disaster management, the objectives of disaster waste management include minimizing risks to human life and health, reducing environmental hazards, and providing benefits to affected communities (Güler, 2018). In the post-disaster debris management process, mobile recycling units (MRUs) and on-site separation methods offer an environmentally and economically efficient alternative. Compared to traditional disposal methods, MRU systems consume less energy, facilitate the separation of recyclable materials within the debris, and reduce waste transportation costs. The widespread adoption of these methods will enhance the sustainability of waste management in disaster-affected areas.

Ecological Restoration Potential of Istanbul: Opportunities, Challenges and Risks

Saliha Akkayüz[a]

[a] Istanbul Technical University, Eurasia Institute of Earth Sciences, Earth System Science Program, Türkiye
kayas16@itu.edu.tr

Keywords: Urban Ecological Restoration, Biodiversity, Istanbul.

Aim

Urban green spaces are among the most important daily contact points with nature for urban residents, and growing evidence highlights their substantial benefits for health and recreation (Dearborn & Kark, 2010; Clarkson & Kirby, 2016). These spaces have also been shown to help prevent the negative effects associated with what is known as "nature deficit disorder" (Hartig & Kahn, 2016).). Moreover, studies indicate that people tend to prefer urban green spaces rich in species and natural diversity over species-poor lawns or standardized vegetation (Sikorski, 2018; Fischer, 2020).

Urban ecosystems have often undergone significant alterations and ecological degradation due to various factors, including green spaces designed with monocultures, low species diversity, and non-native species; soils that have been compacted and modified by human activities; heavy human use; construction activities; and habitat fragmentation that disrupts seed dispersal (McCleery, 2014). These ecological deficiencies significantly limit the capacity of urban areas to support biodiversity and weaken several key ecosystem functions and services that directly depend on biological diversity (Bullock, 2011; Lin, 2015; Lindemann & Matthies, 2018).

Various initiatives, such as the United Nations Decade on Ecosystem Restoration 2021–2030, underline the urgent need to improve urban ecosystems to better conserve biodiversity and make more effective use of the potential benefits provided by ecosystem services. In addition, several studies emphasize the need to reconsider the design and management of urban green spaces to help cities adapt to climate change (Mathey, 2011; Maimaitiyiming, 2014, Liu, 2017).

The often irreversible changes in urban ecosystems show that traditional ecological restoration approaches, which rely on historical reference systems, are only partially applicable to urban areas (Kollmann, 2019). In many cases, factors such as land scarcity, high costs, and permanent environmental alterations make it impossible to fully restore historical reference conditions in cities. Therefore, it is recommended to use urban reference systems — sites that experience similar conditions and constraints as restoration areas, but successfully sustain the desired species composition and ecosystem functions (Klaus, 2019).

This study investigates the ecological restoration potential of Istanbul, one of the most densely populated metropolises in the world. Despite experiencing intense urbanization pressure, Istanbul supports 2,512 plant taxa, exceeding the plant diversity of many European countries such as the United Kingdom and the Netherlands, which highlights the ecological value and significance of the city (Kabakçı, 2016; Akkemik, 2017; Özhatay, 2010; Avcı, 2014). The study aims to develop restoration strategies for improving degraded urban ecosystems, tailored to Istanbul's unique ecological characteristics and rich biodiversity. In this context, the potential increase in species richness and abundance following ecological restoration is also evaluated, with the aim of revealing the contribution of urban ecological restoration to biodiversity conservation.

Material and Method

Using Google Earth Engine (GEE), a 10-meter resolution NDVI map of Istanbul was produced (Figure 1). This map was combined with a spatial dataset obtained from the Istanbul Metropolitan Municipality (IMM), which classifies green spaces under IMM's responsibility according to their functions and types, along with their area measurements. Based on their characteristics, these green spaces defined by IMM were categorized into five

distinct Urban Reference System (URS) classes: severely degraded novel ecosystems, novel ecosystems, hybrid ecosystems (severely degraded historical ecosystems), degraded historical ecosystems, and historical ecosystems. Undefined areas were classified using an object-based spatial analysis approach. To assign areas outside IMM's responsibility to the appropriate URS categories, the NDVI raster data was reclassified using a threshold value of 0.2 to detect green spaces not previously categorized under any URS class. These areas were then converted from raster to polygons. Each resulting green space polygon was assigned values for area size (m²), shape metrics (perimeter-to-area ratio), and average NDVI.

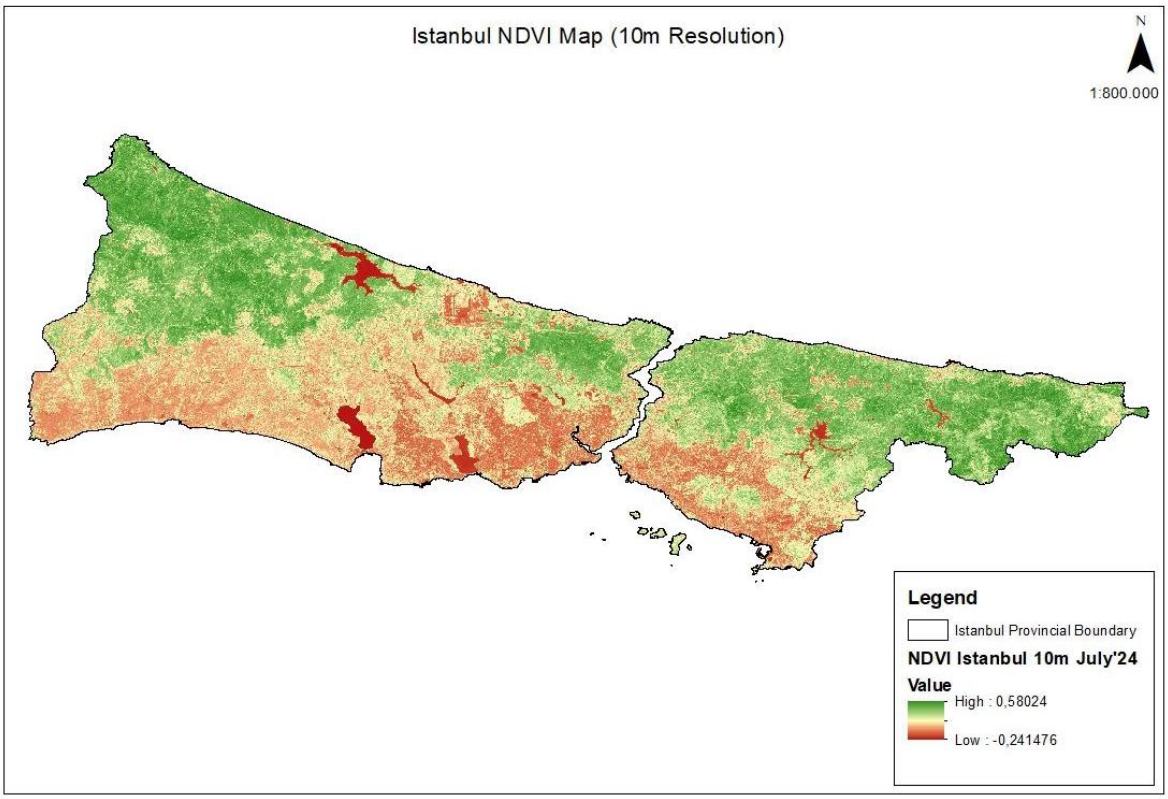

Figure 1. Istanbul NDVI Map (10 m Resolution).

The average NDVI value for each green space polygon was calculated using the "Zonal Statistics as Table" tool, and these values were used alongside area size and shape metrics in the classification rules. A decision tree approach was adopted to assign undefined areas to URS categories. Areas larger than 20,000 m² with NDVI values above 0.5 and shape ratios close to 1 were classified as historical ecosystems; areas with NDVI values between 0.4 and 0.5 and medium size were identified as degraded historical ecosystems. Small, homogeneous areas under 1,000 m² with low NDVI values were assigned to the novel ecosystem category.

The newly generated polygons resulting from this classification were then merged with the IMM-managed areas already categorized under URS, resulting in a comprehensive URS map covering the entire city of Istanbul. As a final outcome, a shapefile dataset was created that includes green space polygons assigned to one of the five URS classes mentioned above, encompassing the entire urban area.

Biodiversity data for Istanbul obtained from the Global Biodiversity Information Facility (GBIF) (GBIF.org (27 February 2025)) were overlaid on this map to analyze species richness and abundance across different ecosystem types.

For novel ecosystems where a return to historical, pre-disturbance conditions is not possible, habitat enhancement strategies aimed at improving ecosystem functions and/or biodiversity were proposed based on recommendations from the literature. Similarly, for severely degraded hybrid ecosystems and degraded historical ecosystems, restoration strategies recommended in the literature were identified (Smith & Fellowes, 2014).

To estimate biodiversity gains, the potential increase in species richness and abundance was calculated under the assumption that severely degraded novel ecosystems could be restored to the level of novel ecosystems. Likewise, the potential biodiversity contributions of transforming hybrid ecosystems into degraded historical ecosystems, and degraded historical ecosystems into historical ecosystems, were assessed.

Findings

The analyses demonstrated that green spaces in Istanbul can be categorized into URS classes based on both NDVI values and functional use classifications. Integrating NDVI data derived from remote sensing with spatial classifications provided by the Istanbul Metropolitan Municipality (IMM) enabled the identification of areas with the highest restoration potential.

Of the approximately 54.8 km² of green space managed by IMM, 42.17% (around 23.1 km²) consists of active green spaces where citizens can engage in recreational activities. The remaining 57.83% (approximately 31.68 km²) comprises passive green spaces, such as roadside slopes and medians, which are not publicly accessible. This indicates that passive green spaces, as they are not primarily designed for recreational use, offer broader opportunities for ecological restoration interventions. While restoration efforts in active green spaces must be balanced with recreational needs, passive areas allow for more flexible ecological interventions.

In active green spaces, ornamental areas designed with shrubs, roses, and flower beds—where direct human contact with vegetation is limited—offer an additional opportunity to enhance biodiversity through the inclusion of various native species. Moreover, creating more natural environments within these areas enhances the psychological benefits people derive from contact with nature (Standish, 2013).

Spatial overlays using GBIF data revealed that novel ecosystems have lower biodiversity compared to historical or hybrid ecosystems. This finding suggests that restoring degraded novel ecosystems could significantly contribute to biodiversity gains.

In hybrid ecosystems, which contain both historical and novel components, interventions such as reducing management intensity and reintroducing native species were found to enhance biodiversity. Proper restoration of these ecosystems could also help establish ecological connections between fragmented historical ecosystems (Anderson & Minor 2020).

The biodiversity analyses based on NDVI-based classifications and municipal maps underline the importance of applying differentiated restoration strategies tailored to each URS category.

Conclusion

Ecological restoration strategies developed specifically for Istanbul's urban context have shown potential to increase species richness and abundance. Through NDVI-based landscape classifications and spatial biodiversity data, ecosystem types with the greatest need for restoration can be identified and prioritized.

Restoration efforts that enhance connectivity, improve habitat quality, and integrate native species are expected to contribute to increased biodiversity both in degraded historical ecosystems and in newly emerging urban ecosystems. The findings demonstrate that even in cases where full historical restoration is not feasible, meaningful improvements in ecosystem functions and biodiversity levels can still be achieved.

In conclusion, ecological restoration efforts in Istanbul's urban green spaces present a significant opportunity not only for enhancing urban biodiversity, but also for strengthening ecosystem resilience and improving the quality of life for city residents.

Keywords: Artificial Neural Network, Gradient Descent, Load Frequency Control, Meta-heuristic Optimization, Renewable Energy Systems.

Aim

With the growing awareness of resource scarcity and the need for sustainable practices, efficiency and sustainability have become critical priorities. As a result, renewable energy sources are increasingly being integrated into power systems, whether in isolated networks or interconnected systems. However, this transition introduces additional complexity and presents significant challenges in maintaining the stability and reliability of modern power systems. One of the main reasons for this complexity is the intermittent nature of renewable energy sources. For instance, solar energy can only be harnessed during daylight hours. Additionally, factors such as cloud cover or the unpredictable nature of wind can lead to sudden variations in power generation. These fluctuations may result in load-generation mismatches and subsequent frequency deviations. In addressing these imbalances, load frequency control (LFC) plays a crucial role. When modeling the system, incorporating nonlinear components of the system, such as the governor dead-band (GDB) and generation rate constraint (GRC), can produce simulation results that more accurately reflect real-world conditions by accounting for physical constraints. Metaheuristic methods are widely employed to determine the global optimum values of controller gains in multi-area power systems because it is very useful in producing solutions for complex systems. For gradient calculation, area-1, area-2 and wind turbine generator which have controllers in the system are modeled with artificial neural network. In this study, an artificial neural network based adaptive controller is designed for a two-area power system integrated with renewable energy systems and it is aimed that the controllers optimized with meta-heuristic algorithms will achieve better reductions in frequency deviations.

Material and Method

Tuning of the commonly used proportional integral derivative (PID) controller is generally preferred for LFC applications. For this purpose, mathematical models are employed to obtain reliable estimates (Kundur, 2022). The small-signal model of the two-area interconnected hybrid power system is shown in Figure 1. In this model, each area incorporates a conventional power plant; in addition, area-1 is integrated with a wind turbine generator (WTG), and area-2 is integrated with a photovoltaic system (PV) system. The power deviation equations provide a fundamental representation of the power balance within each area. As derived from the block diagram, the power deviation equations are presented in Equation 1. The rated power of turbines is 250 MW at nominal frequency of 50 Hz.

$$\Delta P_{total1} = \Delta P_{gc1} + \Delta P_{gw} - \Delta P_{L1} - \Delta P_{tieline} \#(1a)\ \Delta P_{total2} = \Delta P_{gc2} + \Delta P_{gpw} - \Delta P_{L2} - \Delta P_{tieline} \#(1b)$$

The mathematical model of the wind turbine output power is derived from (Mahto, 2017). To regulate the output power of the WTG, a pitch controller is employed, which adjusts the pitch angle of the turbine blades according to wind speed. This is intended to provide an advantage for LFC. The WTG system in this study consists of 20 wind turbines, generating 5% of the Area-1 power at full capacity. The transfer functions of the WTG part of the power system, including the pitch controller, hydraulic pitch actuator, data fit pitch response, blade characteristic, wind generator system and fluid coupling are shown in Figure 1.

The PV system integrated into the power system is focused on Maximum Power Point (MPP) tracking. The PV system is influenced by irradiation levels and temperature. In this study, the temperature is kept constant at 25°C. At full capacity, it generates 5% of the total Area-2 power as output. A detailed description of the PV system is provided in (Masikana, 2024).

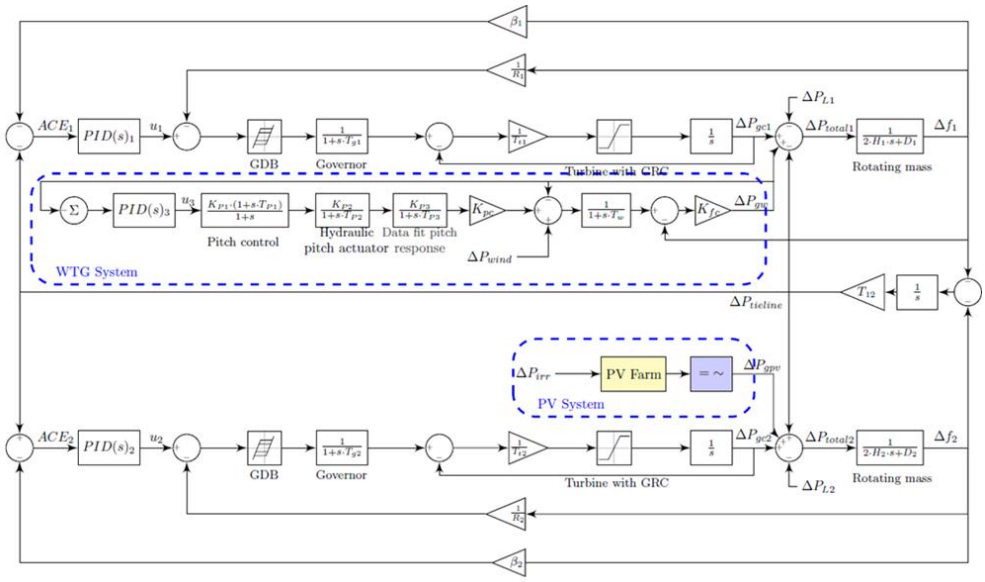

Figure 1. Hybrid two-area power system model for LFC.

As shown in Figure 1, there are three PID controllers in the system. The transfer function of the controller is expressed in Equation 2. where subscripts 1 and 2 represent the controller gains of Area-1 and Area-2, in that order, and subscript 3 represents the controller gain of the PID controller of the WTG. The output of the controller is given in Equation 3.

$$G_{PID1,2,3}(s) = K_{p1,2,3}.\left(1 + \frac{K_{i1,2,3}}{s} + K_{d1,2,3}.\frac{s}{100.s+1}\right) \#(2)$$

$$u_{1,2,3}(s) = G_{PID1,2,3}(s) \times ACE_{1,2,3}(s) \#(3)$$

Firefly algorithm assumes that variables have light intensities, similar to fireflies. The closer a solution is to the optimum, the brighter its light is, and the brighter fireflies attract the less bright ones. Additionally, a small random perturbation is added to this attraction. The closer the distance between them, the stronger the attraction force. Ultimately, the variables that yield the closest value to the desired result are assigned to the controller gains (Heris, 2015). In this study, the population size is selected as 40, and the maximum number of iterations is set to 50. The PID gains for Area-1 and Area-2 are searched within the range of (-1, 15). The gains of the WTG controller are searched within the range of (5, 15). The obtained values are presented in Table 1.

Table 1. Optimal PID gains obtained using FA and GA.

Algorithm	PID	K_p	K_i	K_d
FA	Area-1	1.7909	0.0286	4.1773
GA	Area-1	0.2945	0.1438	12.2079
FA	Area-2	0.4579	0.5274	4.9189
GA	Area-2	0.6035	0.4631	6.0448

FA	WTG	14.8947	9.0423	15
GA	WTG	8.9389	10.5382	10.6384

The dynamic control of a system with nonlinear and dynamic inputs, such as hybrid power systems, enhances control quality. In this study, the focus is on the gradient descent method for auto-tuning the PID parameters. The goal is to determine the variation law of the parameter vector ξ to be added to the system. The PID controller, with parameter vector ξ, needs to be automatically tuned to minimize the deviation function in Equation 4 (Nguyen, 2019). In this study, a separate gradient descent model is applied for each of the three controllers, and the values of e are denoted as ACE1, ACE2, and ACE3, respectively. By using the derivative results and signs of dJ/dξ < 0, dJ/dξ > 0 and dJ/dξ = 0, the minimum value of J is reached using the approach in Equation 5.

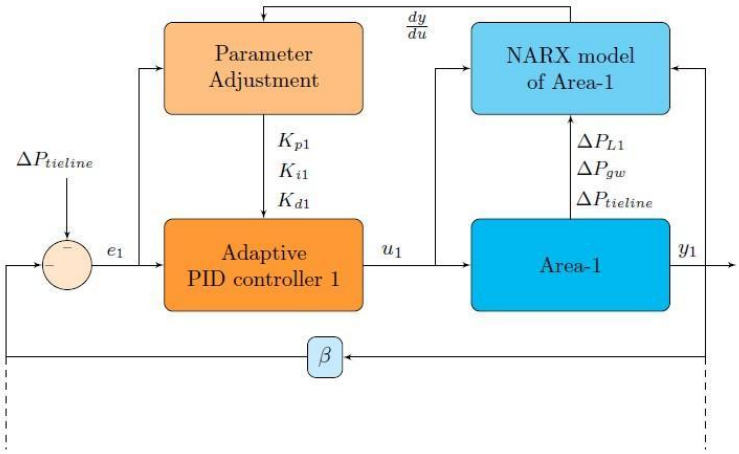

Figure 2. Adaptive PID controller scheme of Area-1.

$$J = \frac{1}{2}.e^2 \#(4)$$

$$\frac{d\xi}{dt} = -\alpha.\frac{dJ}{d\xi} \#(5)$$

The schematic of the power system model with the adaptive PID controller for Area-1 is shown in Figure 3. The schematic consists of four components: Area-1, NARX model, parameter adjustment, and adaptive PID controller. Here, the Area-1 component represents the model of the first area of our basic two-area hybrid power system. The NARX model component represents the trained artificial neural network (ANN) model for the first area. The parameter adjustment block calculates the parameter vector to be added to the controller gains using data received from the ANN and other parts of the system, and then transmits it to the adaptive PID controller.

In this study, the NARX model was chosen for the ANN application to model a time-series nonlinear system. The neural networks generated using the narxnet function in MATLAB have 14 neurons in the hidden layer for Area-1 and Area-2, with an input delay of 30 time-steps, while the WTG model has 10 neurons in its hidden layer with an input delay of 20 time-steps. The activation function used is tanh, and the training function employed is the Levenberg-Marquardt backpropagation. As a result of the input delay, the inputs are represented in the form of (x(t−1), x(t−2), ...x(t−30), y(t−1), y(t−2), ...y(t−30)). The inputs of the ANN models representing Area-1 and Area-2 are u1,2, ΔPL1,2, ΔPgw or ΔPgpv, and ΔPtieline while the output is Δf1,2. The inputs of the WTG ANN model are ΔPwind, Δf1, and u3 while the output is ΔPgw.

Equation 6 shows the mathematical expression of the ANN model. X is the input matrix of the ANN. To obtain the parameter vector of the adaptive PID controller, the chain rule is applied to reach the dJ/dξ (Nguyen, 2019, Taşören, 2020). In Equation 7, dJ/dξ is the derivative of J with respect to the PID parameters, dJ/de is the derivative of J

with respect to the error, and de/dy is clearly shown in Figure 1 and Figure 2, dy/du ≈ dy/dXu is obtained from Equation 6, and du/dξ is derived from Equation 3. As a result, the equality of the PID parameter vector is given in Equation 8.

$$y = W_{out}^{T}.tanh\ tanh\ (W_{in}^{T}.X + b_{in})\ + b_{out} \#(6)$$

$$\frac{dJ}{d\xi} = \frac{dJ}{de}.\frac{de}{dy}.\frac{dy}{du}.\frac{du}{d\xi} \#(7)$$

$$\xi(n) = \xi(n-1) - \alpha.\frac{dJ}{d\xi}(n) \#(8)$$

Findings

In this study, the performances of GA-PID, FA-PID, and a neural network-based adaptive PID controller trained on values obtained from FA have been compared using PID coefficients derived from a single scenario. The study was modeled and simulated in the MATLAB/Simulink environment. In the scenario in this study, the input variables are shown in Figure 3. Under these conditions, the performance of the adaptive PID controller is compared with that of the non-adaptive controllers. Figure 4 presents the responses of Δf1, Δf2, ΔPtie and ΔPgw, respectively. As observed in the graphs, the adaptive PID has demonstrated significant improvements in frequency deviations starting from the 80th second. During the 80–120 second interval, the frequency deviations obtained with the other two controllers exceed 0.02 Hz, with a settling time of up to thirty seconds. In contrast, the adaptive PID limits the deviation to 0.05 Hz and achieves stability within fifteen seconds. A similar behavior is observed from the 130th second onward. This effect is also reflected in the ΔPtie response; however, no noticeable performance improvement is observed in ΔPgw. Furthermore, when examining the performance indices of the three controllers in Table 2, it is observed that the adaptive PID outperforms the other controllers significantly in terms of IAE, ISE, and ITAE results. Finally, Figure 5 presents the real-time variation of the controller coefficients.

Figure 3. Power system input variations (a) ΔP_{L1} (b)ΔP_{wind} (c) $\Delta P_{irr.}$

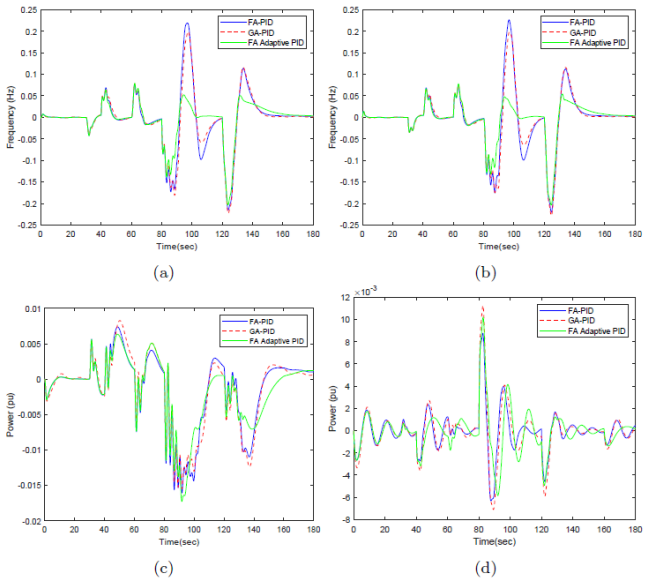

Figure 4. Comparison of the controllers under random input variations (a)Δf_1 (b)Δf_2 (c)ΔP_{tie} (d)ΔP_{gw}.

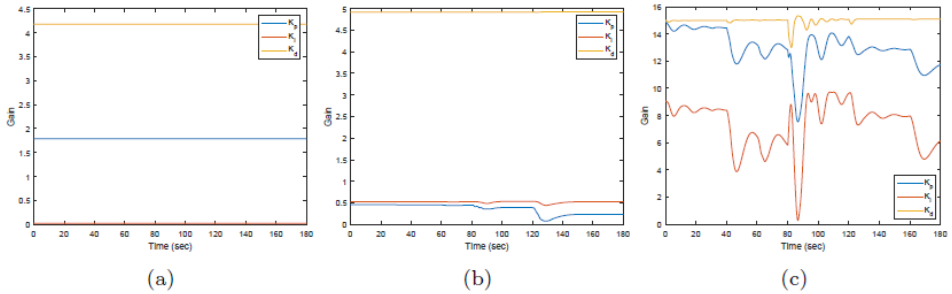

Figure 5. Variation of the adaptive PID coefficients (a)controller-1 (b)controller-2 (c)controller-3.

Table 2. Performance index of the controllers.

PID controller	IAE	ISE	ITAE
FA-PID	5.861	0.281	586.4
GA-PID	5.784	0.267	572.5
FA Adaptive PID	3.877	0.126	385.5

Conclusion

In this study, an ANN-based gradient descent PID controller has been applied to an interconnected power system for LFC with the integration of RES. The power system model incorporates GDB and GRC. For comparison, a PID controller optimized for only a single scenario and not re-optimized under varying conditions has been employed. The proposed method has exhibited superior and faster damping performance in frequency deviations, along with better results in performance indices. However, no noticeable improvement has been observed in the output power of the WTG. Consequently, it is suggested that the proposed method can be adapted to different control techniques to further enhance system performance.

Aim

Electric vehicles (EVs) have emerged as a cornerstone of sustainable transportation, driven by efforts to reduce greenhouse gas emissions and dependence on nonrenewable energy resources. Their low-emission operation, combined with advancements in battery technology, makes them increasingly viable for both personal and commercial applications. However, two critical challenges, such as limited driving range and high energy consumption, continue to hinder their widespread adoption. To address these concerns, a growing body of research focuses on "eco-driving" strategies, which minimize energy usage through deliberate control of speed, acceleration, and braking.

Although much of the eco-driving literature focuses on optimizing acceleration and deceleration under varying road conditions, routes featuring uphill or downhill slopes present additional challenges, as power demand, battery usage, and regenerative braking potentials can shift dramatically (Recalde et al., 2024). While modest slopes may have negligible impact over short distances, these effects accumulate substantially over longer or more frequently sloped routes (Kamal et al., 2011). Consequently, slope-aware eco-driving has emerged as a specialized area, incorporating methods such as Model Predictive Control (MPC) or reinforcement learning to adapt vehicle speed in real time (Bakibillah et al., 2018; Wu et al., 2023). Yet, these techniques often require significant computational resources and repeated planning cycles to accommodate longer or multi-segment trips, posing challenges for deployment.

This study proposes a slope-aware hybrid eco-driving framework for EVs that balances the realism of high-fidelity simulations with the computational efficiency of machine learning (ML) and meta-heuristic optimization. The framework begins with an offline simulation phase, where a comprehensive dataset is generated by simulating various driving scenarios along a basic route composed of multiple segments, including uphill, downhill, and flat sections, with different boundary speeds. Based on this dataset, two surrogate ML models are trained to predict total travel time and total energy consumption for any given speed profile. These models act as fast approximators, replacing repeated calls to computationally expensive simulators during the optimization process. In the online phase, a Particle Swarm Optimization (PSO) algorithm leverages these surrogate models to identify the optimal speed trajectory that minimizes energy consumption while satisfying a user-defined travel time constraint. By decoupling the computational burden of simulation from the real-time optimization, the proposed method ensures scalability and adaptability to various road configurations and constraint sets, making it a practical solution for energy-efficient route planning in EVs.

The methodology is evaluated on a 700-meter route divided into nine segments, each with a known length and slope. Although this example focuses on slopes of ±3° and flat sections, the same procedure can be extended to longer routes, steeper inclines, or more restrictive speed constraints. The underlying principle is to explore local adjustments to segment entry and exit speeds, thereby distributing speed changes more intelligently across uphill and downhill portions of the route.

Material and Method

a. Overall Workflow

The proposed method is organized into three core stages. First, a high-fidelity simulation of the EV is performed offline to generate a large dataset of hypothetical speed profiles and their associated time and energy outcomes. Second, ML surrogates (one model for predicting total travel time, another for total energy consumption) are trained on this dataset. Finally, a PSO algorithm uses the surrogates to explore a range of potential speed profiles, identifying one that meets a specified travel time with minimized total energy. Figure 1 illustrates the complete workflow, from data generation to final performance validation.

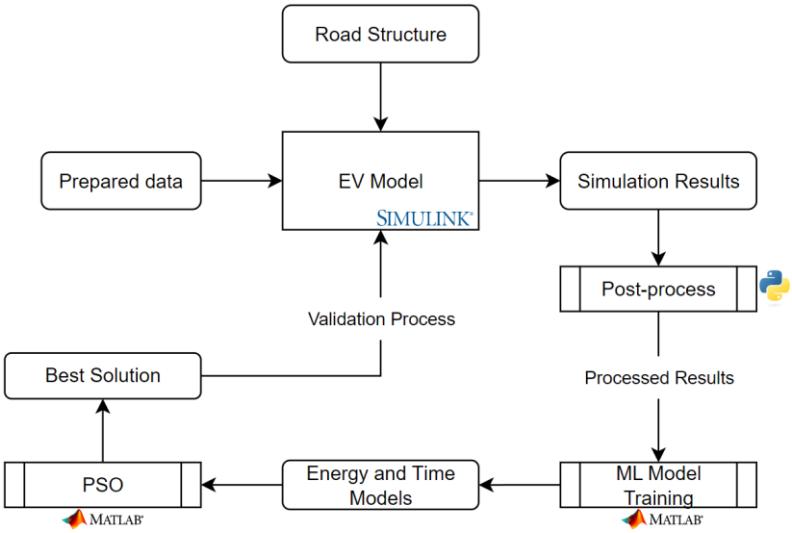

Figure 1. End-to-End Workflow.

b. Route Setup and Road Geometry

To evaluate the proposed methodology, a 700-meter test route composed of segments with varying slopes and lengths is used, as shown in Figure 2. The route includes flat, uphill (+3°), and downhill (−3°) segments, with lengths of 100 m and 50 m.

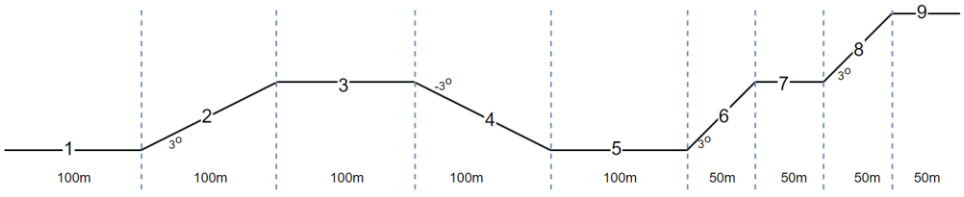

Figure 2. Road Structure.

A constraint enforces that the vehicle's speed at the start of segment 1 must match its speed at the end of segment 9, reflecting a realistic scenario where the vehicle enters and exits the entire route at a specified speed. Additionally, a maximum speed limit ensures that candidate solutions remain physically and legally acceptable. By dividing the route into distinct segments, slope effects are localized, and the optimization algorithm can tailor speed decisions to each individual segment.

c. Offline Simulation for Data Generation and Post-processing

The first step in developing the proposed eco-driving system is to generate an offline dataset that captures how different segment boundary speeds influence total travel time and energy consumption. For this purpose, a Simulink-based EV model is used. The model incorporates rolling resistance, aerodynamic drag, and motor-battery dynamics to ensure a realistic simulation behavior.

Following each simulation run, timestamped data are recorded, including the vehicle's speed, position, and both instantaneous and total energy consumption. From these records, the total travel time and total energy consumption required to complete the route are gathered, as illustrated in Figure 3. Each simulation input consists of systematically generated segment boundary speeds, ensuring that the exit speed of one segment becomes the entry speed of the next. This approach maintains a continuous speed profile along the route, allowing acceleration and deceleration dynamics to be realistically represented under varying slope conditions.

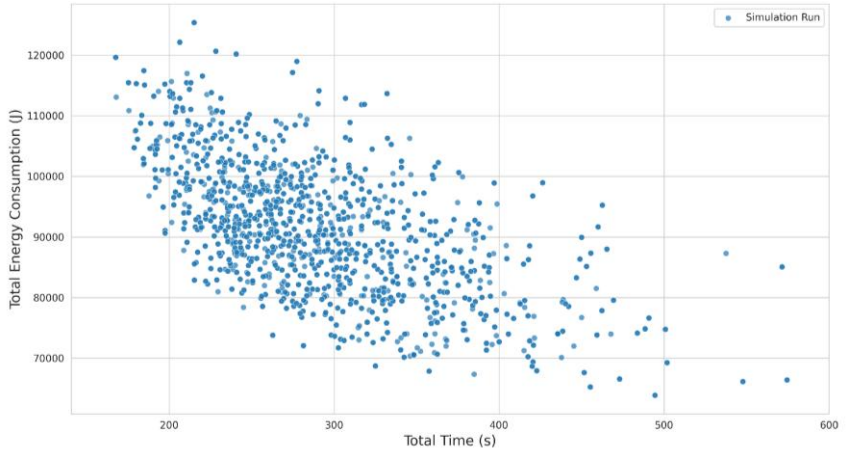

Figure 3. Offline Simulation Results.

A post-processing step compiles the simulation outputs into a structured dataset, associating each road segment with its entry and exit speeds, segment-level energy consumption, and time spent in that segment. This organized format, partially illustrated in Table 1, facilitates the subsequent training of ML models by providing clearly defined inputs and outputs for each simulated scenario.

Table 1. Post-Processed Data for ML.

Simulation No	Segment	Road Angle (°)	Distance (m)	V_{in} (km/h)	V_{out} (km/h)	Time (s)	Energy (J)
1	1	0	100	2.02	21.09	40.25	17136.10
1	2	3	100	21.09	10.32	23.75	20740.37
1	3	0	100	10.32	3.77	55.75	3018.52
1	4	-3	100	3.77	14.76	44.50	90.91

d. Machine Learning Surrogates

Once the offline dataset was compiled, it was randomly partitioned into training and test subsets using an 80–20 split. Several ML algorithms were then evaluated, including neural networks, gradient-boosted trees, and Gaussian process regressors, using each road segment's slope angle, length, entry speed, and exit speed as input features. Ultimately, a Gaussian process regressor with a Matérn 5/2 kernel achieved the lowest root mean square error (RMSE) on the test set for both the Time Model (predicting travel time) and the Energy Model (predicting energy consumption). This result highlights the regressor's capacity to capture the nonlinear relationships introduced by varying speeds and slopes. By adopting these final surrogate models, the time required to evaluate a new speed profile is reduced from a full physics-based simulation —which can take seconds to minutes— to a rapid inference step on the order of milliseconds, thereby enabling a more efficient search for optimal eco-driving strategies.

e. Particle Swarm Optimization

To identify the speed profile that satisfies a desired target travel time while minimizing energy consumption, a PSO algorithm is applied (Kennedy & Eberhart, 1995). Rather than enumerating possible speeds or exhaustively scanning a high-dimensional space, PSO maintains a "swarm" of candidate solutions, each representing a distinct set of nine boundary speeds.

During each iteration of the swarm:

- The Time and Energy surrogate models are queried for each candidate solution, yielding T' (predicted time) and E' (predicted energy).
- A cost function, defined in Equation 1, evaluates each solution's quality, where T_{target} denotes the user-defined travel time, and $\alpha \in [0, 1]$ controls how strictly the algorithm attempts to match that time versus minimize total energy.

$$cost = a\left|T' - T_{target}\right| + (1 - a)\, E' \qquad \text{(Eq. 1)}$$

- Boundary speeds for each candidate are updated according to both its local best performance and the global best solution found so far in the swarm.

After a predefined number of iterations or once the swarm's performance converges, the best-performing solution is selected. This final speed profile is then re-validated in the high-fidelity simulator to verify that the time and energy predictions align closely with the actual simulation results.

Findings

Tests conducted on the defined route demonstrate that the proposed method can significantly reduce energy consumption, even under stringent travel-time constraints. When the weighting factor α is relatively small, the algorithm prioritizes energy savings, often entering uphill segments at lower speeds to limit power demand. Conversely, under tighter time constraints (larger α), the optimizer raises speeds on flat and downhill segments to maintain a higher average speed and carry momentum into subsequent uphill sections.

Table 2. Optimized Segmented Speeds.

Segment No	V_{in} (km/h)	V_{out} (km/h)
1	2.00	12.64
2	12.64	4.33
3	4.33	6.22
4	6.22	17.85
5	17.85	6.82
6	6.82	4.83
7	4.83	12.12
8	12.12	5.47
9	5.47	2.00

In Table 2, the PSO-recommended segment speeds for a route completion time of 370 seconds are presented, along with the corresponding energy consumption estimates from the surrogate models. These predictions enable rapid assessment of candidate speed profiles without resorting to repeated high-fidelity simulations. To verify their accuracy, Figure 4 compares the surrogate-based estimates against results from a full Simulink run, revealing only minor differences between the predicted and actual travel times and energy usage. This close alignment highlights the reliability of the surrogate-driven optimization in meeting the user-specified travel time while still achieving substantial energy reductions. Furthermore, the offline–online structure of the framework provides a foundation for extension to longer routes or more complex slope distributions, requiring only additional simulation data and surrogate model retraining.

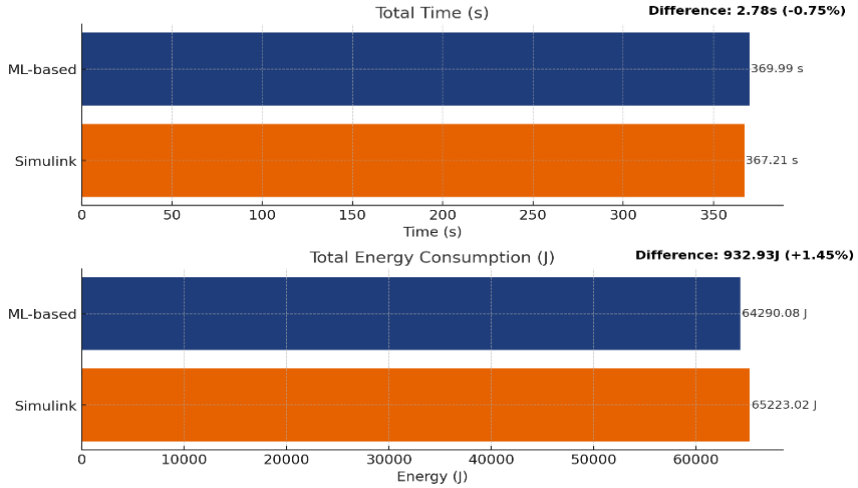

Figure 4. Validation Results.

Conclusion

This paper has presented a hybrid eco-driving framework for EVs on sloped, segmented roadways. By combining a one-time offline simulation with two ML models for travel time and energy consumption, and employing a PSO algorithm to identify an optimal speed profile, the method addresses key challenges in slope-aware driving without incurring excessive real-time computational costs.

The results from a 700-meter, nine-segment route demonstrate the system's capacity to balance energy minimization with a user-defined travel time. Boundary speeds are allocated intelligently, mitigating high power demands on uphill sections and leveraging efficient cruising where appropriate. The offline–online separation further ensures that once a robust dataset has been generated, adaptation to new constraints or route segments only requires re-running the optimization, not the entire high-fidelity simulation.

In principle, this framework can be generalized to larger or more intricate topographies by introducing additional simulation data, retraining the ML surrogates, and recalibrating the PSO. The methodology is also extensible by refining the offline model or road profile to account for further effects—such as curves or more complex geometries. Additionally, users can introduce extra constraints, for instance by specifying target speeds in certain segments, thus enabling the speed profile to meet more diverse operational requirements while still seeking minimum energy consumption. Overall, the proposed approach offers an effective, ML-based method of reducing energy costs for EVs and improving their operational viability in the face of range and efficiency concerns.

Conceptual Power Conversion Architecture for Unmanned Aerial Vehicles Utilizing BLDC Motor as Both Starter and Generator

Keywords: UAV Power Management, BLDC Starter-Generator, Four-Switch Buck-Boost Converter.

Unmanned Aerial Vehicles (UAVs) have become an essential component of various industries, including defense, logistics, agriculture, surveillance, and industrial automation. These applications require high efficiency, extended endurance, and lightweight design for optimal performance. One of the major challenges in UAV power systems is the inefficient energy management and weight constraints imposed by traditional architectures, which employ separate starting motors and generator systems. These conventional approaches lead to increased system and harness complexity, integration difficulties, and reduced energy recovery rates. The primary aim of this study is to develop an integrated BLDC motor-based power electronics system architecture that functions as both a generator and a starting motor, thereby reducing overall system weight and improving power efficiency. This dual-purpose system integrates a Four-Switch Buck-Boost Converter with a three-phase inverter to facilitate bidirectional power conversion. A Proportional-Integral (PI) control strategy is implemented to regulate power transitions and optimize energy recovery. The proposed approach is validated through extensive simulations in MATLAB/Simulink, demonstrating its feasibility in UAV applications.

The study focuses on designing and simulating a lightweight, efficient UAV power management system using a BLDC motor as a combined starter-generator unit. The key elements of the proposed system architecture are a Four-Switch Buck-Boost Converter (FSBBC) and a Three-Phase Inverter. FSBBC is a vital component that enables bidirectional energy transfer between the UAV power supply and the BLDC motor. Unlike traditional unidirectional converters, the FSBBC operates in both step-up (boost) and step-down (buck) modes, ensuring optimal power conversion efficiency in different UAV operational phases. During Startup, the converter operates in boost mode, supplying adequate voltage to the BLDC motor for rapid and efficient starting. During Generator Mode, the converter functions in buck mode, regulating the generated voltage and ensuring efficient energy recovery back to the UAV power system. The four-switch topology reduces switching losses and component count, leading to an overall reduction in system weight and complexity. Additionally, this design provides high dynamic response, making it well-suited for UAV applications that require real-time power management. Three-Phase Inverter is responsible for controlling the BLDC motor drive operation. It converts the DC power from the UAV battery into three-phase AC power required to drive the BLDC motor during start-up. Once the BLDC motor transitions into generator mode, the inverter performs the reverse operation, rectifying AC power back into DC and feeding it into the power management system for reuse. During the start-up phase, it operates as an inverter, converting DC battery power into AC to initiate motor rotation. In generator mode it operates as a synchronous rectifier, converting AC power generated by the BLDC motor into a regulated DC output. The inverter is designed with pulse-width modulation (PWM) control, ensuring precise speed and torque regulation of the BLDC motor while maintaining high conversion efficiency. To ensure stable operation, efficient energy transfer, and smooth mode transitions, a Proportional-Integral (PI) control strategy is implemented in the system. PI controllers are widely used in power electronics due to their simplicity, real-time computation efficiency, and robustness against disturbances. The control strategy is designed to regulate voltage and current levels, to ensure seamless mode transition and to enhance system stability. The PI controller dynamically adjusts the duty cycle of the FSBBC and switching sequence of the three-phase inverter to maintain optimal power levels. Smooth switching between starting and generator modes is critical to prevent voltage fluctuations that could affect UAV operation. The PI controller fine-tunes the system's response to avoid sudden spikes or dips in voltage and current. By continuously monitoring input voltage, output power, and system load, the PI controller maintains steady operation under various flight conditions.

The simulation results confirm that the proposed BLDC-based starter-generator system effectively operates in both generator and starting modes, demonstrating enhanced energy efficiency, weight reduction, and stable power regulation. The system integrates a Four-Switch Buck-Boost Converter (FSBBC) and a Three-Phase Inverter, enabling seamless bidirectional power flow. The PI control strategy ensures that voltage and current levels remain stable throughout mode transitions, avoiding unnecessary energy losses and disturbances. One of the primary advantages of the proposed system is its ability to recover and reuse energy more effectively than traditional UAV power architectures. The simulation results indicate that the system achieves a 15-20% higher energy recovery rate compared to conventional unidirectional power converters. This improvement is attributed to the bidirectional operation of the Four-Switch Buck-Boost Converter, which enables power to be efficiently transferred back to the UAV power supply during several flight phases. Another significant advantage of the proposed system is the reduction in overall UAV system weight, which directly impacts payload capacity and manoeuvrability. By integrating starter and generator functions into a single BLDC motor, the need for separate components is eliminated, leading to a weight reduction of 30% (to be determined based on hardware implementation). Traditional UAV power architectures require two separate electromechanical units: one for start-up and another for power generation. This increases weight and complexity, reducing available payload capacity. The proposed BLDC-based system consolidates these functions, significantly reducing the number of components and overall structural weight.

This study presents a novel integrated UAV power management system based on a BLDC motor-driven bidirectional power converter, offering substantial improvements over traditional dual-component architectures. Simulation results confirm that the proposed system enhances UAV energy efficiency by optimizing power conversion and energy recovery mechanisms. Additionally, by integrating the starter and generator functions into a single BLDC motor, the overall system weight is reduced, leading to increased payload capacity and operational flexibility. The PI control strategy ensures stable voltage and current regulation, contributing to smooth transitions between different modes. These findings suggest that the proposed power management system can play a significant role in next-generation UAV designs, improving operational efficiency and power autonomy. These findings suggest that the proposed power management system can significantly contribute to next-generation UAV designs, enhancing their operational efficiency and power independence. Future work may focus on experimental validation of the proposed system and exploring advanced control strategies for further efficiency improvements. While the simulation results confirm the effectiveness and feasibility of the proposed system, further research is necessary to validate its real-world performance and explore potential enhancements. One of the primary areas for future work involves experimental validation, where the system would be implemented in a real UAV prototype. This would allow for the assessment of its actual performance under practical operating conditions, considering environmental factors such as temperature variations, electromagnetic interference, and mechanical vibrations that are not fully captured in simulations. Additionally, hardware optimization could contribute to further improvements in power conversion efficiency and thermal performance. The use of emerging semiconductor technologies, such as Gallium Nitride (GaN) or Silicon Carbide (SiC) MOSFETs, could significantly reduce switching losses, improve power density, and enhance the system's overall reliability. These materials offer superior electrical and thermal characteristics compared to traditional silicon-based power devices, making them ideal for high-performance UAV power systems.

Comparative Analysis of LSTM and LightGBM for Short-Term Electricity Consumption Forecasting

Muhammet Furkan Baysal[a], Mustafa Berker Yurtseven[a]

[a]Istanbul Technical University/Energy Institute, Energy Science and Technology, Türkiye
baysalm16@itu.edu.tr

Keywords: Forecasting Accuracy, LightGBM, LSTM Model, Short-Term Electricity Consumption.

Aim

Electricity is a fundamental pillar of modern life, driving industries, powering households, and enabling emerging technologies such as electricity vehicles. With ongoing growth, rapid industrialization, and increasing electrification efforts across the globe, electricity demand has risen significantly in recent years (International Energy Agency, 2024). As a result, accurate electricity demand forecasting has become even more essential for the effective planning, management, and reliability of power systems. In particular, short-term electricity consumption forecasts play a crucial role in maintaining the delicate balance between supply and demand, ensuring operational efficiency, minimizing imbalance costs, and reducing price fluctuations in liberalized electricity markets (Bojnec & Križaj, 2021). This study focuses on forecasting short-term electricity consumption within a specific distribution region in Turkey. It aims to evaluate and compare the forecasting performances of two popular models: Long Short-Term Memory (LSTM), a type of deep learning model known for its ability to capture sequential patterns, and Light Gradient Boosting Machine (LightGBM), a decision tree-based gradient boosting algorithm recognized for its speed and scalability. The primary goal is to explore how these two models perform in forecasting hourly electricity demand for the next 24 hours, using historical data enriched with various features. Accurate short-term forecasting not only contributes to better operational decision-making for electricity providers and market participants but also supports strategic planning and the integration of renewable energy sources. Furthermore, it allows for more effective resource allocation and reduces the likelihood of energy imbalances, thereby contributing to a more stable and efficient electricity market.

Material and Method

In the model development process, a comprehensive dataset comprising three years of hourly electricity consumption data was used. This data was collected from transformer substations located in a specific distribution region of Turkey. In addition to consumption data, meteorological variables such as temperature, humidity, and wind speed were obtained from the Turkish State Meteorological Service. The dataset represents real consumer behavior and includes a wide range of consumption sectors: residential areas, industrial facilities, street lighting, agricultural activities, the public sector, and losses due to theft or transmission inefficiencies. To reflect real-world complexities and make the dataset more suitable for machine learning applications, the data underwent several preprocessing steps. These included cleaning, normalization, and the creation of additional variables. Derived features such as month, day, hour, day of the week, season, and a public holiday indicator were added to help capture temporal and cyclical patterns that influence electricity demand. Two models were selected for the analysis. The first, LSTM, is a type of recurrent neural network well-suited for time series data due to its ability to learn long-term dependencies. The second, LightGBM, is a gradient boosting framework that is efficient with large datasets and provides fast, interpretable results. Both models were trained to predict the electricity demand for the next 24 hours, based on historical input data. Model performance was assessed using three widely accepted error metrics: Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), and Mean Absolute Percentage Error (MAPE) (Hyndman & Koehler, 2006). Additionally, a separate validation set was used to test how well each model could generalize to new, unseen data.

Findings

The results reveal that both the LSTM and LightGBM models can forecast short-term electricity consumption with a high degree of accuracy. Due to its deep neural network structure, the LSTM model was particularly successful at capturing time-based dependencies, which are often crucial in predicting electricity demand. Its sequential learning mechanism allowed it to detect complex patterns across consecutive time intervals, making it a powerful tool for time series forecasting.

On the other hand, the LightGBM model delivered strong performance with a significantly faster training time and greater interpretability. This made it especially advantageous for scenarios where quick results and transparency in model decisions are essential. Both models achieved commendable accuracy based on RMSE and MAPE scores. While LSTM was more effective in modeling complex temporal behaviors, LightGBM stood out in terms of computational efficiency and ease of deployment. Both models were also successful in capturing the influence of external variables such as public holidays and seasonal changes. The training and validation loss curves for the LSTM model (Figure 1) demonstrated that after a rapid decline in the early epochs, the validation loss stabilized, indicating that the model had learned the essential patterns without overfitting. This suggests that the LSTM model was able to maintain generalization capability and deliver consistent performance on new data. The performance metrics of the LSTM model are summarized in Table 1. The model achieved a Mean Squared Error (MSE) of 3220.27, a MAE of 42.79, an RMSE of 56.75, and a MAPE of 7.05%. These results indicate that the model effectively learned temporal dependencies and produced reliable forecasts. However, the LSTM's high computational complexity and longer training time could pose challenges in scalability and real-time applications.

In comparison, the LightGBM model achieved better error scores. As shown in Table 2, the model recorded an MSE of 381.52, a MAE of 13.48, an RMSE of 19.53, and a MAPE of 2.10%. These metrics suggest that LightGBM outperformed LSTM in terms of forecast accuracy and is particularly well-suited for real-time forecasting environments due to its speed and low resource consumption. While LightGBM may not capture long-term dependencies as effectively as LSTM, its ability to deliver accurate and rapid predictions makes it highly valuable in many operational contexts. Ultimately, the study demonstrates that both models are viable for short-term electricity demand forecasting. The decision to use one over the other should depend on the specific needs of the task, such as the required speed, computational resources, and the complexity of temporal patterns in the data.

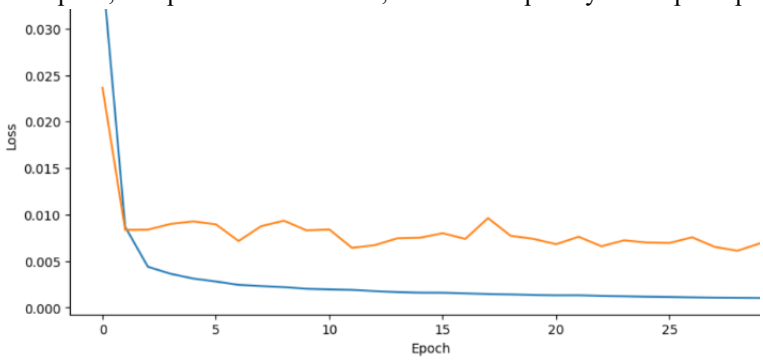

Figure 1. Training and validation loss graph for LSTM model.

Table 1. LSTM model performance metrics.

Metric	LSTM
MSE	3220.27
MAE	42.79
RMSE	56.75
MAPE, %	7.05

Table 2. LightGBM model performance metrics.

Metric	LightGBM
MSE	381.52
MAE	13.48
RMSE	19.53
MAPE, %	2.10

Conclusion

This research has demonstrated that both LSTM and LightGBM are effective modeling approaches for short-term electricity consumption forecasting in Turkey's liberalized electricity market. Each model brings unique strengths to the table. LSTM offers the advantage of learning complex time-dependent structures in electricity consumption, whereas LightGBM provides rapid and accurate forecasts with strong interpretability. These capabilities are valuable for market participants, such as distribution companies, suppliers, and large-scale consumers, in optimizing their strategic planning and bidding strategies, reducing imbalance costs, and enhancing operational efficiency. Moreover, reliable short-term forecasts contribute to the stability of market clearing prices, support grid reliability, and play a vital role in facilitating the integration of renewable energy sources. As energy systems become more dynamic and decentralized, accurate forecasting tools become even more critical. In this context, the selection of the forecasting model should be aligned with the operational requirements, data availability, and desired response time. LSTM might be more appropriate for complex forecasting scenarios that involve strong time dependencies, while LightGBM could be the preferred choice in environments requiring fast and explainable predictions. Future studies may consider developing hybrid or ensemble models that combine the strengths of both LSTM and LightGBM to further improve forecasting performance. In addition, evaluating the adaptability of these models to different regions or varying consumption profiles could offer insights into their scalability and robustness. Such advancements would not only benefit electricity market operations but also contribute to a more resilient and sustainable energy future.

Building Energy Efficiency: A Data-Driven Machine Learning Approach for Energy Management and Planning

Ahmad Reza Darabi[a], Mustafa Berker Yurtseven[a]

[a] Istanbul Technical University, Energy Institute, Türkiye
darabi22@itu.edu.tr

Keywords: Building Energy Consumption, Building Energy Efficiency, Indoor Condition Prediction, Machine Learning, Thermal Comfort.

Aim

Between 1971 and 2019, the world's total energy supply has increased 2.6 times (International Energy Agency, 2020) (Figure 1). We are producing and consuming more and more energy. In recent years, there has been growing recognition of the importance of reducing energy consumption in buildings to address the urgent challenge of climate change. Buildings are responsible for a significant portion of greenhouse gas emissions, representing 35% of energy-related EU emissions (European Commission, 2022), and improving their energy efficiency is essential for achieving the targets set out in international climate agreements such as the Paris Agreement (United Nations Paris Agreement, 2015). The operations of buildings account for 30% of global final energy consumption (Figure 2) and 26% of global energy-related emissions (8% being direct emissions in buildings and 18% indirect emissions from the production of electricity and heat used in buildings). According to the IEA Energy Efficiency Indicators database, almost 50% of final energy consumption in residential buildings is used for heating (International Energy Agency, 2020) (Figure 3). This study aims to enhance energy efficiency in buildings while maintaining thermal comfort by leveraging machine learning (ML) techniques. This approach can help optimize resource usage, reduce operational costs, and mitigate the environmental impact by accurately forecasting and controlling energy consumption in real time. Ultimately, it supports sustainable development goals and promotes a healthier future for society through data-driven, intelligent building management.

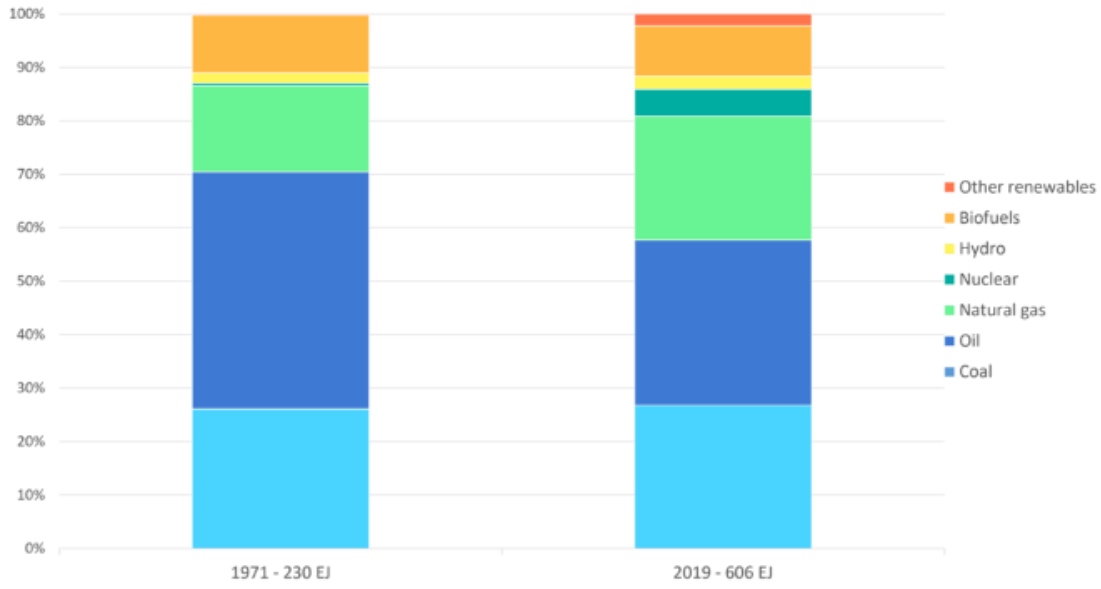

Figure 1: Total Energy Supply by Fuel.

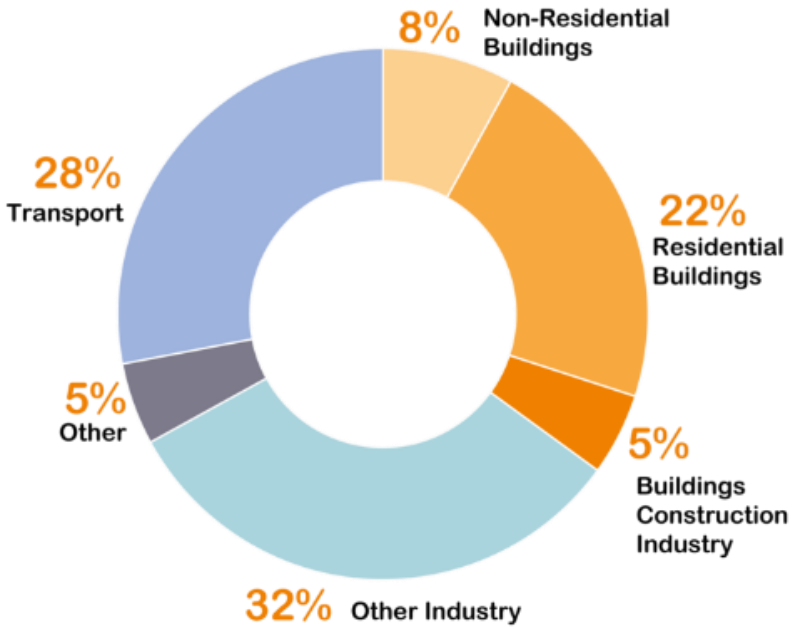

Figure 2: Global Share of Buildings and Construction.

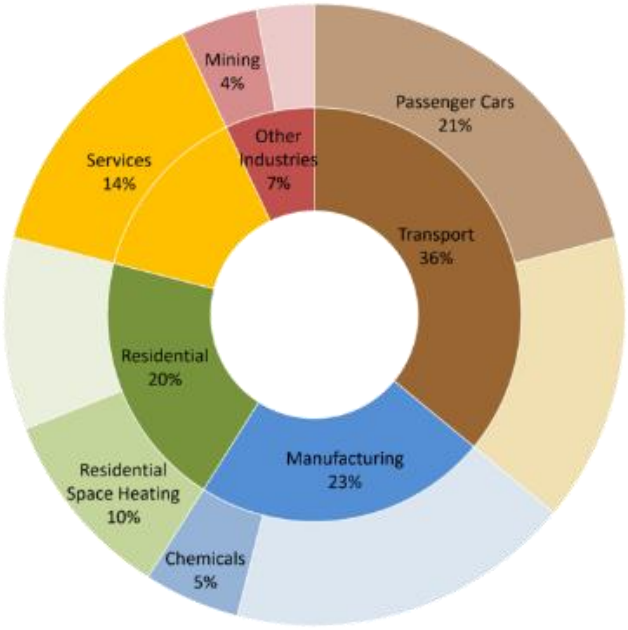

Figure 3. Largest End Uses of Energy by Sector.

Material and Method

This research integrates an internal condition dataset, collected via a Smart Thermostatic Radiator Valve, with an external environmental conditions dataset obtained from online sources based on the case study's location. The internal condition dataset (sampled every 30 minutes) includes features such as Room Temperature, Room Humidity, Target Temperature, Valve State, and Time as an ID number, which is very important for time series datasets. The www.visualcrossing.com website was used to gather external environmental conditions data (sampled every 60 minutes). The dataset for the study period was downloaded and includes many useful features such as External Temperature, External Humidity, Wind Speed, Solar Radiation, and so forth. The data cleaning

process for the integrated dataset involved steps such as removing or filling missing values (about 7% of the total records), and matching rows according to the time column. Furthermore, due to the use of Long Short-Term Memory (LSTM) models and the importance of numeric values, correlation analysis was performed on categorical features such as Atmospheric Condition, and only those with low correlation were removed. In cases where a categorical feature was essential for the research, it was converted to numeric features using Label Encoding.
The dataset was split into 80% for training and 20% for testing, and the final prediction was performed on one day of unseen data. Using an LSTM model, indoor temperature was predicted to determine the optimal times to turn on or turn off the Radiator Valve to control hot water flow to the radiators. The initial models achieved an R^2 value above 0.78. Through feature engineering, some features were removed and the impact of this was examined in the results. On the other hand, new features were created to utilize previous timestep data, which is useful for forecasting. Specifically, two previous timesteps were used as lag features. Hyperparameter tuning was performed on the LSTM parameters, and the most optimized values were used in the final version of the model. The hyperparameters considered in the tuning process included the number of LSTM layers, the number of units (neurons) per layer, the dropout rate, the learning rate, the batch size, the number of epochs, and the activation function. The final model was implemented using the TensorFlow library, and the Adam optimizer was applied with MSE as the loss function. After these steps, the model's performance improved, reaching an R^2 value of 0.95. (Table 1).

Table 1: Initial and Final Model Performance Comparison.

Measurement	Initial Model	Model after Tuning
R-squared	0.78	0.95
Mean Absolute Error	0.50	0.30
Mean Squared Error	0.75	0.17

Findings

Energy usage between the existing heating system and the proposed method was compared using heat transfer equations. Specifically, the fundamental relationship $Q=m\cdot c\cdot\Delta T$ was employed, where Q is the heat energy, m is the mass of the air in the room, c is the specific heat capacity of the air, and ΔT is the temperature difference (room temperature when valve is off - room temperature when valve is on). In this study, m and c remain constant for the same room, so focusing on ΔT and the duration over which hot water flows into the radiator allows for a straightforward comparison of energy transfers. By integrating this equation over time, we can account for the total heat delivered, making it an effective measure to compare the radiator's energy transfer in different heating scenarios. Our results indicate that by implementing this methodology, heating system energy consumption can be reduced by 33% while still maintaining indoor thermal comfort (Table 2).

Table 2: Energy Consumption Comparison between Baseline Model and Optimized Valve State Model.

Measurement	Baseline Model	Optimized Valve State Model	Improved Percent
Radiator Working Time (Hours)	6	4.5	25%
Total Energy Transferred ro Room (W)	23.55	15.67	33%
Energy Transferred by Radiator (W/h)	3.93	3.48	11%

Conclusion

Energy consumption is increasing worldwide, and building heating systems account for a large portion of it. This study aims to provide A Data-Driven Machine Learning Approach to Managing and Planning Energy and to improve energy efficiency in buildings. A smart thermostatic radiator valve and an internet-based source were used to collect data to train and test an LSTM model (Figure 4). Results show that the application of an LSTM model

with a high R^2 value enables us to predict indoor temperature based on the next hours' external conditions. This ability can be used to control the hot water flow to the radiator and optimize heating system operation to reduce energy consumption in buildings. The important point is that the proposed approach achieves energy efficiency while ensuring occupants' comfort remains at the same level as the original approach. These findings highlight the importance of using machine learning for building energy optimization.

Optimization of Ground Heat Exchangers for Sustainable Heating Solutions: A Case Study Approach

Nurullah Yıldırım[a,b], Ece Asan[a], Z. Fatih Ozturk[a]

[a]Istanbul Technical University, Energy Institute, Türkiye
[b]TUBITAK Rail Transportation Technologies Institute, Türkiye
yildirimnur@itu.edu.tr

Keywords: Ground Heat Exchanger, Ground Source Heat Pump, Thermal Energy Demand.

Aim

Ground source heat pump systems provide efficient heating, because the underground temperature is higher than the outdoor temperature in cold climate. In this study, the ground heat exchanger length that meet all the thermal energy demand of the buildings throughout the heating season is calculated. Also, underground temperature profiles are investigated.

A significant portion of the energy consumption at homes is thermal energy [1]. Therefore, considering the thermal energy demands of buildings during the design phase, and using efficient energy systems both provides economical solutions and helps reduce environmental impacts. Especially in recent years, issues such as climate change and environmental pollution have been on the agenda of developed and developing countries. As a result, in line with the European Union's 2050 zero carbon targets [2], the use of renewable energy systems is encouraged both in electricity generation and in thermal energy production and storage. One of the renewable energy systems used to meet the thermal energy demands of buildings is heat pumps. Heat pumps are called as air, water or ground source depending on the environment where the heat exchangers are located [3]. The most commonly used heat pump type is air source heat pumps due to their low initial investment cost, but ground source heat pumps (GSHP) have also become widespread over time, especially in cold climates, due to their high coefficient of performance (COP) values [4,5]. GSHPs can be used for both heating and cooling purposes.

In this study, the length of ground heat exchangers (GHE) is calculated for a region (Ankara, Turkey) where the heating season is longer than the cooling season. The heat exchange of the GHEs with the underground is numerically calculated and underground temperature profiles investigated in five years of operation.

Material and Method

In the study, an underground heat pump system that meets the heat demand of five independent buildings, each of which is 100 m^2, is analyzed. For this purpose, the total heat load is investigated for five years by considering the instantaneous temperature change during the heating season of the region. When the seasonal temperature changes are in recent years examined, the October 15 - May 15 range is accepted as heating season. The comfort temperature of the buildings is taken as 22^0C. If the GHEs interact thermally, thermal shortcuts occur and the system efficiency decreases [6]. For this reason, the GHEs are positioned as far away from each other as possible so that they do not interact thermally. However, if there is not enough space for the proper configuration, either the GHE depths should be changed or GHEs configuration with less interaction should be tried. Of course, positioning them further away than necessary increases the piping costs. The GHEs with a depth of 75 m are used in the study. The unperturbed ground temperature of the field is accepted as the annual average temperature of the region, 11 ^{0}C [7]. This value was accepted as the initial temperature of the underground when performing numerical calculations. Because the changes resulting from the edge effects at the lower and upper points of the GHEs are observed to be around two percent in the numerical experiments, two-dimensional temperature profiles are used to reduce the numerical load. The design characteristics of the GSHP system are given in Table 1.

Table 1: The design and operational characteristics of the ground source heat pump systems.

Number of houses	N_A	5
Effective heat loss area of each houses	A_H	290m^2
Comfort temperature of houses	T_H	22°C
U value for heat loss	U_H	0.286 W/m^{2}K
Number of boreholes	N_B	4
Depth of boreholes	H_B	75m
Radius of boreholes	r_B	0.1m
Ground depth of the model	H_G	200m
Ground radius of the model	r_G	100m
Undisturbed ground temperature	T_∞	11°C
Ground thermal conductivity	k	3.2W/mK
Ground heat capacity	c_p	780J/kgK
Ground density	ρ	2750kg/m^3
Heating Season		15 Oct.-15 May
Standby Season		15 May-15 Oct.

The temperature profile of the GHE field is obtained using the time-dependent 2D heat conduction equation. If the GHEs do not interact, a single GHE can be modeled and the energy extracted during the heating season can be obtained by multiplying it by the number of GHEs. However, if the GHEs interact, all GHEs should be placed in the field and a common solution should be made. The heat transfer equation that gives the underground temperature change is given in equation 1.

$$\frac{1}{\alpha}\frac{\partial T}{\partial t} = \frac{1}{r}\frac{\partial T}{\partial r} + \frac{\partial^2 T}{\partial r^2} \#(\ SEQ\ Equation\ \backslash *\ ARABIC\ 1)$$

where; α is thermal diffusivity of the ground which depends on the conductivity (k), heat capacity (c_p) and the density (ρ) of the ground as $\alpha = \frac{k}{(\rho\, c_p)}$, T is the temperature, t is time and r is te distance from the GHE surface. Because the thermal demand of the houses changes continuously during the heating season, the heat energy extracted from the ground also changes continuously. Therefore, the transient thermal loads of the houses are calculated by using the hourly outdoor temperatures [8] and this value is defined as the transient heat flux boundary condition to the GHEs surface. The transient heat flux boundary condition on the GHEs is written in equation 2.

$$J_Q^{DC}(t) = \frac{\dot{Q}(t) n_H}{n_B A_B} \#(\ SEQ\ Equation\ \backslash *\ ARABIC\ 2)$$

where, $\dot{Q}(t)$ is the thermal energy demand of a single house, n_H is the number of the houses, n_B is the number of the boreholes and A_B is the surface heat transfer area of a single GHE. The heating energy demand of a single house is determined as in equation 3.

$$\dot{Q_D}(t) = U_H A_H \big(T_H - T_{out}(t)\big) \#(\ SEQ\ Equation\ \backslash *\ ARABIC\ 3)$$

where; U_H is the heat transfer coefficient of the house, A_H is the effective heat loss area of a single house, T_H is the comfort temperature of the houses, $T_{out}(t)$ is the time dependent outdoor temperature. The heat flux is coupled to the hourly averaged heat demand of the houses during heating. Furthermore, the underground is considered to be composed of dry rock, and underground flows or saturated environments are not considered. And the outside the heating season the soil temperature recover around the GHEs. This mode is called as the standby mode of the GSHP system. Furthermore, in this analysis the underground is considered as a single layer.

Findings

The thermal energy demand during the heating season is calculated separately for the years 2018-2023. During these years, the total thermal energy demand of a single building for heating varies between 7.13 MWh and 7.92 MWh. Figure 1 shows the five years hourly thermal energy demand of a building.

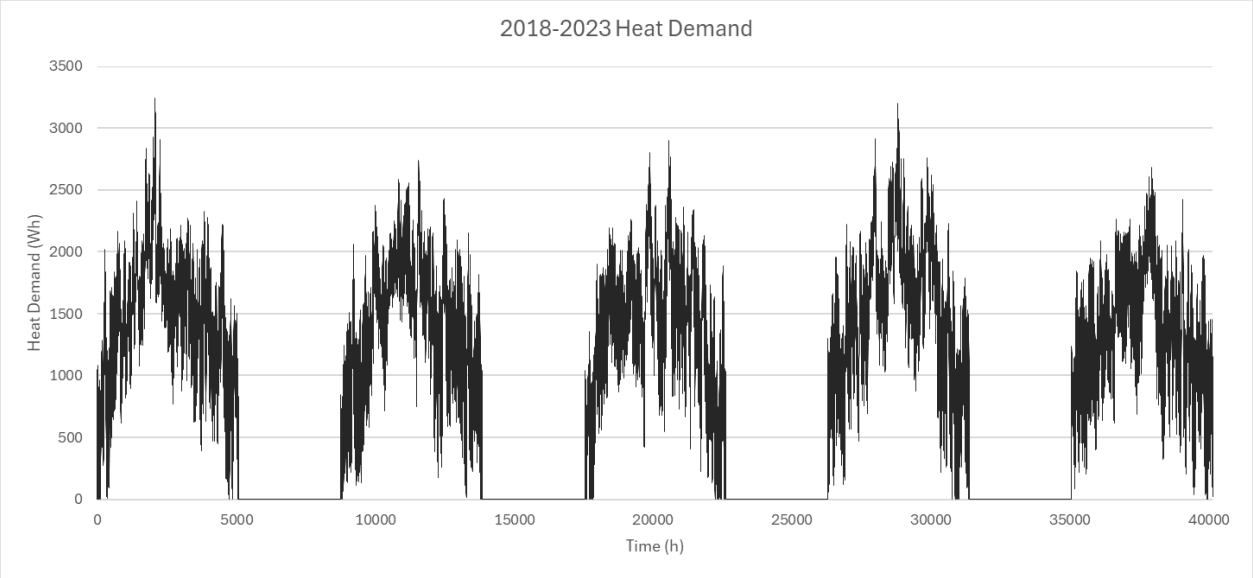

Figure 1: Five years thermal energy demand of a building (2018-2023).

In the numerical calculations, the heat exchangers are placed 6 meters away from each other to minimize thermal interaction. As a result of the analysis by using the different numbers of GHEs with a length of 75 meters, it is seen that four GHEs provides the thermal energy demand when the characteristics of the heat pump is considered. The temperature field at the end of the one and five years of operation is given in Figure 2. At the end of the first year, it is observed that the underground temperature does not fall below zero degrees even in areas close to the GHE surface and does not fall below the characteristic values of the heat pump. In the period after the discharge mode in the first year, it is clear that the GHE surface temperature almost completely increased by conduction heat transfer from the surroundings. At the end of the fifth year, it is also seen that the underground temperatures do not exceed the desired values and the thermal needs of the houses are met without interruption.

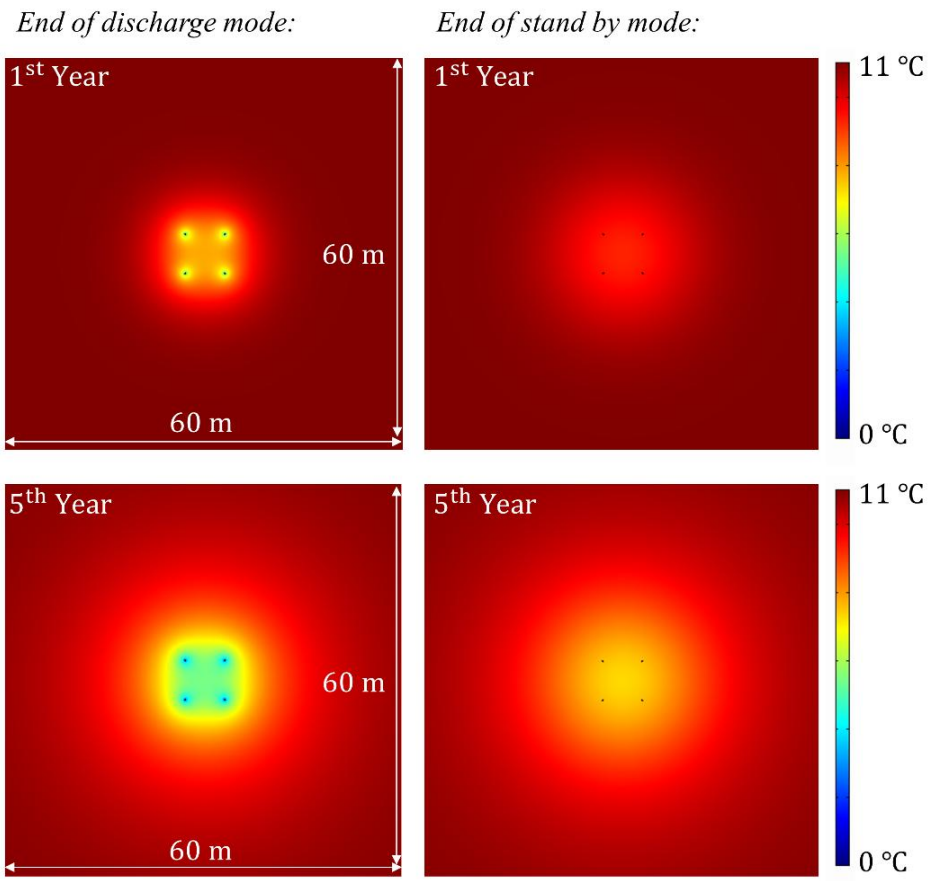

Figure 2: Underground temperature distribution at the end of the discharge and stand by modes for the first and fifth years of operation.

Conclusion

In the study, the underground heat pump system for the heating demand of five houses is analyzed and it is seen that four GHEs at a depth of 75 meters meet more than the thermal energy demand (7.92 MWh). In the next study, the system will be converted into a borehole thermal energy system (BTES) by charging solar thermal energy. Thus, the required heat exchanger length for the BTES system will be calculated and the economic analysis for the two systems will be compared.

Carbon Capture and Utilization in the Cement Industry: Opportunities for Methanol and Urea Production from Process Emissions – A Systematic Literature Review

Gökçe Yalin[a]

[a] Istanbul Technical University, Faculty of Civil Engineering, Department of Environmental Engineering, Türkiye
yalin22@itu.edu.tr

Keywords: Carbon capture, Cement industry, CO_2 utilization, Methanol synthesis, Urea synthesis.

Aim

The cement industry is a significant source of global greenhouse gas emissions, responsible for nearly 7% of total anthropogenic CO_2 output (IEA, 2023; Andrew, 2019). A substantial portion of these emissions stems from the calcination of limestone during clinker production, where calcium carbonate ($CaCO_3$) is thermochemically converted into calcium oxide (CaO), releasing CO_2 as a by-product of the process. Since these process-related emissions are inherent to the chemistry of cement manufacturing, they cannot be effectively eliminated through conventional energy efficiency improvements or fuel switching alone (Habert et al., 2020). In response to increasing climate change concerns and regulatory pressures, Carbon Capture and Utilization (CCU) technologies are gaining traction as a promising industrial decarbonization strategy. These technologies offer the potential to capture CO_2 emissions directly from point sources such as cement kilns and enable their transformation into value-added products, thereby supporting both mitigation goals and resource circularity. Among various utilization pathways, methanol and urea production have emerged as particularly relevant due to their established industrial applications, global market demand, and potential to integrate captured carbon into existing chemical supply chains (Artz et al., 2018; Kätelhön et al., 2019). This study presents a systematic literature review on the application of CCU technologies in the cement sector, with a focus on evaluating their technological maturity (Technology Readiness Levels), integration potential with cement production infrastructure, and specific applicability to methanol and urea synthesis routes. Through this review, the study aims to highlight current research trends, identify existing gaps, and contribute to the discourse on feasible decarbonization pathways for the hard-to-abate cement industry.

Material and Method

This study employs a structured Systematic Literature Review (SLR) approach consisting of four integrated stages: article selection, classification scheme development, systematic mapping, and synthesis. Relevant studies were gathered through comprehensive searches in Scopus, Web of Science, and ScienceDirect databases, supplemented by references from selected venues and manual browsing. A total of 114 records were initially retrieved. Following the application of inclusion and exclusion criteria—based on study relevance, publication quality, and thematic fit—a refined pool of 79 articles was selected for full-text analysis. Following selection, attribute identification was performed to extract key classification categories such as capture technology type, utilization pathway, and TRL (Technology Readiness Level). These attributes were iteratively generalized and refined to ensure consistent application across studies of varied structure. The resulting classification framework enabled systematic mapping of the literature, allowing the visual distribution of studies by CCU technologies and application focus (e.g., methanol and urea synthesis). Insights derived from this mapping were then synthesized to identify prevailing research trends, technological challenges, and underexplored areas in the application of CCU in the cement industry. Special attention was given to the maturity and integration potential of CO_2-based methanol and urea production systems, given their dual relevance for emissions reduction and industrial value creation.

Findings

This systematic literature review evaluated current approaches for capturing CO_2 emissions from the cement industry and their subsequent utilization in chemical production. The cement sector, being one of the most carbon-intensive industries, has prompted a growing body of research into feasible Carbon Capture and Utilization (CCU) strategies that can address both environmental and industrial demands.

Among the carbon capture technologies identified in the literature, the most frequently studied are:

- Post-combustion capture, particularly using amine-based solvents like MEA (monoethanolamine) and solid looping systems such as Ca-looping, has been widely adopted at pilot and demonstration scales. These methods are compatible with existing cement kilns, making them attractive for retrofitting.
- Oxy-fuel combustion, which involves burning fuel in a pure oxygen environment, produces a flue gas with high CO_2 concentration that simplifies the separation process. However, the requirement for large-scale oxygen production introduces significant energy and cost barriers.
- Direct Air Capture (DAC) stands out as an emerging and flexible option that captures CO_2 directly from ambient air, enabling decentralized operation. Despite its novelty, DAC is still in early development stages due to the low atmospheric CO_2 concentration and high energy input required for sorbent regeneration and compression.

The Technology Readiness Levels (TRLs), capture efficiencies, and challenges of key CCU technologies are summarized in Table 1. MEA-based post-combustion systems show the highest TRL and efficiency, while DAC technologies face energy and cost barriers despite their potential. Two main CO_2 utilization pathways stand out:

methanol synthesis: $CO_2 + NH_3 \rightarrow CH_3OH$
especially when integrated with green hydrogen and,
urea synthesis: $CO_2 + NH_3 \rightarrow CO(NH_2)_2$

relevant for fertilizer production. These routes can reduce emissions and create value-added products. Successful deployment depends on access to renewable inputs, infrastructure readiness, and supportive policies. While technically promising, CCU in cement still requires scale-up and system-level integration for real impact.

Conclusion

This study systematically explored the current state of Carbon Capture and Utilization (CCU) technologies in the cement industry, with a particular emphasis on their applicability to methanol and urea production. The findings demonstrate that while post-combustion capture methods, especially MEA-based chemical absorption, are technologically mature and relatively well-studied, other methods such as Ca-looping and Direct Air Capture (DAC) remain in experimental or pilot stages. These latter technologies, although promising in terms of flexibility and long-term scalability, face significant obstacles related to high energy demand, infrastructure needs, and operational costs. The reviewed literature indicates that methanol synthesis from captured CO_2 is widely explored and offers integration opportunities with green hydrogen technologies, aligning well with broader decarbonization and Power-to-X strategies. On the other hand, urea synthesis, despite its large-scale industrial potential, remains underrepresented in academic research, suggesting a key knowledge gap that should be addressed through future investigations. Another critical insight from the review is the importance of technology readiness level (TRL) assessment and lifecycle analysis when evaluating CCU applicability. While some technologies appear technically viable, their environmental and economic performance across the full value chain must be further validated. Additionally, coupling CCU technologies with renewable energy inputs, such as green H_2 and sustainable NH_3, will be essential to ensure that CO_2 utilization pathways truly contribute to climate mitigation.
In conclusion, CCU technologies represent a vital tool in the decarbonization of hard-to-abate sectors like cement manufacturing. Their successful implementation, particularly for methanol and urea production—depends on continued interdisciplinary research, policy support, infrastructure development, and real-world pilot applications. Bridging the gap between academic innovation and industrial deployment will be key to unlocking the full potential of CCU within circular and low-carbon economy frameworks.

Aim

Cold plasma technology has been a technology that has been widely preferred in the food sector in recent years due to its nonthermal feature (Özdemir et al., 2023). Plasma is an ionized gas consisting of charged particles, electric fields, ultraviolet photons, and reactive oxygen and reactive nitrogen species (Ziuzina et al., 2020). In addition to gases such as helium and nitrogen, atmospheric air can also be used in cold plasma systems (Sudarsan & Keener, 2022). The use of atmospheric air is preferred because it is extremely economical and sustainable (Min et al., 2017). These systems are also called atmospheric cold plasma or dielectric barrier discharge (Bermúdez-Aguirre et al., 2013). The cold plasma produced in the system can be applied directly to samples or at a certain distance. In both applications, it can lead to the inactivation of various microorganisms that are important for food sterilization and does not have a negative effect on the sample surface (Ermis et al., 2021). Microbial inactivation can be explained by the fact that various reactive species released as a result of chemical reactions during cold plasma production create oxidative stress in the cell on the product surface and cause the destruction of the cell wall (Shah et al., 2019). Cold plasma can be preferred to kill possible pathogenic microorganisms after harvest, especially in products with short shelf lives such as fresh herbs, spices, and vegetables (Pankaj et al., 2018). This study aims to increase the shelf life of such fresh spices as bay leaf, basil, mint, rosemary, and thyme with short shelf lives but high economic value in foreign trade; to develop an alternative method to chemical disinfections used in the food industry; and to ensure that cold plasma application is spread to a wider area. For this purpose, a new system has been designed to perform atmospheric cold plasma production. This designed system is a highly effective system in terms of being scalable and applicable to many products.

Material and Method

For this purpose, various herbs and spices with different texture and surface properties were selected. The effect of direct application of atmospheric cold plasma to the product surface on quality properties, shelf life, and microbial inactivation was investigated for a certain shelf life. In order to observe the effect of atmospheric cold plasma on quality properties, physicochemical (color, pH, titratable acidity, moisture, and water activity), spectrophotometric (total phenolic, total flavonoid, total antioxidant, total anthocyanin, total chlorophyll, and essential oil composition) and scanning electron microscope (SEM) analyses were performed. A total viable count was performed to obtain information about the natural microflora of the samples. In addition, samples inoculated with microorganisms with different inoculation loads were exposed to atmospheric cold plasma for different durations, and the inactivation rate was determined.

Findings

When the physicochemical properties of the samples were examined, it was found that the effect of atmospheric cold plasma on pH was significantly lower than the control samples. In some samples, the total flavonoid content increased with the extension of the treatment time; moreover, it was observed that some monoterponoids preserved more than 50% and increased their amount. However, in some samples, a decrease in the total chlorophyll amount was observed after 3 minutes of treatment. Scanning electron microscopy (SEM) revealed that the tissue integrity

was affected by atmospheric cold plasma in some samples. However, atmospheric cold plasma extended the shelf life of samples stored at 4°C up to 8 days. It was observed that other analysis results were not affected by the increased atmospheric cold plasma exposure. The results were not found to be statistically significant. When the effect of atmospheric cold plasma on microbial inactivation of the samples was examined, it was determined that the greatest decrease was in the natural microflora load as a result of long-term exposure. When the samples were compared with the microorganisms inoculated at different concentrations, a higher inactivation was observed with the increase of the exposure time in the pathogenic species with higher concentrations. The results obtained showed that the selected system, plasma duration, initial concentration of the inoculation fluid, selected microorganism type, and storage period were effective on the samples. In addition, it was observed that the optimized conditions and selection of the appropriate system could increase the sample quality.

Conclusion

In our research, we compared the exposure time and investigated the suitability of the system parameters to observe the effect of atmospheric cold plasma application on microbiological decontamination and quality properties of fresh spices. Atmospheric cold plasma application showed a positive effect on the physicochemical properties of fresh spices and extended the shelf life. While the microbial loads of control samples increased rapidly during storage, the applied samples remained more stable in terms of physicochemical and microbial quality. Especially, the fact that it does not leave any chemical residue compared to other methods used today suggests that it can be used as an alternative method. However, the reliability of plasma sources and plasma composition are important concerns that should be evaluated in future studies in the development of post-harvest pretreatment technologies for agricultural products with short shelf lives in large industrial volumes. Our study shows that the variety of plasma systems and the direct exposure time affect general quality parameters and microbial inactivation, and this is confirmed by the analysis results. Although there are positive effects on the commercialization of products processed with atmospheric cold plasma, the interaction between plasma and the sample remains uncertain with the application. Therefore, more studies are needed on different samples and under different application conditions.

Evaluation of Pasting and Rheological Properties of Modified Starches for Use in Plant-Based Products

Muhammed Harun Giray[a], Meral Kiliç Akyilmaz[a]

[a]Istanbul Technical University, Food Engineering, Türkiye
giraym22@itu.edu.tr

Keywords: Pasting, Rheological Proporties, Starch, Structure.

Aim

Starch is one of the major components in structure formation of plant-based products. Starch is traditionally used to regulate food texture and improve stability during shelf life of food products due to its pasting, thickening and gelling abilities. Therefore, it is an important structure forming and stabilizing ingredient in plant-based food products (Dobson & Marangoni, 2023). In this study, four different starches including three modified waxy corn starches and modified tapioca starch were evaluated for pasting and rheological properties.

Material and Method

Prepared aqueous solution of each starch was been prepared at a concentration of 6% by weight. Pasting properties were determined by monitoring viscosity in a temperature sweep test applying a controlled temperature program by using a rheometer with cone/plate geometry at a shear rate of 225 s^{-1}. A sample from the solution was placed on the plate of the rheometer and a temperature program was applied where the sample was held at 50 °C for 1 min, and then the temperature was increased to 95 °C linearly in 7.5 min. After reaching this temperature, the sample was kept at a temperature of 95 °C for 5 min and then it was cooled to 50 °C in 7.5 min and kept at this temperature for 2 min (Ishiwata et al., 2007). According to the data, onset temperature, peak viscosity, peak temperature, trough viscosity and final viscosity were determined for each starch. Rheological properties of gel form of starch samples were also measured. A gel was prepared using an aqueous solution of each starch at a concentration of 10% by heat treatment at 95 °C for 10 min and then cooling. Rheological properties of the gel were determined by using the rheometer with cone/plate geometry and changesin elastic (G') and viscous (G'') moduli were measured (Wang & Ren, 2020). Temperature and frequency sweep tests were carried out for determining changes in the gel structure by heating and application of constant strain at increasing frequency, respectively. Properties of starch samples were compared statistically by anova and Tukey's test.

Findings

Pasting measurements showed onset temperatures of modified tapioca starch and modified waxy corn starch 1 were lower than those of the modified waxy corn starch samples.Modified tapioca starch had the lowest peak viscosity among the other samples. Moreover, one of the modified waxy corn starch (1) samples had lower peak viscosity than the other two modified waxy corn starches. Peak temperature of the tapioca starch was lower than those of the modified waxy corn starch samples. While, trough viscosity of the modified tapioca starch was also the lowest, modified waxy corn starch 1 had the highest trough viscosity. In additon, final viscosity of the modified tapioca starch was the lowest among the starch samples. On the contrary, modified waxy corn starch 1 and 2 had the highest final viscosity.

In frequency sweep tests, the gel of the modified waxy corn starch sample 1 had the strongest structure at constant strain with increasing frequency. This sample was followed by the other modified waxy corn starch samples while modified tapioca starch sample had the weakest structure among the samples. In the temperature sweep tests, modified waxy corn starch samples 2 and 3 were found to have the highest initial G' value and the values were reduced by increasing temperature to 95 °C by 1.26-fold and 1.4-fold, respectively. On the other hand, the modified waxy corn starch sample 1 and modified tapioca starch sample had lower initial G' value. While G' values of modified waxy corn starch sample 1 declined by 1.2-fold, G' values of modified tapioca starch sample reduced by

3.4-fold by increasing temperature.All samples had higher G' values than G'' values during temperature sweep with no crossover.

The results showed that each starch had different pasting properties. In addition, they formed a viscoelastic gel with varying strength (Zhong et al., 2009). Moreover, tapioca starch is differentiated from the modified waxy corn starches clearly. In addition, some properties of tapioca starch were similar to those of modified waxy corn starch sample 1. The low onset temperatures of these starches indicate that they gelatinize at an early stage during heat treatment and potentially, they are less suitable for applications that require high cooking temperatures. Furthermore, these two starch samples had relatively low viscosity with a weak structure compared to those of the other starches. This shows that these two starches might not be suitable for application where a strong gel structure is required. However, they can be used for thickening of plant-based products. Pasting measurements exhibited that the modified waxy corn starch sample 2 and 3 had high peak viscosity and a stable gel structure. All starches have a weak gel structure with declining G' and G'' values with increasing frequency according to the frequency analyses. Temperature sweep analysis showed that the starch samples form thermoirrevesible gels with no clear liquefaction temperature. The modified corn starch sample 2 had a more elastic gel structure and the modified corn starch sample 2 had a hard gel structure which are suitable for use in plant-based products.

Conclusion

This study provide data for structure forming ability of different starches that will be beneficial in various food applications including plant-based products. Four different starches will have different potential in plant-based food applications. In light of the findings, combining starch as an ingredient with plant-based sources can pave the way for the development of new food products.

Use of Chlorella Vulgaris in Development of a Functional Ice Cream

Büşra Yalçın[a], Meral Kılıç Akyımaz[a]

[a] Istanbul Technical University, Department of Food Engineering, Türkiye
yalcin16@itu.edu.tr

Keywords: *Chlorella*, Clean label, Ice cream, Microalgae, Quality.

Aim

Ice cream is a dairy product that is produced by freezing a pasteurized mixture of milk, other dairy ingredients, emulsifiers, stabilizers, colorants, and flavorings while incorporating air. It is a popular dessert with high nutritional value for consumers of all ages. (Ozturk et al., 2018). Due to the high sugar and fat content of ice cream, along with the use of synthetic colorants, stabilizers, and emulsifiers, consumer preferences have shifted towards reduced fat, reduced sugar and functional ice cream with the market expected to grow rapidly. (Villaró-Cos et al., 2023). Microalgae have been used in human and animal nutrition since ancient times and recently gained popularity due to consumers' growing interest in healthy, nutritious, and clean-label food products. (Boukid and Castellari, 2021). Among microalgae, *Chlorella vulgaris* has attracted attention of food industry by its nutrient- and bioactive compound-rich composition with a potential to serve as a food ingredient. (Nurko et al., 2023) *Chlorella* is referred to as a "green health food" by the Food and Agriculture Organization (FAO). This study aimed to investigate the enrichment of ice cream with *Chlorella vulgaris* at different levels and its effect on product quality and stability. Additionally, the study examined effectiveness of *Chlorella vulgaris* as a stabilizer and emulsifier substitute in ice cream formulation.

Material and Method

Chlorella vulgaris was obtained from a local producer in powder form. The nutritional composition of the *Chlorella* used in this study was measured as containing 61.7% protein, 4.7% fat, 0.4% fiber, and 12.0% carbohydrates. Notably, 60% of protein content of *Chlorella* consists of amino acids allowing enrichment with essential amino acids. *Chlorella* powder was added to three different low-fat ice cream formulations, without stabilizers and emulsifiers, without stabilizers only, and without emulsifiers only, at concentrations of 1%, 3%, and 5%. According to the Turkish Food Codex, low-fat ice cream must contain at least 31% total dry matter, 3-8% milk fat, and a minimum of 10% non-fat milk solids by mass. The ice cream formulations used in this study were prepared in accordance with these standards, with a dry matter content of 37.1%, fat content of 5.3%, and non-fat milk solids of 10.1%. The composition, physical, chemical, and sensory properties of the ice creams were analyzed according to standard methods.

Findings

In the control mix without stabilizers and emulsifiers, the protein content was 3.76%, while formulations containing 1%, 3%, and 5% *Chlorella* showed protein levels of 4.65%, 5.33%, and 5.97%, respectively. The highest protein increase was obtained in the 5% *Chlorella* mix, representing approximately 58.7% more protein compared to the control. Compared to the control formulation with 5.3% fat, formulations with 1%, 3%, and 5% *Chlorella* showed fat contents of 5.2%, 5.5%, and 6.0%, respectively. Additionally, the dry matter content, which was 36.6% in the control mix, ranged between 36.7% and 38.9% in the algae-containing formulations. Since low-fat formulations require at least 31% dry matter by mass, the increase in dry matter from the algae mass could reduce the required sugar content, offering consumers a product with potentially lower sugar levels. The average pH of low-fat ice cream formulations ranges between 6.30 and 6.90. In the control sample, the pH was measured at 6.23, which increased to 6.58 in the formulation containing the highest *Chlorella* concentration without stabilizers and emulsifiers, indicating a pH increase with rising algae concentration.
The addition of *Chlorella* raised the freezing point from -2.60 °C in the control to -2.76 °C at a 5% concentration. The initial drip and complete melting times of the ice cream samples stored at -28 °C were measured on the first

day of storage at 24 °C, and the times for the first and last drips were recorded. Samples containing *Chlorella* exhibited greater resistance to melting. Hardness of the ice cream was reduced by microalgae addition. While the control formulation with stabilizers and emulsifiers achieved a 50% overrun, the overrun rates for ice creams containing 1%, 3%, and 5% *Chlorella* as stabilizer and emulsifier substitutes were measured at 25%, 25%, and 30%, respectively. Samples containing algae as a stabilizer substitute in emulsifier-only formulations exhibited overrun rates between 42% and 45%, closest to the control.

One major drawback is the color and aroma of microalgae which are foreign to food products. Overall, the color and sensory properties of the ice creams were significantly influenced by the *Chlorella* concentration, with samples containing lower percentages being preferred by the panelists. Furthermore, natural green color of *Chlorella* was darkened with the highest concentration of *Chlorella* added to the ice cream formulation.

Conclusion

This study demonstrated that *Chlorella* addition to ice cream formulation increased nutritional value with highly digestible proteins along with bioactive compounds, minerals, vitamins and dietary fiber. Effect of *Chlorella* on physical, chemical and sensory properties of ice cream was enhanced with the level of addition. The addition of *Chlorella* reduced overrun, freezing point and hardness while it increased melting resistance. Sensory properties and color of ice cream were significantly influenced by *Chlorella* addition at the highest level while lower levels were acceptable by the panelists. The findings of the study have shown that *Chlorella* can be used in ice cream formulations; however, optimum usage level that does not affect quality and stability should be determined.

The global demand for protein-rich and clean-label foods has increased by the health-concious consumers. Finding sustainable alternative protein sources is crucial due to the environmental impact of traditional protein sources. Microalgae such as *Chlorella* contain protein at levels up to twice as high as the traditional protein sources that make them promising alternative protein sources. While microalgae can be used to enhance the color and functional properties of ice cream, the optimization of their usage level is critical to minimize their sensory drawbacks.

Novel Nutritional Yeast Formulation as a Functional Ingredient for Healthy Snacks

Aleyna Nur Karslı[a], Beyza Saricaoglu[a], Esra Capanoglu Guven[a]

[a] Istanbul Technical University, Faculty of Chemical and Metallurgical Engineering, Department of Food Engineering, Turkiye
karsli22@itu.edu.tr

Keywords: Utritional yeast, Healthy snacks, Bioaccessibility, Phenolic compounds.

Aim

In recent years, the increasing awareness of healthy living has driven consumers to prefer foods that not only provide basic nutrition but also offer functional benefits. In this context, natural compounds with biological activity such as phenolic compounds have gained prominence in the food industry due to their antioxidant properties, which support the immune system and help reduce the risk of chronic diseases (Czech et al., 2018; Karaman, 2021).

At the same time, the rising demand for clean-label and sustainable production practices has increased interest in foods rich in protein and phenolic compounds (Ma et al., 2023). This trend has encouraged the development of innovative and functional products, particularly in the category of healthy snacks. Nutritional yeast (*Saccharomyces cerevisiae*) has emerged as a valuable alternative in this context, offering a rich profile of proteins, B vitamins, and minerals. As a microbial protein source that is neither plant- nor animal-based, it represents a sustainable and unique ingredient with significant potential (Jach et al., 2022).

The purpose of this thesis is to investigate the potential of nutritional yeast enriched with phenolic-rich fruit and vegetable powders pecifically apple, beetroot, and black carrot as a functional food ingredient. The study aims to enhance the bioactivity, nutritional value, and sensory properties of nutritional yeast through natural enrichment.

Within this scope, total phenolic content, antioxidant capacity, and the bioaccessibility of phenolic compounds after in vitro digestion were analyzed. In addition, sensory evaluations were conducted to assess consumer acceptance in terms of taste, color, and texture. This study aims to contribute to the development of health-promoting and sensorially acceptable functional food products. Furthermore, it seeks to enrich the limited scientific literature on the enhancement of microbial proteins with plant-based bioactive compounds.

Material and Method

In this study, nutritional yeast with a minimum dry matter content of 17%, a gas production capacity of ≥700 mL CO_2/2 hours and a pH range of 4.5–7.0 was used. It was stored at +0 to +4 °C throughout the study to preserve its functional properties. For enrichment, apple, beetroot, and black carrot powders were used in their dried form. Each formulation was prepared by mixing 100 g of liquid yeast with 10 g of plant-based powder. The mixtures were homogenized, frozen at –20 °C for 12 hours, and then freeze-dried at –56,7 °C. The dried materials were ground into a fine powder for further analysis.

Phenolic compounds were extracted using an ultrasound-assisted ethanol method adapted from Zuo et al. (2021). Total phenolic content was determined by the Folin–Ciocalteu colorimetric method (Singleton & Rossi, 1965), and antioxidant capacities were measured using ABTS (Miller & Rice-Evans, 1996) and CUPRAC (Apak et al., 2004) assays. Results were expressed as mg gallic acid equivalent (GAE) or mg Trolox equivalent (TE) per gram of dry weight. In vitro digestion was simulated based on the standardized protocol of Minekus et al. (2014), which includes oral, gastric, and intestinal phases. At each stage, total phenolic content and antioxidant capacity were evaluated using Folin–Ciocalteu, ABTS, and CUPRAC assays.

Texture profile analysis (TPA) was performed to assess mechanical properties of the freeze-dried samples. A double compression cycle simulating mastication was applied to evaluate parameters such as hardness, cohesiveness, and springiness (Bourne, 2002). Descriptive sensory analysis was conducted using the Quantitative

Descriptive Analysis (QDA) method with 10 trained panelists (Stone & Sidel, 2004). Sensory attributes including taste, color intensity, acidity, and umami perception were evaluated using coded yoghurt samples under controlled conditions.

Gas production capacity of the samples was assessed by measuring CO_2 release over a 2-hour period at 30 °C, following a modified version of the method by Ktenioudaki et al. (2015).

All analyses were performed in triplicate, and the results were expressed as mean ± standard deviation. Statistical analysis was conducted using IBM SPSS Statistics 27.0. One-way ANOVA followed by Tukey's test was applied to determine significance. Additionally, independent sample t-tests and Pearson correlation coefficients were used to evaluate group differences and relationships. Statistical significance was set at $p < 0.05$.

Findings

In this study, formulations were developed by combining nutritional yeast (*Saccharomyces cerevisiae*) with apple, beetroot, and black carrot powders, and their performance was evaluated in terms of phenolic compound bioaccessibility, antioxidant capacity, textural and sensory properties, and gas production potential during in vitro digestion.

Phenolic compound analysis revealed that yeast enrichment significantly improved the intestinal bioaccessibility of phenolics in ingredients with low to moderate initial phenolic content, such as apple and beetroot. In the apple formulation, the phenolic content increased approximately 24-fold in the intestinal phase. In contrast, black carrot naturally rich in phenolics showed a lower bioaccessibility ratio when combined with yeast, suggesting that part of the phenolics may have been bound within the yeast matrix.

In terms of antioxidant capacity, a substantial increase was observed in ABTS radical scavenging activity in the apple formulation, whereas CUPRAC results showed only minor changes. Beetroot and black carrot formulations demonstrated a general decrease in antioxidant capacity after digestion. These findings indicate that the effect of yeast varies depending on the structural composition of the plant matrix.

Texture analysis showed that the addition of plant powders reduced the hardness and stickiness of the yeast matrix, resulting in a softer and more chewable product. Especially with beetroot and black carrot, the products were more elastic and consumer-friendly in texture. Sensory evaluation revealed that although plain yogurt was the most preferred in overall acceptability, yeast-enriched formulations enhanced umami perception and reduced sourness. The black carrot formulation stood out with its dark color, while the apple variant was rated highest for fruity aroma.

Gas production measurements showed low levels of CO_2 release in all samples, indicating that the freeze-drying process effectively inactivated the yeast cells and eliminated their fermentative potential.

Conclusion

Formulations developed by enriching nutritional yeast with apple, beetroot, and black carrot powders stand out as sustainable and functional food ingredients. Initially aimed at enhancing the nutritional and sensory properties of microbial proteins, this study demonstrated a significant improvement in the bioaccessibility of phenolic compounds, particularly in low phenolic matrices such as apple, along with notable textural enhancements and improved umami perception.

The consistently low CO_2 production across all samples indicates a digestion-friendly profile, making these products attractive to individuals seeking non-fermentative, gut-friendly food options. With its non-animal and non-plant origin, high protein content, and compatibility with phenolic-rich plant matrices, nutritional yeast emerges as a unique and scalable raw material for the development of healthy snacks (Jach et al., 2022; Karaman, 2021).

This work contributes to the advancement of next-generation functional products that combine microbial proteins with plant-based bioactives to deliver both health benefits and consumer satisfaction. Given the rising demand for clean-label products and the global shift toward plant-forward nutrition, these formulations show strong commercial potential, particularly in the rapidly growing healthy snack segment (Ma et al., 2023).

Keywords: Lemon Peel, Antioxidant, Antidiabetic, Emulsifying, Sustainability.

Aim

Lemon is an important citrus species widely appreciated for its refreshing aroma and high antioxidant activity. Antioxidant activity of lemon is due to its high vitamin C and phenolic compound contents. These attributes of lemon contribute not only to its appeal in food formulations but also health-promoting properties. However, approximately 50% of the fruit is wasted after processing to juice leading to loss of valuable nutritional and health-improving components. Currently, lemon waste is utilized as animal feed, dietary fiber source and feedstock for fermentations. Lemon waste is composed of flavedo, albedo, membranes and seeds. Among the by-products of lemon, the peel including flavedo and albedo, is particularly abundant and offers numerous components with techno-functionality and bioactivity. Biopolymers present in lemon peel can have techno-functionalities such as emulsification, gelling and foaming ability which are important in formation of different food structures (Magalhães et al., 2023). Other components like flavonoids, terpenes, vitamin C, and essential oil found in lemon peel and dietary fiber are known to enhance the positive health effects of this natural by-product, including antidiabetic, anti-inflammatory, anticancer, and antimicrobial properties (González-Molina et al., 2010; Figuerola et al., 2005). Valorization of lemon by-products has the potential to reduce waste, increase the efficiency of food production, and create revenue while supporting environmental sustainability. In this context, the lemon peel stands out as an unused resource of bioactive compounds with the potential to be transformed into valuable functional ingredients for various applications, including the food, pharmaceutical, and cosmetic industries. Therefore, this study aims to investigate valorization of lemon peel as a techno-functional and bioactive food additive.

Material and Method

Fresh lemons of Lamas cultivar were obtained from a local supplier. Peels were separated manually and then dried using an oven at a temperature of 50°C until constant weight. This temperature was chosen to avoid the degradation of sensitive bioactive compounds while efficiently removing moisture from the peels. After the drying process, the lemon peels were ground into a fine powder using a grinder. The powdered material was then sieved to obtain uniform particle size to obtain a natural additive. The proximate composition of lemon peel powder was determined. Moisture content was determined by infra-red moisture analyzer. Oil content was measured by Soxhelet extraction. Protein content was measured by Kjeldahl method. Ash content was detected by gravimetric methods. Total carbohydrate content was calculated by proximate analysis. Emulsifying capacity was measured by preparation of oil-in-water emulsion with and aqueous solution of lemon peel powder at a concentration of 1% and sunflower oil at a volume ratio of 3:1. Stability of the emulsion was determined by heat treatment. Foaming capacity was measured by whipping the aqueous solution of lemon peel powder. Oil binding and water binding capacity were measured by using one g of powder (Garau et al., 2007; Ghanem RomDhane et al., 2015). Antioxidant activity of lemon peel was determined by CUPRAC and DPPH antioxidant activity assays (Apak et al., 2005). Antidiabetic activity of lemon peel powder was measured by in vitro α-amylase and α-glucosidase inhibition assays (Esfandi et al., 2021).

Findings

Lemon peel powder from Lamas cultivar was found to contain 76% total carbohydrate, 8.0% protein 3.8% oil, 2.9% ash, and 9.3% moisture. Water binding capacity of lemon peel powder was measured as 4.99 g/g powder. Oil binding capacity of lemon peel powder was determined to be 4.29 g/g powder. In addition, lemon peel powder exhibited 100% emulsifying capacity and 68.8% emulsion stability in oil-in-water emulsion. The foaming capacity and foam stability were found to be 25% and 50%, respectively. Lemon peel powder showed antioxidant activity of 6.93 mg TE/g dry weight in the DPPH assay and 12.22 mg TE/g dry weight in the CUPRAC assay. In in vitro antidiabetic activity. assays, lemon peel powder was found to inhibit the activity of α-amylase and α-glucosidase enzymes at a level of 4% and 100%, respectively.

Conclusion

The compositional analysis showed that the lemon peel powder contained mostly carbohydrates which includes high amounts of polysaccharides along with some protein. These components can be responsible for the measured techno-functional properties of lemon peel powder. The antioxidant and antidiabetic properties of lemon peel powder are possibly due to these polymeric compounds, phenolic compounds and essential oil. Antioxidant activity is important in prevention of free radical-induced oxidative stress while antidiabetic activity can be beneficial in diet-induced glucose metabolism disorders. The obtained data also suggests that lemon peel powder can be evaluated as a tecno-functional additive to improve emulsifying properties in food systems. In addition, lemon peel powder can be utilized as a water or oil binding agent in food structures. On the other hand, foaming ability is not at a significant level for use solely as an additive in practice. However, it can contribute positively to other foaming agents in food systems.

Lemon peel from a local cultivar was used for development of a food additive with techno-functionality and bioactivity. The findings of this study will provide valuable insights into upcycling of lemon peel, ultimately highlighting its potential as a sustainable and functional food additive. This could not only contribute to reducing food waste but also offer a healthier, more natural alternative to synthetic additives in the food sector, aligning with current trends towards clean-label and health-improving ingredients. Future studies can examine other possible techno-functional and bioactive properties of lemon peel powder. In addition, improvement of techno-functional and bioactive properties of lemon peel powder by different novel techniques can be investigated. Moreover, the developed additive can be applied in formulations of various food products to demonstrate its effectiveness. Bioactivity of the lemon peel powder can also be evaluated in in vivo systems to determine its effectiveness in human body.

From Waste to Packaging: Biodegradable Films from Artichoke Products Phenolics via Subcritical Water Extraction

İlayda Hızır Kadı[a], Beraat Özcelik[a]

[a]Istanbul Technical University, Food Engineering Department, Food Engineering Program, Türkiye
hizir17@itu.edu.tr

Keywords: Artichoke Waste, Biodegradable, Food Packaging, Sustainability.

Aim

The aim of this study, focusing was to the production of PVA-based films by solvent casting, with the incorporation of natural antioxidant artichoke waste extract phenolics to obtain biodegradable food packaging. The study successfully produced films comprising PVA and artichoke extracts, blended at varying ratios (1%, 2%, 3%), and characterized them. The findings indicated that the incorporation of extracts into PVA films has considerably improved the optical properties (colour-UV light blocking), thickness, and water vapor permeability of the prepared films. The elongation at the break of PVA-extract films was enhanced with rising extract concentration, which resulted in a decline of tensile strength. The composite films exhibited enhanced overall characteristics with increasing artichoke extract concentrations, primarily attributable to the presence of polyphenolic compounds. Similarly, the antibacterial activity of films including artichoke extracts was found to be superior to that of neat PVA and stretch film. It is proposed that a 3% artichoke waste extract concentration may be optimal.

Material and Method

Extraction of Artichoke Waste

Artichoke waste was subjected to subcritical water extraction at 200°C and 10 bar to separate the liquid and solid fractions. The liquid extract, which contained phenolic compounds with strong antioxidant and antimicrobial properties, was incorporated into the PVA film matrix to improve its functional properties (Kasapoglu et al., 2022).

Figure 1. The appearance of Artichoke Waste.

Film Preparation and Characterization

The solution casting method was employed to fabricate the biodegradable composite film, using PVA as the polymer matrix. To prepare the PVA solution, 5% PVA was heated in distilled water at 70°C for 1 hour. Subsequently, 1 ml of carboxymethyl cellulose (1%), 350 uL of glycerol as a plasticizer, and 850 uL of citric acid as a crosslinker (1%) were mixed into the warm PVA solution (Arun et al., 2022). Different concentrations were prepared for the PVA-AE composite films (1, 2, and 3% w/v PVA) Three replicates were prepared for each

concentration. Samples were coded with, control (neat PVA film), AE-I (1%), AE-II (2%), and AE-III (3%) (Fig 2). These mixtures were then poured onto a clean, smooth glass plate and left to dry overnight at room temperature. The prepared films were characterized in terms of mechanical strength (tensile strength, elongation at break), and optical properties (transparency, color). The optical properties of the films were analyzed using a UV-Vis spectrophotometer to determine light transmittance and opacity, which play a crucial role in food preservation by limiting exposure to harmful UV radiation (Rhim et al., 2009; Passareti et al., 2019).

The antioxidant activity of the artichoke extract was determined using TPC and CUPRAC assays to assess their potential to inhibit the oxidation processes (Table 1) Furthermore, the antimicrobial efficacy of the films was assessed against common foodborne pathogens, including *Escherichia coli* and *Staphylococcus aureus*, utilizing both agar diffusion and plate count methods. Additionally, the water vapor permeability (WVP) and moisture content of the films were evaluated, as these factors influence the ability of the packaging to maintain food quality by controlling moisture exchange (Suganthi et al., 2020).

Table 1. Total phenolic content (TPC) and total antioxidant activity (TAA) of AE.

Sample	TPC (mg GAE/g sample) FOLIN-CIOCALTEU	TAA (mg TE/ g sample) CUPRAC
Artichoke waste extract	30.02 ± 1.42^{a}	20.44 ± 1.42^{b}

*AE: Artichoke waste extract, GAE: Gallic acid equivalent, TE: Trolox equivalent, values are expressed as mean ± standard deviation
Different letters in the same column indicate significant differences in mean ($p<0.05$).

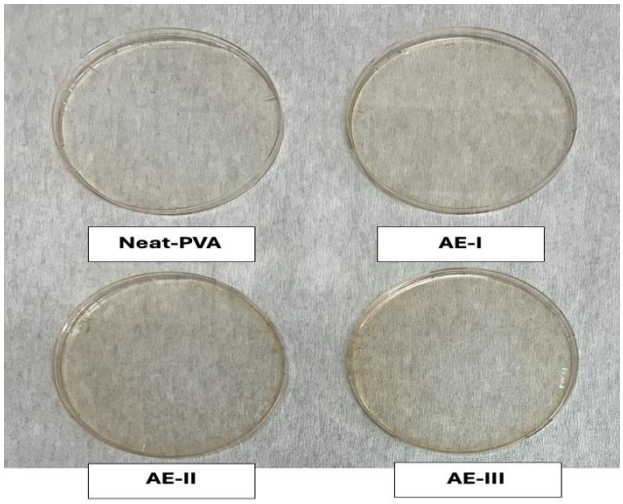

Figure 2. The physical appearance of prepared PVA-based film.

Applications of the Films on Fresh Cut Apple in storage life

An examination of the packaging properties of the prepared PVA films was conducted using fresh-cut apples. The samples were randomly divided into equal groups and sealed with prepared films. The storage containers were sealed with the prepared film samples (AE-I, AE-II, AE-III, neat PVA, and conventional stretch film. All samples were stored in the refrigerator.

Quality parameters of the stored fresh-cut apple were recorded after 0 and 7 days of storage. Following the designated period, the alterations (color, juiciness, appearance, and weight loss) in the quality of the samples were noted. The decay progression in fruits was monitored, documented, and photographed using a digital camera (Nkede et al., 2023).

Findings

The study successfully produced films comprising PVA and artichoke extracts phenolics blended at varying ratios (1%, 2%, 3%), and characterized them. The findings indicated that the incorporation of extracts into PVA films has considerably improved the optical properties (colour-UV light blocking), thickness, and water vapor permeability of the prepared films (Table 2&3). The elongation at the break of PVA-extract films was enhanced (24.87 %) with rising extract concentration, which resulted in a decline of tensile strength (8.02 mPa). (Fig 3). The composite films exhibited enhanced overall characteristics with increasing artichoke extract concentrations, primarily attributable to the presence of polyphenolic compounds. Similarly, the antibacterial activity of films including artichoke extracts was found to be superior to that of neat PVA and stretch film. It is proposed that a 3% artichoke waste extract concentration may be optimal (Fig 4).

Furthermore, the packaging films demonstrated effective preservation effects, slowing color changes, and minimizing weight loss during storage. The film with the highest extract (AE-III) ratio was found to offer optimal protection, resulting in a weight reduction of 4.3 % (Fig 5). The quality of this film is similar to that of a stretch film (4.4%). The water vapor permeability analysis suggested that the films maintained an optimal moisture barrier, which is essential for prolonging the freshness of perishable food (Fig 6).

Additionally, food storage trials revealed that packaged food items retained better color and texture compared to those stored in conventional plastic packaging or without any covering.

Table 2. Results of color, thickness, and WVP measurements of biodegradable films.

Sample Name	L*	a*	b*	ΔE	Thickness (mm)	WVP (g.mm/m^2.h.kPa)
Neat PVA	85.05	0.98	-1.39	10	0.060	$11.3*10^{-2}$
AE-I	65.50	0.32	1.78	12	0.082	$9.82*10^{-2}$
AE-II	74.22	0.35	1.28	13	0.087	$9.34*10^{-2}$
AE-III	75.28	0.38	1.007	14	0.095	$10.2*10^{-2}$

AE-I	62.3	65	70	73.5	79	81
AE-II	23	25.4	31.9	35	38	40
AE-III	21	23	28.5	31.6	34.3	38.2

AE: Artichoke waste extract

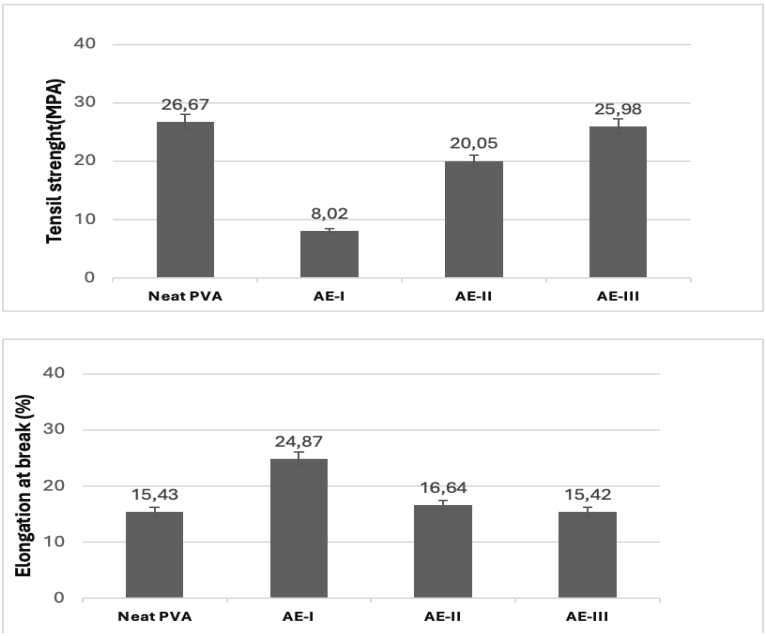

Figure 3. Tensile strength and elongation at break of neat PVA and composite films.

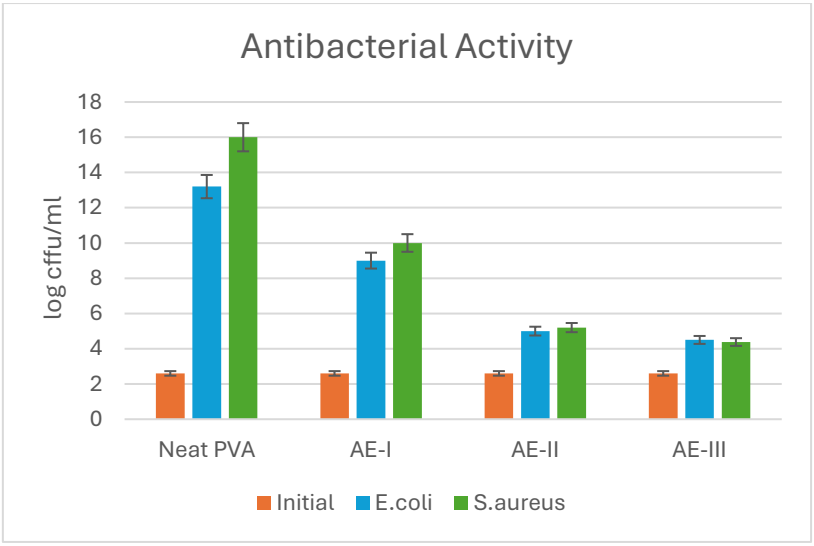

Figure 4. Antibacterial activity of films.

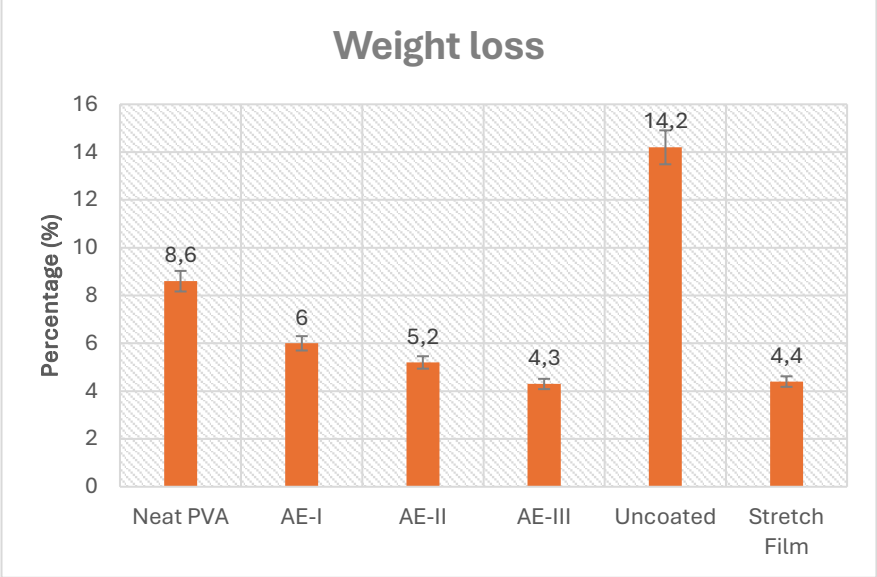

Figure 5. Weight loss of films after 1 week of storage in refrigerator.

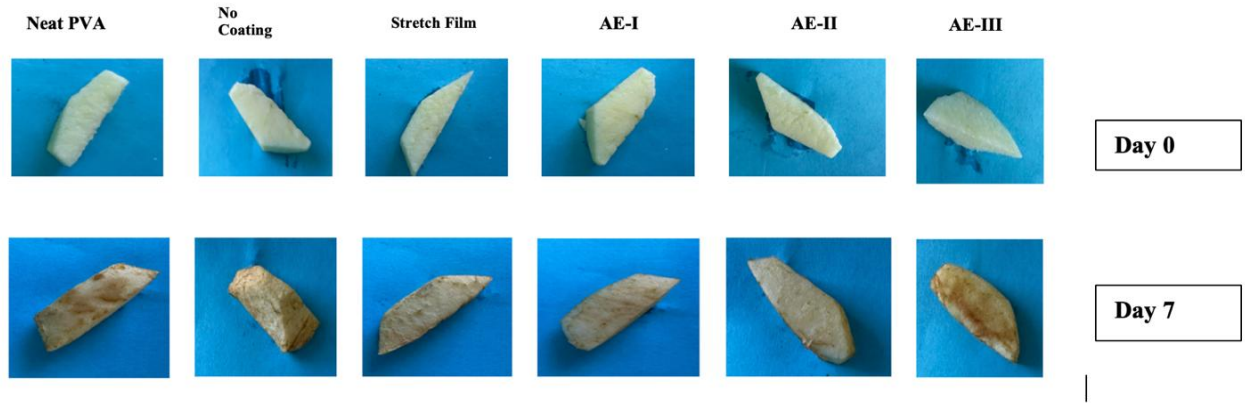

Figure 6. The shelf-life studies with fresh cut apples before and after 7 days of storage in the refrigerator.

Conclusion

This study successfully demonstrates the potential of artichoke waste-derived phenolic compounds as a sustainable bioactive additive for biodegradable food packaging. The developed films exhibit promising mechanical, antioxidant, and antimicrobial properties, making them suitable for extending the shelf life of fresh produce. Given their enhanced structural and functional properties, these films could serve as viable alternatives to synthetic food packaging materials, contributing to reducing plastic waste and promoting a circular economy. Future work will focus on the optimization of film formulations to enhance their functional properties, the scaling up of production for commercial applications, and extensive shelf-life studies to evaluate long-term performance.

Earthquake Risk Analysis of Water Transmission Lines in Istanbul

Emir Ekrem Barutcu[a], Himmet Karaman[a]

[a] Istanbul Technical University, Department of Geomatics Engineering, Geomatics Engineering, Türkiye
barutcue17@itu.edu.tr

Keywords : Earthquake Hazard, GIS, Istanbul, Seismic Risk, Water Transmission Lines.

Aim

Water has been a decisive factor in the development of civilizations throughout history, encouraging agriculture, enabling the establishment of cities, and contributing to the shaping of trade routes. In particular, Middle Eastern civilizations developed on the shores of major water sources such as the Euphrates, Tigris, Nile, and Yellow River, discovering and developing water management systems over time. In terms of water resources, Istanbul also has historical significance; advanced infrastructure including arches, cisterns, and dykes was developed to satisfy water needs during the Roman, Byzantine, and Ottoman periods (Yoon et al., 2018). But given population growth, climate change, and rising water consumption today, the city's water security has become a progressively important concern. Furthermore, Istanbul's geological composition poses a significant risk. Historically, the city, which sits on the North Anatolian Fault Line and is highly prone to earthquakes, has suffered terrible shocks. The city's dense population, historical buildings, and old earthquake-unresistant building stock, combined with unplanned urbanization, aggravate the effects of a possible major earthquake. In this context, developing a sustainable and resilient urban model in terms of both water management and earthquake risk stands out as a vital necessity for the future of Istanbul (Istanbul Metropolitan Municipality, 2009).

The February 6, 2023, earthquake Turkey experienced revealed the shortcomings in disaster management and had terrible multi-dimensional effects. The effects of the disaster were worsened by elements including buildings not constructed in line with earthquake rules, defective interventions in the load-bearing systems of buildings, and insufficient emergency plans. In this regard, the state of transmission lines, a key component of infrastructure, also catches great interest for study. The Maraş earthquake seriously damaged the transmission lines, which were not built to withstand quakes or were not sufficiently reinforced, so disrupting water supply in the area for days. Moreover, the absence of efficient data backup systems for these units made emergency response challenging, and only one- to two-year-old backups could be applied (Alemdar, 2025).

Similar issues were noted during the Gölcük Earthquake on August 17, 1999, when widespread water shortages, particularly during the hottest time of the summer, were caused by damage to the water transmission systems in the affected areas (Istanbul Metropolitan Municipality Department of Earthquake and Soil Survey, 2002). These disturbances in the densely populated Marmara Region highlighted the urgency of efforts to improve the disaster resilience of these systems and exposed the susceptibility of vital infrastructure to earthquakes.

Therefore, the earthquake resilience of the transmission lines that supply water to about 16 million people in Istanbul is a major concern in the event of a major earthquake. To make Istanbul disaster-resistant, a seismic resilience analysis of the city's water management infrastructure is essential. This study aims to assess the seismic risk of Istanbul's water transmission lines using Geographic Information Systems (GIS) based risk mapping and structural vulnerability analysis. The primary objectives include identifying high-risk areas, evaluating pipeline weaknesses.

Material and Method

The methodology of this study consists of several basic steps. Firstly, the data of the transmission lines in Istanbul was obtained from Istanbul Water and Sewerage Administration (ISKI) together with the parameters such as material and diameter to be used in the analysis and calculations. Earthquake risk map and geological and geophysical data to be used in earthquake risk scenarios were collected from relevant institutions such as the Disaster and Emergency Management Presidency (AFAD) and Istanbul Metropolitan Municipality (IBB).

Using the collected data, an earthquake risk map was first created with the help of ArcGIS Pro software. In order to create an earthquake risk map, each of the data obtained for use in earthquake risk calculations was added in separate layers. After this stage, since the data to be used in earthquake risk calculation will be used in raster format, the remaining vector data were converted to raster format. In order to make the earthquake risk data more understandable and to create a standard, the datasets contained in the added layers were arranged probabilistically, and a normalization process was applied to take values from 1 to 5 (1 being the lowest, 5 being the highest risk). These normalized data were combined using the weights, and a raster with a single risk value was obtained. This raster was colored according to the risk value, and what is actually called the Earthquake Risk Map was obtained for Istanbul.

The purpose of this earthquake risk map in our study is to classify the transmission lines according to earthquake risk by integrating with the transmission lines data obtained from ISKI. This process was done as follows. The earthquake risk data in raster format created with the data used for the earthquake risk calculation was overlaid with the data of the transmission lines that provide water transfer to Istanbul in vector format. As a result of this overlapping process, an earthquake risk value was assigned for each line in the transmission lines data. What is obtained as a result of the above procedure is actually the data of the transmission lines classified according to earthquake risk from 1 to 5 (1 is the lowest risk, 5 is the highest risk), and the earthquake risk is known for each line.

Using the data of transmission lines with earthquake risk values, possible earthquake scenarios in Istanbul were simulated with HAZTURK software (Istanbul Metropolitan Municipality Department of Earthquake and Soil Survey, 2019). In line with these scenarios, HAZTURK software estimated the potential damages that may occur in the transmission lines carrying water to all across the city (Karaman, 2008).

Findings

The results of earthquake risk analysis try to shed light on how vulnerable the water transmission lines in Istanbul indeed are to an earthquake. The GIS-based earthquake risk analysis implied that quite a considerable area of the water infrastructures of the city lay within the high-risk zone. The risk classification of the transmission lines was 1 to 5, with 5 being associated with the highest risk. This translates to the fact that the older and more fragile a pipe, the more vulnerable it is to destruction.

The earthquake risk map, generated with ArcGIS Pro software, identified the areas where transmission lines may be exposed to the highest seismic hazard. Overlaying this data with the network of transmission pipelines in Istanbul confirmed that critical water supply lines also pass-through areas with a high probability of strong ground motion and soil liquefaction.

By HAZTURK simulation, different magnitudes and locations of earthquakes gave the potential scenarios of damage. The simulation output was that the transmission lines which were aligned over the fault zones and structurally unstable geological formations had the greatest risk of collapsing. In the results, major earthquakes could bring a sharp decline in water supply, mostly in urban areas. From the results, it can also be said that the material quality of the pipeline is fundamental in its resilience since older and more brittle pipework has a higher risk of failure.

Conclusion

The results of the study underline how urgently Istanbul's water network's seismic resilience has to be strengthened. Given the city's sensitivity to major earthquakes, deliberate interventions must be carried out to minimize possible disruptions of the water supply.

Among the key suggestions is to give high-risk locations top priority for infrastructure strengthening. Replacing or retrofitting existing pipes with materials resistant to earthquakes will significantly lower the possibility of damage and consequent disturbances. Moreover, early identification of transmission line defects will benefit from the network's real-time monitoring systems' integration. Faster reaction and repair will follow from this.

This study also underlines the need of incorporating seismic elements in urban planning and infrastructure development and advises that future transmission line planning should avoid locations with high liquefaction risk and as much as feasible active fault zones. Furthermore, backup water supply systems should be part of emergency ready plans to guarantee ongoing access to pure water following an earthquake.

Eventually, constant risk assessment and mitigating strategy planning depend on cooperation among government agencies, local authorities, and research facilities. Istanbul can provide sustainable and consistent water access even in the face of significant seismic occurrences by means of data-driven strategies and innovative technologies, hence strengthening the resilience of its water system.

Spatial Estimation of Potential Utilization Performance of Electric Vehicle Charging Stations in Türkiye Using Machine Learning

Serkan Tanrıverdi[a], Adalet Dervişoğlu[b]

[a] Istanbul Technical University, Graduate School, Geomatics Engineering Program, Türkiye
[b] Istanbul Technical University, Faculty of Civil Engineering, Department of Geomatics, Türkiye
tanriverdise@itu.edu.tr

Keywords : Electric Vehicles, Charging Stations, Machine Learning, Spatial Analysis, Regression Models.

Aim

Electric vehicles (EVs) are increasingly recognized as key solutions to environmental challenges and energy security concerns, occupying a central position in sustainable transportation policies (International Energy Agency [IEA], 2023; Zaino et al., 2024). Effective adoption of EVs necessitates strategically planned and adequately developed charging station infrastructure (T.C. Enerji ve Tabii Kaynaklar Bakanlığı [ETKB], 2023; T.C. Ulaştırma ve Altyapı Bakanlığı [UAB], 2023). Proper and efficient infrastructure facilitates hassle-free charging experiences, significantly enhancing the adoption rate of electric vehicles (Acar & Taşkın, 2024; Salari, 2022). Motivated by this necessity, this study employed extensive datasets derived from various socioeconomic factors and regions across Türkiye. The primary objective of this research is to estimate the future usage performance of potential EV charging station locations nationwide based on charging station usage data and various socioeconomic indicators obtained from selected regions of Türkiye (Kazempour et al., 2025; Soczówka et al., 2024).

Material and Method

The study utilized, datasets from the Turkish Statistical Institute (TÜİK), education statistics, EV charging station data, administrative boundaries of Türkiye, OpenStreetMap (OSM) road network data, Sentinel-2 satellite imagery, and shopping center locations.

Data from TÜİK were meticulously analyzed to understand household consumption expenditure, income distribution, and demographic structure. These datasets are critical for uncovering the economic and social disparities across countries. The regional distribution of household consumption expenditures and expenditure behaviors across different income levels has allowed a deeper understanding of regions with concentrated economic activities and consumer profiles. Income distribution analyses have provided valuable insights into the development of regional development policies and the mitigation of economic inequalities. Moreover, detailed demographic data, including population density, age group, and gender distribution, have facilitated more precise infrastructure planning, significantly improving public service efficiency.

Educational data have been extensively analyzed to assess education levels, graduation rates, and labor market participation of young populations. These analyses have clearly demonstrated the impact of educational attainment on labor market outcomes, providing the necessary insights to improve educational policies and address unemployment issues. Additionally, charging station data provided by Zorlu Energy Solutions (ZES), Türkiye's largest EV charging network provider, encompassing major cities such as Istanbul, Ankara, Izmir, Eskişehir, and Antalya, were integrated into the study. These cities were chosen because of their high economic activity and significant electric vehicle usage (Güray & Merdan, 2021). A detailed analysis of ZES data, including usage patterns, socket types, and user preferences, has provided valuable insights for future infrastructure planning (Jonas et al., 2023).

Another critical dataset used was OpenStreetMap (OSM). Comprehensive transportation infrastructure metrics were calculated for Türkiye at hexagonal levels 4, 5, 6, 7, and 8 using Python-based algorithms and the OSMNX library. These metrics include counts of motorways, trunk roads, primary, secondary, and tertiary roads, residential roads, service roads, unclassified roads, living streets, node counts, total roads, average graph level, streets per node average, intersection counts, total street lengths, street segment counts, and average street lengths. These

parameters critically influence the accessibility and usage of charging stations, serving as independent variables in the developed machine learning models, thus enabling robust and comprehensive infrastructure analyses (Cai et al., 2014; Shahraki et al., 2015).

Sentinel-2 satellite imagery, provided by the European Space Agency, constitutes a significant portion of the research and offers high-resolution and up-to-date remote sensing data. The 10-meter resolution facilitated clear differentiation between urban and rural areas, accurately determining settlement boundaries, densities, and spatial distributions. These detailed spatial data are essential for regional population estimations and prioritization of infrastructure investments. Additionally, the geographic locations of shopping centers provided critical insights into consumer mobility and regional economic activities, significantly influencing the selection of potential charging station locations (Soczówka et al., 2024).

In spatial analyses, administrative boundary data at the provincial, district, and neighborhood levels have enabled detailed regional evaluations, revealing the socioeconomic dynamics and enhancing the effectiveness of public policies. Furthermore, the H3 hexagonal indexing system, developed by Uber and internationally recognized, allows analyses at various spatial resolutions, providing coherent and precise insights into regional differences.

Machine learning techniques were chosen for data analysis, integrating multiple data sources into a unified spatial database to inform future strategic decisions regarding charging infrastructure investments. Additionally, data integration and modeling approaches used in this study aim to provide both scientific and practical contributions to addressing the challenges of transitioning to sustainable transportation.

All the datasets underwent extensive preprocessing and transformation processes suitable for machine learning. Missing data were corrected, inconsistencies were resolved, and data integrity was ensured. The datasets were integrated and aggregated at the neighborhood level, enhancing the consistency of the spatial database. This comprehensive database was analyzed primarily through regression analysis and various machine-learning methods. Regression analysis provides a powerful statistical approach to quantitatively evaluate the relationships between dependent variables (such as charging station usage, transmitted electricity in kW, and transaction counts) and independent variables (such as population density, income level, and infrastructure features).

Numerous linear and nonlinear regression models (e.g., random forest and gradient boosting) have been explored to achieve an optimal prediction performance. Model performance was assessed using statistical metrics, such as the Coefficient of Determination (R^2), Mean Absolute Error (MAE), and Mean Squared Error (MSE). The results indicated that some models achieved R^2 values above 0.6, demonstrating a satisfactory predictive capability. Detailed analyses of the MAE and MSE further enhanced the prediction accuracy by thoroughly evaluating the error magnitudes.

Findings

Research findings have underscored the significant relationships between socioeconomic indicators and EV charging station usage (Salari, 2022; Zaino et al., 2024). The charging infrastructure was found to be densely concentrated in major cities, displaying varying usage patterns across locations (Güray & Merdan, 2021; Jonas et al., 2023). Despite the geographical limitations of the analyzed data, general predictions applicable to Türkiye are possible. The findings provide a generalized model that is adaptable to regions with varying geographical and economic conditions.

This study highlights the vital importance of integrating spatial data, particularly transportation infrastructure and settlement data, for charging station planning (Erol, 2022; Karasu Asnaz & Özdemir, 2021). Variables such as shopping center locations have emerged as important indicators of potential charging station usage (Soczówka et al., 2024). Furthermore, population data enhanced by Sentinel-2 imagery significantly improved the accuracy of demographic and spatial analyses.

This study provides meaningful insights into the strategic planning of Türkiye's EV infrastructure, emphasizing the importance of socioeconomic and demographic indicators (Acar & Taşkın, 2024; Güray & Merdan, 2021). The high predictive performance achieved by machine learning-based regression models facilitates effective decision-

making for infrastructure investments (Hecht et al., 2021; Kazempour et al., 2025). High R^2 values further underscore the reliability and applicability of the model across different cities and regions.

In Figure 1, the hexagon-level map for western Türkiye reveals substantially higher predicted monthly kW consumption, with the darkest cells clustering around major urban and industrial centers—particularly the Marmara and Aegean regions—indicating strong demand for EV charging infrastructure. By contrast, Figure 2 shows eastern Türkiye's hexagons shaded in much lighter tones, reflecting lower population density, less developed EV networks, and correspondingly reduced predicted consumption. The clear east–west gradient in these visualizations underscores how socioeconomic and demographic factors drive regional variation in charging-station usage. Together, these maps highlight the necessity of tailoring infrastructure investments: prioritizing capacity expansions in the high-demand west while strategically developing charging networks in the understudied eastern provinces.

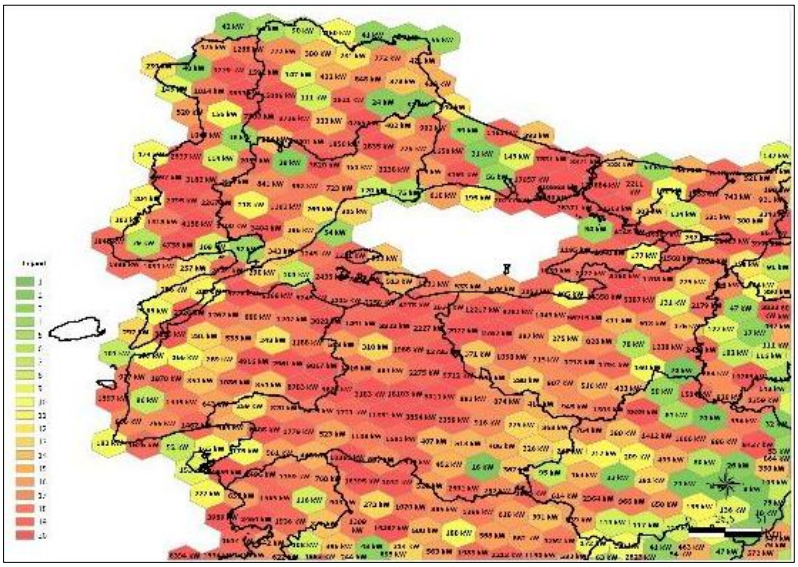

Figure 1. Western Regions of Türkiye.

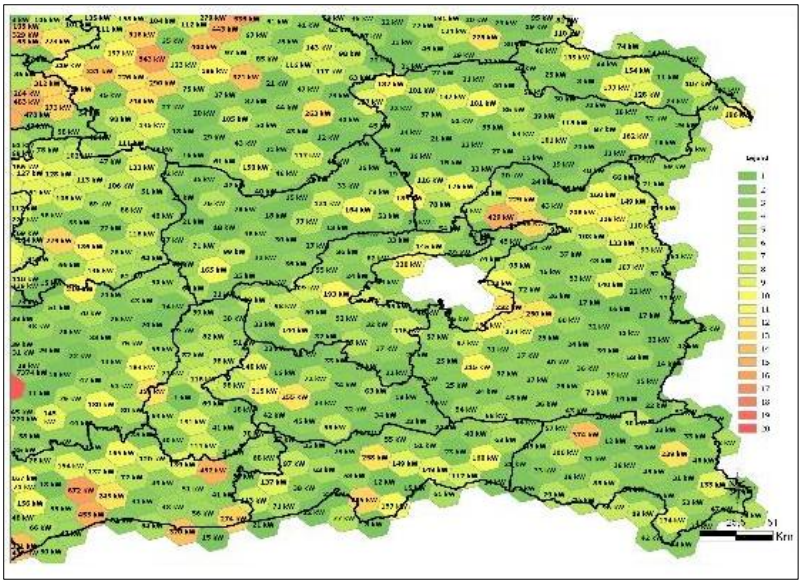

Figure 2. Eastern Regions of Türkiye.

Conclusion

Despite extensive analysis, this study has several limitations. First, charging station data are limited to certain major cities, which reduces generalizability across Türkiye. Second, the datasets focused solely on 2024, excluding temporal variations. Future studies should broaden the scope of geographic and temporal data to enhance model generalizability and predictive precision.

Future research may also investigate the impact of alternative energy policies and economic incentives on EV user behavior, enabling more effective public and private sector strategies (Salari, 2022; Zaino et al., 2024). This study offers significant academic contributions and practical recommendations for developing sustainable transportation policies (Banister, 2008).

In addition to the limitations noted, the present work undertook a systematic evaluation of multiple regression frameworks, combining several feature-selection strategies(Exhaustive Feature Selection, Sequantial Feature Selection) with parameterized cross-validation protocols (k = 2, 3, 5, and 10 folds) in order to identify the most robust modeling approach. By carefully tuning model complexity and validation parameters, the coefficient of determination (R^2) was established at approximately 0.60, demonstrating solid predictive accuracy without evidence of overfitting. Notably, demographic indicators collectively emerged as the most influential predictors of monthly kW consumption. Moreover, spatially disaggregated results uncovered a marked east–west divide: hexagon-level estimates of monthly energy use were consistently higher in western Türkiye, whereas eastern regions exhibited substantially lower consumption levels.

Keywords : Disaster Management, Disaster and Emergency Assembly Areas, Geographic Information Systems, Accessibility Analysis, Esenyurt District.

Aim

Disasters and emergencies occur unexpectedly, leading to substantial losses of life, property, and social structures. Historically, the severity of damage caused by such events has often been exacerbated by factors such as high population density, unplanned urbanization, structurally vulnerable buildings, and inadequate preventive measures (UNISDR, 2011; Aşıkoğlu, 2009). Additionally, ineffective implementation of disaster mitigation regulations and the lack of consistent monitoring of urban transformation processes have further increased these vulnerabilities (Aşıkoğlu, 2009).

In the aftermath of a disaster, it is crucial to designate safe assembly areas that are accessible to the public without disruption. Therefore, the accessibility of disaster and emergency assembly areas is a critical component of effective disaster management (Kırçın et al., 2017). Poorly planned assembly areas may cause confusion among both the public and emergency response teams, significantly delaying response operations and potentially escalating panic and chaos. Moreover, inadequate planning can lead to overcrowding at some assembly points, whereas others remain underutilized because of insufficient communication or poor location choices. This imbalance can reduce the overall effectiveness of emergency services, increase response times, and ultimately lead to greater risk. Furthermore, poorly accessible or distant assembly areas may discourage people from using them, causing them to seek unsafe alternatives and thus further complicating rescue efforts. To mitigate these risks, comprehensive analyses of assembly point accessibility—combined with clear communication strategies, regular drills, and community engagement—are integral components of disaster preparedness programs. By ensuring that assembly areas are strategically located, clearly marked, easily accessible via multiple safe routes, and effectively communicated to the public, communities can better manage disaster situations and minimize the potential loss of life and resources.

The selection criteria for disaster and emergency assembly areas include ground stability, accessibility, ease of evacuation, infrastructure availability, regional population density, and risk factors (Aman & Aytaç, 2022; Kırçın et al., 2017). In addition to ensuring a sufficient number of these areas, access time and route availability are equally vital considerations. Factors such as road capacity, potential road closures, and the availability of alternative routes significantly affect accessibility. The quality and adequacy of pedestrian infrastructure, including sidewalks and crosswalks, also play a crucial role. Thus, analyzing the accessibility of these assembly areas using Geographic Information Systems (GIS) contributes to the development of robust disaster management strategies, enhancing local preparedness and raising community awareness (Arca, 2012).

Istanbul is Turkey's most populous city, located near the North Anatolian Fault Line, which poses significant disaster risks, particularly from earthquakes. A major earthquake expected in the Marmara Sea region could cause catastrophic damage to Istanbul, potentially affecting millions of residents, disrupting vital infrastructure, and overwhelming emergency response systems (Parsons, 2004; Hürriyet Daily News, 2023). Following the devastating 1999 Gölcük earthquake, detailed investigations revealed that many structures across the city were insufficiently earthquake-resistant due to outdated construction practices, inadequate enforcement of building codes, and poor maintenance (Demirelli, 2001). Despite ongoing urban transformation efforts to reduce these vulnerabilities, the city's uncontrolled and rapid urbanization continues to pose severe challenges. High-density

development, informal (illegal) settlements, and structurally unsafe buildings all amplify existing earthquake risks, particularly in densely populated districts (Aşıkoğlu, 2009). Additionally, issues like heavy traffic congestion, thousands of narrow streets, inadequate road infrastructure capacity, and a lack of clearly defined evacuation routes exacerbate these problems. These logistical constraints hinder emergency service accessibility and reduce the speed and effectiveness of disaster-response operations (Hürriyet Daily News, 2023). Moreover, limited emergency response resources, inadequate training, and insufficient coordination among response agencies further complicate the effective management of disaster scenarios (Corbacioglu & Kapucu, 2006). To comprehensively address these issues, the city requires strengthened disaster preparedness initiatives, enhanced infrastructure resilience, expanded public awareness programs, and significant investments in emergency response capacity and planning.

Material and Method

GIS offers significant advantages in disaster management, including streamlined data sharing between institutions, the integration of diverse data formats, ease of regular updates, and rapid analytical capabilities. GIS also facilitates clear and effective communication of spatial data through visualizations such as maps, tables, and charts (Arca, 2012).

Within this research, the accessibility of disaster and emergency assembly areas in Esenyurt was analyzed using GIS techniques. Initially, the spatial and attribute data required for the analysis were collected, including road networks, existing buildings, population statistics, officially designated assembly areas (as identified by the Istanbul Metropolitan Municipality and AFAD), roads likely to be blocked during earthquakes, and high-risk disaster zones. These data were obtained from relevant institutions and integrated into the analysis.

Following data collection, ArcGIS (ArcMap) was used for data preparation, while ArcCatalog was utilized to organize data for analysis readiness. Detailed network topologies were established for the road network, and the entrance points to each assembly area were precisely identified using high-resolution satellite imagery. Additionally, building data were correlated with neighborhood population densities to incorporate demographic factors into the accessibility analysis. Data verification steps were implemented to ensure accuracy and reliability of all datasets.

Network analysis, a GIS-based analytical approach, examines the relationships and connections between points in a network. It is frequently used to determine the shortest or quickest routes, delineate service areas, locate nearest facilities, and perform logistical planning involving interconnected transportation networks. Network analysis is particularly beneficial in disaster management scenarios to establish emergency routes, facilitate access to critical locations, and identify alternative paths when primary roads are blocked.

Findings

For the Esenyurt District, we applied a suite of GIS-based network analyses to evaluate both spatial coverage and pedestrian accessibility of designated assembly areas. First, walking-distance catchments around each site were delineated and their service capacities quantified. We then executed closest-facility analyses from high-risk zones, deliberately excluding road segments predicted to be impassable during seismic events, in order to identify viable alternative evacuation routes.

These calculations revealed significant disparities in the distribution, capacity, and accessibility of existing assembly areas. In particular, several peripheral neighborhoods fall entirely outside any 250 m service buffer, while central zones exhibit overlapping coverage. Such insufficiencies threaten to impede orderly evacuation, risking delays, public confusion, and potentially greater loss of life and property.

Table 1 synthesizes these capacity imbalances by grouping all 40 neighborhoods into eight priority levels. Four "None" neighborhoods (0 % capacity) lack any permanent gathering points; six are "Very Insufficient" (> 0–10 %); eight each are "Insufficient" (> 10–50 %) and "Moderate" (> 50–100 %); six qualify as "Sufficient" (> 100–200 %); and a further eight exceed full demand by over 200 %. This tiered framework provides clear guidance on

interventions—from the urgent deployment of temporary units in "None" areas to routine maintenance and capacity-preservation measures in over-served sectors.

Table 1 and Figures 1–3 deliver a multidimensional portrait of Esenyurt's assembly-area landscape. They not only quantify capacity shortfalls but also trace the precise evacuation routes and service gaps that must be addressed. These empirical insights directly inform the intervention packages detailed in the Conclusion.

Table 1. Summary of Prioritization of Assembly Areas in Esenyurt Neighborhoods (Esenyurt Municipality Data, 2025).

Priority Level	Number of Neighborhoods	Capacity Range (%)	Recommended Interventions
1. None	4	0	Immediate establishment of temporary assembly units (schools, mosques, etc.)
2. Very Insufficient	6	>0–10	Implementation of modular, infrastructure-supported permanent assembly areas
3. Insufficient	8	>10–50	Expansion of existing areas; increase capacity
4. Moderate	8	>50–100	Regular maintenance, drills, and infrastructure improvements
5. Sufficient	6	>100–200	Focus on routine drills and maintenance programs
6. Excessive	4	>200–300	Implement capacity preservation and environmental regulation measures
7. Highly Excessive	1	>300–500	Provide additional support for extremely high usage potential
8. Extremely Excessive	6	>500	Subdivide space into smaller units to distribute demand

Figure 1 illustrates the spatial distribution of all existing assembly sites alongside their 250 m service radii. High-capacity clusters are concentrated in Esenyurt Merkez, Yeşilkent, and Talatpaşa, whereas Sultaniye, Güzelyurt, and other outlying neighborhoods lie almost entirely beyond these buffers.

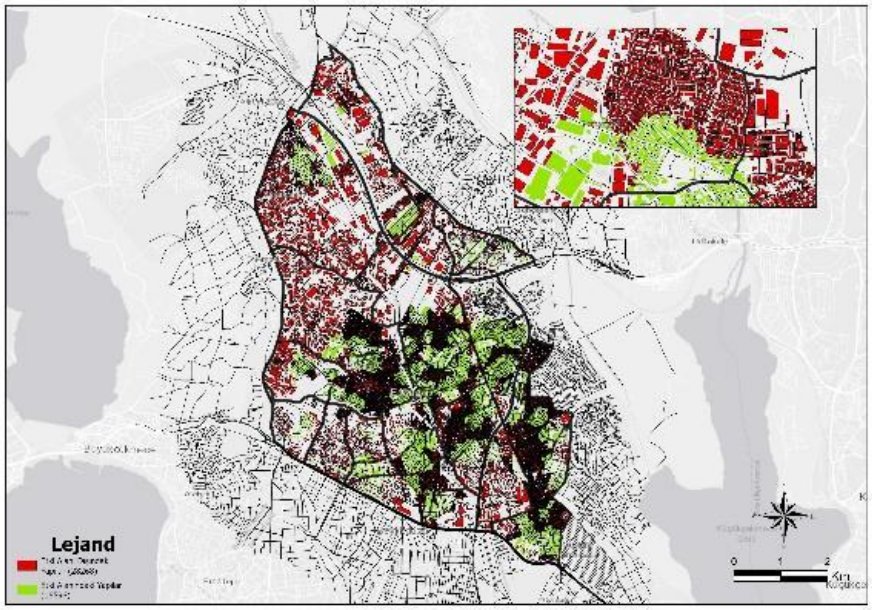

Figure 1. Distribution of Assembly and Service Areas in Esenyurt.

In Figure 2, the closest-facility routes depict the actual pedestrian pathways residents would use. Whereas corridors in Esenkent and Ardıçlı remain under 250 m (confirming their high-priority status), routes serving Soğanlı and Yayla exceed 500 m—well beyond recommended emergency planning standards.

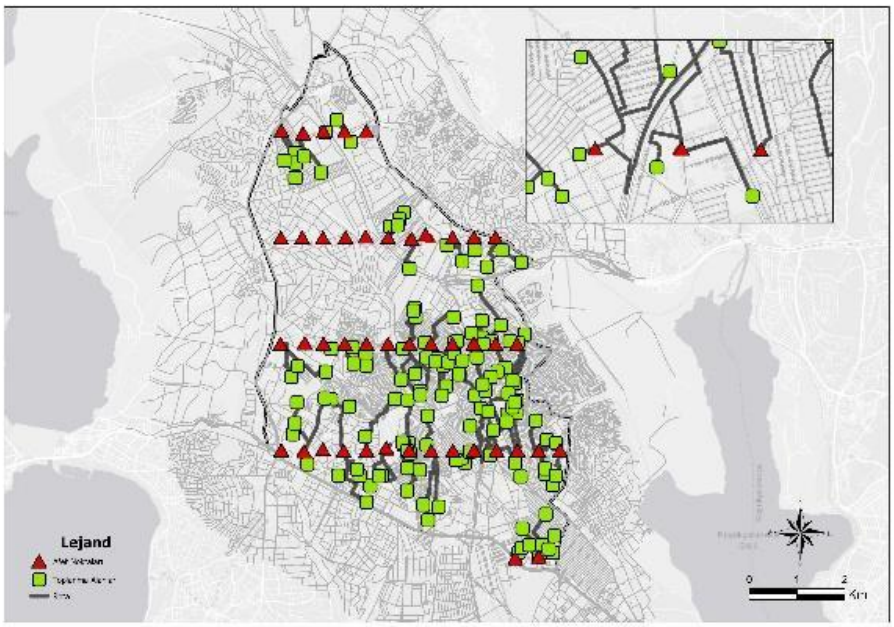

Figure 2. Closest Facility Analysis in Esenyurt.

Finally, Figure 3 overlays the service radii with a near-comparison buffer to highlight "dead zones" where neither proximity nor route quality meets minimal thresholds. These combined visualizations pinpoint exactly which corridors and intersections require new sidewalks, alternative paths, or interim gathering centers.

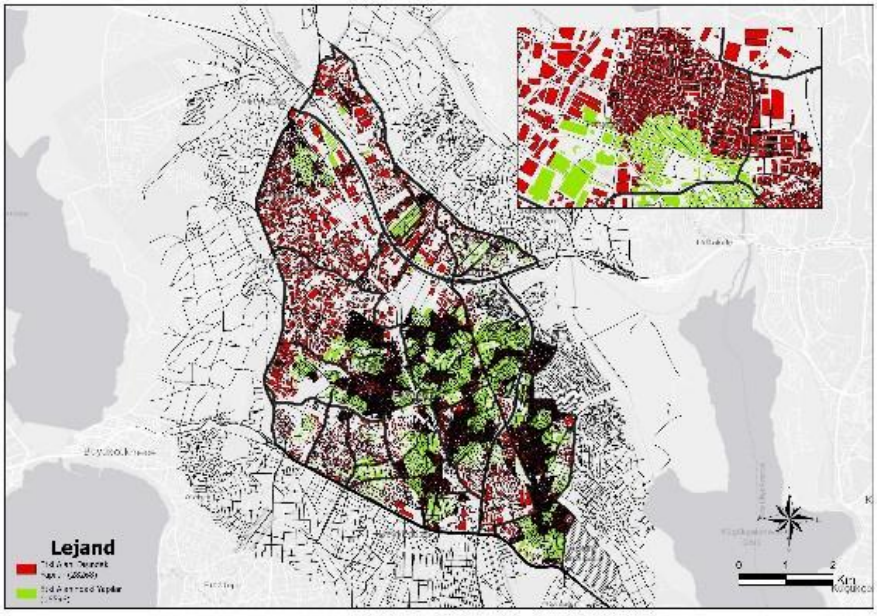

Figure 3. Closest Facility & Near Comparison in Esenyurt.

Conclusion

The study recommends increasing the number and capacity of assembly areas and establishing alternate evacuation routes in critical zones. Furthermore, key recommendations include enhancing public awareness through targeted educational campaigns and improving pedestrian infrastructure around assembly points. These measures are intended to help policymakers allocate resources more efficiently for disaster preparedness and to strengthen urban resilience. Ultimately, this work seeks to advance the scientific understanding of disaster management and urban planning in the Esenyurt District.

Our analyses reveal pronounced imbalances in both capacity and accessibility at the neighborhood level. Esenyurt Merkez, Yeşilkent, and Talatpaşa neighborhoods possess comparatively high person-capacity ratios, whereas Sultaniye and Güzelyurt exhibit critically low capacities that could render these areas severely underserved in the event of a major disaster. Examination of the 250 m service-radius building counts further underscores this spatial heterogeneity: Esenkent, Ardıçlı, and Pınar demonstrate high potential demand, while Soğanlı and Yayla fall well below average, confirming that physical accessibility issues are unevenly distributed across the district.

When classified by priority level, four neighborhoods with virtually no existing capacity ("None") require the immediate deployment of temporary assembly facilities. In the combined fourteen neighborhoods categorized as "Very Insufficient" and "Insufficient," the construction of modular, infrastructure-supported permanent assembly sites should be prioritized. In those ranked "Moderate" and "Sufficient," efforts should focus on expanding current areas and implementing regular maintenance and drill programs. Together, these targeted intervention packages will substantially elevate each neighborhood's preparedness for emergency scenarios.

Accordingly, Esenyurt Municipality and relevant agencies should adopt a dual strategy: first, prioritize both temporary and permanent solutions in the "None" and "Very Insufficient" neighborhoods; second, reinforce infrastructure, training, and drills in the "Insufficient," "Moderate," and "Sufficient" areas. Additionally, in neighborhoods with low building density within the 250 m service radius, investment in new pedestrian routes and improved sidewalks is essential. By aligning resource allocation with these prioritized actions, Esenyurt can achieve a more holistic and resilient urban framework against future disasters.

The Impact of Gödel's Incompleteness Theorem on Artificial Intelligence: The Roger Penrose Approach

Fatma Nur Bilke[a]

[a]Istanbul Technical University, Faculty of Science and Letters, History of Science and Technology, Turkiye
bilke21@itu.edu.tr

Keywords: Artificial Intelligence, Gödel's Incompleteness Theorems, History of Science and Technology, Roger Penrose.

Aim

The primary objective of this study is to evaluate Kurt Gödel's Incompleteness Theorem not merely as a boundary-setting result in mathematics, but as a philosophical turning point that has shaped modern debates on knowledge, consciousness, and computability. In this context, the study aims to systematically analyze both the historical position of the theorem within the history of science and Roger Penrose's approach, which redefines the distinction between human cognition and artificial intelligence based on Gödel's insights. At the beginning of the 20th century, the formalist approach—shaped by Hilbert's program for absolute certainty and the logical positivism of the Vienna Circle—sought to reconstruct the language of mathematics and science through axiomatic systems. Within this intellectual climate, Gödel's publication of the Incompleteness Theorem in 1931 revealed the inherent limitations of such systems, creating not only a mathematical but also an epistemological and ontological rupture. Against this background, the study aims to revisit the question, "Is the human mind fully computable?", particularly in light of the debates on artificial intelligence that emerged in the postGödel era. This question gained significant depth through the arguments developed by Penrose within the framework of Gödel's theorem in his works The Emperor's New Mind (1989) and Shadows of the Mind (1994) (Penrose, 1989; Penrose, 1994). Penrose's assertion that conscious thought cannot be fully explained by algorithmic processes will be situated within the evolving conceptual frameworks of the history of science and technology. The human–machine distinction will thus be reopened for discussion within both historical and philosophical contexts. In doing so, this study aims not only to introduce a philosophical argument but also to reconsider the boundaries of modern knowledge on a historical plane.

Material and Method

This study is a qualitative research structured within a historical-conceptual framework. Its primary aim is to understand the rupture caused by Gödel's Incompleteness Theorem in the history of scientific thought and to reveal how this rupture has become an epistemological foundation in Roger Penrose's critique of artificial intelligence. Accordingly, the methodology adopted is based on textual analysis, historical contextualization, and conceptual comparison. The principal sources of this research include Gödel's Proof by Ernest Nagel and James R. Newman, which interprets Gödel's theorem from both mathematical and philosophical perspectives (Nagel & Newman, 2008); Penrose's own works—The Emperor's New Mind (1989) and Shadows of the Mind (1994)—which offer direct access to his ideas (Penrose, 1989; Penrose, 1994); and the Turkish translation Yapay Zekâya Karşı Doğal Zekâ (2023) (Penrose, 2023). These sources are treated as key references for understanding both the impact of Gödel's theory on the history of science and the debates on consciousness and computability that Penrose develops in its wake. The intellectual environment in which Gödel's theorem emerged is examined within the context of Hilbert's program for certainty and the logical positivist efforts of the Vienna Circle. The historical background of the belief in formal systems is clarified accordingly. Penrose's arguments are positioned not merely as technical critiques but as part of a broader historical discourse; through this lens, the study questions how the relationship between the human mind and

machines has been historically constructed. Within this framework, by employing literature-based analysis and historical reading methods, the study aims to contribute to the debates on computability in artificial intelligence from the perspective of the history of science and technology.

Findings

Kurt Gödel's Incompleteness Theorem, presented in 1931, opened up new avenues of discussion not only regarding the limits of mathematics but also concerning the nature of human reasoning. According to the theorem, any sufficiently powerful and consistent formal system will contain propositions that are both true and unprovable within that system (Nagel & Newman, 2008). Developed in the intellectual context of Hilbert's pursuit of absolute consistency and the formalist school, Gödel's theorem is not merely a technical delimitation—it represents a profound critique of the 20th-century ideal of the absoluteness of knowledge. In this regard, the theorem marks a pivotal moment in the history of science, challenging not only the scope of mathematical reasoning but also the nature of knowledge systems and the boundaries of the human mind. Building on this historical and theoretical context, Roger Penrose interpreted Gödel's theorem not solely as a mathematical discovery, but as a fundamental indication of how the human mind operates. According to Penrose, the human mind has an intuitive capacity to grasp truths that lie beyond formal systems (Penrose, 1989). This view evolves into a compelling argument that consciousness and the capacity for understanding cannot be fully explained through algorithmic structures. As Penrose asserts, machines may operate on symbols, but human beings generate meaning (Penrose, 1989). Penrose articulates this idea as follows: "If, as I believe, Gödel's argument does force us towards accepting view C, then we must also face up to the other consequences of this position. We shall find ourselves driven towards a Platonic viewpoint" (Penrose, 1989). The "view C" referenced here denotes the non-computational view, which maintains that the mind is not entirely a computable system. According to Penrose, conscious awareness and the ability to understand cannot be modeled by an algorithmic system akin to a Turing machine (Penrose, 1989; Penrose, 2023). In Shadows of the Mind, Penrose extends this argument to the physical domain by proposing that conscious experiences must be explained at the quantum level (Penrose, 1994). In his view, the laws of classical physics fall short of accounting for the phenomenon of consciousness: "I believe that certain quantum-level processes taking place in some microscopic structures of the brain play a role in the emergence of what we call consciousness" (Penrose, 1994). Penrose grounds this claim in the Orchestrated Objective Reduction (Orch-OR) theory, which he co-developed with Stuart Hameroff. According to this theory, conscious experiences can be explained through quantum processes. While the theory remains controversial within scientific circles, it is regarded as a distinctive example in the ongoing search for a physical explanation of consciousness (Penrose, 1994).

Conclusion

This study has examined, within a historical context, how the early 20th-century pursuit of grounding scientific knowledge gained momentum through the goal of achieving certainty via formal systems—and how Gödel's Incompleteness Theorem revealed the structural limitations of this ideal. The boundaries introduced by Gödel do not merely constitute a technical obstacle to the internal consistency of mathematical systems; they also serve as a profound critique of the representative epistemology that underlies modern science's conception of knowledge and the mind (Nagel & Newman, 2008). Following this epistemological rupture, Roger Penrose carried the notion of Gödelian limits into the domain of artificial intelligence, arguing that the human mind is too complex and profound to be reduced to a purely algorithmic framework (Penrose, 1989; Penrose, 1994). Penrose's approach characterizes the human mind through its capacity for meaning-making, intuitive understanding, and conscious experience—qualities that signify a qualitatively distinct cognitive domain inaccessible to machines. Thus, the link established between Gödel's theorem and the mind's capacity for meaning transcends the bounds of computation theory, evolving into a fundamental philosophical inquiry into the nature of mind. In the context of the history of science, this debate reflects not only the evolution of mathematical thought but also the paradigm shifts in modern science's approach to knowledge. The formalist ideal—embodied in Hilbert's program for certainty and aligned with positivist thought—was fundamentally disrupted by Gödel's theorem. With Penrose's intervention, this disruption was brought to the forefront of contemporary debates on consciousness, computability, and artificial intelligence. In conclusion, by bringing together the views of Gödel and Penrose within a framework

of historical continuity, this study has aimed to demonstrate that the concepts of knowledge, consciousness, and intelligence are shaped not only by technical or computable systems, but also by interpretation, meaning, and subjective experience. In this respect, the study reaffirms that the history of science is not merely a record of the past, but a dynamic framework for understanding today's intellectual crises.

Keywords: Industrial Design, Manufacturability, Mass Production, Design for Manufacturability.

Aim

Production is a multidisciplinary creation event. When mass production is considered, there are many subjects and objects that enable the realization of the object to be produced. These subjects can be defined as stakeholders. It is undeniable that the number and diversity of stakeholders will change depending on the type of product to be produced. These stakeholders are involved in many different stages of a product's development processes. The industrial designer is also one of the important stakeholders of a created product (Pedgley, 2009; Todić at al., 2012). This study aims to explore what the concept of manufacturability means to industrial designers by focusing on the stage of industrial design for mass production. he approaches of industrial designers who work or have worked professionally to the concept of manufacturability in the electrical appliances sector are investigated in this research.

Material and Method

The study began with a literature review and progressed by examining the framework of the concept of manufacturability in depth. In continuation of the research, interviews were conducted with industrial designers who previously worked or are still working in the electrical appliances sector. It is important that designers have different years of experience within the scope of the same sector and in different companies.
It aims to deeply understand how designers create a bridge between mass production, design and their experiences with the concept of manufacturability. In addition, after the interviews are completed, survey questions will be created, and a survey will be conducted and analyzed to reach more designers and support the outputs. The interview questions begin with the designers' professional background in the sector and include questions aimed at exploring their practices and experiences in their professional lives within the scope of the concept of manufacturability.

Findings

"Manufacturability" or "producibility," is described as the ease to realize an effective product with the lowest cost through the implementation of manufacturing technology. Nevertheless, the manufacturability of a design could not be measured quantitatively until the 1970s (Boothroyd et al., 2010; Lianos, 2020). Cong and Zhang defined the manufacturability of a product as a relative term, including whether the product meets the design requirements or not, in terms of concepts such as function, performance, cost, and quality (Cong & Zhang, 2012). According to Fabricius, manufacturability focuses on these three strategies: modular design, standardization and ease of assembly (Fabricius, 1994). On the other hand, Korol and Petrosyan accepted manufacturability as a combination of features that provide the highest performance with the least energy, materials and tools, using advanced technology and at the lowest cost (Korol & Petrosyan, 2020). It has been stated that manufacturability is not the accuracy but the degree of being able to be produced correctly. This degree may vary according to each variable (Todić et al., 2012).
In the literature the term manufacturability combines with many different terms to create new conceptual phenomena. One of the most common phenomena is design for manufacturability (DFM) which is a design philosophy that advocates the use of production inputs in the early stages of design so that the designed product can be produced more easily and more economically (Poli et al., 1992). Das et al. defined DFM as a "product

design approach" that can enable the design to be produced in a short time and at low cost, and the distribution of the product with low energy (Das et al., 2000).

Historically, designers have followed the mindset of "we create the design, and you handle the manufacturing.". This approach, referred to as the "over-the-wall approach" involves designers working independently and passing their designs along to manufacturing engineers, who must then address production challenges due to their lack of involvement in the design process. A solution to this issue is to involve manufacturing engineers early in the design phase and this involvement promotes teamwork, preventing numerous complications (Boothroyd, 1992). In the past, traditional production activities caused loss of energy and time as the design and production stages were carried out at different stages. Today the design and production phases were intertwined and started to be carried out together. This strategy resulted in an increase in the efficiency of the designed products, a decrease in the costs and a shortening of the time to market (Boothroyd et al., 2010).

The costs of the product design and manufacturing processes constitute a small portion of the total product price. However, the decisions made during these processes significantly affect the total costs of new product development and are crucial for market success. Therefore, it is necessary to consider the manufacturing task as early as possible, even in the product design phase, because the costs of changes are higher if they are implemented at a later stage of the product (Todić at al., 2012). Unfortunately, designers often lack the in-depth manufacturing experience necessary to determine the impact of various design features on manufacturing difficulty and cost. Therefore, collaboration between designers and manufacturers is crucial to share manufacturing experience when evaluating the product's structure, to modify the design or its components and receive prompt feedback regarding the impact of these changes (Geng, 2004). Conflicting perspectives on product development processes due to different levels of knowledge and differences of backgrounds often lead to inadequate integration of the industrial design profession within the industry (Svengren, 1995; Persson, 2004).

Creating multidisciplinary teams ensures industrial design competence by integrating industrial and engineering design roles and creating a more homogeneous unit. However, team members often have challenges in collaborating smoothly because each individual brings distinct responsibilities, perspectives, and experiences related to design tasks (Svengren, 1995). Industrial designers focus on social benefit values such as aesthetic concerns, trends and originality, while engineering designers focus on material benefit such as function performance (Muller, 2001). Industrial designers use an outside-in approach; however, engineering designers take an inside-out approach (Hubka & Eder, 1996). According to the research conducted by Kim and Lee, engineering designers stated that industrial designers are less knowledgeable about construction, manufacturing methods, materials and mold structure, thus industrial designers can often design things that cannot be manufactured (Kim & Lee, 2014).

In the interviews, industrial designers emphasized that they need to be familiar with production processes in order not to increase production costs, resource usage and production time. This research revealed that professional designers have limited awareness and priority for manufacturability, and designers apply manufacturability principles as a secondary priority in design practice. However, the production competence of the designer plays a key role in shortening the design process and reduces the need for revisions during the design phase. On the other hand, some of the participants stated that manufacturability concerns conflict with creativity and aesthetic perspectives. It was also reported that the aesthetic thought and creativity are more restricted when the knowledge and experience in terms of manufacturability increases. The balance between the manufacturability concerns and creativity of designers is critical for product creation.

Conclusion

This study demonstrated that the design product and the production process are directly related to each other. The more problem-free the production process is, the closer the designed product can be produced to what is desired and imagined. It is a fact that the product is in contact with the designer from the first stage when it starts to take shape. The participants emphasized that designers should be involved in the entire process until the last step of the product development. Considering the production process in every stage of a product design provides great savings in cost by reducing the revisions required. At this point, it is clear that the design must be imagined as manufacturable by the designer. On the other hand, what is important for the designer is that the designer's dream

turns into a real product with the least amount of change. The designer's experience plays a big role here and his/her success can also be measured in the form of time, material and cost savings that the designer can provide during the product development process. In this context, one of the critical elements for creating a manufacturable design is the designer's relationship with manufacturability. Three issues are highlighted in this research: the designer's lack of production knowledge, the designers' conflict of communication with multidisciplinary group members, and the resistance of the manufacturability concern to the designer's aesthetic concern.

In summary, the involvement of the designer in the production process has the potential to make a significant contribution to the change in production costs, time and resource usage. This research addresses the gaps in the literature by focusing on the understanding of manufacturability of industrial designers working in the electrical home appliances sector. It reveals the various approaches of industrial designers towards the concept of manufacturability and sheds light on their contribution and effects on the production process.

Keywords: Project Management, Organizational Capabilities, Turkish Construction Industry, Multi-Criteria Decision Making.

Aim

The construction industry has played a crucial role in global economic and social development from the past to the present. The broad scope of the industry, including urbanization, infrastructure, transportation, and establishment of communication networks, has ensured that the industry holds a large share of national economies, especially in Türkiye, by offering extensive employment opportunities. Given the industry's role in the national - and global- economy, adapting to change to survive, ensure sustainability, and grow in a dynamic environment characterized by intense competition and continuous transformation is essential. In this dynamic environment, due to the high level of competition, the complexity of project management activities, and rapid technological advancements, companies need to be aware of their organizational capabilities. These capabilities determine not only their current performance but also their ability to adapt to changes in the industry and market demands. Therefore, it is crucial for companies to continuously assess, develop, and enhance their organizational capabilities to preserve their competitiveness and achieve long-term success.

The sustainability of organizational success and competitive advantage depends on effectively utilizing and developing a firm's resources, capabilities, and competencies. Resources refer to all tangible and intangible assets "controlled by a firm that enable the firm to conceive of and implement strategies that improve its efficiency and effectiveness" (Barney, 1991). However, merely having resources does not guarantee success and competitive advantage. Firms must also be able to effectively allocate and coordinate these resources (Teece et al., 1997). Capabilities are the organization's ability to perform specific tasks and activities by integrating and utilizing its resources efficiently (O'Regan & Ghobadian, 2004). While capabilities define what a firm can do with its resources, competence arises when these capabilities are effectively combined and harmonized across different functions to create superior performance. Competence refers to the integration of capabilities from different disciplines and working together in harmony (Javidan, 1998). Core competency represents a firm's unique and strategically valuable competencies that provide a sustainable competitive advantage (Prahalad & Hamel, 1990). While the literature extensively discusses organizational competencies, this study primarily focuses on capabilities, as they form the foundation for firms to develop competitiveness, achieve project objectives, and respond to dynamic market conditions.

The first definitions of organizational competencies were given by researchers within the framework of the organization's ability to maintain its current performance and achieve goals by using existing resources and structuring its processes. With increasing competition and rapid advancements in technology, researchers have expanded the concept of organizational competence by including aspects such as achieving competitive advantage, adapting to changing market conditions, and developing new products and processes.

A detailed literature review reveals that numerous studies have evaluated organizational capabilities across various industries including the construction industry using methods such as performance measurement models and capability maturity models. However, there is a limited number of studies applying multi-criteria decision-making (MCDM) methods to organizational capabilities especially those specific to the construction industry in Türkiye. To address this gap, this study aims to examine the organizational capabilities that construction companies must recognize and develop to gain competitive advantage, achieve their growth targets, and adapt to market changes

using the MCDM approach. For this purpose, a capability model has been developed by reviewing the relevant literature to identify the key organizational capabilities in construction companies. Using the developed model, this study aims to prioritize organizational capabilities in construction companies with respect to their impact on project success.

Material and Method

The main contribution of this study is to develop an organizational capability model for companies in the construction industry. In developing this model, the first step was to examine studies and models in the literature related to organizational capabilities across various industries. Subsequently, the research was refined specifically for the construction industry analyzing industry-specific organizational capability models. The 21 capabilities identified through this analysis are functional capabilities, which are defined as "the technologies, abilities, and knowledge necessary to perform work-related tasks effectively and to produce specific desired outcomes within the functional domains of an organization." (McDermott 2003; Loufrani-Fedida and Missonier 2015 as cited in G. Tiruneh & Fayek, 2020).

These functional capabilities are categorized under three groups: General Administration, Technical, and Project Management Capabilities. This grouping will enable the evaluation of capabilities both in relation to each other and within the relevant capability groups through the analyses to be conducted. The complete list of capabilities is provided in Table 1.

Based on the established organizational capabilities model, data will be collected through an online survey administered to managers in the Turkish construction industry. The survey will include pairwise comparison questions aligned with the selected MCDM approach, and the results will be analyzed accordingly.

	Procurement Management	(Omar & Fayek, 2016; Pariafsai & Behzadan, 2021; G. Tiruneh & Fayek, 2020; G. G. Tiruneh & Fayek, 2017)

Findings

The survey data collected from the participants will be analyzed using an MCDM approach suitable for the purpose of the study. The expected findings include determining the relative importance of different capability groups and prioritizing capabilities with respect to their contribution to the project success in the construction industry.
These findings will serve as a strategic guide for companies and provide valuable insights for both academic research and practical applications. By enabling companies to effectively allocate resources, this study will help them develop the most relevant capabilities based on their current circumstances and market position.

Conclusion

This study emphasizes the importance of organizational capabilities in preserving their competitiveness and achieving long-term success of companies in the Turkish construction industry. By addressing a gap in the existing literature, it provides a structured framework for evaluating the impact of organizational capabilities on project success using the MCDM approach. This model provides companies in the industry with a comprehensive tool to evaluate their performance and identify strategic areas for development.

The findings of the analyses are expected to provide valuable insights into which capabilities should be prioritized based on their impact on project success and offer companies a strategic foundation for improving their practices.

As a suggestion for future studies, considering the dynamic capabilities that enable companies to adapt to changing market conditions and innovative processes (Zollo & Winter, 1999) with an approach similar to this study may provide insights into which dynamic capabilities are effective in developing the existing organizational capabilities of companies.

Furthermore, including behavioral capabilities, such as managerial and individual skills, in the organizational capability model can help to understand how human factors contribute to project success and how they compare with functional capabilities.

Value Co-Creation in Banking: Service-Dominant Logic and Service Logic Perspectives via Electronic Wallets

Zübeyde Buket Aydın[a], Adnan Veysel Ertemel[a]

[a] Istanbul Technical University, Faculty of Management, Department of Management, Türkiye
aydinzu16@itu.edu.tr

Keywords: Customer Satisfaction, Electronic Wallets, Service Logic, Service-Dominant Logic, Value Co-Creation.

Aim

Today, the banking sector, propelled by the rapid pace of digital transformation and technological innovations, has shifted away from traditional service approaches toward customer-centric, interactive, and holistic service models. In this context, the value co-creation achieved through the collaboration between customers and banks has become a strategic element that enhances the competitive strength of banks and deepens customer experience. At the core of this thesis is an examination of how electronic wallet technologies strengthen the collaboration between customers and banks and contribute to the value creation process, and how this process can be explained through the perspectives of Service-Dominant Logic (SDL) and Service Logic.

Introduced by Vargo and Lusch (2004), Service-Dominant Logic argues that value is not created by a one-sided presentation of products; rather, it is generated through a dynamic process in which the resources of both the service provider and the customer are integrated and co-created. This approach enables a model in the banking sector where customers evolve from mere service consumers to active participants in the service process, thereby co-producing value with the enterprise. On the other hand, Service Logic emphasizes that customer relationships should not remain merely transactional but must evolve into sustainable value creation through mutual interaction and the restructuring of business processes. The Service Logic Business Model Canvas developed by Ojasalo and Ojasalo (2018) serves as a guide in developing customer-centric strategies in the increasingly digital banking environment, thereby underscoring the strategic importance of electronic wallet applications.

This thesis comprehensively analyzes how the collaboration between customers and banks in the Turkish banking sector, in the context of electronic wallet usage, transforms into value co-creation from the perspectives of SDL and Service Logic. The study aims to reveal the effects of electronic wallets on customer satisfaction, perceived value, and usage habits, while also discussing how banks can strategically position digital payment systems as tools to achieve competitive advantage.

Literature suggests that digital banking applications—especially mobile banking and digital payment systems—are transforming customer experience and value creation processes (Dabare, Hewapathirana, & Fernando, 2023). However, the effects of electronic wallets on the banking sector and their contribution to deepening the interaction between customers and banks, thereby enhancing value co-creation, have not yet been sufficiently examined. This gap highlights the significance of the thesis both academically and practically.

The scope of the research is supported by a quantitative data analysis conducted on individuals using electronic wallets across Türkiye; the survey data were analyzed in detail using SPSS 29.0 In this way, the usage habits, perceived benefits, and impacts on customer satisfaction of electronic wallet technologies are systematically evaluated.

In conclusion, this study aims to demonstrate how the innovative payment solutions brought about by digital transformation strengthen the collaboration between customers and banks and contribute to sustainable value creation. Additionally, it offers recommendations on how banks can strategically develop digital payment systems within the framework of SDL and Service Logic.

Material and Method

The data collection procedure in this study was carried out using quantitative research methods. Examining how electronic wallet technologies affect value co-creation through customer-bank collaboration in the Turkish banking industry is the main goal of the study. People that use electronic wallets all around Türkiye make up the sample, and information was gathered from 300 participants in total. Demographic traits including age, gender, income, and education are diverse among the participants, which improves the findings' generalizability.

A specifically created questionnaire that supports the study's objectives was employed as the data gathering tool. Three primary sectionsmake up the questionnaire: the first gathers demographic data about the participants; the second discusses their usage patterns, preferences, and experiences with electronic wallets; and the third uses Likert scale statements to gauge attitudes and perceptions regarding electronic wallets. Using Google Forms, the survey was distributed via LinkedIn and WhatsApp, with responses collected voluntarily and anonymously from December 22, 2024, to February 8, 2025. Data were analyzed using SPSS 29.0. Descriptive statistics, including frequency distributions, means, medians, and standard deviations, were first calculated. Then, using parametric and non-parametric techniques, such as the t-test, one-way ANOVA, Mann-Whitney U test, Pearson correlation, and Chi-Square test, the associations between the participants' attitudes and their electronic wallet usage patterns were investigated.

Furthermore, multiple regression analyses were performed to further investigate the relationships between the independent and dependent variables. The study hypotheses have been able to be meaningfully and consistently tested thanks to this methodological technique.

Findings

The results of the study are presented in this section, which also examines how electronic wallets affect customer-bank relationships from the viewpoints of service logic and service-dominant logic (SDL). The findings came from statistical analysis of survey information gathered from 306 individuals throughout Turkey, which covered e-wallet perceptions, usage patterns, and demographic characteristics. With regard to e-wallet acceptance, consumer satisfaction, and perceived value, the results provide important information that banks may use to strategically position digital payment systems. Significantly, 60.8% of respondents did not know the difference between an e-wallet and a digital wallet, indicating that there is a need for more financial literacy with relation to digital payment methods.

Given that respondents indicated a significant association between the frequency of e-wallet usage and the feeling of ease, the study validates that people believe e-wallets save time. Furthermore, it was discovered that e-wallet users had substantially higher customer satisfaction than those who used more conventional payment methods. With statistical analyses showing that consumers who believe e-wallets to be secure also report higher levels of overall satisfaction, security emerged as a critical issue. These results suggest that securityfeatures have a significant impact on adoption and confidence.

The study also looked at whether e-wallet features like discounts, promotions, and quick payment services raise the perceived worth of the product. The findings, however, revealed no connection between these variables and users' assessments of e-wallets, indicating that promotional incentives might not be enough on their own to improve consumer opinion. Rather, elements like ease and security seem to have a bigger influence on user happiness and retention.

Demographic trends indicate that younger users (18–35 years old) are significantly more likely to adopt e-walletscompared to older age groups. The results also show a positive trend between income level and e-wallet adoption, though the relationship was not statistically significant at the 5% level. This suggests that while higher-income individuals may be inclined to use e-wallets, other factors such as accessibility, awareness, and usability may also play a role in adoption.

All things considered, the results highlight how strategically significant electronic wallets are for raising customer satisfaction and building closer ties between banks and their clients. In order to increase adoption and confidence, banks should concentrate on improving the e-wallet technologies' dependability and user experience, given the importance of security and usability. Additionally, focused marketing campaigns and instructional programs that target various demographic groups may boost the uptake of digital payments even more. These findings highlight

how important digital financial tools are becoming for influencing consumer experiences and maintaining a competitive edge in the banking industry.

Conclusion

In conclusion, this study demonstrates that electronic wallet technologies make a significant contribution to value co-creation through the collaboration between customers and banks in the Turkish banking sector. The analyses reveal that the use of electronic wallets saves time for users, that customer satisfaction is higher compared to traditional payment methods, and that the security features have a positive impact on customer satisfaction. Notably, an increase in the adoption of this technology among young users has been observed, and similar trends have been detected among individuals in higher income groups. However, it has been concluded that the effects of demographic factors need to be subjected to more comprehensive analysis. These findings indicate that electronic wallets are a strategic element in enhancing competitive advantage in the banking sector and that future studies conducted across different demographic groups will contribute to a clearer understanding of this relationship.

Selection of an Electronic Marketplace for Micro-Exports by SMEs: A Hierarchical IFS-WASPAS Approach

Cidal Ustun[a], Cafer Erhan Bozdağ[a]

[a] Istanbul Technical University, Industrial Engineering, Engineering Management, Türkiye
ustunc21@itu.edu.tr

Keywords : E-Export, Electronic Marketplace Selection, Weighted Aggregated Sum Product Assessment (WASPAS), Intuitionistic Fuzzy Sets, IFS-WASPAS.

Aim

E-export create opportunities for SMEs by overcoming resource limitations and entry barriers, enabling them to compete not only in local but also in international markets. The correct selection of electronic marketplaces (EMP) is a vital strategic decision to enhance SMEs' export potential. To make this decision effectively, a structured approach is essential, as it must align with multiple objectives while considering various quantitative and qualitative factors. These include the platform's business model and expertise, technical aspects such as software and security, regulatory frameworks, cost implications, sales and marketing strategies, and the process of integrating with the platform. Despite the diversity of studies in the literature on customer perspectives and their choices regarding EMPs, research adopting the sellers' perspective on the same subject, as well as the variety of MCDM (Multi-Criteria Decision-Making) techniques, remains limited. The purpose of this study is to develop a decision model for determining the most suitable platform for micro-export among EMPs from the sellers' perspective for two SMEs operating in different sectors and possessing different organizational capabilities. The study seeks to answer the following questions: "What are the decision criteria affecting SME's selection of international digital marketplaces?" and "How do varying criterion weights – shaped by the SME's priorities- influence the result of the decision?"

Method

This research adopts a MCDM approach, employing the hierarchical Weighted Aggregated Sum Product Assessment (WASPAS) method, which is integrated with Intuitionistic Fuzzy Sets (IFS) as proposed by Koç and Bozdağ (2024). The solution process begins with the development of a two-layer hierarchical criteria structure and follows determination of criteria weight then a systematic progression from the lowest to the highest level, calculating weighted sums and weighted products of alternative performance evaluations at each stage. Ultimately, this process yields a single aggregated WASPAS score for each alternative in the final phase (Figure 1).

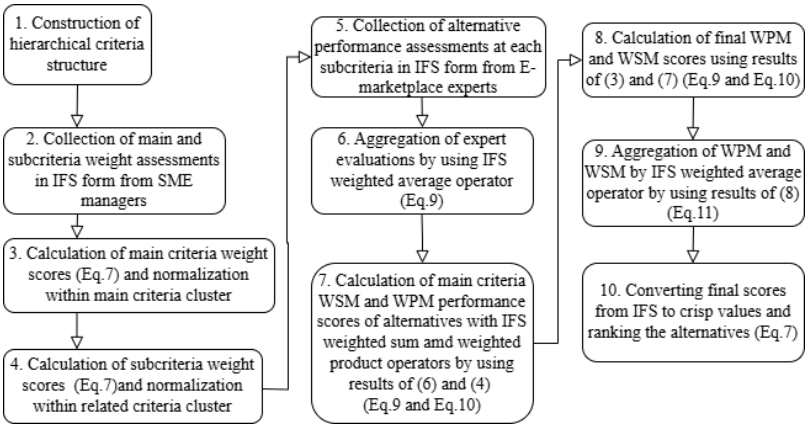

Figure 1. Flowchart of the Proposed Solution Model.

The decision criteria framework, comprising 10 main categories and 70 sub-criteria, was established through literature review, risk assessments, expert consultations, and evaluations of existing EMP seller interfaces. The

primary criteria encompass platform recognition (F1), usability and compatibility of EMP (F2), costs and payments (F3), store management within EMP (F4), order processing mechanisms (F5), reporting and analytics tools (F6), support programs (F7) , security and reliability of EMP (F8), advertising and marketing functionalities (F9) , and the localization of EMP (F10) (Figure 2).

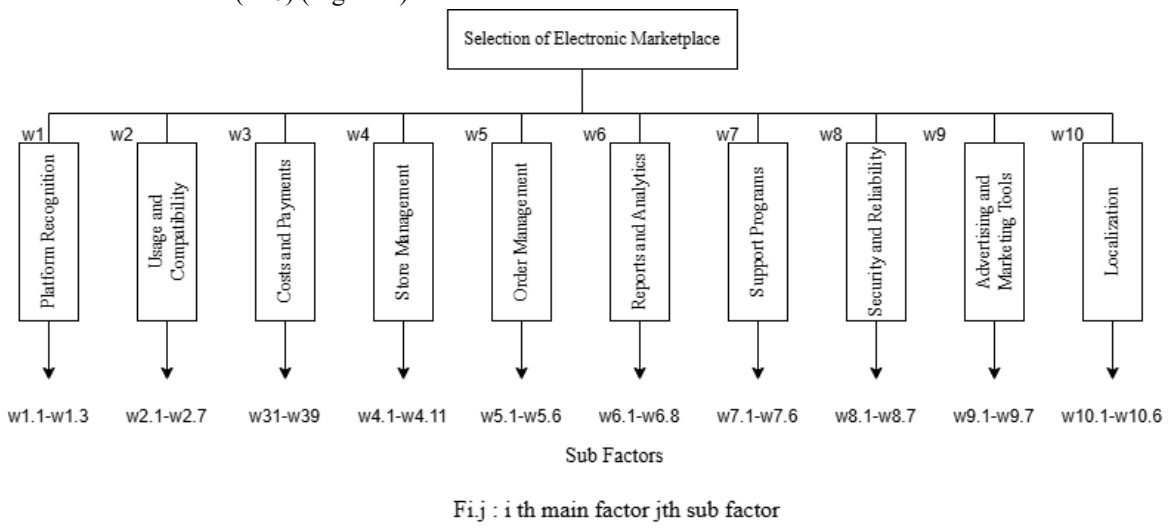

Figure 2. Hierarchical Structure of the Proposed Model.

To observe differences stemming from firm-specific characteristics and priorities, two distinct companies Firm1 and Firm 2 were analyzed separately. The alternative platforms are chosen among the marketplaces most frequently used for micro-exports by SMEs in Turkiye. In the performance evaluation of alternatives, assessments were conducted in collaboration with four independent EMP experts. The inclusion of four experts was intended to ensure a comprehensive and balanced evaluation by incorporating diverse perspectives and minimizing potential bias. It was assumed that all experts have equal weight of value 0.25. Their aggregated assessments provided a more robust and objective basis for decision-making. To ensure consistency in expert evaluations and maintain methodological reliability, it was prioritized that the experts had enough knowledge about all the three alternatives and the target markets of the two companies. This situation may lead into a limitation in the study in terms of EMP options, but the primary aim of the study is to demonstrate the applicability of the methodology and define the decision criteria. To ensure consensus on the terms used, maintain linguistic consistency, and provide immediate explanations when needed, face-to-face or telephone interviews were preferred during the data collection process. Company representatives evaluated the criteria based on their business models, organizational capabilities, and priorities using the linguistic expressions provided in Table 1. To ensure the impartiality of the study, avoid potential misguidance, and focus solely on the features of alternatives the names of the EMPs are referred to as EMP-A, EMP-B and EMP-C. The evaluation of EMPs' competencies regarding the sub-criteria was conducted by the experts, who are professionals at various consultancy firms specialized in e-export at the EMPs, by using the linguistic expressions given in Table 1.

Table 1. Intuitionistic Fuzzy Linguistic Scale (IFLS) (Adapted from Koç and Bozdağ (2024).

Linguistic variables (used by firm representatives)	IFLS	Linguistic variables (used by experts)
Extremely important	(0.99, 0.01)	Extremely Sufficient
Intermediate value	(0.9, 0.1)	Intermediate Value
Very important	(0.8, 0.1)	Very Sufficient
Intermediate value	(0.7, 0.2)	Intermediate Value

Quite important	(0.6, 0.3)	Quite Sufficient
Moderately important	(0.5, 0.4)	Moderately Sufficient
Relatively less important	(0.4, 0.5)	Relatively Less Sufficient
Intermediate value	(0.25, 0.6)	Intermediate Value
Very less important	(0.1, 0.75)	Very Insufficient
Intermediate value	(0.1, 0.9)	Intermediate Value
Extremely low importance	(0.01, 0.99)	Extremely Insufficient

Subjectivity and limited rationality in decision-makers' judgments can be significant sources of uncertainty in problem structuring. IFS, an extension of traditional fuzzy logic, provide comprehensive analysis by modeling not only the membership and non-membership degrees of an element but also the remaining hesitation caused by uncertainty (Atanassov, 1986). The foundational terms and operators that enable the understanding and application of the IFS-WASPAS method used in our study are as follows:

Definition 1 (Atanassov,1999): Let a (non-fuzzy) set E be fixed. An IFS A in E is defined as an object of the following form $A = \{x \epsilon E\}$ where the functions $\mu_A: E \rightarrow [0,1]$ and $v_A: E \rightarrow [0,1]$ define the degree of membership and the degree of non-membership of the element x ∈ E, respectively, and for every x ∈ E.

$$0 \leq \mu_A(x) + v_A(x) \leq 1 \quad \text{(Equation 1)}$$

Definition 2 (Atanassov, 1999) :The value of

$$\pi_A = 1 - \mu_A(x) - v_A(x) \quad \text{(Equation 2)}$$

is called the degree of non-determinacy of the element x ∈ E to the IFS A. For computational practicality, an intuitionistic fuzzy number (IFN) is represented as $\tilde{a} = (\mu_{\tilde{a}}, v_{\tilde{a}})$.

Definition 3 (Atanassov, 1999): Let A and B be two different IFS' defined in E, and let the function f_{A+B} map x ∈ E to the point f_{A+B} ϵ F with coordinates specified in Equation3.

$$\langle (\mu_A(x) + \mu_B(x) - \mu_A(x)\mu_B(x), v_A(x)v_B(x) \rangle \quad \text{(Equation 3)}$$

Definition 4 (Atanassov, 1999): Let A and B be two different IFS' defined in E, and let the function $f_{A\times B}$map x ∈ E to the point $f_{A\times B}$ ϵ F with coordinates specified Equation 4.

$$\langle (\mu_A(x)\mu_B(x), v_A(x) + v_B(x) - v_A(x)v_B(x), \rangle \quad \text{(Equation 4)}$$

Definition 5(Xu, 2007): Lets $\tilde{a} = (\mu_{\tilde{a}}, v_{\tilde{a}})$ be an IFN

$$\lambda\tilde{a} = \left(1 - \left(1 - \mu_{\tilde{a}}\right)^{\lambda}, v_{\tilde{a}}^{\lambda}\right), \lambda > 0 \quad \text{(Equation 5)}$$

$$\tilde{a}^{\lambda} = \left(\mu_{\tilde{a}}^{\lambda}, 1 - (1 - v_{\tilde{a}})^{\lambda}\right), \lambda > 0 \quad \text{(Equation 6)}$$

Definition 6 (Xu,2007): Let $\tilde{a} = (\mu_{\tilde{a}}, v_{\tilde{a}})$ and $\tilde{b} = (\mu_{\tilde{b}}, v_{\tilde{b}})$ be two IFNs. The normalized score function s(ã) and accuracy function h(ã) of ã are calculated using the formulas provided below:

$$s(\tilde{a}) = 0.5\ (1 + \mu_{\tilde{a}} - v_{\tilde{a}})\ ,\ 0 \le s(\tilde{a}) \le 1 \quad \text{(Equation 7)}$$

$$h(\tilde{a}) = \mu_{\tilde{a}} + v_{\tilde{a}}\ , 0 \le h(\tilde{a}) \le 1 \quad \text{(Equation 8)}$$

Using the normalized score and accuracy functions $\tilde{a}$ ve $\tilde{b}$ can be compared as follows:

1. If $s(\tilde{a}) < s(\tilde{b})$ then $\tilde{a} < \tilde{b}$
2. If $s(\tilde{a}) = s(\tilde{b})$ and
   a. If $h(\tilde{a}) = h(\tilde{b})$ then $\tilde{a}$ ve $\tilde{b}$ represent the same information.
   b. If $h(\tilde{a}) < h(\tilde{b})$ then $\tilde{a} < \tilde{b}$.

Definition 7 and 8: Let $\tilde{a}_i = (\mu_{\tilde{a}_i}, v_{\tilde{a}_i})$ represent different IFNs and w_is represent their corresponding weights. (i = 1,2,……,n) , $w_i \in [0,1]$ ve $\sum w_i = 1$. As Xu (2007) stated The IFWA (Intuitionistic Fuzzy Weighted Average) operator first weights all given arguments and then averages them into a single value. The aggregated weighted value obtained through the IFWA operator can be expressed using the Equation 9.

$$IFWA_w(\tilde{a}_1, \tilde{a}_2, \dots\dots, \tilde{a}_n) = (1 - \prod_{i=1}^{n} \left(1 - \mu_{\tilde{a}_i}\right)^{w_i}, \prod_{i=1}^{n} \left(v_{\tilde{a}_i}\right)^{w_i}) \quad \text{(Equation 9)}$$

As Xu and Yager (2006) stated The IFWG (Intuitionistic Fuzzy Weighted Geometric) operator first weights all given arguments and then calculates the geometric mean of them into a single value. . The geometric weighted value obtained through the IFWG operator can be expressed using the Equation 10.

$$IFWG_w(\tilde{a}_1, \tilde{a}_2, \dots\dots, \tilde{a}_n) = (\prod_{i=1}^{n} \left(\mu_{\tilde{a}_i}\right)^{w_i}, \prod_{i=1}^{n} \left(1 - v_{\tilde{a}_i}\right)^{w_i}) \quad \text{(Equation 10)}$$

The IFWA operator is applied for aggregation of expert evaluations and in the weighted sum (WSM) section, and the IFWG operator is employed in the weighted product (WPM) part of the WASPAS method to solve our problem. Since the weighted aggregated sum product assessment (WASPAS) method is the weighted combination of WSM and WPM methods , final scores for ranking of alternatives is calculated as by using the IFWA and IFWG values obtained at the top level of the hierarchy (Zavadskas et al, 2014) :

$$S = f_{0.5IFWA + 0.5IFWG} \quad \text{(Equation 11)}$$

Findings

For the determination of main factor weights first by using normalized score function given in Equation 7 all IFS formed assessments were transferred to crisp values and then normalized . The same procedure has been repeated for the subcriteria, and the subcriteria have been normalized within the cluster to which they belong. For Firm1 the most important criteria have been identified as F1,F8 and F9 whereas for Firm 2 most significant ones are F3, F1,F8 and F10. Comparison of the main criteria priorities for Firm 1 and Firm 2 are given in Figure 3.

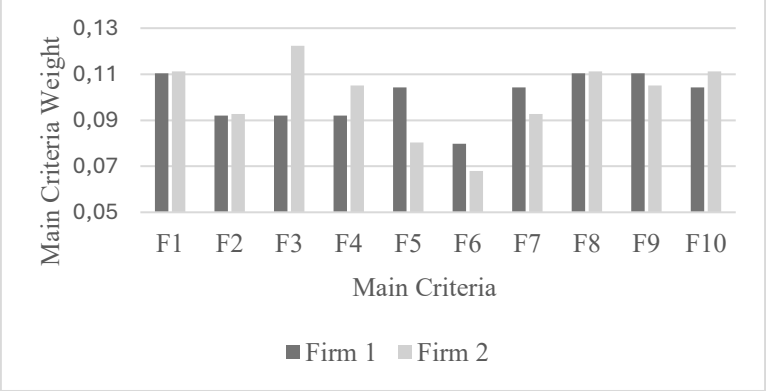

Figure 3. Comparison of Criteria Weights Assessed by Firm1 and Firm 2.

The final performance scores of alternatives obtained through weighted aggregation of WSM and WPM are given in Table 2.

Table 2. Final IFS-WASPAS Scores of EMPs.

	Firm1			**Firm 2**		
	EMP-A	**EMP-B**	**EMP-C**	**EMP-A**	**EMP-B**	**EMP-C**
Final IFWA	(0.906,0.076)	(0.859,0.107)	(0.782,0.162)	(0.916,0.069)	(0.834,0.124)	(0.789,0.155)
Final IFWG	(0.828,0.130)	(0.746,0.174)	(0.668,0.237)	(0.825,0.128)	(0.722,0.188)	(0.674,0.228)
WASPAS average	(0.873, 0.099)	(0.811,0.136)	(0.731, 0.195)	(0.879,0.094)	(0.785,0.153)	(0.738,0.188)
Final Score	0.8868	0.8374	0.7679	0.8925	0.8161	0.7750

Using the applied methodology, the ranking of alternatives for selecting the electronic marketplace for sales was determined based on the ranking criteria specified in Definition 6:

- For Firm 1: EMP-A > EMP-B > EMP-C
- For Firm 2: EMP-A > EMP-B > EMP-C

Conclusion

In this study, a hierarchical decision model integrating Intuitionistic Fuzzy Sets (IFS) and WASPAS was developed. With a properly designed questionnaire structure, IFS enable the evaluation of responses on a unified measurement scale thereby eliminating the necessity for data normalization. One of the key advantages of WASPAS is its computational efficiency, making it well-suited for structured decision problems involving multiple criteria. In cases where WSM and WPM yield different rankings, identifying the weight parameter at which the ranking changes is crucial for result interpretation.

SMEs tend to overcome resource gaps through tools offered by EMPs. Financial constraints affect the assessment of criteria weights. Platform recognition, security and reliability of EMP, advertising and marketing tools provided by EMP and localization skills of EMP are among the top priorities for sellers. Support programs and marketing tools are critical for firms with less digital expertise, while cost sensitivity varies based on financial structure. Reporting tools are undervalued unless directly enhancing competitive visibility and marketing performance. EMP-A ranked highest despite operational and financial burdens, demonstrating its overall market strength.The study highlights that EMP selection is not solely about customer alignment but also involves operational and technical factors.

Future research can expand the criteria set, considering regional differences in logistics and localization strategies for local EMPs. A broader sample size is necessary to statistically validate SMEs' decision-making criteria for selecting digital marketplaces. The WASPAS method proves efficient for objective data analysis but requires comparison with the Analytic Hierarchy Process (AHP) to assess its applicability in subjective decision-making scenarios.

MARITIME STUDIES

Maritime Human Resources

Maritime Security

Advancing Maritime Security With Unmanned Maritime Systems

Deniz Çiçek[a], Bihter Erol[a]

[a]Istanbul Technical University, Faculty of Civil Engineering, Department of Geomatics Engineering, Türkiye
cicekd22@itu.edu.tr

Keywords: Maritime Security, Mine Countermeasures, NATO Naval Exercises, Precise Positioning Systems, Unmanned Maritime Systems.

Aim

Maritime security faces escalating challenges, including piracy, smuggling, illegal fishing, and underwater mine threats. These illicit activities not only disrupt international trade routes but also pose significant risks to national security and marine ecosystems. Traditional manned surveillance and intervention methods involve substantial risks to personnel and often lack the agility needed to counter these evolving threats effectively (Liu & Bucknall, 2015). Addressing these challenges requires innovative approaches and the integration of advanced technologies. Unmanned Maritime Systems (UMSs) have emerged as pivotal assets in this domain, offering versatility, resilience, and reduced risk to human operators. Their effectiveness critically depends on precise positioning, ensuring safe and efficient navigation in complex maritime environments. Given the growing role of autonomous systems in modern naval operations, NATO has prioritized UMS integration to enhance interoperability, strengthen coalition operations, improve joint maritime defense strategies, and support key missions such as mine countermeasures, surveillance, and threat deterrence (NATO, 2020).

The DACIA/TOMIS ROU OPEX 2024 (Romanian Operational Experimentation Exercise 2024) is an international, NATO-led maritime exercise focused on operational experimentation. Its inaugural edition, organized by the Romanian Naval Forces, took place in the Black Sea near Mangalia, Romania, from May 27 to May 31, 2024, aiming to evaluate and enhance UMS interoperability within a multi-domain operational environment (NATO Maritime GEOMETOC CoE, 2024). Figure 1 shows an international formal gathering of military and civilian personnel, highlighting international cooperation during the event.

By leveraging data from this exercise, this study examines the integration and operational impact of UMSs in contemporary multinational naval operations. It highlights their adaptability to dynamic maritime threats by analyzing their sensor systems, autonomous functionality in challenging conditions, and precision positioning capabilities.

Figure 1. Turkish Naval Officers Inspecting UMSs During The Exercise (Romanian Naval Forces, 2024).

Material and Method

The study will tackle the main UMSs outlined below.

1. Ocean Aero – Triton Autonomous Unmanned Surface Vehicle (AUSV)

The Triton AUSV, developed by Ocean Aero, is the world's first and only unmanned system capable of both sailing on the surface and diving below the ocean. Powered by wind and solar energy, Triton is designed for extended deployments and broad-scope operations, making it a versatile platform for various mission requirements. As shown in Figure 2, the exercise involved the deployment and handling of Triton by naval personnel, demonstrating the integration of unmanned systems into maritime operations. The key specifications of the Triton platform are summarized in Table 1 (Ocean Aero, n.d.).

Figure 2. Deployment of Ocean Aero – Triton (Romanian Naval Forces, 2024).

Table 1. Specifications of Triton AUSV.

Parameter	**Specification**
Length	4.4m
Weight	350 kg
Power Source	Electricity
Maximum Surface Speed	5 knots
Maximum Subsurface Speed	2 knots
Max Submergence Depth	100m
Solar collection	740W (peak)
Surface Endurance	14 + Days at sea
Subsurface Endurance	5 + Days at sea
Sensor Systems	Multi-beam sonar Side-scan sonar Radar Electro-optical camera
Comms	Silvus, Iridium and cell
Navigation	GPS, IMU (Inertial Measurement Unit), automatic route planning

2. Teledyne - Z Boat

Z-Boat has demonstrated its value in mine detection operations using its integrated sonar sensors. It is equipped with advanced navigation and telemetry systems, high-resolution sonar capabilities, and optional autonomous features. As shown in Figure 3, the Z-Boat platform was presented during a naval demonstration event, where its operational capabilities and onboard systems were introduced to Turkish military personnel. The key technical specifications of the Z-Boat are summarized in Table 2 (Teledyne Marine, n.d.).

Figure 3. Teledyne Z-Boat (Romanian Naval Forces, 2024).

Table 2. Specifications of Z-Boat.

Parameter	**Specification**
Boat Length	1.8 m
Boat Width	1.0 m
Boat Height	1.1 m
Weight of Base Boat	38 kg
Payload Weight	30 kg
Navigation System	Remote Hitec with Vessel Telemetry
Navigation Frequency	2.4 GHz FHSS
Navigation Range	Up to 1200 m
Battery Endurance	Up to 4.5 hours
Multibeam Echosounders	Teledyne Odom MB1, MB2
ADCPs	Teledyne RD Instruments
Sonars	Tritech Side Scan Sonars
Cameras	HD video cameras
Autonomous Features	Optional autonomous operation, on-board data logging, and waypoint navigation

3. YellowScan – Navigator

It is a high-performance LiDAR system designed for professional mapping and surveying applications. Known for its versatility and precision, the Navigator is equipped with cutting-edge technology, enabling accurate 3D point cloud generation for both aerial and ground-based operations. As shown in Figure 4, the system can be deployed via Unmanned Aerial Vehicles (UAVs) for bathymetric scanning and generates high-resolution data that

can be visualized in real-time. The key specifications of the Navigator LiDAR system are summarized in Table 3 (YellowScan, n.d.).

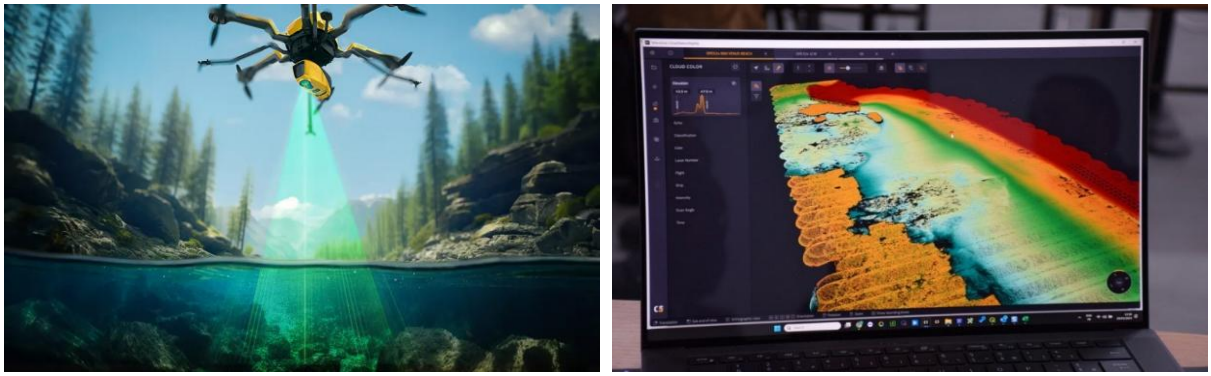

Figure 4. The Navigator and Collected Data During the Exercise (Romanian Naval Forces, 2024).

Table 3. Specifications of Navigator.

Parameter	**Specification**
Size	L 350 x W 160 x H 190 mm
Weight	3.7 kg (8.15 lbs) batt. excl
Laser class	Class 3B - Avoid direct exposure to beam
GNSS inertial solution	SBG Quanta Micro
Precision	3 cm
Accuracy	3 cm
Typ. flight speed	5 m/s
Typ. flying height	80 m
Laser range	Up to 120 m
Laser wavelength	532 nm
Min. Depth	0.30 m
Max. Depth	2 Secchi

4. Hydroid Inc. - REMUS 100 Unmanned Surface Vehicle (USV)

The REMUS 100 USV is a compact, lightweight, and highly versatile autonomous system designed to support a wide range of underwater missions. Its portability and modular structure enable rapid deployment in diverse environments—from shallow littoral zones to offshore operational theaters. As illustrated in Figure 5, two REMUS 100 units are securely housed in a rigid container onboard a support craft, demonstrating the system's ease of transportation and mission readiness. The color-coded handles and compact form factor emphasize the system's operational efficiency and modularity.

Engineered for high-resolution hydrographic surveys, the REMUS 100 also supports environmental monitoring, mine countermeasure operations, and scientific data collection. Table 4 provides a detailed overview of its performance specifications, including endurance, sensor payload capacity, and depth rating—underlining its utility in both defense and civilian applications (Aulinas et al., 2010).

Figure 5. Remus 100 USV (Romanian Naval Forces, 2024).

Table 4. Specifications of REMUS 100 USV.

Parameter	**Specification**
Depth Rating	100 meters (328 feet)
Diameter	19 cm (7.5 inches)
Length	1.6 meters (63 inches)
Weight	37 kg (80 lbs)
Speed	Up to 5 knots
Endurance	Up to 22 hours at 3 knots cruising speed
Navigation Systems	Long Baseline (LBL), Ultra-Short Baseline (USBL), Dead Reckoning, Inertial Navigation System (INS)
Communication	Acoustic modem, Wi-Fi, Iridium satellite (optional)
Sensors	Side-scan sonar, Conductivity-Temperature-Depth (CTD) sensor, Acoustic Doppler Current Profiler (ADCP), optional cameras and environmental sensors

UMS platforms are deployed in various maritime settings, including open seas, coastal regions, and areas with complex underwater terrains. These trials assess the systems' performance in real-world conditions, evaluating factors such as sensor accuracy, data latency, environmental influences (e.g., water salinity, temperature, turbidity), and the UMS's ability to execute mission-specific tasks. The primary sensors under evaluation include:

- **Inertial Measurement Units (IMUs):** These devices provide critical data on the UMS's orientation, acceleration, and angular velocity, enabling precise calculation of position and movement. IMUs are essential for dead reckoning navigation, especially in environments where Global Positioning System (GPS) signals may be degraded or unavailable, such as underwater or in areas with significant signal interference.
- **GPS Receivers:** They determine the UMSs' exact global position by receiving satellite signals. This information is crucial for mission planning, real-time navigation, and coordination with other assets. The integration of GPS data with IMU outputs allows for enhanced accuracy through sensor fusion techniques, mitigating the limitations of each individual system.
- **High-Resolution Sonar Systems:** High-Resolution Sonar Systems emit sound pulses and analyze echoes to create detailed images of the underwater environment. They are essential for seabed mapping, obstacle

avoidance, and detecting underwater mines and hazards, thereby enhancing situational awareness and safe navigation in uncharted waters.

- **Bathymetric LiDAR:** Bathymetric Light Detection and Ranging (LiDAR) systems, also known as airborne LiDAR bathymetry (ALB), use laser pulses to penetrate water and measure underwater topography. They offer rapid, high-resolution data for coastal mapping, shallow-water surveys, and environmental monitoring. By capturing both water surface and bottom reflections, these systems produce precise bathymetric maps essential for navigation, coastal engineering, and marine habitat assessment.
- **Data Integration and Sensor Fusion:** Advanced data fusion algorithms integrate inputs from IMUs, GPS receivers, and sonar systems. Techniques like Kalman filtering combine sensor data to enhance navigation accuracy and robustness. This fusion compensates for individual sensor shortcomings, such as GPS signal loss or IMU drift, by leveraging the strengths of each system to deliver a cohesive and reliable navigation solution.

Findings

The integration of advanced sensor systems such as Real-Time Kinematic GPS (RTK-GPS), enhanced IMUs, LiDAR, and sonar has significantly improved the capabilities of UMSs. These technologies enable precise navigation, improved environmental awareness, and greater mission autonomy. However, several key limitations still affect operational performance in real-world maritime conditions.

RTK-GPS delivers high-accuracy positioning under ideal conditions, but its effectiveness decreases in GPS-denied or obstructed environments such as ports or narrow straits. Signal disruptions — whether caused by physical obstructions or intentional interference such as GPS jamming — can lead to localization errors and reduced system reliability. Similarly, sonar and LiDAR systems perform well in calm, clear waters but become less effective in rough seas or turbid environments due to signal scattering and instability, which degrade data quality.

IMUs, despite technological advancements, remain prone to drift during long missions without GPS corrections. This makes accurate localization increasingly difficult in deep-sea or GPS-limited operations. Furthermore, communication between unmanned and manned systems is hindered by limited bandwidth, latency, and protocol incompatibilities, reducing interoperability and complicating real-time coordination during joint missions.

Although these integrated systems have expanded the operational scope and success rates of UMSs, performance still varies significantly based on environmental conditions and system hardware limitations. Complex sea states, weather variability, and mission duration all contribute to this operational uncertainty.

The study indicates that current sensor fusion methods are insufficient to fully overcome the weaknesses of individual navigation components in such complex conditions. Moreover, navigation and communication systems show performance degradation when exposed to GPS-denied or signal-obstructed maritime environments. These findings emphasize the urgent need for more robust sensor integration strategies and advanced communication frameworks to ensure the resilience and effectiveness of UMSs in critical applications such as maritime security, infrastructure monitoring, and environmental assessment.

Conclusion

The increasing reliance on UMSs highlights their transformative impact on modern naval operations. The findings from the DACIA/TOMIS ROU OPEX 2024 exercise demonstrate that UMSs not only enhance maritime security through precise positioning technologies and advanced sensor integration but also contribute to the seamless coordination between autonomous and manned assets. Their ability to operate in complex environments, execute critical tasks, conduct high-accuracy measurements, and integrate into NATO's strategic framework underscores their growing importance. Future research should focus on refining these technologies to overcome existing limitations, ensuring UMSs remain central to maritime security and coalition-based defense strategies.

Structural and Mechanical Characterization of Repair Welded Steels

Berk Çakır[a], Faiz Muhaffel[a]

[a] Istanbul Technical University, Department of Metallurgical and Materials Engineering, Materials Engineering, Türkiye

Keywords: 4130 Steel, Tungsten Inert Gas Welding, Mechanic Characterization, Repair Welding, Residual Stress.

Aim

High-strength low-alloy (HSLA) steels exhibit superior mechanical properties, including enhanced toughness and strength, along with improved corrosion resistance compared to carbon steels. Additionally, their high weldability makes them widely preferred in various industrial applications. These alloys are commonly used in pressure vessels, where high toughness is a critical requirement.

HSLA steels have a low carbon content like mild steel and contain small amounts of alloying elements such as copper, nickel, niobium, vanadium, chromium, molybdenum, and zirconium. Due to their relatively low alloying element concentrations, they are classified as micro-alloyed steels. The yield strength of HSLA steels ranges from 250 to 600 MPa, making them suitable for applications in industries such as automotive, trucking, and bridge construction (Cochrane, 2012). However, their use in aircraft is limited due to their low specific strength and poor corrosion resistance in harsh environments.

AISI 4130 is a low-alloy carbon steel that contains chromium and molybdenum as alloying elements. Due to its low carbon content, it is highly weldable. However, despite its good weldability, welding defects can still occur due to factors such as process parameters and operator errors. These defects create weak points in the weld areas of pressure vessels, potentially leading to structural failures at pressures lower than the intended levels (Antonini, 2014). The process of eliminating welding defects through an additional welding operation is known as repair welding. Some international standards limit the number of repair welding to one or two. Additionally, as the number of repair welding increases, residual stress in the metal also increases, which can cause structural deterioration, such as distortion, during the welding process (Salami et al., 2014).

Repair welding is a critical procedure in the manufacturing of certain structures. Properly executed repair welding can restore static strength, ductility, fracture toughness, and fatigue strength to levels comparable to the original, defect-free weld areas (Bailey, 1994). Repair welding can be carried out systematically to ensure the production of durable and reliable components, or they can be performed inconsistently. An alternative approach often leads to poor-quality workmanship, failure to fully correct defects, and noncompliance with quality standards, ultimately compromising the integrity of the repaired parts.

Repair welding can be classified into three main categories: the repair of weld defects, the repair of defective parts, and the repair of worn parts (Bailey, 1994). Most existing research on repeated repair welding focuses on the distribution of residual stresses, primarily using finite element simulations (Mallick, 2021). In contrast, studies examining the effects of repeated welding on the microstructure, mechanical properties, and corrosion behavior of steels are limited and primarily concern non-hardenable steels (Bouchard et al., 2005). To date, no detailed investigation into the impact of repeated welding on quenched and tempered steels has been reported in the literature.

In this study, the production process involved repeated weld thermal cycles applied to high-strength low-alloy (HSLA) steels. Subsequently, heat treatment processes were conducted. Mechanical characterizations such as tensile testing, cross-sectional hardness testing, and impact toughness testing were performed on the produced specimens. In addition, residual stress analyses were conducted to investigate the stress accumulation within the structure during repeated weld thermal cycling.

Material and Method

In this study, AISI 4130 plates were obtained and welded using the tungsten inert gas (TIG) welding method. The welded areas were then ground and re-welded under identical parameters to simulate the repair welding process. This process was repeated up to five times, resulting in six different sample groups: an unmodified welded plate and plates subjected to one to five repair welding. Following welding, the plates underwent oil cooling and tempering heat treatments to complete the production process. Additionally, non-heat-treated plates were produced to evaluate the structural effects of repeated welding on the material.

Mechanical test specimens and microstructural characterization samples were taken from both heat-treated and welded plates. Residual stress measurements using the X-ray diffraction (XRD) method were conducted on non-heat-treated plates. The study aims to evaluate the influence of repeated repair welding and increased heat input on the material's microstructure and mechanical properties while evaluating the structural effects of repeated welding. Furthermore, SEM, EDS, and XRD analyses will be used to examine the relationship between the microstructure and properties.

Table 1 provides details regarding sample naming. Each sample set included five tensile test specimens, four notch impact test specimens, two hardness test specimens, and one specimen for microstructural, macrostructural, and SEM/EDS analyses. Additionally, one welded plate without heat treatment was produced for each sample set for residual stress measurements. Mechanical test specimens, both with and without heat treatment, were taken from the same plate to determine base metal properties.

Table 1. Naming of Different Specimens and Welding Procedures.

Sample Name	Welding	1st Repair Welding	2nd Repair Welding	3rd Repair Welding	4th Repair Welding	5th Repair Welding
BM	-	-	-	-	-	-
0R	X	-	-	-	-	-
1R	X	X	-	-	-	-
2R	X	X	X	-	-	-
3R	X	X	X	X	-	-
4R	X	X	X	X	X	-
5R	X	X	X	X	X	X

Findings

The results of the mechanical tests (tensile and impact tests) are presented in Figure 1. The ultimate tensile strength and yield strength of the material are not significantly influenced by the repair welding process, showing only a slight increase. Fracture in all tensile specimens occurs within the heat-affected zone (HAZ). The heat treatment processes ensure uniform strength across all plates. Toughness values increase with multiple repair welding processes, and further studies on material characterization will help clarify the reasons for this increase.

The residual stresses of each repair-welded plate are presented in Figure 2. X-ray diffraction (XRD) has been used to measure residual stress with a portable XRD device that allows measurements to be made at a variety of distances from the weld region. For each specimen, Figure 2 only shows maximum stress values, which are all found near the area of welding. To isolate the effects of repair welding, measurements are carried out on non-heat-treated plates, eliminating residual stresses introduced by the heat-treatment process.

Tensile tests are performed on specimens machined from non-heat-treated plates to determine the threshold points of residual stress. The yield strength of the plates is 350 MPa. This means that if residual stresses form during

welding that exceed this strength, plastic deformation occurs. According to Figure 2, after the third repair, residual stress exceeds the yield strength. This indicates that performing three or more repair welding processes harms the structural properties of the material.

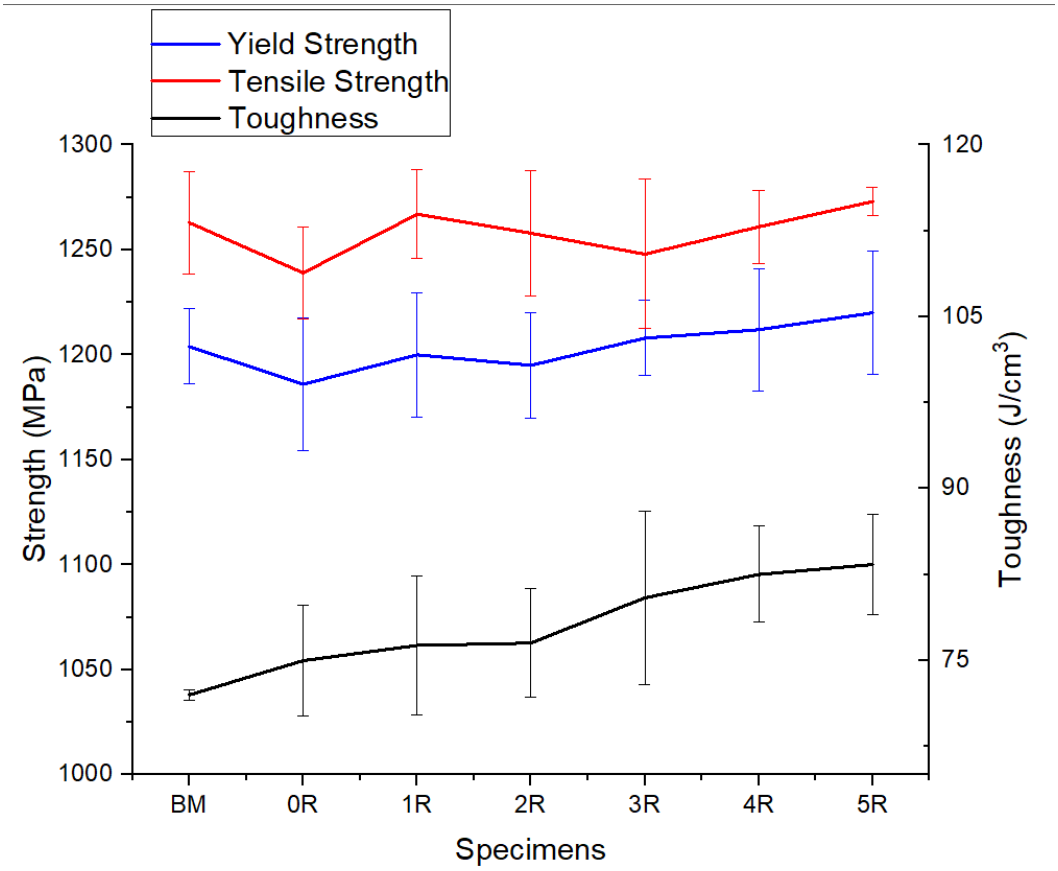

Figure 1. Average Tensile Strength, Yield Strength and Impact Toughness as a Function of Number of Repairs.

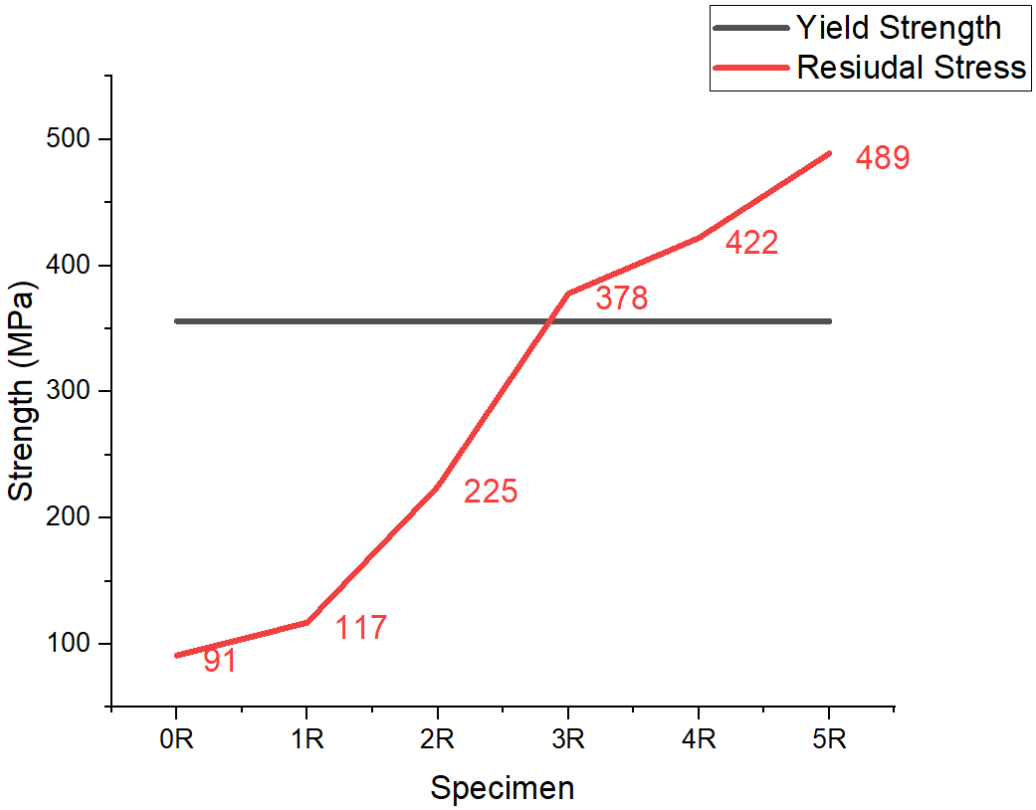

Figure 2. Maximum Residual Stresses as a Funciton of Number of Repairs and Yield Strength of Welded Plate.

Conclusion

In conclusion, the mechanical properties of the plates remain largely unchanged with an increasing number of repair welding. However, residual stress can negatively impact the structural integrity of the material. Future studies will focus on material characterization, including microstructural and macrostructural analyses as well as SEM/EDS examinations, to further investigate the effects of multiple repair welding on both mechanical and structural properties.

Synthesis of Boron Carbon Nitride Particles for Adsorptive Heavy Metal Removal

Sibel Şentürk[a], H. Enis Karahan[a,b], and Hale Gürbüz[a]

Keywords: Thermolysis, Surface adsorption, Lead removal, Wastewater, Adsorbent.

Aim

Alternative adsorbents are being sought for various wastewater treatment applications to replace or complement activated carbon, the staple of the field (GadelHak et al., 2023). Among candidates, boron carbon nitride ($B_xC_yN_z$) materials (in short, BCNs) recently attracted growing attention with their tunable chemical and physical attributes akin to graphene and boron nitride materials (Bahadur et al., 2023; Liu et al., 2018; Panda et al., 2023; Portehault et al., 2010; Mighri et al., 2023). Also, BCNs can be synthesized through rather facile and poorly investigated methods, such as thermolysis, which is intriguing to make an exploratory investigation.

To test the potential utility of BCNs in common wastewater treatment problems, such as heavy metal removal, we primarily focused on existing synthesis conditions for preparing adsorbents. In a prominent study dealing with heavy metals removal (i.e., Hg^{2+} and Pb^{2+}), Peng et al. (2018) synthesized BCNs via thermolysis using melamine and boric acid as precursors (at a ratio of 3:0 and 3:5) and deionized water as the solvent. They tested the effect of temperature (in the range of 500-650 °C) at a holding duration of 4 hours. In another study, boron oxide and melamine were reacted at 550 °C (holding duration: 2 hours) using ethanol (Zhong et al., 2019). In a similar study, another group employed the same precursors and solvent for the thermolysis step at 500 °C by keeping the holding time the same (2 hours). However, these researchers subjected their BCN products to heat treatment at 520-600 °C for 2 hours before use (Yan, Li, & Zou, 2010).

Considering the experimental space summarized above, we decided to test the impact of solvent selection (i.e., deionized water and ethanol) and thermolysis temperature (in the range of 500°C to 600°) on the materials properties and performance of resulting BCN materials in adsorption-based Pb^{2+} removal. To analyze the structure and morphology of produced BCN materials, we employed various techniques for characterization, including scanning electron microscopy (SEM), X-ray diffractometry (XRD), energy-dispersive spectroscopy (EDS), and Fourier-transform infrared spectroscopy (FTIR). Lastly, we assessed the gas adsorption behavior and heavy metal removal potential of BCNs using Pb^{2+} as a model contaminant.

Material and Method

In this study, the precursor mixture was prepared by using melamine (MA) and boric acid (BA) in either deionized water or ethanol. The MA-BA mixture was prepared at a ratio of 3:5. Thermolysis experiments were carried out in a muffle furnace by placing the precursor mixtures inside lid-covered alumina crucibles to limit air exposure. The process duration was kept constant at 4 hours for all experiments, while the synthesis temperatures were set at 500 °C or 600 °C. SEM and XRD studies were performed to examine the overall morphology and structural characteristics of as-produced BCN materials. And the elemental and functional compositions of BCNs were evaluated by EDS and FTIR analyses. Finally, the adsorption behavior of the products was evaluated by using nitrogen gas as a probe and Pb^{2+} as a model contaminant. Heavy metal adsorption tests were carried out by exposing the as-produced BCNs (0.4 g/L solids) to 50 ppm Pb^{2+} solution for 24 hours in a thermostatic shaker bath (185 rpm) at 30 °C), and the amount of Pb^{2+} remaining in the solution was determined by inductively coupled plasma mass spectrometry (ICP-MS). The products prepared in deionized water at 500 and 600 °C were named BCN-W500 and BCN-W600, while the ethanol-based samples were named BCN-E500 and BCN-E600, again according to the holding temperatures (500 or 600 °C).

Findings

BCN materials were initially synthesized through thermolysis at 500 °C using different solvents (water or ethanol). Based on the SEM and EDS observations, both solvents (water and ethanol) gave morphologically irregular and agglomerated particles with no visibly large pores (Figure 1). EDS measurements, summarized in Table 1, confirmed the inclusion of B. XRD measurements revealed that those irregular and B-containing agglomerates are amorphous-like in nature with broad peaks belonging to BCN materials observed at around 26.3° and 41.3° (Figure 2). And increasing the synthesis temperature (600 °C) also resulted in similar patterns with minimal shifting (Kokulnathan & Wang, 2019; Yu et al., 2023), with the exception of superimposed sharp features in BCN-W600, which potentially comes for currently unidentified contaminants. FTIR analyses, on the other hand, showed the rich functional group profile of resulting materials, including $-NH_2$, $-NH-$, O−H, C−N, B−O, C−N−(C)−C or C−NH−C, and B−N−B bonds (Figure 3) (Shang et al., 2018). Thus, overall, the BCN synthesis was carried out successfully. Nevertheless, we could not modulate the structural or chemical characteristics of the samples substantially under the tested conditions. Yet still, the adsorption performances of produced materials differed noticeably. While the material synthesized using deionized water achieved virtually 100% Pb^{2+} removal, the ethanol-based samples exhibited much lower performance (Figure 4). Curiously, however, none of the produced BCN materials were highly porous at the (ultra)micropore level with specific surface area values ranging from ~9.2 to ~9.8 m2/g, based on nitrogen adsorption test results analyzed by Brunauer-Emmett-Teller (BET) analyses. As a result, we argue that the observed variations in the Pb^{2+} removal performances could be attributed to the surface charge variations of the synthesized materials. We plan to perform further studies to explore this possibility.

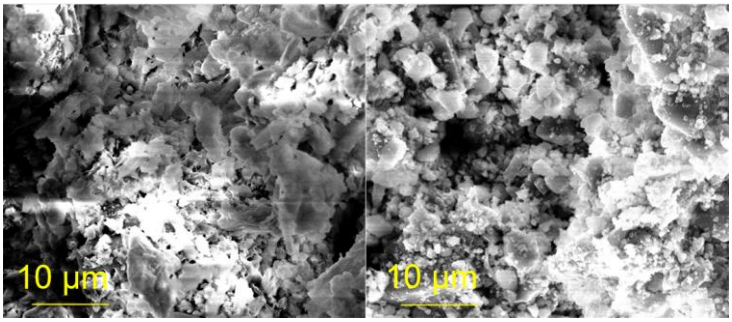

Figure 1. SEM images of BCN-W500 and BCN-E500. (Scale bars indicate 10 µm.).

Table 1. The EDS-based elemental compositions of the samples prepared at 500 °C.

Sample	B (at %)	C (at %)	N (at %)	O (at %)
BCN-W500	21.1	21.4	35.0	22.4
BCN-E500	15.8	33.0	40.6	10.7

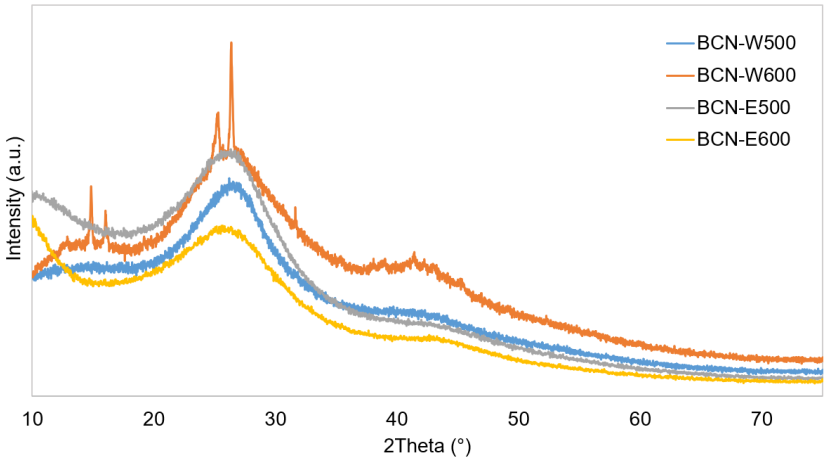

Figure 2. XRD patterns of water- and ethanol-based BCNs.

(Note that BCN-W600, which has not been repeated in this preliminary study.)

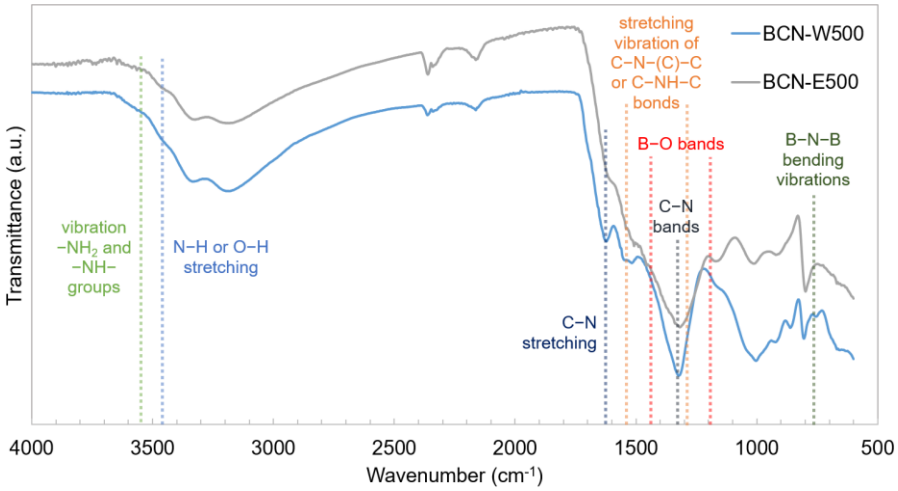

Figure 3. FTIR spectra of BCN-W500 and BCN-E500.

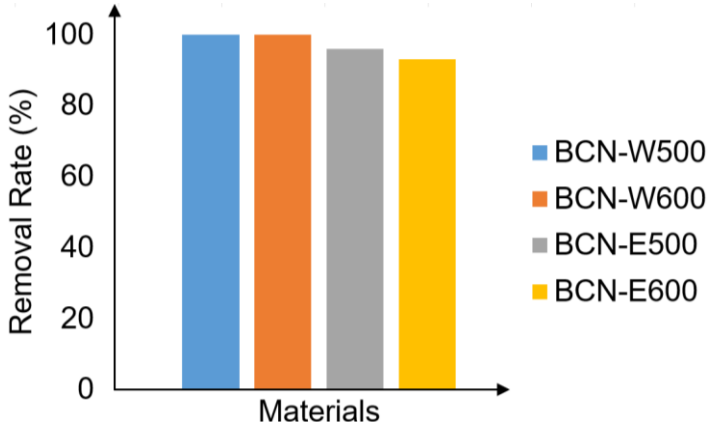

Figure 4. Pb^{2+} adsorption performances of all BCN materials produced.

Conclusion

In this preliminary exploration, we examined the effect of solvent selection and synthesis temperature on the materials' properties and Pb^{2+} removal performances of thermolysis-based BCN products. The produced materials exhibited similar structural characteristics. However, while the lead removal efficiencies of water-based samples were superior, we observed that all samples exhibited promising performances for heavy metal removal applications as adsorbents. Nevertheless, we could not yet explain the mechanism behind the lead removal behavior of produced BCNs as the overall (nitrogen-adsorption-based) porosity of the produced samples was much lower than typical activated carbons. Therefore, we plan to further explore the impact of thermolysis conditions on contaminant removal by employing additional modal contaminants and analytical tools.

Combustion Simulation of HCNG Fueled Single-Cylinder Research Engine Using Fractal Combustion Model

Eren Özdemir[a], Alper Tolga Çalık[a]

[a] Istanbul Technical University, Faculty of Mechanical Engineering, Department of Automotive, Türkiye
ozdemire22@itu.edu.tr

Keywords: Engine Simulation, Fractal Combustion Model, CNG, HCNG, AVL Cruise M.

Aim

This study investigates the effects of hydrogen (H_2) addition to compressed natural gas (CNG) on combustion and performance in a single cylinder spark-ignition (SI) engine. Two combustion modeling methods are particularly emphasized: AVL Spark Ignited (SI) and Fractal-based models (Ma et al., 2008, 2012) by comparing simulation results with experimental measurements. The Fractal model is used for its ability to more accurately simulate turbulent flame propagation and combustion timing in hydrogen-rich fuel scenarios.

Material and Method

1. Engine Setup and Experimental Data

A diesel single-cylinder research engine was converted to CNG PFI mode, reducing the compression ratio from 17 to ~12 by replacing the injector with a spark plug (Doğan et al., 2019). The relevant specifications are:

Bore: 85 mm, Stroke: 80 mm, Conrod: 145 mm, Compression ratio: ~12.

Control: Spark timing and injection pulse width driven by a custom electronic control system.

Instrumentation: A 70-kW eddy-current dynamometer and AVL GU21D piezoelectric pressure sensor for in-cylinder pressure. Air flow rate is measured by a Dresser G65 flow meter, and the CNG flow rate is tracked by a digital scale.

Experimental runs were at 1500–2000 rpm, 3–5 bar BMEP and additional conditions shown in Table 1. Additional H_2 doping tests were conducted to evaluate the impacts on torque, BSFC, and IMEP (Khodamrezaee & Keshavarz, 2020).

Table 1. Experimental conditions.

Engine speed (rpm)	Lambda (-)	Air Flow Rate (kg/h)	Throttle Control (%)	Atm. Pressure (mbar)	Atm. Humidity (%)	Atm. Temperature ('C)	Fuel Mass (kg)	Fuel Measurement Duration (s)	Vol. Efficiency (%)
2000	1	18.24	23.70	1004	44.5	20	0.032	114	55.97

2. Modeling in AVL Cruise M

AVL Cruise M is a simulation platform for model-based vehicle system development.
The engine model used AVL Spark Ignited and Fractal combustion models, which are more sophisticated than the Wiebe model (Ayad et al., 2021), and was validated at 5 bar BMEP and 2000 rpm. Initially, CNG was used.
The engine model was initially built with AVL Spark Ignited (SI) combustion and 1D intake-exhaust components.

Then, due to its improved representation of turbulent flame propagation which is critical in hydrogen-enriched combustion (Ma et al., 2012), the Fractal model was selected. To ensure compatibility, the engine model was simplified to a zero-dimensional (0D) structure.

Model components included: Intake boundary → manifold → cylinder block → exhaust manifold → exhaust boundary.

Throttle valve to match the measured airflow.
Mass Flow Connection adjusts the fuel flow based on the air–fuel ratio.

3. Combustion Model Selection and Implementation

AVL Spark Ignited (SI) Model:

Quasi-dimensional approach regulates flame speed with parameters like flame speed multiplier (FSM), combustion multiplier (CM), ignition delay multiplier (IDM), swirl ratio, and heat transfer multipliers. It requires tuning CM and FSM to align PFP and crank angle.

Fractal-based Combustion Model:

A two-zone approach with fractal flame surface expansion was used (Ma et al., 2012). The model has a calibrated wall-combustion submodel for HCNG. It captures faster flame speeds and turbulence, especially in hydrogen-enriched cases (Ma et al., 2011, 2012). Fractal geometry improves combustion phasing in lean-burn and HCNG. The interaction between the flame front and turbulence is also modeled (Doğan et al., 2023; Ma et al., 2008, 2012). After CNG validation, the Fractal model was used for hydrogen addition due to its better suitability. The mass burning rate is defined by Equation 1.

$$\left(\frac{dm_b}{dt}\right)_{cfractals} = \rho_u \left(\frac{L_{max}}{L_{min}}\right)^{D_3-2} A_L S_L$$

Equation 1. Mass burning rate with fractal wrinkling.

Where

m_b: Mass of burned fuel
t: Time
ρ_u: Density of unburned fuel
S_L: Laminar flame speed
A_L: Laminar flame area
L: Length scale
D_3: Fractal dimension

Some critical parameters:
Fractal Dimension (D_3): Increases flame surface area → faster combustion, higher PFP, more NOx.

Turbulence Production Constant (C_t): Boosts turbulence → faster flame propagation, higher knock and NOx risk.
Turbulent Length Scale (c_l): Sets eddy sizes affecting flame wrinkling → controls flame surface and burning rate.

4. Hydrogen Addition

Fuel properties were updated, AFR was adjusted, laminar flame speed and turbulence parameters were adjusted to match the combustion dynamics to H_2 (Khodamrezaee & Keshavarz, 2020).

5. Manual Calibration and Global Optimization

There are three stages of calibration and optimization in the study:

First, manual parameter sweeps were performed to evaluate the sensitivity of key combustion variables and their effects on BMEP, torque, PFP, T_{exh}, and BSFC.

Second, Latin Hypercube sampling and discrete genetic algorithms were used as a multi-parameter optimization. The focus was minimizing the error between experiment and simulation (Kavathekar et al., 2021; Ma et al., 2011).

Third, fine-tuning was applied with PID controllers to improve convergence to target operation.

Findings

1. Baseline CNG Results (No H_2)

As shown in Table 2, baseline CNG simulations closely matched experimental data, with less than 5% error in BMEP, BSFC, torque, and PFP at 2000 rpm and 5 bar BMEP (Ma et al., 2012).
The Fractal model accurately reproduces pressure trace shape and combustion duration when it's tuned but requires complex calibration (Ma et al., 2012).
The simulated pressure and ROHR curves (Figure 1 and Figure 2) show an earlier start and broader peak compared to experiments which indicates calibration sensitivity in flame speed and ignition delay parameters.

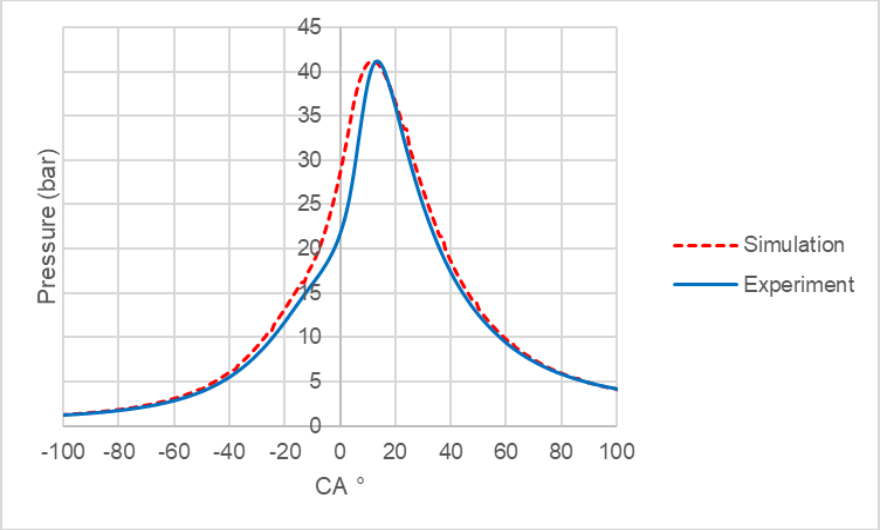

Figure 1. Comparison of experimental and simulated pressure vs. crank angle for CNG.

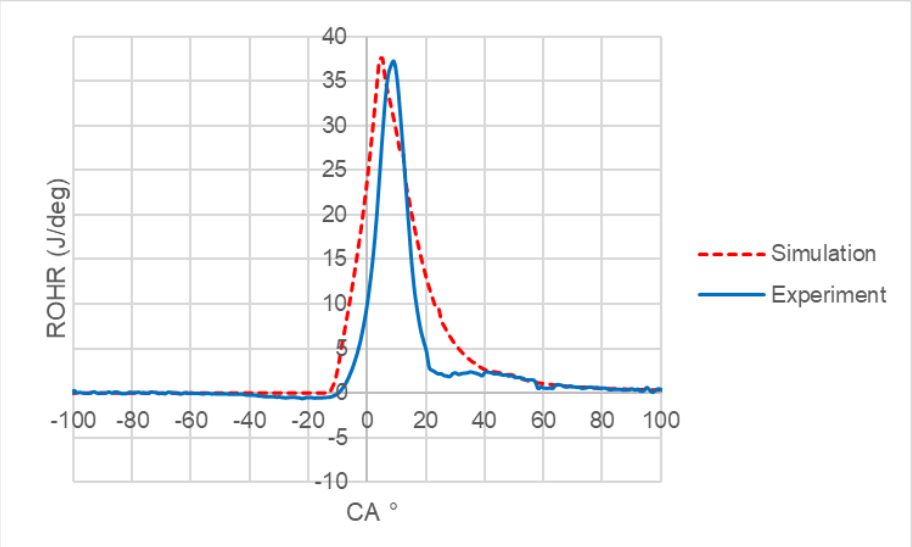

Figure 2. Comparison of experimental and simulated rate of heat release vs. crank angle for CNG.

Table 2. Engine performance metrics: Experimental vs. simulated data for CNG.

5 BMEP	Brake mean effective pressure	Brake specific fuel consumption	Power	Torque	Fuel Consumption Rate	Net indicated mean effective pressure	Peak Firing Pressure (PFP)	PFP Crank Angle	Exhaust Temperature

λ=1.0	BMEP	BSFC	N_e	M_e	$\dot{m}_f$	$IMEP_N$	P_{max}	CA@ P_{max}	T_{exh}
2000 rpm	bar	g/kWh	kW	Nm	kg/h	bar	bar	deg	°C
Simulation	5.22	252.525	3.96	18.85	1.00	6.11	41.37	12.00	498.00
Experiment	5.01	262.275	3.80	18.092	0.996	6.002	41.18	13.0	523.00
%Error	4.12	-3.72	4.24	4.19	0.37	1.80	0.46	-7.69	-4.78

2. Effects of Adding ~15% H_2

Literature reports that BMEP increases with hydrogen addition due to faster flame speeds (Khodamrezaee & Keshavarz, 2020; Park et al., 2020). The peak firing pressure (PFP) typically rises by 1–2 bar, BSFC improves by 2–4%, and optimum spark timing advances slightly (Kavathekar et al., 2021; Khodamrezaee & Keshavarz, 2020). The simulation results reflected similar trends as shown in Figure 3, with faster combustion and increased PFP (Khodamrezaee & Keshavarz, 2020) requiring adjustments in turbulence, laminar flame speed or swirl ratio parameters to prevent over-predictions and maintain combustion stability. Further effects can be seen in Table 3.

In general, these findings are consistent with previous observations in dual-fuel hydrogen-diesel engines as well (Ekin et al., 2022). In addition, the effect of swirl strategies for improving in-cylinder flow have been applied successfully in other studies (Calik et al., 2018). Exhaust temperature (T_{exh}) discrepancies were noted: experiments showed a minor rise, while simulations predicted a decrease. This can be corrected by adjusting the heat transfer multiplier (Khodamrezaee & Keshavarz, 2020).

In future studies, simulations with more than 35% hydrogen enrichment will be conducted as measured data becomes available. These studies will focus on combustion stability, feasibility, and performance impacts using the Fractal model (Ma et al., 2011).

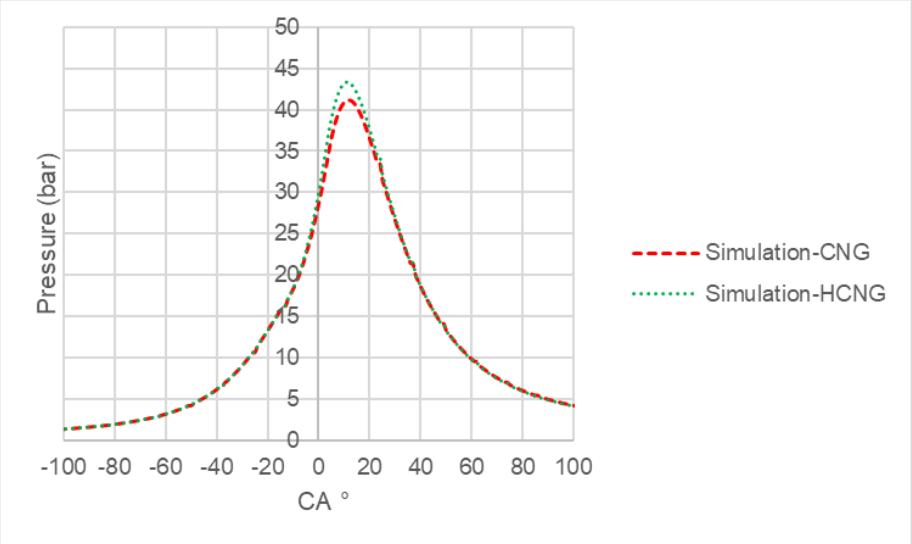

Figure 3. Comparison of simulated pressure vs. crank angle for CNG and HCNG.

Table 3. Engine performance metrics: Simulated data for CNG vs. HCNG.

5 BMEP	Brake mean effective pressure	Brake specific fuel consumption	Power	Torque	Fuel Consumption Rate	Net indicated mean effective pressure	Peak Firing Pressure (PFP)	PFP Crank Angle	Exhaust Temperature
λ=1.0	BMEP	BSFC	N_e	M_e	$\dot{m}_f$	$IMEP_N$	P_{max}	CA@ P_{max}	T_{exh}
2000 rpm	bar	g/kWh	kW	Nm	kg/h	bar	bar	deg	°C
CNG Simulation	5.22	252.53	3.96	18.85	1.00	6.11	41.37	12.00	498.00
HCNG Simulation	5.25	220.55	3.99	18.98	0.88	6.14	43.48	11.0	488.14
%Deviation	0.57	-12.66	0.76	0.69	-12	0.49	5.10	-8.33	-1.98

Conclusion

Both AVL Spark Ignited and Fractal combustion models can precisely predict key performance and combustion parameters in a single-cylinder CNG spark-ignition engine, with less than 5% deviation from experimental data under baseline conditions. Comparable accuracy has also been reported in the literature (Ma et al., 2008, 2011), supporting the modeling approach used. This study found that the Fractal model was more effective for hydrogen-enriched scenarios, particularly in representing turbulent flame propagation and combustion phasing, which aligns with previous findings (Ma et al., 2012).

Simulations with 15% hydrogen addition showed improvements in BMEP, combustion stability, and fuel efficiency, which are consistent with empirical trends and literature findings (Ma et al., 2011, 2012). However, the potential for increased peak firing pressures and NOx emissions requires careful optimization of ignition timing and combustion parameters to ensure stable operation (Khodamrezaee & Keshavarz, 2020).

The current 0D model configuration limits the analysis of transient behavior with exhaust gas characteristics. Combustion chamber designs, such as piston bowl modifications, can enhance turbulence and flame propagation in HCNG engines (Temizer & Cihan, 2021), and these aspects should be addressed in future studies.

Future studies will explore hydrogen enrichment beyond 35% for combustion stability and performance. EGR and advanced spark control may be needed to mitigate knock and NOx (Ma et al., 2008).

CFD Analysis of The Effects Of Hydrogen Addition On The Performance And Emissions Of A Natural Gas-Fuelled Single-Cylinder Internal Combustion Engine

Barış Bingül[a], Hikmet Arslan[a]

[a] Istanbul Technical University, Mechanical Engineering, Automotive, Türkiye
bingul18@itu.edu.tr

Keywords: CFD, Hydrogen, ICE, Natural Gas.

Aim

The single-cylinder test engine, modified from original production of Anadolu Motor Production and Marketing Inc., located in the Automotive Laboratory of Istanbul Technical University, has been used for various academic studies. With the engine, which was converted from compression ignition to spark ignition, these studies have been conducted with gasoline and natural gas fuels on different combustion chambers. In this study, after validating the experimental data of the engine operated with natural gas fuel by using three-dimensional computational fluid dynamics, an emission and performance analysis will be conducted by adding hydrogen to the mixture in different ratios.

Along with the advancing technology, consumption habits, and production relations, the number of polluting gases released into nature has risen to critical levels throughout human history. As the concentration of these gases in the atmosphere increases, they contribute to the greenhouse effect. The primary greenhouse gases are carbon dioxide (CO_2), nitrogen oxides (NOx), and methane (CH_4). The excess of these polluting gases causes the greenhouse effect, raising the average global temperature over the years. 25% of the gases responsible for this problem come from the transportation sector, and 25% of this portion is released due to the use of internal combustion engines in automobiles (Al-Wreikat et al., 2021).

The hydrogen-natural gas mixture offers significant advantages in internal combustion engines, both environmentally and in terms of their performance. Natural gas is a fuel with a low combustion rate. When mixed with hydrogen, which has a wide combustion range and high combustion speed, a more homogeneous and efficient combustion process is achieved, providing stability even under low load conditions, thereby increasing fuel efficiency (Mariani et al., 2013; Park et al., 2011). Additionally, adding up to 20% hydrogen by volume can be applied without major changes to the existing engine structure, resulting in power increase while significantly reducing harmful emissions, particularly carbon monoxide (CO) and unburned hydrocarbons (HC). However, when hydrogen exceeds 20% by volume, thermal losses increase, leading to a decrease in efficiency (Bundele et al., 2022). Although hydrogen addition may sometimes cause an increase in NO_x emissions, this can be controlled with proper calibration and combustion strategies (Costa et al., 2021). Thus, hydrogen-natural gas fuel presents an innovative alternative for the future of internal combustion engines in a time when emission regulations are becoming stricter.

Material and Method

In this study, a single-cylinder spark-ignition internal combustion engine produced by Anadolu Motor will be used. The Antor 3LD 450 engine, originally manufactured as a diesel engine, has been converted to a spark-ignition engine (Kutlar, 1999). Various doctoral students have conducted experiments on this engine, which retains the construction of a diesel engine. The experiments with natural gas fuel in doctoral thesis (Doğan, 2019) will be used to validate the CFD analyses in this study. Table 1 shows the general specifications of the engine, while Table 2 presents the experimental information.

Table 1: Specifications of test engine.

Parameter	Value	Unit
Engine	Antor 3LD 450	-
Number of Cylinder	1	-
Stroke x Bore	80 x 85	mm
Compression Ratio	12	-
Stroke Volume	454	cm^3

The mass and mole ratios of the natural gas mixture used in the experiments conducted by Hüseyin Emre Doğan are provided in Table 3 below. Since butane (C_4H_{10}) fuel is not present in the combustion mechanism, it could not be included in the calculations. Since the engine operates with a homogeneous mixture, the fuel-air mixture will be introduced into the combustion chamber as the initial condition. In Figure 1 below, the mass ratios of the gas mixture at the initial conditions for different fuel-air mixtures are shown. The hydrogen ratio in the mixture was increased in such a way that the thermal energy of the fuels remained constant.

Figure 1: Initial Gas Mixture of Different Cases.

Ansys Forte was used for 3D computational fluid dynamics analysis. To reduce and simplify the computational time, a combustion chamber with a compression ratio of 12 was modelled as a quarter geometry, using Creo Parametric. The model imported into Ansys Forte was meshed using an adaptive mesh method, with finer mesh regions around the spark zone, walls, and areas of high velocity and pressure, while the remaining parts of the model were assigned a coarser mesh.

For the combustion model in Forte, the Grimech 3.0 model was selected. This model, whose characteristics are presented in Table 4, has been widely used in the literature for methane-hydrogen mixtures, yielding successful results (Cameretti et al., 2023; De Robbio et al., 2022; Halter et al., 2005). Subsequently, the initial and boundary conditions were determined based on experimental conditions and measurements. The parameters within the Flame Speed and Turbulence Model, as mentioned in the Ansys Forte Theory Manual, were manipulated to validate the calculations (Ansys Forte Theory Manual, 2023).

Table 4: Properties of Grimech 3.0 Mechanism.

Grimech 3.0 Mechanism	
Fuels	Hydrogen, Methane
Oxidizer	Air
Number of species	53
Number of reversible reactions	325

Findings

The comparison between the analysis results and experimental data is illustrated in the Pressure – Crankshaft Angle graph shown in Figure 2. During the compression phase, it is evident that the curves closely overlap, with only minor discrepancies that remain within acceptable limits. This alignment highlights the strong correlation between the simulation outcomes and the experimental measurements, providing a solid foundation for the reliability of the analysis.

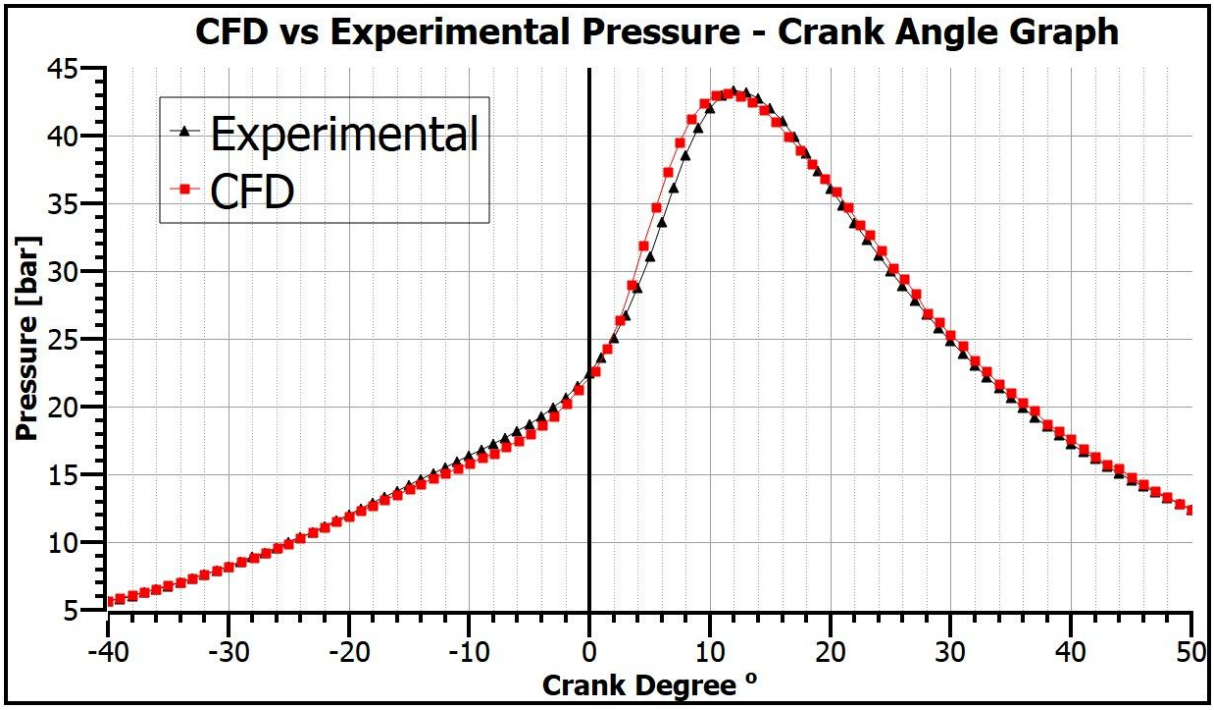

Figure 2: Graph of CFD vs Experimental Pressure – Crank Angle Degree.

After the validation process, results were obtained by adding hydrogen to the mixture in different ratios. As shown in Figure 3, as the amount of hydrogen added to the mixture increases, the combustion rate also increases, causing the peak pressure to occur at an earlier time. Additionally, it is observed that the maximum pressure value increases. Since the same spark advance value was used for all five models, the curves shift to the left as the hydrogen ratio increases. This shift indicates an early pressure rise, which results in a decrease in efficiency. To mitigate this, spark ignition advance values should be optimized. As the hydrogen ratio increases, without the optimization of spark advance, early pressure rise occurs, leading to a decrease in thermal efficiency, as shown in Figure 4. Consequently, due to the decrease in efficiency, the gross indicated power (GIP) value also decreases. Theoretically, when hydrogen is added, the combustion is faster, and an increase in thermal efficiency is expected. To observe this result, spark advance optimization, as previously mentioned, must be performed.

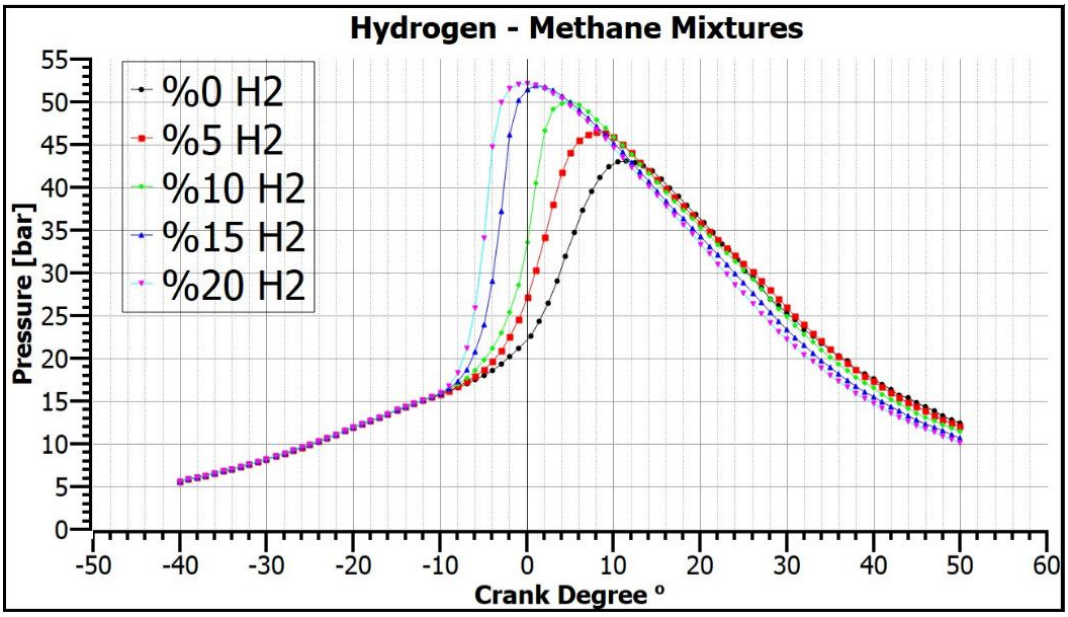

Figure 3: Graph of Pressure – Crank Angle Degree for Different Hydrogen-Methane Mixtures.

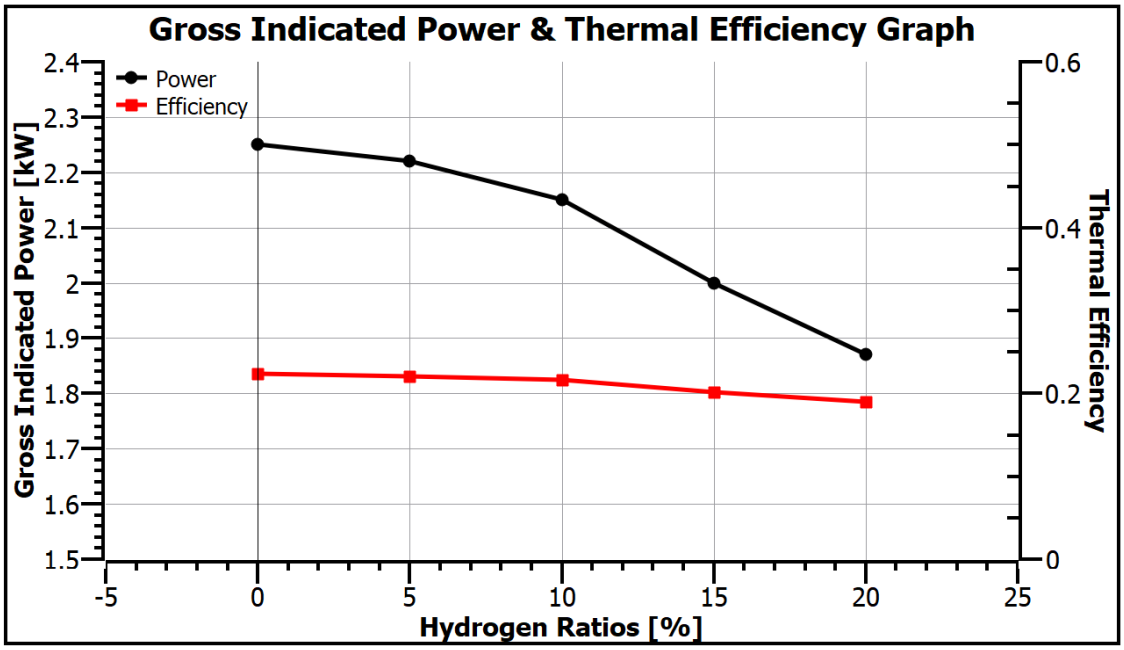

Figure 4: Graph of Gross Indicated Power & Thermal Efficiency for Different Hydrogen-Methane Mixtures.

Since hydrogen has a higher combustion temperature compared to other fuels, it is expected that the maximum temperature value will increase as the hydrogen ratio increases. However, when hydrogen is first added to the mixture, the maximum temperature value decreases, due to the previously mentioned reasons that lead to a reduction in thermal efficiency. As the hydrogen ratio in the mixture increases, the maximum temperature value also rises. In internal combustion engines, NO_X emissions are directly proportional to the temperature in the combustion chamber. As the combustion temperature increases, NO_X formation accelerates, and as shown in Figure 5, NO_X emissions also rise with the increasing hydrogen ratio in the mixture. The cause of this phenomenon is the increase in the maximum temperature value. On the other hand, CO emissions decrease as the hydrogen ratio increases. Since the amount of natural gas in the mixture decreases as the hydrogen ratio increases, a reduction in carbon-containing emissions is an expected outcome. However, as the hydrogen amount increases, the rate of CO emission reduction progressively decreases.

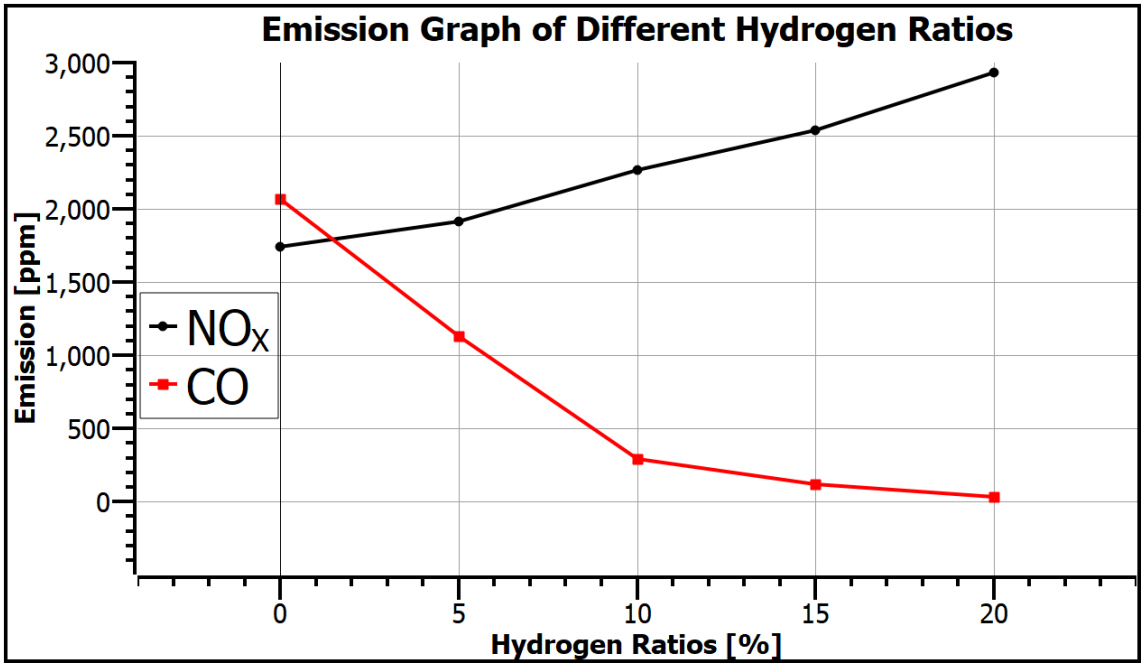

Figure 5: Graph of NOx and CO Emissions for Different Hydrogen-Methane Mixtures

Conclusion

In this study, the effects of hydrogen addition on the performance and emissions of a converted spark-ignition engine fuelled with natural gas were analysed using experimental data and computational fluid dynamics (CFD) simulations. The results showed that increasing the hydrogen ratio in the fuel mixture led to an earlier peak pressure due to the faster flame speed, which caused a reduction in thermal efficiency when the spark timing was not optimized. This indicates that spark advance optimization is necessary to fully utilize the benefits of hydrogen addition without sacrificing engine efficiency. Furthermore, while the initial introduction of hydrogen resulted in a slight decrease in peak temperature due to efficiency losses, further increases in hydrogen concentration led to a higher combustion temperature. This directly impacted NO_x emissions, which increased as the hydrogen ratio rose, confirming the strong correlation between combustion temperature and NO_x formation. In contrast, CO emissions decreased with higher hydrogen content due to the reduced presence of carbon-based fuel components. However, the reduction rate of CO emissions diminished as hydrogen concentration increased.

Overall, this study highlights the potential of hydrogen as a supplementary fuel to improve combustion characteristics while emphasizing the need for optimized engine parameters to mitigate efficiency losses and control emissions effectively. Future work should focus on refining spark timing and exploring exhaust gas recirculation (EGR) strategies to balance the trade-offs between performance and emissions.

Design Optimization of Crane Hook by using Generative Design Approach

Cihat Sofracı[1], Eren Kalay[1], C. Erdem İmrak[1]

[1]Istanbul Technical University, Faculty of Mechanical Engineering, Department of Mechanical Engineering, Turkiye
sofraci20@itu.edu.tr

Keywords: Crane hook, Generative Design, Optimization, Weight Reduction.

Aim

The primary aim of this research is to conduct design optimization of NR025 crane load hook, which is manufactured according to the DIN15401 standard, by using a generative design methodology. Crane hooks are important mechanical components which are commonly used in various industries, such as construction and logistics[1]. While it is serving in the field, it should also meet safety and efficiency requirements[2]
Main motivation of proposed project is based on limitations that we had from past to the present [6]. Analytical approach (Equation 1) was conventional method to improve existent designs and to conduct design optimization related studies. Considering current capabilities, growing finite element methods and their solvers, on top of that, artificial intelligence based software being implemented to these methods, it is vital to engage with these methods and take advantage of these opportunities to improve current designs and re-think over the limitations that we had for years. In this direction, generative design offers a new solution to these challenges by integrating artificial intelligence-driven algorithms that simultaneously optimize material, geometry and manufacturability.

$$\sigma = \frac{F}{A} + \frac{My}{I}$$

Equation 1 – Analytical Approach

Where M is the maximum bending moment, Y is the distance from the centroid axis to the neutral axis, and I is the moment of inertia for different cross-sections

Material and Method

1.Crane Hook Modeling: Single crane hook is modeled in a computer-aided design (CAD) environment using industry-recognized software which is SolidWorks 2017 Student Edition. The standard dimensions have taken based on DIN15401 specifications, and the model has been analyzed under different loading conditions using finite element analysis (FEA). The stress distribution, deformation characteristics, and failure points have been identified through this simulation process. Special attention is given to stress concentration areas, as these are the primary indicators of structural weaknesses in the traditional crane hook design.
The most critical sections of the single hook are called A-B and C-D sections according to DIN15401 standard. These sections will be mentioned in the following parts of the extended abstract.

2.Finite Element Model: Mesh structure of analysis was created by using Ansys Structural 19.2 software. The element size was selected as 1mm. 511562 nodes and 147625 elements with hexagonal 3D shape were used. Large deformation has not been used since the expected maximum equivalent stress is below than yield strength of the material. Afterwards, hook model was loaded within the range of 0,5KN to 10KN. It has been fixed from all degree of freedooms from top of the hook in a way that it could reflect the test. Load direction is passed through the shaft axis as test is conducted. In this regard, stress and strain results were recevied as shown in Figure 1. below.

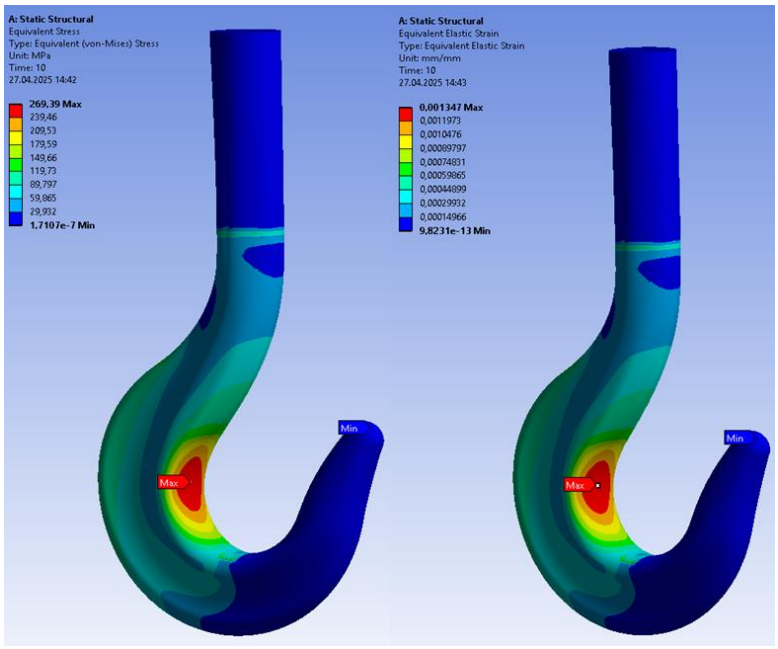

Figure 1. FEA Model Von-Mises Stress and Elastic Strain Results.

3.Experimental Validation: Accuracy of FEA model is verified through tensile testing, which is conducted under controlled laboratory conditions. To validate both the FEA model, CAD model and the material properties, bi-axial rosette types strain gauges which are able to measure the strain in both horizontal and vertical directions, were deployed on the inner and outer surfaces of Section A-B as shown in Figure 2. Sample hook was loaded within a specific load range between 0,5KN and 10KN, and the results of biaxial strain values were recorded. These values were compared with the corresponding results from the FEA model under the same load conditions.

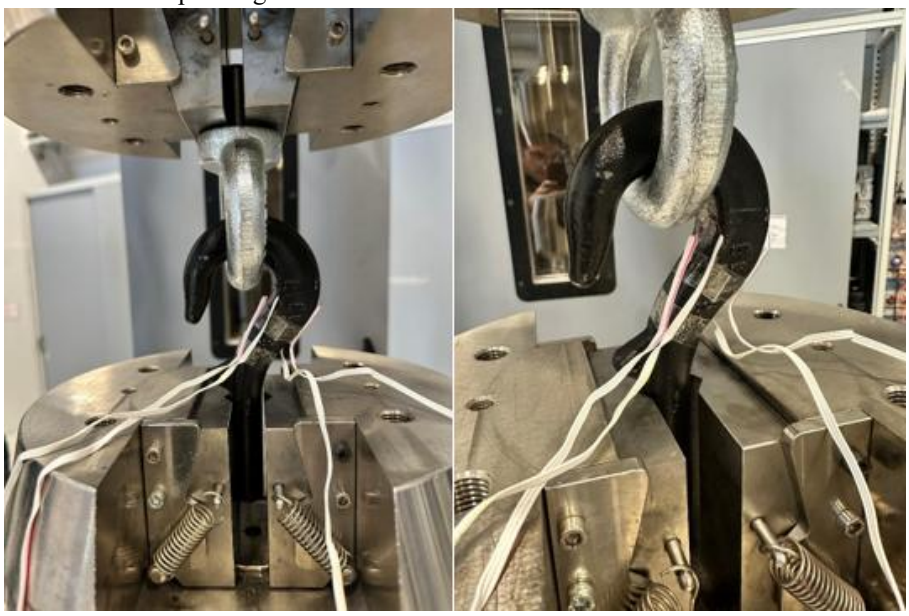

Figure 2. Test Instrumentation of single hook.

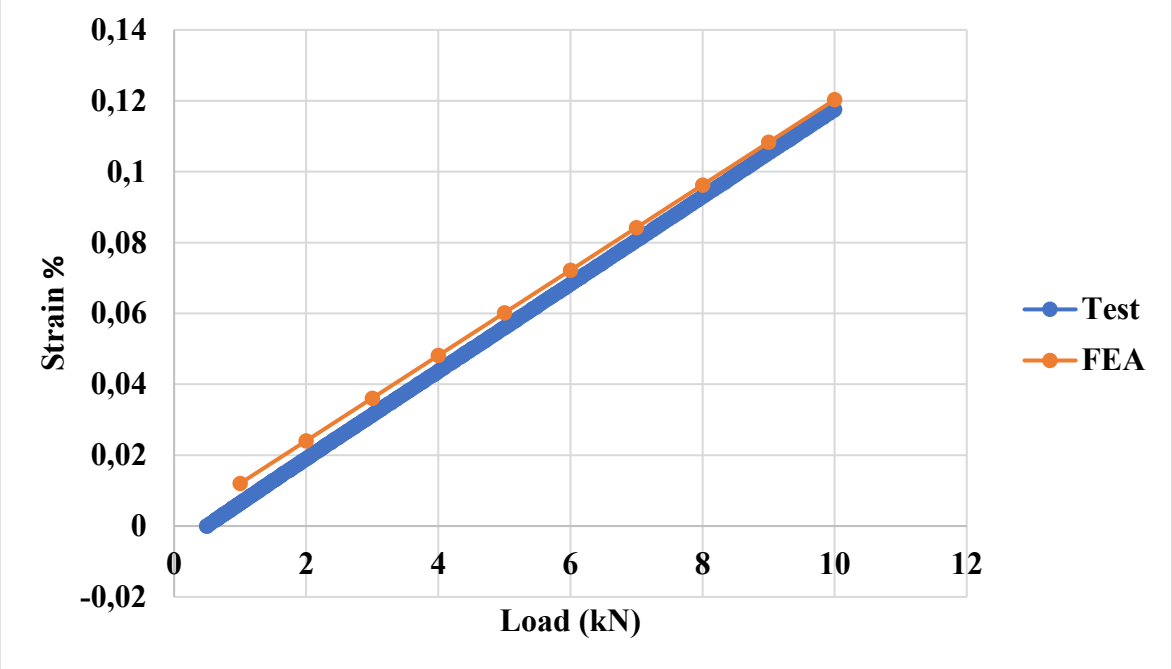

Figure 3. Test and FEA Model Comparison.

Deformation occured is within elastic limit of material since strain vs load graph shows the slope is lineer. Additionally, poisson ratio has been calculated by Equation 2. Results show that poisson ratio is between 0.3 and 0.34.

$$\upsilon = -\frac{\varepsilon_{horizontal}}{\varepsilon_{vertical}}$$

Equation 2 – Analytical Approach

Where υ is poisson's ratio, ε is strain.

In this comparison, the elastic modulus and Poisson's ratio were changed within the limits set by the Taguchi method (L9 orthogonal array) to identify the most consistent elasticity modulus and poisson ratio with experimental data. It is observed that 220GPa Elasticity modulus and 0,32 poisson's ratio are the best match with FEA model over other trials as it is shown in Figure 3. Besides, detailed comparison results with factors chosen is shown in Table 1.

Table 1. με (%ε x 1000) Delta Between FEA and Test.

E (Gpa)	Poisson's Ratio	Inner Surface		Outer Surface		Average Delta
		Vertical	Horizontal	Vertical	Horizontal	
200	0.3	14,44	1,849	5,944	0,597	5,7075
200	0.32	14,82	4,647	5,996	0,642	6,52625
200	0.34	15,2	7,479	6,046	1,883	7,652
220	0.3	2,44	1,581	0,309	2,269	1,64975
220	**0.32**	**2,79**	**0,963**	**0,355**	**1,142**	**1,3125**
220	0.34	3,14	3,537	0,401	0,014	1,773
240	0.3	7,55	4,44	4,388	3,661	5,00975
240	0.32	7,23	2,107	4,345	2,628	4,0775
240	0.34	6,92	0,253	4,303	1,594	3,2675

4. Generative Design: Using the validated CAD model and physical material properties, the process has proceeded with the generative design phase in Fusion 360 (version 2021). Based on the stress distribution of the hook, the volume with the highest potential for material reduction was identified. This volume with constraints and boundary conditions, entered as an input into the software.

As per catalog values of hook, maximum load that it can carry has been applied, passing through the shaft axis. Top area of the shaft of the hook has been fixed within all degrees of freedom. Factor of safety has been chosen as 1.5. As for material selection, Fusion 360 has wide range of materials. Choosing the right material is vital since it puts some limitations on the software. Physical properties of material, elasticity modulus, poisson's ratio and yield strength has been entered as 220GPa, 0,32 and 315MPa respectively. Yield strength of material data comes from DIN15400 standard for hook P-Grade material. The other ones received from test validation.

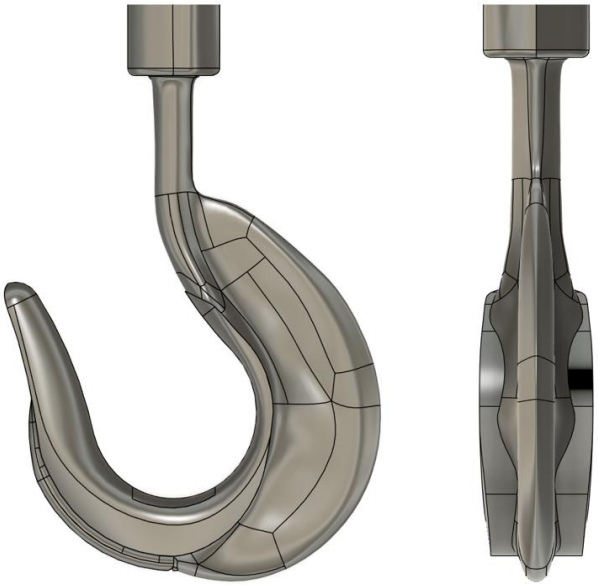

Figure 4. Final alternative front and side view.

Findings

The weights of the proposed designs were compared with the original hook's weight (640 gr). The third alternative achieved the lowest weight reduction at 38.1%, whereas, the second alternative achieved at 46.5% which is the highest.

Initially, four prominent alternatives among others have been identified and assessed in terms of durability, producibility and weight reduction. It was seen that up to 46.5% weight reduction was achieved with various

manufacturing methods. To validate the second design offering highest weight reduction, finite element model with fine mesh was created. It was noticed that maximum von-mises stress is 281MPa which is below yield strength of P-Grade material. However it is above from the value that Fusion 360 has given as maximum (210Mpa.)
After considering the stress concentration since there is sharp transition towards free tip of the hook, it was decided that an action is required to make this transition smoother. For this purpose, durability related improvement has been made between free tip of the hook and C-D section. In order to ensure material integrity and increase the safety in this section, preserved geometry has been revised and final alternative was created. In addition, this final alternative is the closest one to the original design in terms of manufacturability. It is symmetrical and does not have an undercut.
Based on these conditions, final alternative has been proposed in this study considering producibility, fit, form and function of the hardware. Figure 4 shows front and side views of proposed design of hook.
When we compare the weight reduction between the original model and the final alternative proposed, only in sections C-D and E-F, reduction was observed from 306.6 g to 139.8 gr. This reduction in this region constitutes 66% of the total weight reduction. In other words, the highest reduction occurred in this region.

Conclusion

This study indicates that considerable weight reduction is possible through generative design approach by re-designing mechanical components which were designed traditionally.
The weight of Crane hooks with higher load capacity such as NR250 can reach up to 4800kg. In this case, the weight reduction will naturally be much higher and meaningful. Figure 5 shows overlapping demonstration of single hooks growing in size gradually.
As future work, final proposed design could be subjected to detailed fatigue, fracture mechanics, creep related studies including test validation in these domains. Futhermore, other studies could focus on extending this methodology to other mechanical components, validating the feasibility of AI-driven design optimization.

Figure 5. Demonstration of single crane hooks growth in size [12].

Keywords: Ethylene Propylene Diene Monomer, Hyperelastic Characterization, CSR (Compression Stress Relaxation), Sealing Setup.

Aim

Effective sealing is critical in defense industry projects, as aerospace, maritime, and land-based systems face harsh environmental conditions like humidity, pressure fluctuations, saltwater, precipitation, and chemical agents over their lifespan. Protecting sensitive internal electrical components from these factors is vital. Sealing components at connection points must withstand deformation and wear caused by such conditions, balancing flexibility to prevent damage and strength to endure external loads. They must also conform to surrounding contours and compress under specific reaction forces. Elastomers, known for their hyperelastic behavior, can recover after significant deformation, unlike metals. Their incompressibility results from strong bonds between overlapping carbon and hydrogen chains. In the automotive sector, elastomers are widely used as damping elements due to their physical and mechanical properties. In industries such as construction, electronics, and automotive, they are extensively employed as sealing elements, with their usage is consistently rising [1,2].

The mechanical properties of elastomers are evaluated through tests like uniaxial tensile, biaxial tensile, planar shear, and volumetric compression. Data from these tests help develop material models such as Yeoh, Ogden, and Mooney-Rivlin [3]. Their varying responses to strain and compression complicate the establishment of design standards. Accurate estimations require thorough material characterization and reliable finite element analysis (FEA) models. While companies like Parker Hannifin&Chomerics provide general guidelines for gasket applications, challenges remain in defining critical parameters like groove dimensions, positioning, bolt spacing, and material selection, all of which impact sealing efficiency [4]. However, due to the distinct characteristics of each design, generalization is not feasible; therefore, it must be both modelled and verified by experimentation for accuracy in material behaviour definition.

The main objective of this study is to analyze the material behaviour of a specific sealing element, validate the findings via FEA modelling, and reproduce the product-level assembly in a numerical setting. A leakage test is performed to determine the precision of the analytical model and to ascertain the occurrence of stress relaxation.

Material and Method

The research started by analyzing the material properties of a rubber-based sealing element. EPDM rubber with 70 Shore-A hardness was selected for its suitability in defense applications, considering its hardness, chemical and corrosion resistance, and optimal temperature range. Literature review revealed that EPDM, unlike NBR and FVMQ elastomers, operates effectively across a wider temperature range (-57 to 204°C). It also offers superior ozone resistance and higher tensile strength compared to silicone gaskets [4,5].

Considering literature review and commercial catalogues, two different EPDM 70 materials were purchased from 'Tombak Rubber LLC.' and 'Babacan Kauçuk'. The EPDM based sealing elements have a 1x1 meter square sheet gasket and a 'Hollow-O' type sealing gasket with an inner diameter of 2.29 mm and an outside diameter of 5.49 mm. The hardness of the supplied sheet gaskets was assessed according to the ASTM D2240 standard using a Shore A hardness measurement tool, as illustrated in Figure 1. The sample under measurement must possess adequate thickness to prevent interference from the hardness of the underlying table. These measurements confirm whether the sourced material adheres to the qualities delineated in the manufacturer reports.

Figure 1: 'Durometer Type A' Hardness Measurement [6].

Samples were extracted from the sheet gasket utilizing a die that adheres to ASTM D412 standards to assess the material's mechanical properties. Specimens of the dog bone type were manufactured utilizing 'Die C,' which ensures an appropriate aspect ratio of '>10:1,' as illustrated in Figure 2. Rubber materials exhibit lower tensile strength and higher elongation compared to metals, necessitating the use of precise tensile testing equipment. Testing was performed utilizing small force level, high-precision machines such as the 'Instron 5864'. which are fitted with 10 kN load cells. Gripping fixtures adhere to ASTM standards to mitigate slipping, excessive pressure, or damage in proximity to observation areas. Compression testing and product-level tensile testing were conducted at the METU Materials Laboratory. Additional tests are currently ongoing at Axel Products Inc., a recognized authority in elastomer testing [6,7]. The laser extensometer method was employed, with tensile speeds established in accordance with ASTM D412 (500±50 mm/min) or ISO 37 (100±10 mm/min). To obtain strain rate independent results, the tests were conducted at a rate of 1% strain per second.

Figure 2: ASTM D412 Die and Specimens [6].

The data from characterisation tests were included into the material modelling exhibiting optimal convergence by curve fitting techniques. Upon integrating the test data into finite element software (ANSYS_23R1), the material and incompressibility constants were ascertained. The curve fitting method will be selected based on the invariant it depends on, its extent, and the strain range where it performs best [3]. Yeoh proposed omitting I_2 term because strain energy is less sensitive to changes in I_2 than I_1. In cases where only limited test data is accessible, it has been demonstrated that disregarding the second invariant results in more accurate predictions of general deformation states [9,10]. This procedure determines the material's characteristics and mathematical framework, establishing the basis for commercial software.

This study used 'Hollow-O' type gaskets for compression testing at the product level. Two graphs delineating compression stress and deformation percentages for the seal are created based on compression testing and the 'Chomerics Design Guide' (Figure 3). The test data, although not intended for material characterization, was compared with the documentation from 'Chomerics.' The gasket response force was assessed in relation to these data within different analysis configurations.

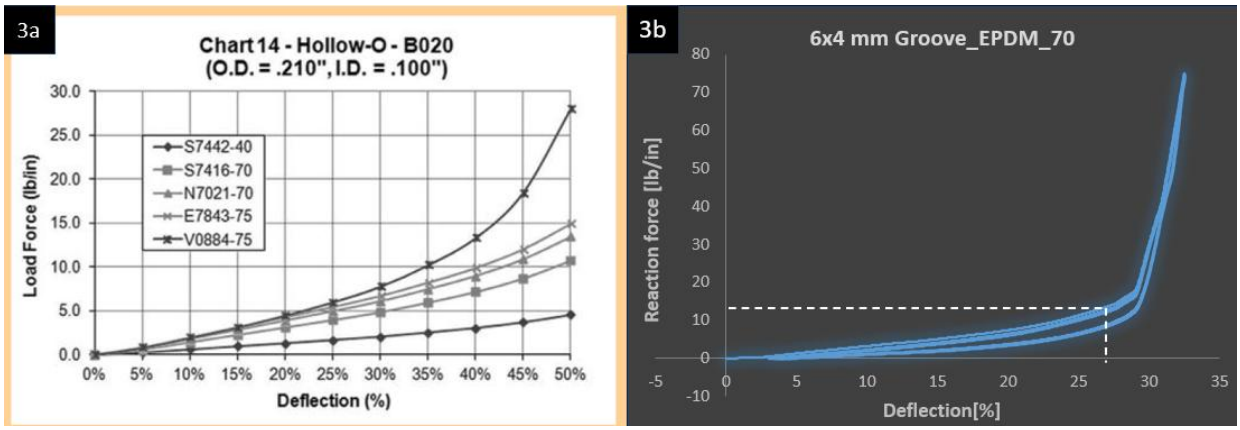

Figure 3: Reaction force of gasket and deflection percentage graphs: (3a) Chomerics, P. (2014). PARFABTM design guide deflection graph p.39; (3b) Our compression test results.

This research concentrates on finite element analysis modeling and evaluating the sealing efficiency of a 'Hollow-O' type seal. The sealing element is composed of 'Ethylene Propylene Diene Monomer' with a hardness grade of 'Shore-A 70'. A 'Sealing Test Setup' measuring 1m x 0.5m x 0.2m was constructed in accordance with the design criteria specified by the relevant authorities such as design guide of Chomerics Elastomer Handbook p. 4-17. The test configuration comprises a pressurized air inlet, a relief valve, and an observation manometer, as illustrated in Figure 4. The friction coefficient between the aluminum cover and the flange is considered to be 0.21. The bolt size is designated as metric 5 A4-70 grade, with a presumed bolt pretension of 4510 N.

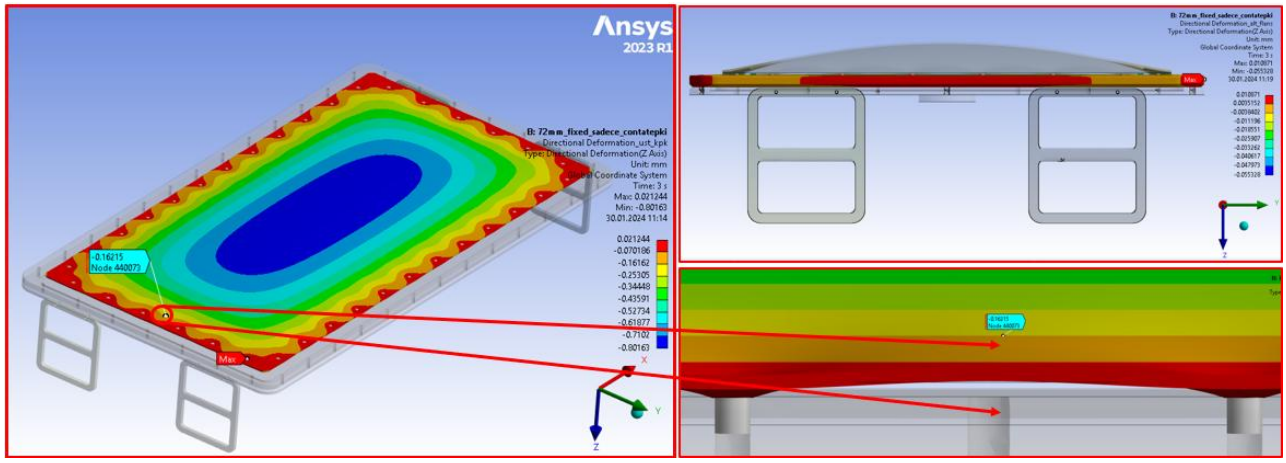

Figure 4: Sealing Setup FEA Model, directional deformation Al-6061 cover plate, 0.16 mm.

The gasket reaction force induces bending during the installation of the cover, referred to as 'Cover Bowing,' as illustrated in Figure 5. This phenomenon, increasing with internal pressure, is analyzed using analytical methods and finite element modeling. 'Cover Bowing' and gasket compression percentage are evaluated to identify the sealing failure threshold. The study also examines stress relaxation in the sealing component through controlled pressure monitoring. When an elastomer is held at constant strain, its polymer chains initially stretch and align, generating stress. Over time, these chains reorganize, break, or reform crosslinks, reducing stress. This process is influenced by temperature, chemical composition, crosslink density, and additives. After installation, the gasket experiences compressive stress, which relaxes over time due to its viscoelastic properties [8].

The stress relaxation testing of solid specimens is governed by ISO 3384 and ASTM D6147-97, which establish standards for times spanning from 10 to 168 hours. In accordance with these standards, this research evaluates the relaxation of the product-level (Hollow-O) gasket by monitoring internal pressure. Data on pressure fluctuations were gathered within identical timeframes and settings. Analytical methods, taking into account cover bowing and

gasket deflection force (GDF), established internal pressures (25 to 50 mbar) for bolt spacing of 72 mm and 110 mm, while considering groove dimensions, GDF, cover thickness, and material configuration.

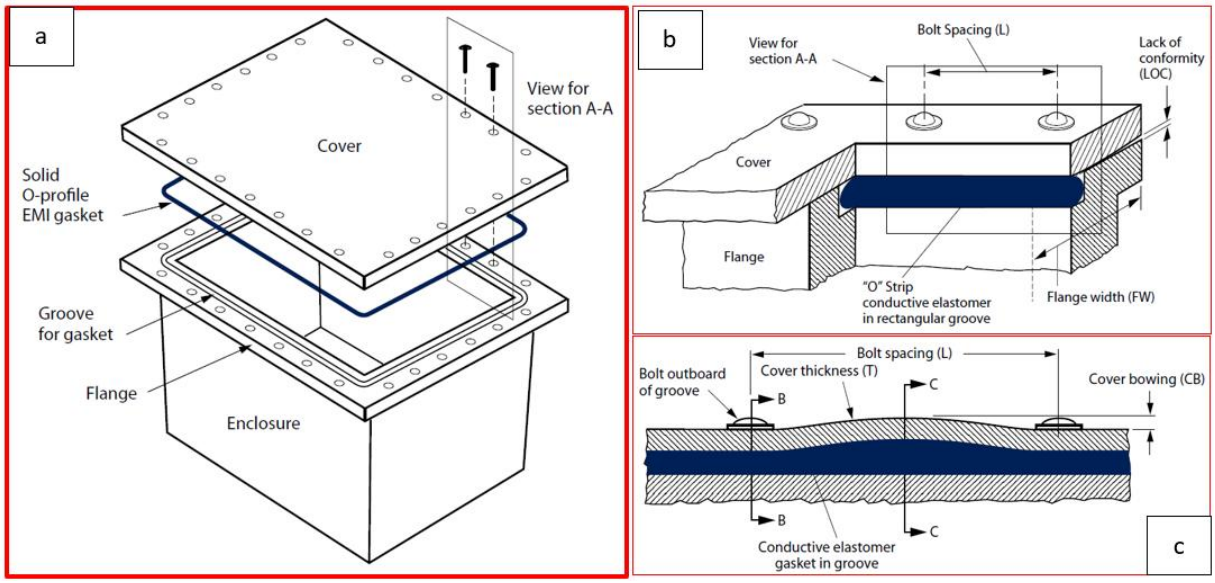

Figure 5: 'Cover Bowing' description, (a) assembly isometric view, (b) Cover, flange cut-away view, (c) section A-A of assembly, sectioned midway through gasket and groove [4].

$$CB_{min} = \frac{GDF\ X\ (L_{max})^4}{FW_{min}\ X\ (T)^3 X\ E\ X\ 32} \quad (1)$$

CB_{min}: Cover bowing (in)
GDF: Gasket deflection force (lb/in)
L_{max}: Max. bolt spacing (in)
FW_{min}: flange width (in)
T: Cover thickness (in)
E: Young's modulus (psi)

Findings

The material constants were determined from the curves obtained in the elastomer characterisation experiments, as seen in Table 1. The selected material model is the 'Third-order Yeoh' model.

Table 1: Hyperelastic curve fitting results, material constants, (W) strain energy density, $(\boldsymbol{I_1})$ first invariant of the Cauchy-Green deformation tensor, $(\boldsymbol{C_{i0}})$ material constants.

3-Parameter Yeoh Model		
C_{10}	C_{20}	C_{30}
0.7472	-0.0707	0.0397
$W = C_{10}(I_1 - 3) + C_{20}(I_1 - 3)^2 + C_{30}(I_1 - 3)^3$ (2)		

The squeeze percent of 'Hollow-O' gasket is 27.1 percent which decided and designed regarding gasket deflection recommendation table as shown in Figure 6. Since a 6x4 mm slot size is feasible to produce and the outer diameter of the gasket is 5.49 mm, it has been concluded that this design is the most reasonable and closest to the recommended value.

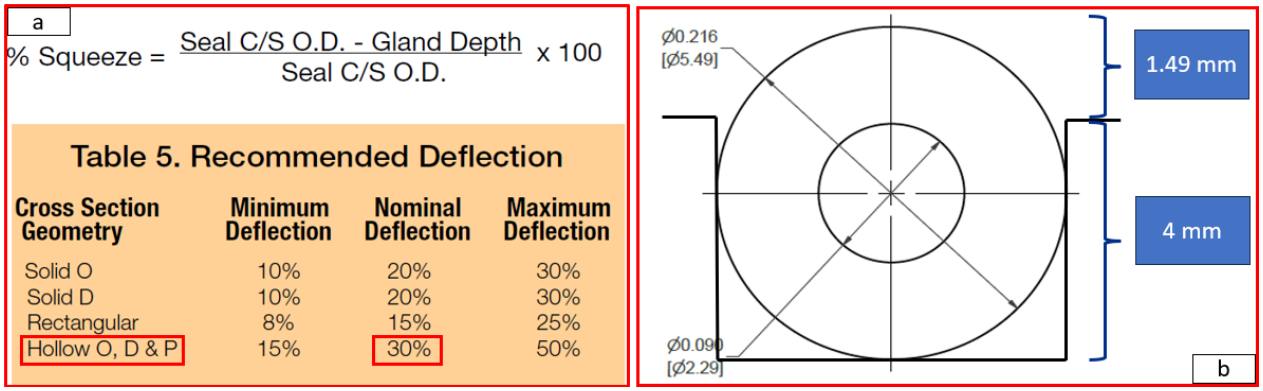

Figure 6: Groove size selection, (a) Chomerics gasket recommended deflection table p.7 [5], (b) Squeeze percent calculation.

$$\text{(b) } Squeeze\ Percent = \frac{1.49\ mm}{5.49\ mm} = \%27.1 \quad (3)$$

The gasket's reaction force was measured at 12.25 lb/in with a squeeze percent of 27.1, as illustrated in Figure 3 (3b). To determine the initial cover bowing during mounting, it was necessary to establish an assumption about the bolt spacing. A spacing of 72 mm was selected because of its high number common divisors, providing versatility in following design guidelines related to proximity, distance, and spacing.

GDF (at %27.1 squeeze) = 12.25 lb/in

$$CB_{min} = \frac{12.25\ X\ (2.83)^4}{1\ X\ (0.0787)^3 X\ 10^7 X\ 32} = 0.00504\ in = 0.128\ mm \quad (4)$$

The reaction force per unit length of the gasket, derived from compression tests, served as input for both analytical calculations and the FEA model. The total gasket groove length measures 2488 mm, and the reaction force of 2146 N/mm, converted from US units, results in an applied force of 5340 N on the aluminum cover plate during the initial mounting process. The 'Cover Bowing' was calculated to be 0.128 mm (4), whereas the FEA model estimated it at 0.16 mm under identical conditions, leading to a 25% error rate.

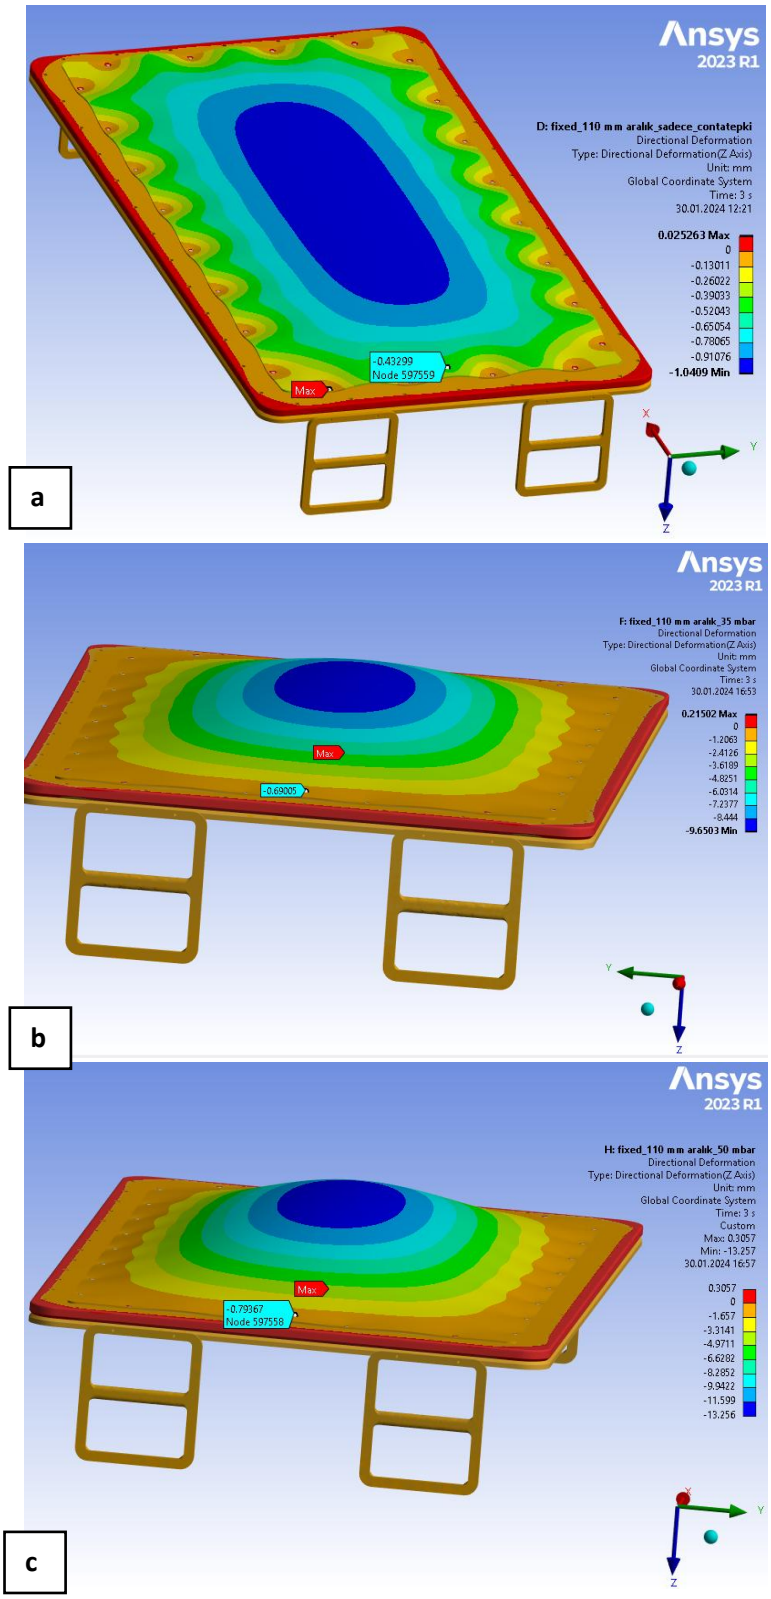

Figure 7: Directional deformation *z* axis under internal pressure (a) 0 mbar, 043mm, (b) 35 mbar, 0.69mm (c) 50 mbar, 0.79mm.

The minimum recommended squeeze percentage is 15 percent, suggesting that the designer may not observe a pressure drop even with increased internal pressure. A second configuration is established with a bolt spacing of

110 mm and begins operation with a 15 percent compression at cover bowing points, represents the threshold for seal failure. Analytical methods calculate 'Cover Bowing' at 0.66 mm, while the finite element analysis model shows a directional deflection of 0.43 mm, reflecting a 35% error rate. The FEA model's squeeze rate is 19%, closely matching the design guideline's critical minimum. At internal pressures of 35 mbar and 50 mbar, specific locations in the 110 mm configuration experience compressions of 14.5% and 12.75%, respectively. Both the FEA and analytical models suggest that the sealing configuration may fail within 35-40 mbar, with an estimated error margin of 30%.

In airtightness testing, defense sector standards require maintaining system pressure within ±2% of the target pressure. Errors may stem from compressor inaccuracies, manometer discrepancies, or human factors. Results are shown in Table 2. In Test Setup 1, 5.5 mbar pressure drop occurred at 40 mbar internal pressure, representing a 13.75% reduction, exceeding the 2% limit. These findings align with FEA results. As internal pressure approaches the critical threshold, gasket stress relaxation becomes more likely. The system with 72 mm bolt spacing showed no pressure loss at 45 mbar initially, but 12% drop was observed after 72 hours. Systems with initial pressure drops had already reached the gasket's tolerance limit, showing minimal variation over time, as detailed in Table 2.

Conclusion

The two sealing designs were subjected to incremental pressure via a compressor, with the observation manometer recording each pressure increment. A material model, based on uniaxial tensile test results, was included into an analytical model to estimate the leakage point. The research anticipated leakage at 35 mbar; however, testing indicated leakage at 40 mbar, yielding an error of around 12.5%. This technique established a material model for future systems and validated the reliability of the FEA model for predictive applications.

Table 2: Air tightness test at sealing setup.

Internal Pressure (mbar) - Pressure Drop Over Time				
Test Configuration	Int. Pressure (mbar)	Pressure Drop **(1 hour)**	Pressure Drop **(24 hours)**	Pressure Drop **(48 hours)**
1-EPDM Gasket 5.49-2.27 M5 Bolts: **110 mm** dist.	25	0.5	0.6	0.5

Design and Analysis of the Drive System Prototype for a Wire Rope Fatigue Test Setup

Ardıl Adar Yalçın[a], Mohsen Seyyedi[a], Adem Candaş[a], C. Erdem İmrak[a]

[a] Faculty of Mechanical Engineering, Istanbul Technical University, Gumussuyu Istanbul, 34437, Türkiye
yalcin24@itu.edu.tr

Keywords: Drive System Design, Fatigue, Four Bar Mechanism, Wire rope.

Aim

Steel wire ropes are widely used in various industries due to their high axial strength and bending flexibility, making them essential components in lifts, cranes, bridges, and other structural applications. Effective use of steel wire ropes consists several must have components whose are rope drums, rope sheaves, rope wedges and clamps. In their operating conditions, ropes are subjected to cyclic bending over sheaves, leading to fatigue due to fluctuating loads and progressive structural degradation. In recent works, the fatigue and degradation processes were studied by many authors [1-10]. To ensure their durability and reliability in such demanding conditions, fatigue testing is important in the design and evaluation process.

Cyclic bending over sheaves (BoS) fatigue in steel wire ropes can be analysed using a specialized fatigue test setup, as discussed in studies [3,4,5,11,12], which replicates operational conditions through repeated bending cycles. The steel wire rope fatigue testing system for cyclic bending over sheaves has been specially designed and developed. The setup features a four-bar mechanism [12] powered by a permanent magnet synchronous motor. The primary bar of the mechanism generates an up-and-down motion, causing the steel wire rope to bend over a sheave continuously. To maintain the required tension in the rope, a weight carrier system has been integrated into the setup. Given the prolonged cyclic loading in this system, components within the drive mechanism are also prone to fatigue over time.

One of the bars in the four-bar mechanism is directly coupled with the synchronous motor shaft, making its fatigue resistance a critical factor in the performance of test suit. Additionally, the bar responsible for creating the up-and-down motion experiences the highest range of motion, making it a key component for fatigue and vibration analysis. Evaluating the long-term performance of these components is essential for ensuring the reliability of the entire system. The main aim of this study is to calculate and analyse the forces and stress distributions within the drive mechanism of the test setup under different operating conditions. The findings contribute to optimizing the system's design for improved durability and performance in long-term cyclic loading applications.

Material and Method

The proposed drive mechanism design has been developed to meet the requirements of a steel wire rope fatigue test as shown in Fig. 1. The performance of the four-bar mechanism was analysed through mathematical model generated in Python. The propsed model calculates the linear and rotational speeds, accelerations, and forces acting on the bars. These calculations serve as a basis for validating further design analysis. The Python code takes input parameters such as bar dimensions, motor specifications, pivot points, weight on the carrier mechanism, and the length of the steel wire rope.

In furthermore, Finite Element Analysis (FEA) is performed to simulate dynamic forces acting on the four-bar mechanism components. The analysis is conducted using ANSYS Mechanical software to evaluate stress distribution and deformation under cyclic loading conditions. To ensure the accuracy of the FEA results, they were validated using the mathematical model developed earlier. A comparison of directional forces on the bars helps assess the consistency between the two approaches. By analysing the results, the total deformations and stresses on critical parts are determined, helping to improve the system's durability and performance. The combined use of mathematical modelling and simulation ensures a comprehensive evaluation of the design.

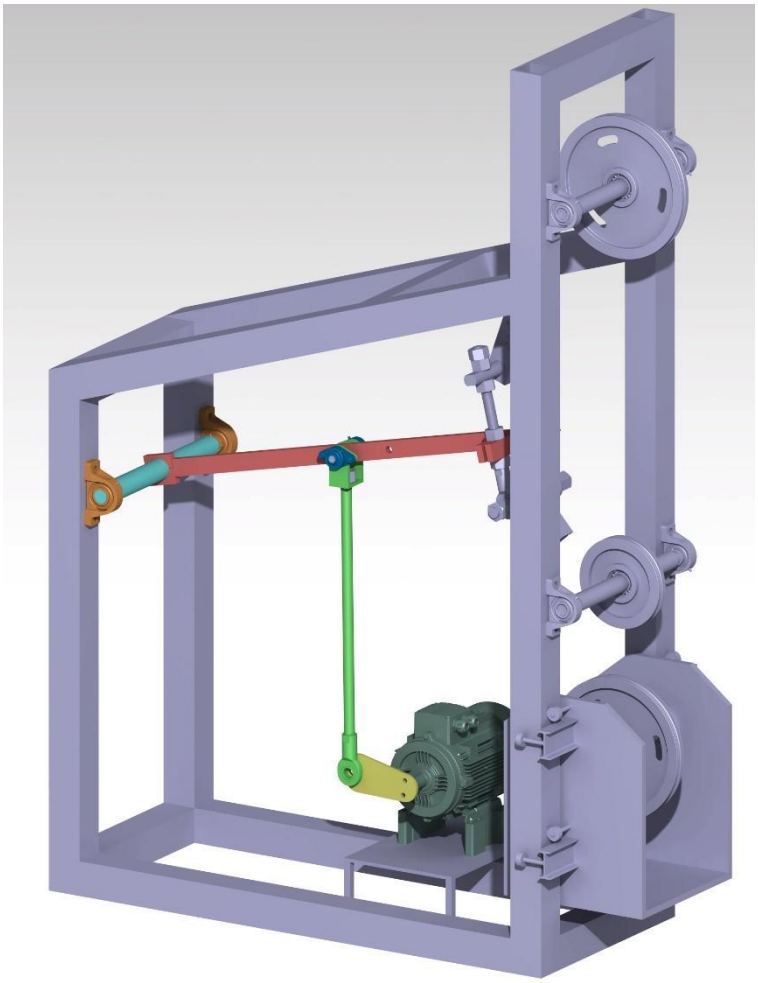

Figure 1. CAD model of the steel wire rope fatigue test setup's four-bar mechanism.

Findings

The four-bar mechanism ensures realistic operating conditions by producing the motion required for the fatigue testing setup for cyclic bending over sheaves. The mechanism's kinematic design allows controlled movement, which makes it easier to perform the cyclic loading required for the fatigue study. By utilizing this mechanism, the system enables the weight carrier to be pulled with variable acceleration, effectively simulating real-world conditions. The mechanism is driven by a permanent magnet synchronous motor, which guarantees accurate and steady action. A short bar that is mechanically connected to a connecting rod is rotated by the motor. The rotating motion is transferred to the primary bar via this rod, which transforms it into oscillatory up-and-down movement at its free end with respect to the ground. In order to enable controlled bending and unbending of the wire rope during the test cycles, the Primary Bar experiences an angular displacement of 32°. This angular displacement also creates a horizontal displacement. In this way the ropes pulled away the axis between the top and bottom sheaves, resulting in lifting the weight carrier. Fig. 2 shows the four-bar mechanism's schematic representation, highlighting the functional connections between its parts and how each one contributes to the intended movement pattern [13]. In Fig. 2, X and Y coordinates of the fixed points are, A (0,800) and B (780,0), in millimetres. The Connecting Rod is 920 mm, Crank is 170 mm. Primary Bar's length |AC| is 615 mm and |CE| is 580 mm.

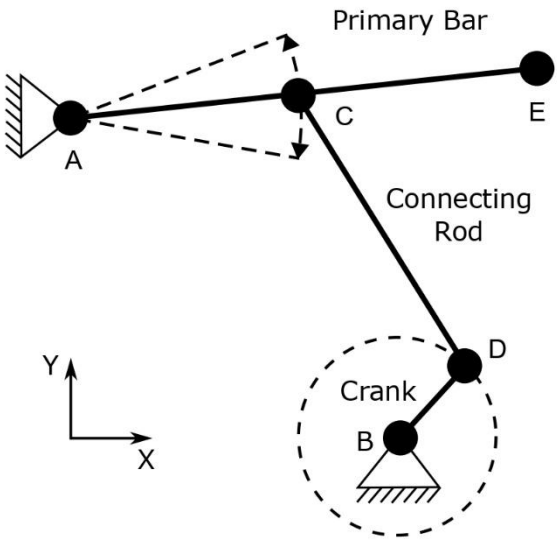

Figure 2. Four-bar mechanism schematic for the steel wire rope fatigue test setup.

Conclusion

This study successfully validates the design and functionality of the test setup for bending-over-sheave (BoS) fatigue testing. The proposed mechanism effectively replicates real-world operating conditions by incorporating a four-bar system that enables controlled cyclic loading on the steel wire rope. The design considerations ensure that the system can accommodate different test parameters, providing flexibility for various experimental conditions. In addition to the validation of the design, the dynamic analysis of the system will be conducted by comparing the results with analytical calculations performed using Python-based calculations. This step help refine the model and improve its accuracy in predicting real-world fatigue behaviour. In further studies, fatigue analysis will be carried out to evaluate the long-term durability of the fatigue testing setup under continuous loading. By integrating computational validation, this research contributes to the advancement of fatigue testing setup designs, providing valuable insights for future studies and industrial applications involving steel wire ropes and load-bearing structures. Dynamic analysis will be validated by comparing with the outputs from the mathematical model generated in Python. Then the results of the analysis can be utilized in the further studies. In the further studies fatigue analysis and developing different test mechanisms including variation of four-bar or similar mechanisms will be done.

Aim

Power transformers and shunt reactors are indispensable components of electrical power system, playing a critical role in energy transmission and distribution networks. They are essential for minimizing energy losses, ensuring voltage regulation, and enhancing system stability. However, for these electrical machines to operate efficiently and have a long service life, several factors must be carefully considered during their design and manufacturing process. Some of the variables influencing the service life and performance of power transformers and shunt reactors include vibrations caused by Maxwell forces, Lorentz forces acting on current-carrying windings, and magnetostriction forces in electrical steel [1,4]. Additionally, the vibration and noise adversely affect human health and comfort, resulting from the increasing demand for electrical power, particularly in urban regions, has necessitated new high-capacity substations nearby to residential areas. This may lead to neighboring inhabitants experiencing uncomfortable noise levels [2,3].

The core, consisting of yokes, main limbs and vertical return flux limbs significantly influences the dynamic performance of power transformers and shunt reactors. The core is made of stacked silicon steel laminations, secured and tightened with bolts, together with continuous glass fiber reinforced polyesterimide resin composites (Polyglass) or polyethylene terephthalate (PET) bands to attain a specific lamination pressure to ensure its structural stability. Non-linear contact rigidity between laminations leads to complex dynamic behavior. Thus, it is important to understand the clamping performance of the components which ensure the structural integrity of the core.

Currently, the majority of research on power transformers and shunt reactors core vibration mostly concentrates on the magnetostrictive properties of materials, noise sources, vibration transfer paths etc. No specific investigations have been published on the evaluation of clamping components performance on lamination pressure and the influence of them on dynamic properties of power transformers and shunt reactors. Polyglass offer distinctive mechanical properties and used as an important core clamping component. Therefore, this study is extensively focus on to examine its influence.

One of the performance criteria expected from clamping elements is to be able to provide the desired clamping force continuously. Since the creep phenomenon is unavoidable in viscoelastic materials such as Polyglass, the creep performance of this material should be examined. Therefore, the creep properties of the Polyglass material were examined in accordance with the application practice. Moreover, a combination of experimental and numerical methodology was employed to determine the influence of lamination pressure, which was ensured by Polyglass. Experimental Modal Analysis (EMA) was conducted on a yoke mock-up to evaluate the non-linear contact stiffness between laminations. The data were subsequently employed in the modal analysis of the mock-up to examine the impact of core lamination pressure.

Material and Method

Test samples were prepared using Von Roll Polyglas® P30 B-stage banding tape, which is composed of parallel glass strands that have been pre-impregnated with a thermosetting polyesterimide resin.

The creep test samples were made from 50mm wide x 0.3mm thick tape. Each band had four turns of the Polyglass, with two in parallel, and therefore each sample composed of 8 layers in total. A pair of steel buckle clamp pins were used to tension each band assembly. The curing procedure was conducted under a complete vacuum. The

specimen was subjected to a temperature of 120 °C, with a heating rate of 0.8 °C per minute. The process involved a waiting period of 14 hours at a temperature of 120 °C. Subsequently, the temperature was reduced to 60°C at a cooling rate of 1.2°C per minute. Creep tests were conducted with the Instron 5982 universal testing machine and temperature-controlled chamber depicted in Figure 1. The tests were performed with 3 samples. To conduct the creep tests, the samples were initially maintained at room temperature for one hour after a displacement equivalent to 2000N was achieved at a constant crosshead speed of 0.5 mm. The chamber temperature was increased to 120°C, and the total time required for heating and sample conditioning was three hours. The chamber was subsequently cooled to ambient temperature, a process that lasted for 30 minutes. A constant force was maintained while measuring the corresponding elongation.

Figure 1. Positioning of the creep test specimen between the grips.

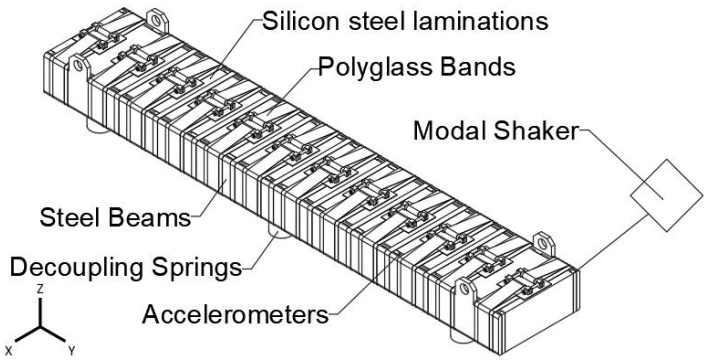

Figure 2. Mock-up with a modal testing setup.

Figure 2 illustrates the EMA, which contains the modal shaker equipment. The mock-up dimensions were 150 mm in height, 358 mm in width, and 2000 mm in length, with silicon steel laminations measuring 0.3 mm in thickness. The laminations were secured between nonmagnetic steel beams and fiberglass insulation using Polyglass. In modal analysis experiments, the bands were initially positioned to exert 1 MPa on the laminations, and this lamination pressure was subsequently reduced by incrementally cutting the bands to assess the impact of varying lamination pressures. A modal shaker was employed to stimulate the mock-up at an angle of 45° using sine sweep excitation ranging from 30 Hz to 1000 Hz. The mock-up was mounted to six decoupling springs to replicate free-free boundary conditions. Subsequently, initial hammer impacts were applied to the structure to verify that the supporting springs and the mock-up behaviors remained non-interactive. Thirty triaxial accelerometers were placed and structural responses recorded. The EMA was conducted for three lamination pressures: 1 MPa, 0.5 MPa, and 0.15 MPa. Eigenfrequencies, mode shapes, and structural damping ratios were quantified for each evaluated design.

Findings

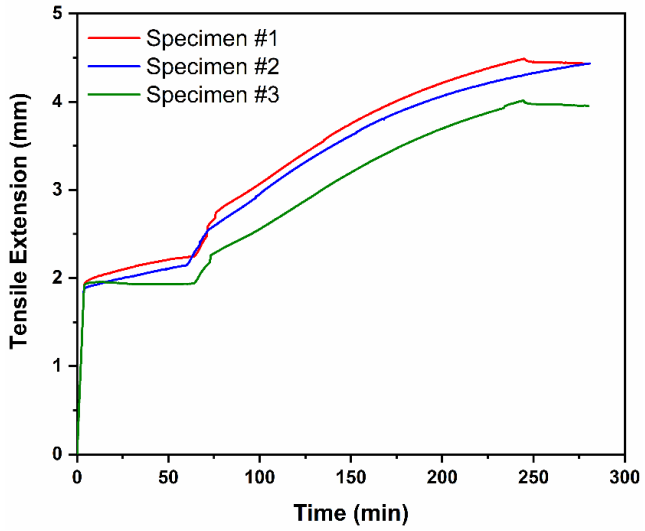

Figure 3. Creep test results for a constant force vs elongation.

The short-term creep results for a constant force was maintained while measuring the corresponding elongation, as shown in Figure 3. Examining Figure 3, elongation of about 2 mm was observed after applying the load, which remained constant. It was observed that after the 60th minute, when the temperature began to rise, there was a additional increase in elongation, which reached 4 mm after 3 hours.

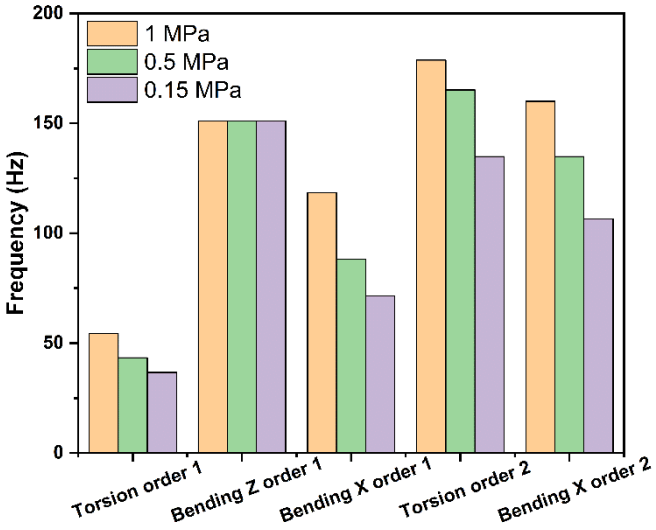

Figure 4. Modal frequency dependency with respect to core lamination pressure.

Figure 4. demonstrates the modal frequency dependency with respect to core lamination pressure. A distinct trend is observed for torsion mode orders 1 and 2, as well as for bending modes in the horizontal (X, Y) direction order 1 and 2. Modal frequencies decline when core lamination pressure drops. It is concluded that the friction among laminations significantly influences the dynamic behavior of the laminated structure in these modes. However, no alteration was seen in the first bending mode in the vertical (Z) direction, independent of lamination pressure. The initial bending mode is unaffected by the friction between laminations, thereby functioning as a homogeneous vibrating system only dictated by mass and elastic characteristics.

Conclusion

The creep behavior of Polyglass bands used in electrical transformer cores was experimentally examined to evaluate their structural response and explore the effects of the creep phenomena. Experimental results led to the following observations:

- After the forming and curing process of the Polyglass band, load loss due to heat effects are prominent and needs to be considered. Review of manufacturing process stages and retightening of Polyglass bands is recommended after the drying process of the power transformer or shunt reactor active part.

- The friction among laminations significantly influences the dynamic behavior of the laminated structure. The examination revealed that torsion orders 1 and 2, as well as horizontal bending modes 1 and 2, are affected by lamination friction. The modal frequency diminishes with a decrease in lamination pressure. But lamination friction exhibited no effect on the vertical bending modes.

Keywords: Deep Reinforcement Learning, Flight Control, Intelligent Control, Nonlinear Control.

Aim

The primary goal of this study is to develop a mission-oriented flight control system for the F-16 aircraft, utilizing the Deep Reinforcement Learning (DRL) approach, specifically the Deep Deterministic Policy Gradient (DDPG) algorithm, to autonomously track commanded altitude and attitude parameters. The primary objective is to explore the applicability of DRL methodologies in military aviation, where executing high-precision tactical maneuvers is critical. The research focuses on how a reinforcement learning-based controller can effectively manage the complex, nonlinear dynamics inherent in fighter aircraft, ensuring stability and accuracy in altitude and attitude tracking under various operational conditions. Also, one of the objectives of this study is to show the performance of the trained DRL controller in different flight regimes.

Material and Method

The design of the flight control system is based on the DDPG algorithm, a DRL approach that combines the benefits of both value-based and policy-based reinforcement learning. The F-16 aircraft is represented in a simulation environment where the control inputs such as throttle, aileron, and elevator deflections are adjusted to track the commanded altitude and attitudes.

The proposed system utilizes a six-degree-of-freedom (6-DoF) flight dynamics model of the F-16, implemented in MATLAB/Simulink. The DDPG algorithm, an off-policy actor-critic method, is employed to learn a deterministic policy that maps observed states to continuous control actions [6]. This approach is particularly suited for environments with continuous action spaces, such as aircraft flight control systems.

The training process involves simulating various flight scenarios to enable the agent to learn optimal control strategies that minimize tracking errors in altitude and attitude. The reward function is carefully designed to penalize deviations from the desired flight parameters, promoting precise control behavior. The trained agent's performance is evaluated across different flight regimes, demonstrating its capability to maintain stable and accurate control in dynamic and unpredictable conditions. The model is implemented in MATLAB/Simulink environment shown in Figure 1.

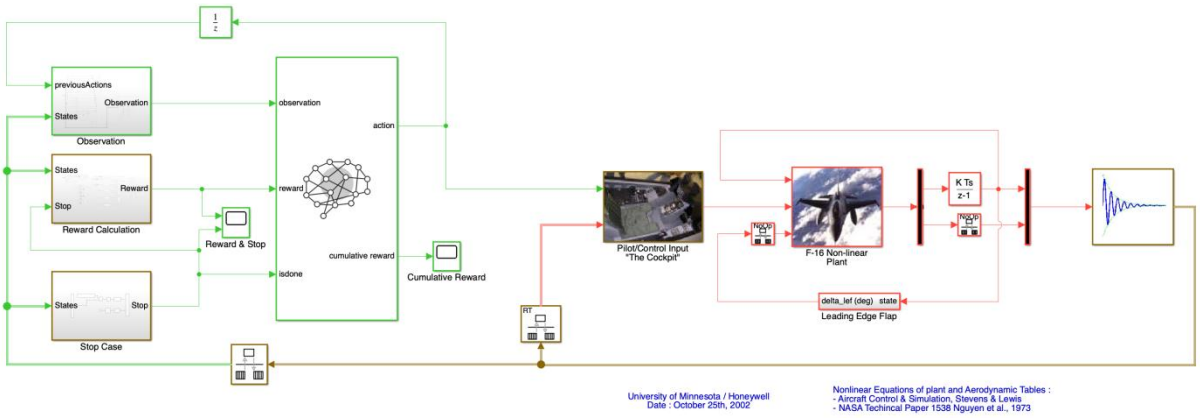

Figure 1. Deep Reinforcement Learning Controller MATLAB/Simulink Model.

Aircraft Dynamics Model

In this study, open-loop F-16 flight dynamics MATLAB/Simulink model which is known as Minnesota University model in the literature is used [3]. This model incorporates aerodynamics, control surface dynamics, and the non-linearities associated with aircraft behavior.

Flight Control System

The F-16 dynamics model is used in order to design Stability Augmentation System (SAS) and then Control Augmentation System (CAS) [5]. This flight control system (FCS) includes in Pitch-Rate (Longitudinal) and Lateral-Directional CAS. All FCS has been modeled on MATLAB/Simulink environment, and then integrated into the open-loop aircraft dynamics model.

Deep Reinforcement Learning Method

In the Deep Deterministic Policy Gradient (DDPG) algorithm, which is one of the DRL techniques, the Actor network is responsible for selecting actions based on the current state, effectively exploring the environment and making decisions. The Critic network, on the other hand, evaluates the chosen actions by estimating their expected long-term rewards, providing feedback to the Actor. This feedback guides the Actor's learning process, enabling it to improve its action selection strategy over time [4].
The DDPG framework operates in an off-policy manner, utilizing experience replay and target networks to stabilize training. The Actor and Critic networks are updated through back-propagation, with the Critic's evaluation influencing the Actor's policy gradient updates. The framework structures and the specific process of the DDPG algorithm are shown in Figure 2. This algorithm is modeled as DRL agent in Simulink model via Reinforcement Learning Toolbox of MATLAB.

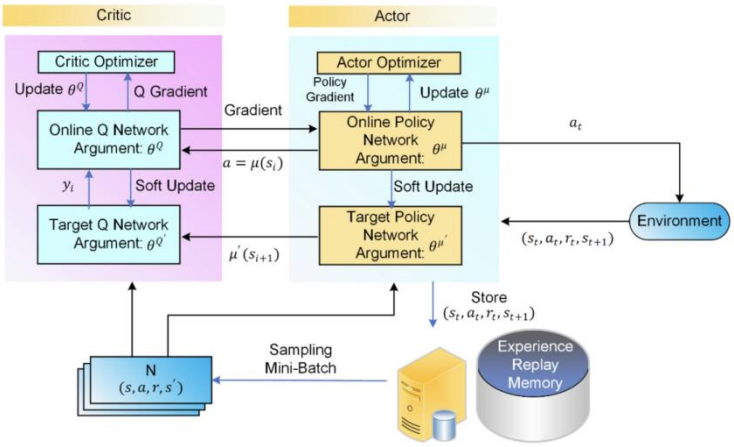

Figure 2. Block Scheme of Deep Deterministic Policy Gradient Method [2].

Reward Function

$$r(x) = \lambda(x - x_{min}) - \sqrt{\lambda^2(x - x_{min})^2 + \tau^2} + \lambda(x_{max} - x) - \sqrt{\lambda^2(x_{max} - x)^2 + \tau^2} \qquad (1)$$

In equation (1), τ and λ are non-negative shape parameters. The reward function employs a hyperbolic penalty function to quantify deviations from desired flight parameters, including altitude, roll angle, pitch angle, heading angle, roll rate, and pitch rate. These parameters have been used to calculate error between desired and current values by implementing as "x" in equation (1). This formulation ensures that the agent is penalized for deviations outside the specified range, promoting precise control. The total reward is the sum of individual rewards for each parameter [1].

Action Vector:

- The agent outputs commands for roll rate and pitch rate to the Flight Control System (FCS).
- Yaw rate is maintained at zero to act as a damper, enhancing stability.
- Throttle control is managed by a Proportional-Integral (PI) controller to maintain a constant true airspeed.

Observation Vector:

- The state vector comprises 16 parameters: Roll rate, pitch rate, yaw rate, roll angle, pitch angle, yaw angle, angle of attack (α), side-slip angle (β), altitude, error terms from the reward function, and previous actions.

This comprehensive observation set enables the agent to assess the aircraft's state and make informed control decisions.

Training Setup and Process

The agent is trained using a F-16 flight dynamics model implemented in MATLAB/Simulink Reinforcement Learning Toolbox. Training occurs over multiple episodes, each lasting 30 seconds, with a simulation time step of 0.2 seconds and a FCS sampling time of 0.01 seconds.
The actor's neural network has 16 observation inputs and 2 outputs. It has 3 hidden layer with 128 neurons. The critic's neural network has 18 inputs. It has 2 input paths. First is observations and the other is actions. These paths are concatenated and occur common path which has 3 hidden layers with 128 neurons.

Initial Conditions:

- Altitude: 25,000 ft
- Roll Angle: 0°
- Pitch Angle: 4.32°
- Heading Angle: Random between -180° and 180°
- True Airspeed: 600 ft/s

Target Conditions:

- Altitude: 22,000 ft
- Roll Angle: 0°
- Pitch Angle: 4.32°
- Heading Angle: 0°
- Roll Rate: 0°/s
- Pitch Rate: 0°/s

The agent learns to adapt its policy to achieve the target conditions, balancing control precision and smoothness. Training parameters, including learning rate, exploration strategy, and reward structure, are fine-tuned to optimize performance.

Findings

The trained agent was used for 2 different cases than training conditions scenario:

1. Start: 14,000 ft altitude and 120 deg heading >> Reach: 15,000 ft altitude and 0 deg heading
2. Start: 8,000 ft altitude and -90 deg heading >> Reach: 4,000 ft altitude and 0 deg heading

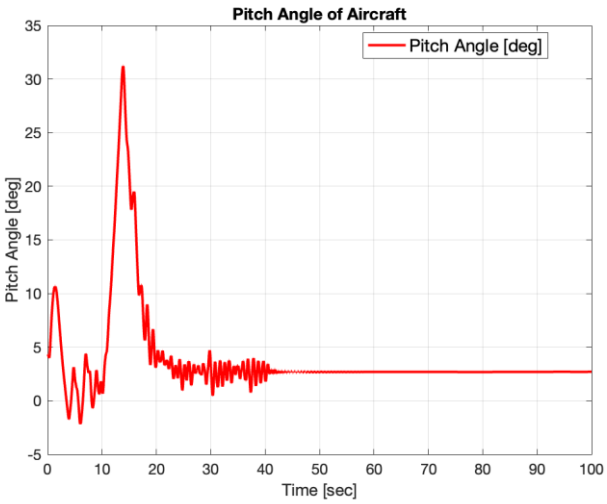

Figure 5. Pitch Angle Tracking for The First Case.

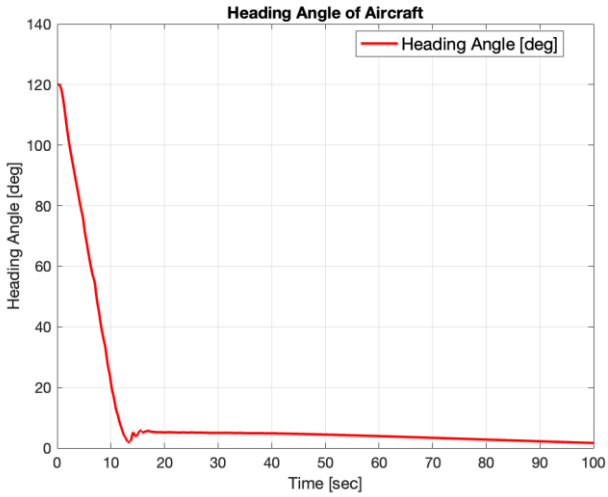

Figure 6. Heading Angle Tracking for The First Case.

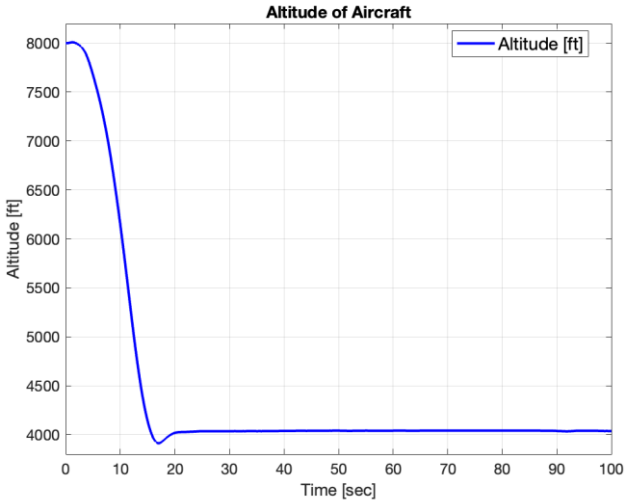

Figure 7. Altitude Tracking for The Second Case.

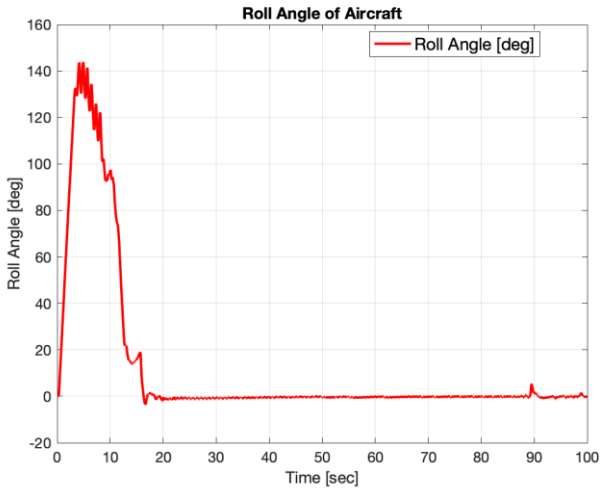

Figure 8. Roll Angle Tracking for The Second Case.

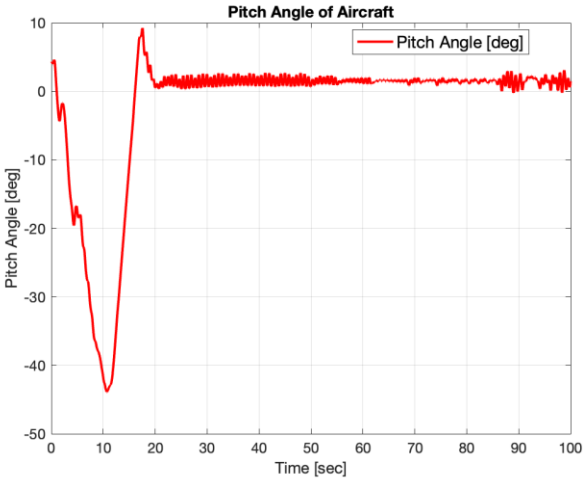

Figure 9. Pitch Angle Tracking for The Second Case.

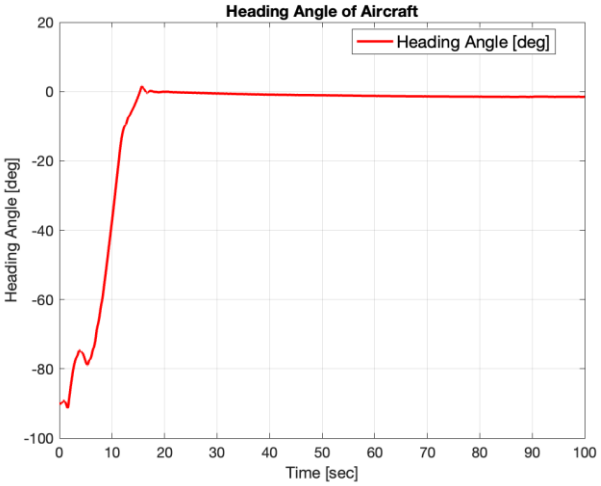

Figure 10. Heading Angle Tracking for The Second Case.

Conclusion

The results from this study demonstrate the potential of applying Deep Reinforcement Learning techniques, specifically the DDPG method, to the design of flight control systems for modern aircraft such as the F-16. The DDPG controller achieved high precision in tracking commanded altitude and heading while maintaining stability and smooth control actions.

The results underscore the potential of DRL methods in enhancing the performance of flight control systems, particularly for complex, high-performance aircraft like the F-16. By leveraging the DDPG algorithm, it is possible to create intelligent control systems that autonomously adapt to changing flight conditions and optimize aircraft performance. One of the future work will be enhancing precision of the responses and reducing the noisy behaviors. Another one of the future work is to focus on extending this approach to other aspects of intelligent flight control, such as implementing fuzzy logic structures into the system to improve learning and training processes.

The Impact of Different Dispersing Agents Used in Ball Milling onto The Electrochemical Performance of Spinel $LiNi_{0.5}Mn_{1.5}O_4$ Cathode Material

Yunus Emre Gul[a], Ozgul Keles[a], Billur Deniz Karahan[a]

[a]Istanbul Technical University, Department of Metallurgical and Materials Engineering, Istanbul, Maslak, 34469, Türkiye
bdkarahan@itu.edu.tr

Keywords: Lithium-Ion Battery, Spinel Lnmo, High Voltage Applications, Ball Milling.

Aim

Lithium ion batteries must meet today's challenging requirements of high energy and power densities, a long cycle life, low toxicity, and affordability. Therefore, new cathode materials must be designed since the cathode active material is a crucial factor in determining the lithium ion cell's overall performance. Among alternatives, spinel type cathode chemistries like lithium nickel manganese oxide ($LiNi_{0.5}Mn_{1.5}O_4$: here after named as 'LNMO') are one of the candidate for the high energy applications. Because, the spinel structure has three-dimensional Li^+ ion diffusion pathways that mitigate and increase the amount of Li^+ ions during charge and discharge. Given that the working voltage of a lithium manganese oxide spinel material is 4.2 V, its operational voltage is raised to 4.7 V by adding nickel to its structure. Recent studies have revealed that not only the chemistry but also the atomic arrangement affect the cycle performance of the spinel LNMO material. Therefore, an optimization is needed to arrange the atoms in LNMO in an ordered or disordered manner [1].

Even though LNMO has a high theoretical energy density, capacity fading has been a general problem due to possible electrolyte oxidation at high potentials, parasitic processes at the electrolyte-cathode interface, and its degradation by Jahn Teller distortion [2,3]. Knowing that accurate dopant element selection may create stronger bonds with oxygen in the lattice, doping has been used to increase the structural stability over cycles. Modifying electrolyte compositions to restrict HF formation has also been studied to enhance the electrochemical performance of LNMO at higher working voltages. Additionally, researchers have looked into coating LNMO surface with a more stable chemistries or adjusting the heat treatment process parameters to change the atoms' orientation, to restrict the capacity fading by reducing side reactions with the electrolyte.

There are numerous ways to create spinel LNMO cathode materials, including solid-state ball milling, spray drying, molten salt synthesis, combustion synthesis, and wet chemistry techniques including sol-gel and co-precipitation. A high-temperature heat treatment is used to modify the atoms' orientation and produce the final spinel structure. Although solid state ball milling is one of the most practical method and it may be used successfully in mass production, its parameters must be carefully adjusted to regulate the particle size distribution of the resulted powder [4].

In this study, spinel LNMO cathode powder is synthesized by typical 'one pot' solid state ball milling. All of the initial raw materials ($Mn(CH_3CO_2)_2.4H_2O$, $Ni(CH_3CO_2)_2.4H_2O$, $LiOH.H_2O$) are introduced to the vial along with dispersing agents i.e. ethanol and citric acid. Based on the structural and morphological investigations, a thorough analysis of the impact of the dispersing agent type on the final powder qualities is conducted. When utilized as cathode active material, the electrochemical performances of these resultant powders (LNMO-ETH and LNMO-CA) are evaluated both galvanostatically and potentiostatically.

The outcomes show that dispersing agent would interfere particle interaction in the vial during the synthesis leading to differentiation in the particle size distribution and the phase purity, which would lead cycle performance eventually.

Material and Method

In this work, two different cathode powders (LNMO-ETH and LNMO-CA) were synthesized by one pot solid state synthesis method where the dispersing agents were selected as ethanol and citric acid. In the synthesis of LNMO-ETH and LNMO-CA, firstly the stoichiometric amount of $Mn(CH_3CO_2)_2.4H_2O$, $Ni(CH_3CO_2)_2.4H_2O$, $LiOH.H_2O$ were added to the vial (Retsch PM100) along with the dispersing agent (10% wt. ethanol and 50% wt. citric acid), then after the ball milling, wet powders were separated from the zirconia balls and dried in vacuum furnace overnight. Then, the dried powder was heated in three steps: to 180°C for 2 hours, to 500°C for 2 hours and to 800°C for 12 hours with a heating rate of 2°C/min.

In both experiments, ball milling parameters were selected as follows: 400 RPM milling speed, 8 hours milling time, 5:1 ball to powder ratio.

For structural characterization and evaluation of atomic ordering in LNMO-ETH and LNMO-CA, XRD (Bruker D2 PHASER) and Raman Analyses (i-Raman Plus 785H that utilizes 785 nm laser source) were realized. SEM (Zeiss Gemini 500) analysis was done to identify the morphology of each powder.

Then, to make a cathode electrode, firstly a slurry made of 80%wt. cathode active material, 10%wt. carbon black and 10%wt. PVDF binder was formed, and Dr Blade method was applied to create a film of 150 micron thickness on aluminum foil. Once the film was vacuum dried, and rolled, then electrodes were punched in 14 mm size. Finally, CR2032 coin cells were produced where the fabricated electrodes were used as a cathode working electrode versus Lithium metal foil, Celgrad 2400 was utilized as separator, and a commercial solution made of 1M $LiPF_6$ salts in EC:DMC (1:1 as volume) was selected as an electrolyte. Once cells were assembled, they were galvanostatically tested at 1C rate between 3V-4.8V (1C = 147 mAh/g), and potentiostatically tested between 3V-4.8V vs Li, in the cyclic voltammetry testing conditions for 4 cycles with 0.1 mV/s scan rates.

Findings

XRD analyses of LNMO-CA and LNMO-ETH reveal that they both display peaks related to the spinel cubic structure with space group Fd$\underline{3}$m (Figure 1). In addition, due to oxygen deficiency in the high temperature calcination above 700°C, both samples have rock-salt impurity phases like NiO and $Li_xNi_{(1-x)}O$ which were noted at 37.5, 43.6 and 63.4 2θ values, with small intensities. A scrutiny look on the peak ratio of $I_{(311)}/I_{(400)}$ shows that LNMO-CA sample has higher ratio, which reveals that LNMO-CA has higher crystallinity compared to LNMO-ETH.

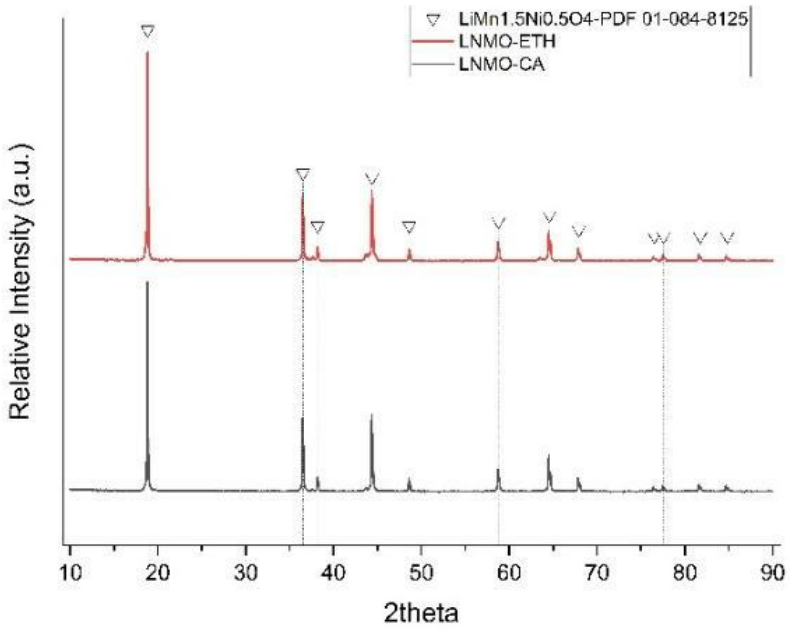

Figure 1. XRD diagram of LNMO-ETH and LNMO-CA.

SEM images taken from both samples, show the agglomeration of powder is less remarkable in LNMO-CA as citric acid forms cation complexes that repel one another electrostatically during ball milling [5]. Both samples have octahedron morphology with variable particle sizes at sub-micron level (Figures 2a-d).

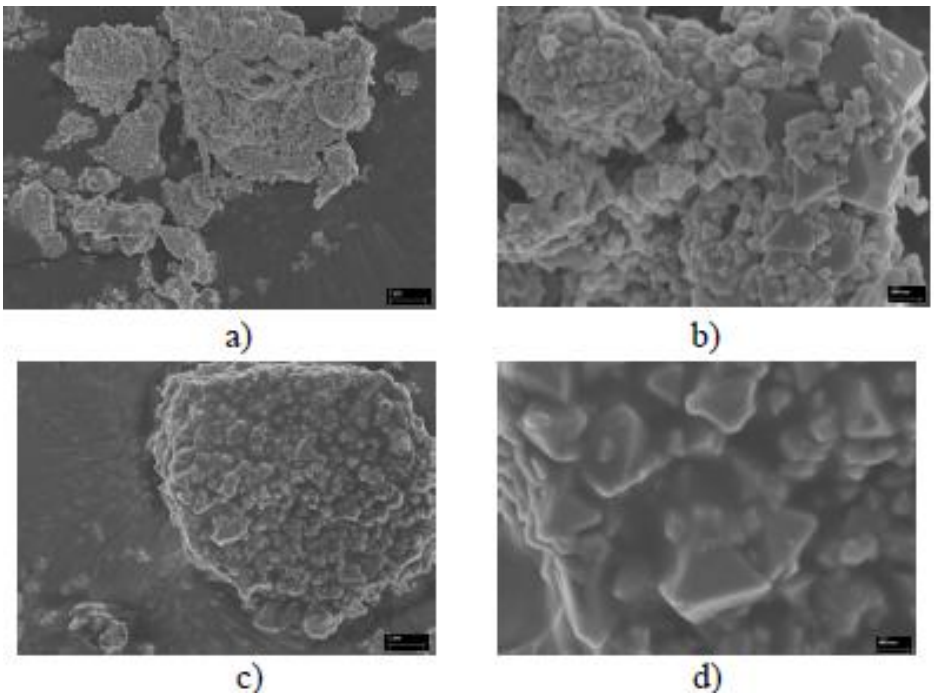

Figure 2. SEM images of LNMO-CA (a,b) and LNMO-ETH (c,d) at 5kX and 20kX magnifications.

In Raman analyses, both samples have shown disordered atomic arrangement as expected by the presence of broaden peeks at 590 and 612 cm^{-1} which is account for vibration of Mn-O_6 bonds (Figure 3) [6].

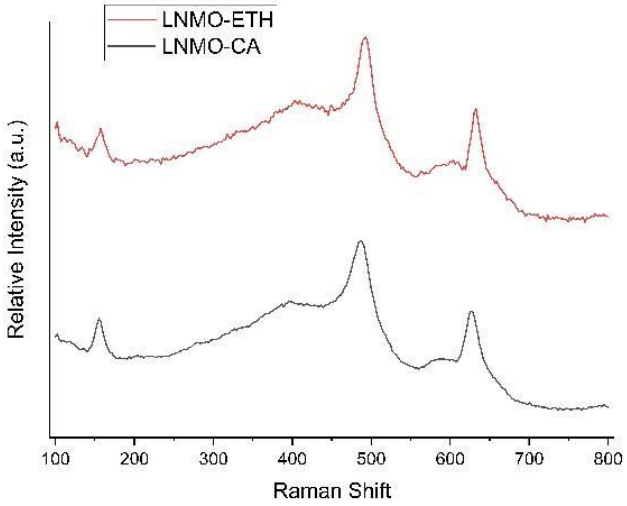

Figure 3. Raman shifts of LNMO-ETH and LNMO-CA.

In the cycling tests of both samples, they reveal low 1st cycle Coulombic efficiency due to the unstable cathode electrolyte interface formation. Moreover, the existence of rock salt structure and partial agglomeration in the powder prevent lithium ions to take their places back easily in cycling which causes a progressive capacity degradation. The comparison of the cycle performances of both electrodes (Figures 4a-b) shows that the improved electrode active surface area accessible for Li^+ ion transportation as a result of less agglomerated and smaller particle size is the reason why LNMO-CA offers superior cycle performance even at different C-rates.

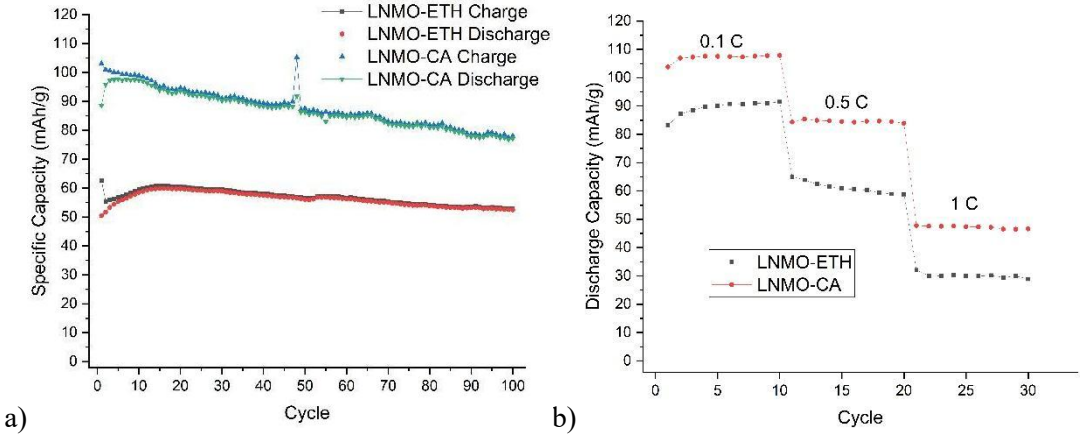

Figure 4. a) Galvanostatic test at 0.1C rate for 100 cycles, b) Rate tests performances.

Then, to study the electrode/electrolyte interface in detail, the potentiostatic test results of both electrodes (LNMO-ETH and LNMO-CA) are analyzed (Figures 5a-b). CV curves clearly demonstrate a lot of similarities, with two redox peaks in the 4.7–4.8 V range and a tiny peak at 4 V. At around 4.7 V and 4.75 V, the two redox peaks indicate the existences of redox couples $Ni^{2+}/Ni^{3+}$and Ni^{3+}/Ni^{4+}. Knowing that the oxidation peak in the Fd3m spinel is separated into two distinct peaks due to the larger voltage difference between the $Ni^{2+}/Ni^{3+}$and Ni^{3+}/Ni^{4+} redox couplings in the nonstoichiometric spinel, both samples have revealed a dominant Fd3m space group atomic arrangement, which is consistent with the Raman results above (Figure 3). Moreover, as the minor redox peak near 4 V is assigned to the Mn^{3+}/Mn^{4+} redox couple, LNMO-CA displays lower peak intensity at about 4 V, indicating lower Mn^{3+} content within the product. When the peak positions and intensities are compared, they are overlapped in LNMO-CA as opposed to LNMO-ETH, where they fluctuate from the 1st to the 4th cycle, indicating an unstable electrode/electrolyte interface formation.

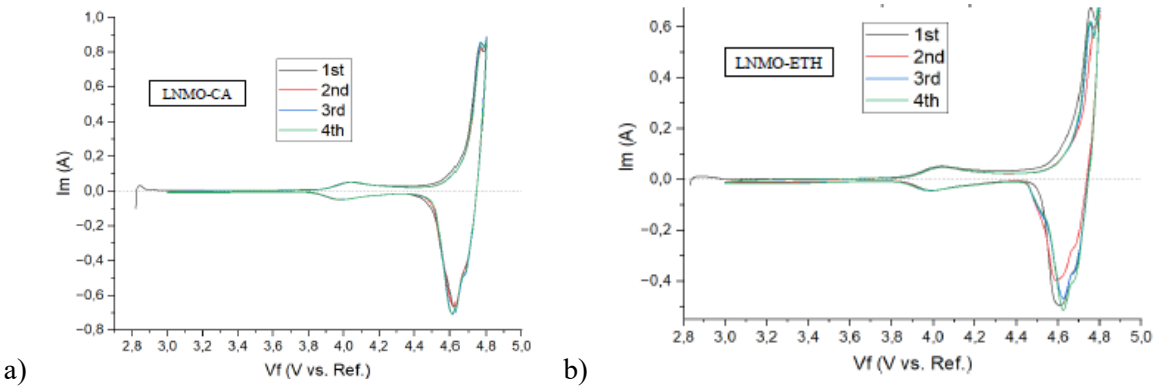

Figure 5. a) Cyclic voltammetry test result of LNMO-CA, b) Cyclic voltammetry test result of LNMO-ETH.

Conclusion

This work fabricates spinel structured LNMO via one pot solid state synthesis. Using citric acid as a dispersant agent in ball milling can form more uniformly distributed submicron sized powders with less agglomeration, which results in better electrochemical performance when used as cathode, even at high C-rates. This is in line with the understanding that controlling the particle size, morphology, and atomic arrangement would perform better cycle performance.

Efficient Leaching of Valuable Metals from NMC Cathodes of Li-Ion Batteries with Green Deep Eutectic Solvents

Gizem Burcu Bilgin[a], Ozgul Keles[a], Billur Deniz Karahan[a]

[a] Istanbul Technical University, Department of Metallurgical and Materials Engineering, Turkiye
bdkarahan@itu.edu.tr

Keywords: Lithium-Ion Battery, Cathode, Leaching, Deep Eutectic Solvent, Recycling.

Aim

The quantity of used batteries and process scrap-electrodes are increased as a result of the growing use of lithium-ion batteries (LIB) in the energy storage industry. The growing need for essential minerals necessitates recycling spent LIBs and process scrap-electrodes. Strategic metals like lithium, nickel, cobalt, and manganese can be recovered, which has benefits for the economy and sustainability. Among alternative recycling methods, deep eutectic solvents (DESs) used in the leaching of metals has shown promising results in terms of high metal recovery rates and low environmental impact. DESs are solvents formed by mixing two or more solids in a certain ratio to obtain a liquid. The melting point of the mixture is lower than the constituents due to hydrogen bond interactions (Abbott et al., 2004). DESs are also biodegradable, reusable and nearly non-toxic (Zhang et al., 2012).

Up to now, various DES combinations have been studied to leach Ni, Mn, Co and Li from NMC cathode. Among alternatives, DES with choline chloride (ChCl) stands forward due to the biocompatibility of ChCl referred to as vitamin B4. However, recent DES experiments with ChCl need higher leaching temperatures or longer leaching times to increase leaching efficiency. Therefore, usability of DESs in milder leaching conditions must be developed to enhance the practical applications of DES in the recovery of valuable metals of cathode active materials.

Previous studies reveal that the choice of DES composition is determined based on the cathode chemistry and structure. $LiNi_xMn_yCo_{1-x-y}O_2$ has a layered structure consisting of lithium, oxygen, and transition metals. Leaching is obtained by destroying the covalent bonds of metal oxides to form a metal(II)-chlorine complexes (Lu et al., 2022). Also, in order to increase the dissolution of metal ions, hydrogen ions are needed to destroy the structure by removing oxygen from it (Luo et al., 2023). Ethylene glyocol (EG) and urea being utilized in previous studies of DES are neutral compounds and need high temperatures for leaching. For high-yield leaching under mild conditions, DES made of ChCl and reducing acids could be a suitable option for metal extraction.

In this study, to form DES, 5-sulfosalicylic acid (SSA) is chosen uniquely for cathode recovery to be used along with ChCl due to its environmentally friendly behaviors (Xu et al., 2021). 5-sulfosalcylic acid (SSA) is a potent organic acid with three functional groups: a carboxyl group, a sulfonic acid group, and a phenolic OH group. Deprotonation, or the separation of protons, will occur in these groups, potentially generating acceptor sites for hydrogen bonding (De Vries et al., 2016). Additionally, it is possible to generate sulfonic acids as hydrogen bond donors (HBD) because of their high metal oxide solubility properties. This results from the presence of protons that function as oxide acceptors and are supplied by the high acidity of sulfonic acids (Liao et al., 2022).

Literature review reveals that the intermolecular interactions between compounds of DES have an impact on the DES properties, thus the molar ratios of DES need to be studied carefully. The optimum molar ratios vary depending on the hydrogen-binding ability of the components (Sazali et al., 2023). A change in the molar ratio can affect the intermolecular hydrogen bond network within DES, altering the ability to complex with metal ions and thus the leaching activity. High hydrogen bond donor (HBD) ratios can increase proton activity, while extreme ratios can inhibit the formation of DES or increase the viscosity, making mass transfer difficult. For example, in a DES system based on ChCl:DL-malic acid:Glycerol, a molar ratio of 1:1:3 was found to keep viscosity in equilibrium while providing high leaching efficiencies (Zheng et al., 2024).

Therefore, in this work, first time in the open literature, DES made of ChCl and SSA is firstly proposed to leach NMC cathode active material. Then, this study will examine the impact of altering the molar ratio in the ChCl:SSA

mixture on the leaching efficiency.After recovery of metals with leaching, oxalate precipitation of Ni, Co and Mn is conducted to exemplify the circular behavior of the process.

Material and Method

The process flowchart used in this work is given in Figure 1. In this research, firstly the process scrap cathodes are heated to 500ºC and 600ºC for 1 hour with 5ºC/min heating rate in air atmosphere to peel off the cathode layer from the aluminum foil, current collector. Then, the recovered black mass' composition, structure and morphology is characterized by means of inductively coupled plasma–mass spectrometry (ICP-MS, X-ray diffraction (XRD; Bruker D2 Phaser) and scanning electron microscopy (SEM, Zeiss Gemini 500) techniques. Then two different mixtures of ChCl:SSA solvent (1:1, 2:3) is prepared (see Table 1) and the effects of leaching temperature (25ºC, 50ºC) and solid/liquid ratio (20g/L, 200g/L) are optimized for each DES mixture. After leaching, Ni, Mn and Co ions are co-precipitated with oxalic acid at pH 2 to form metal oxalates to be used in cathode synthesis.

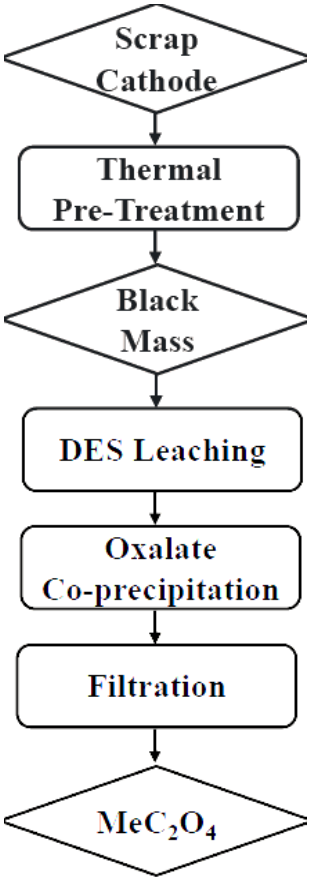

Figure 1. Process flowchart of this study.

Table 1. Leaching experiment parameters.

HBA:HBD	Temperature (ºC)	S/L Ratio (g/L)
1:1	25	20
	50	20
	50	200
2:3	25	20
	50	20
	50	200

Findings

SEM images of cathode powders without thermal pretreatment (Figure 2a-b), pretreatment at 500°C for 1h (Figure 2c-d), and pretreatment at 500°C for 1h followed by 600°C for 1h (Figure 2e-f) are given.

SEM images demonstrate that the average particle size and their spherical morphology of the cathode active material (NMC) are similar for each case, independent on the heat treatment temperature, as expected. The comparison of images shows that heat treatment enables to remove PVDF and carbon black residues while faciling the removal of the black mass from Aluminum foil.

XRD analysis of the black mass (with no Al current collector) after being heat treated at 500°C and 600°C reveals that in each case, no additional peak related to any impurities is detected. XRD patterns of the heat-treated samples show that both samples exhibit well-defined diffraction peaks of the hexagonal structure of α-$NaFeO_2$ with the $R\bar{3}m$ space group. Crystallinity is maintained in both samples with no impurity phases. Diffraction peaks of CAM-600 are slightly weaker than CAM-500 diffraction peaks, which indicates a lower degree of crystallization (Figure 3).Therefore, choosing 500 °C as heat treatment temperature is the best option to lower energy input of the process without compromising material integrity.

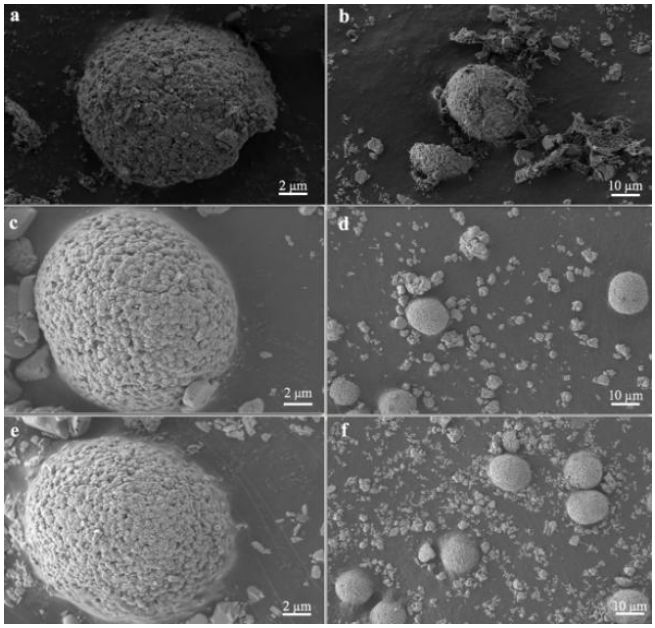

Figure 2. SEM images of cathode powders (a-b) without thermal pretreatment, (c-d) pretreatment at 500°C for 1h: CAM-500 , (e-f) pretreatment at 500°C for 1h followed by 600°C for 1h : CAM-600 .

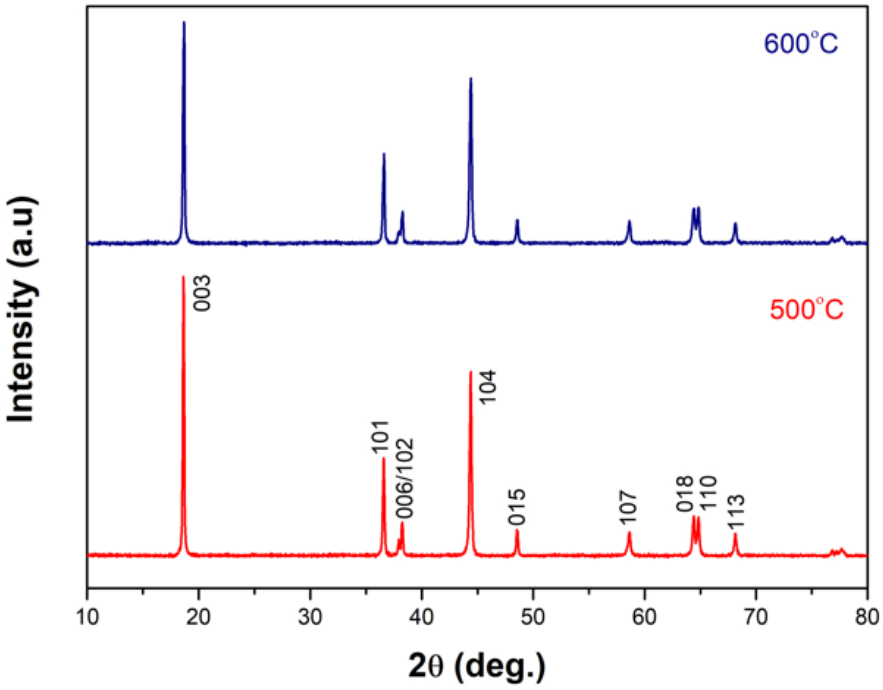

Figure 3. XRD patterns of heat-treated samples.

After peeling off the black mass from the Al foil at 500ºC, ICP-MS analysis is used to obtain the composition of the powder. ICP-MS results from Table 2 indicate that cathode powder stoichiometry is close to NMC811 with exception of a less amount of Mn.

Table 2. ICP-MS results of the black mass.

Sample	Li%	Ni%	Mn%	Co%	Al%
Black Mass	98.25	81.00	5.68	10.89	0.09

Figure 4 shows changes in solution's color after leaching at different conditions, presented in Table 2. DES leaching conducted based on the parameters given in Table 1 indicate that dark, poorly dissolved liquid at 25°C turns clear green at 50°C, indicating a higher metal dissolution. Also, with the increasing S/L ratio it is seen that dissolution remains incomplete and undissolved residues remain in the solution since high S/L ratios lead to slower Ni/Co/Mn dissolution, decreasing overall recovery. Following leaching, with the oxalic-acid precipitation step, targeted ions were effectively removed from solution and converted into an insoluble oxalate product, settled at the bottom of the beaker. The oxalate ion acts as a precipitating agent because of it coordinates with metal ions, such as Ni^{2+}, Co^{2+}, or Mn^{2+}, to form a five-membered ring structure oxalate complex (Choi et. al, 2022). These metal ions precipitate as solids due to their limited solubility. In this precipitation process, due to the solubility of $Li_2C_2O_4$ is much greater than the transition metal oxalate compounds, Li is not precipitated (Sidiq et. al, 2022). The obtained precipitate is suitable for calcination to form oxides for the regeneration of the new cathode material.

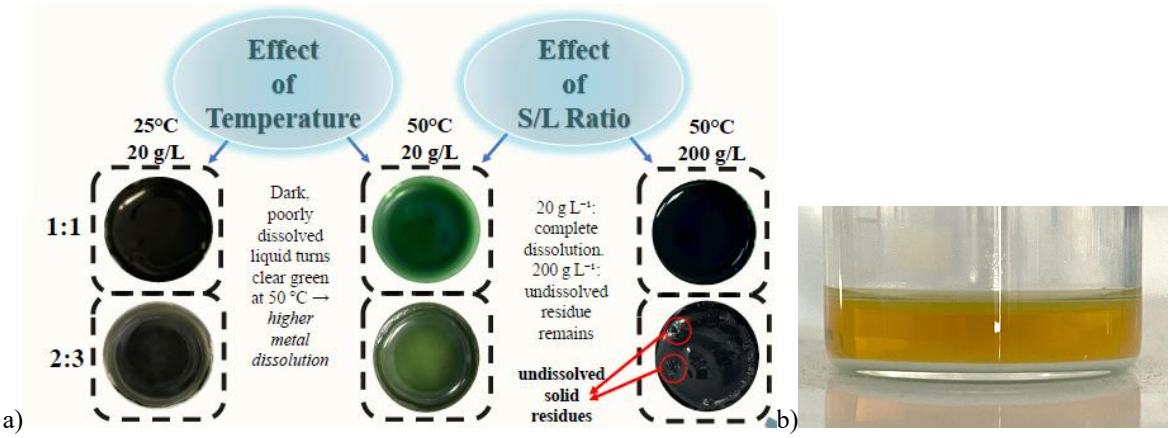

Figure 4. (a) Results of leaching experiments at different parameters (b) Image of the solution and precipitate after oxalic acid precipitation.

Conclusion

In this work, 2 different heat treatments then 6 different leaching experiments are realized to optimize NMC cathode recycling process parameters by DES. Herein first time in the open literature SSA:ChCl mixrture is proposed to be used in NMC leaching. The results show that black cathode layer is peeled off from aluminum current collector when the cathode is heat treated at 500°C for 1 hour at air atmosphere. without destructing the CAM structure. Then the highest efficiency in leaching with SSA:ChCl is achieved with a 1:1 ratio at 50°C and 20 g L^{-1} solid load. The outcomes demonstrate that raising temperature decreases DES viscosity and accelerates diffusion, leading to higher metal dissolution. Higher ChCl in the DES promotes more free Cl^- existence in the solution to form stable M-Cl complexes while keeping viscosity moderate; excess HBD in 2:3 reinforces H-bond network, raising viscosity and slowing mass transfer. Finally, by means of chemical precipitation at pH 2 Ni, Co and Mn are coprecipitated effictively which exemplifies the circularity of the designed process in the synthesis of CAM.

Development of NiCoCrTiAl Alloy's High Temperature Deformation Resistance With Refractory Alloying

Emin Yiğit Taşdelen[a], Cevat Bora Derin[a]

[a]Istanbul Technical University/Graduate School, Metallurgical and Materials Engineering, Materials Engineering, Turkey
tasdelene18@itu.edu.tr

Keywords : Aerospace Materials, Computational Modeling, High-Entropy Alloys, High-Temperature Mechanical Properties.

Aim

The primary aim of this study is to develop a high-entropy NiCoCrTiAl-based alloy with enhanced high-temperature mechanical properties and thermal stability for aerospace applications with additions of refractory metals. By incorporating refractory elements such as W, Nb, and Mo in small molar percentages (1% and 2%), with the helps of their solubility in Ni3(Ti,Al) phase which also can be seen on Figure 1., the objective is to optimize the microstructure, improve high-temperature deformation strength and enhance the overall mechanical performance of the alloy. These refractory elements are deeply discussed in literature whether they are beneficial in aspect of strengthening the material or not, as stated by Grudzień, Loomis, Maniar, Manriquez et al.. This study aims to design and validate an alternative material to traditional nickel-based superalloys, utilizing computational thermodynamics to guide experimental processes, heat treatments, and similar to the main reference work, which is done by Zhang et. al., whose simulation results can be seen on Figure 2. Lastly, the second aim of the study is to increase the solvus temperature of the strength increasing phases such as gamma prime and gamma double prime without too much addition of given refractory metals which can make the material heavier.

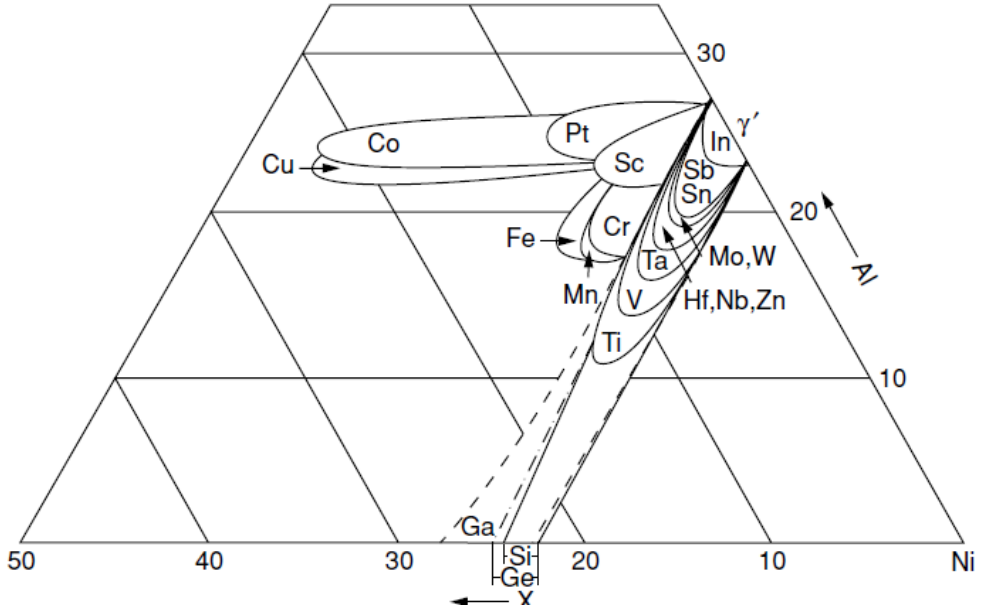

Figure 1. Solubility Values of Different Elements in Gamma Prime Phase

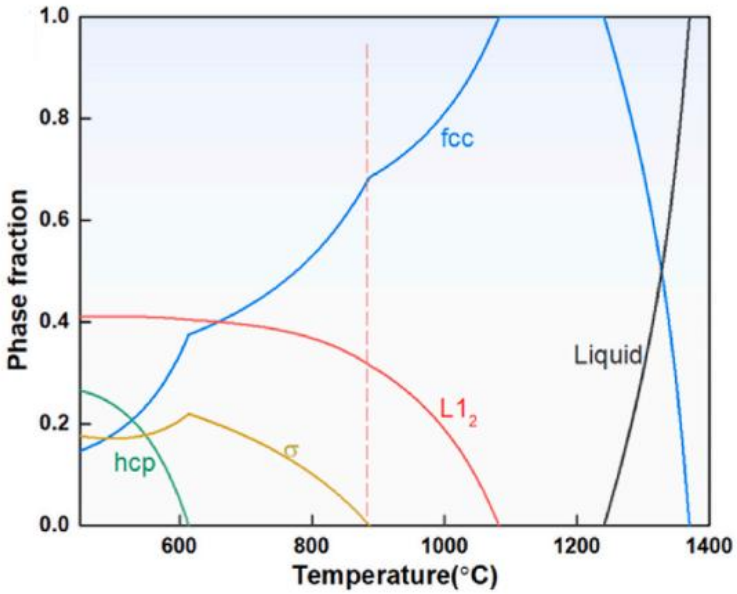

Figure 2. An Example ThermoCalc Modelling For the Given High Entropy Alloy, NiCoCrTiAl
Zhang, H., Meng, H., Meng, F., Tong, Y., Liaw, P. K., Yang, X., ... & Chen, S. (2024). Magnificent tensile strength and ductility synergy in a NiCoCrAlTi high-entropy alloy at elevated temperature. *Journal of Materials Research and Technology*, *28*, 522-532.

Material and Method

The NiCoCrTiAl alloy system with a fixed composition of 33.3Ni-33.3Co-23.4Cr-5Ti-5Al (at. %) will be produced using vacuum arc melting (VAM) to ensure homogeneity and minimize contamination. Small additions of W, Nb, and Mo (1% and 2% molar) will be introduced to analyze their impact on the alloy's microstructure and mechanical properties. Instead of trial-and-error heat treatment optimization, FactSage thermo-chemical software will be used to determine the most effective homogenization and aging parameters, allowing for precise phase stability predictions. Right after obtaining different alloy compositions for each refractory metal added to the high-entropy alloy system, tensile test specimens and ingots that have rectangular cross sections will be cast with the helps of suction casting unit in the vacuum arc remelting device. The most optimized factsage modelling heat treatment conditions which are made up of 2 stages, homogenization and aging, will be experimentally implemented to verify their effectiveness. The characterization process will involve X-ray diffraction (XRD) for the detection of the solid solution matrix gamma and gamma prime phase as a precipitation phase and scanning electron microscopy (SEM) to examine phase distribution, grain morphology, and elemental dispersion. Transmission electron microscopy (TEM) will provide more reliable insights into atomic-scale structural features, while differential scanning calorimetry (DSC) will determine phase transformation behavior and thermal stability of the precipitation and different phases of interest with changing temperature. Mechanical properties will be assessed through tensile, hardness, and wear tests at both room temperatures, along with high-temperature rolling and tensile test experiments to evaluate workability and deformation response at elevated temperatures. Fractography using SEM will be conducted to analyze failure mechanisms and crack propagation patterns after tensile tests which will determine the principle of the failure.

Findings

Expected results include an improvement in high-temperature mechanical properties due to the incorporation of refractory metals, which are anticipated to enhance creep resistance and refine the microstructure due to their lattice distortion and contribution to precipitation of specific phase effects. The computational thermodynamics approach is expected to optimize the gamma prime precipitation process, leading to a more stable microstructure under prolonged exposure to high temperatures and to prevent over-aging, homogenization stages so that poor mechanical properties and high-cost heat treatment procedures will not be involved. The characterization studies

will provide detailed insights into phase evolution and strengthening mechanisms, helping identify the most effective alloy composition for potential industrial application. Mechanical testing will reveal the alloy's ability to withstand operational stresses and deformation experiments will determine its feasibility for industrial-scale manufacture which has a possibility to be proved from the Figure 3. in the main reference article[6]. Consequently, alloy design with its advanced operation conditions will be experimentally calculated and interpreted if they are compatible with real-life results so that more precise and accurate works will be performed in further metallic alloying studies.

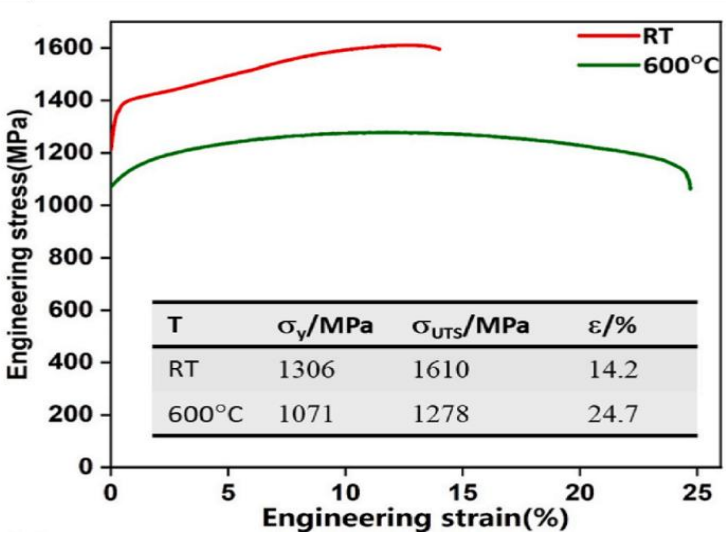

Figure 3. Tensile Test Result of NiCoCrTiAl Alloy Performed at Room and High Temperature

Zhang, H., Meng, H., Meng, F., Tong, Y., Liaw, P. K., Yang, X., ... & Chen, S. (2024). Magnificent tensile strength and ductility synergy in a NiCoCrAlTi high-entropy alloy at elevated temperature. *Journal of Materials Research and Technology*, *28*, 522-532.

Conclusion

This study aims to establish a new class of high-entropy nickel-based superalloys that can serve as a viable alternative to conventional aerospace materials in aspect of high-temperature strength, long-life usability and lower cost. The integration of computational modeling with experimental validation will provide a systematic approach to alloy development, reducing energy waste by helping the estimation of the homogenization and aging conditions in heat treatment procedure as well as improving process efficiency by impeding excessively long heat treatment operations which will eventually decrease the strength of the material at both ambient and high temperatures. By leveraging refractory metal additions, the alloy is expected to exhibit superior thermal stability, improved high-temperature deformation resistance and enhanced other mechanical performance such as hardness, fracture toughness, wear resistance when it is compared with the unalloyed state of the high-entropy alloy. The insights gained will contribute to the broader understanding of high-entropy and nickel or cobalt based alloys' behavior in high temperature environments and lay the foundation for further material optimization and industrial applications in aerospace and other high-temperature engineering sectors where these highly similar alloys systems are continuously developed .

Investigation of the Properties of Micro-Arc Oxidation Coating on Selective Laser Melted AlSi10Mg Alloy

Aysima Güzel[a], Murat Baydoğan[a]

[a]Istanbul Technical University, Department of Metallurgy and Materials Engineering, Türkiye
guzela18@itu.edu.tr

Keywords: Alsi10mg, Selective Laser Melting, Micro-Arc Oxidation, Additive Manufacturing.

Aim

Aluminum and aluminum alloys are widely used in various industries, particularly in the aerospace sector, due to their lightweight nature, high corrosion resistance, and excellent thermal and electrical conductivity. With the advancement of additive manufacturing technology, the production of these alloys has become feasible, making the investigation of the effects of additive manufacturing methods on these alloys a highly intriguing topic for researchers.

Aluminum alloys produced by additive manufacturing generally exhibit relatively lower hardness and wear resistance due to the challenges in precisely controlling their surface properties during the manufacturing process. Surface coating is one of the most used methods to enhance surface quality and improve surface mechanical properties.

Micro-arc oxidation (MAO) is an efficient coating technology used for aluminum alloys. In this method, a ceramic oxide layer is formed on the surface of the alloy. The properties of the resulting layer can be controlled by adjusting the electrical parameters applied during the coating process, such as coating duration and applied voltage. One of the most significant advantages of using Micro Arc Oxidation (MAO) is its ability to reduce the porosity of the substrate material's surface. Relatively more ductile materials produced by the Selective Laser Melting (SLM) process, surface roughness issues such as keyhole defects are highly likely to occur [1]. Therefore, AlSi10Mg alloys produced by SLM are highly suitable materials for the MAO process.

MAO enhances surface quality by forming a homogeneous and less porous oxide layer, which improves the mechanical properties of the material [2]. Additionally, MAO coatings provide high-temperature and corrosion resistance, making AlSi10Mg alloys more useful in aerospace, automotive, and biomedical applications. Thus, MAO is considered a highly suitable surface treatment method for AlSi10Mg alloys produced by SLM.

The MAO coating consists of three distinct layers. The outermost layer is highly porous and brittle, predominantly composed of metastable gamma-alumina (γ-Al_2O_3), which accounts for approximately 5-30% of the total coating thickness. Below this layer, a dense and hard alpha-alumina (α-Al_2O_3) layer forms due to the high-temperature transformation of gamma-alumina into alpha-alumina. This phase constitutes 70-95% of the coating thickness and is responsible for its high wear and corrosion resistance. The interface region between the coating and the substrate can be further divided into three sublayers, where the first sublayer displays an amorphous structure, and the crystallization level increases towards the substrate. These sublayers function as a diffusion barrier, enhancing the material's anti-corrosion properties .

In this study, the properties of the ceramic oxide coating formed under different electrical parameters were investigated. The applied voltage values and duration caused variations in surface roughness, coating thickness, and surface properties of the material. The coating thickness and surface roughness were analyzed. SEM, XRD and optical microscope analyses were done.

Material and Method

The material and method section should be written in Times New Roman font, justified-alignment and in 10-point size. Selective Laser Melting (SLM) method was used to produce AlSi10Mg samples. To better observe the surface

effects, the samples were first sanded with 800, 1200, and 2500-micron sandpapers. After sanding, the surfaces were coated using the Micro-Arc Oxidation (MAO) method.

The MAO method operates with a bipolar power source. While stainless steel was used as the cathode, the samples were placed in the anode. Due to the electrical arcs generated on the surface of the samples immersed in a conductive electrolytic solution, a ceramic-oxide coating layer was formed. A mixer was placed at the bottom of the system to ensure homogeneous mixing of the electrolyte. A cooling system was also used to control the system temperature.

The parameters used to control the properties of the coatings are shown in Table 1. The first four samples were coated in a solution containing 10 g/L $NaAlO_3$, 2 g/L NaOH, and 2 g/L Na_3PO_4, whereas the 5th and 6th samples were coated in a solution with 20 g/L $NaAlO_3$, 2 g/L NaOH, and 2 g/L Na_3PO_4. After the Micro-Arc Oxidation (MAO) process, the surface thickness and roughness of the samples were measured, followed by Scanning Electron Microscopy (SEM) and X-ray Diffraction (XRD) analyses. Subsequently, the samples were sectioned in half, and the cross-sectional area was examined using an optical microscope.

Table 1. Applied Voltage Parameters and Solutions**.**

Sample	Positive Pulse Duration (µs)	Negative Pulse Duration (µs)	Off time (µs)	Positive Voltage (V)	Negative Voltage (V)	Duration (minute)
1	600	1200	400	480	80	3
2	600	900	400	480	80	4
3	600	600	400	480	90	5
4	400	400	600	480	90	5
5	400	400	600	450	100	5
6	400	400	600	450	100	5

Findings

The surface coating thicknesses of the samples were measured as 6, 8, 11, 10, 38, and 37 microns, respectively. Considering the coating thickness, we can conclude that the increase in negative voltage values and voltage duration leads to an increase in coating thickness.

The surface roughness (Ra, Rz) values of the samples were measured before and after the MAO process. The results are presented in Table 2.

In the As-Built samples, the Ra and Rz values appear to be quite low, indicating a relatively smooth surface. Due to the increased surface thickness and the formation of a ceramic coating after the MAO process, the surface became rougher in all samples. The highest surface roughness was observed in Samples 5 and 6. This is likely explained by the fact that the coating was most prominent in these samples.

When examining the SEM surfaces, the presence of micropores on the coating is observed. This phenomenon occurs when the released energy exceeds the dielectric breakdown strength of the substrate material, leading to the formation of an electric arc between the substrate and the coating surface. [4] Consequently, this results in the development of cracks and pancake-like morphology on the coating.

As the coating thickness increases, ceramic particles generated during the process progressively fill the existing pores, thereby reducing porosity. However, this also leads to an increase in surface crack formation. Excessive coating thickness can negatively impact the uniformity of the coating and contribute to an increase in surface roughness.

The examination of the cross-sectional area shows that the coating thickness increases in direct relation to the processing duration and applied voltage. As the coating becomes thicker, surface roughness also increases, leading

to a less uniform surface morphology. This suggests that excessive coating growth may negatively affect surface homogeneity.

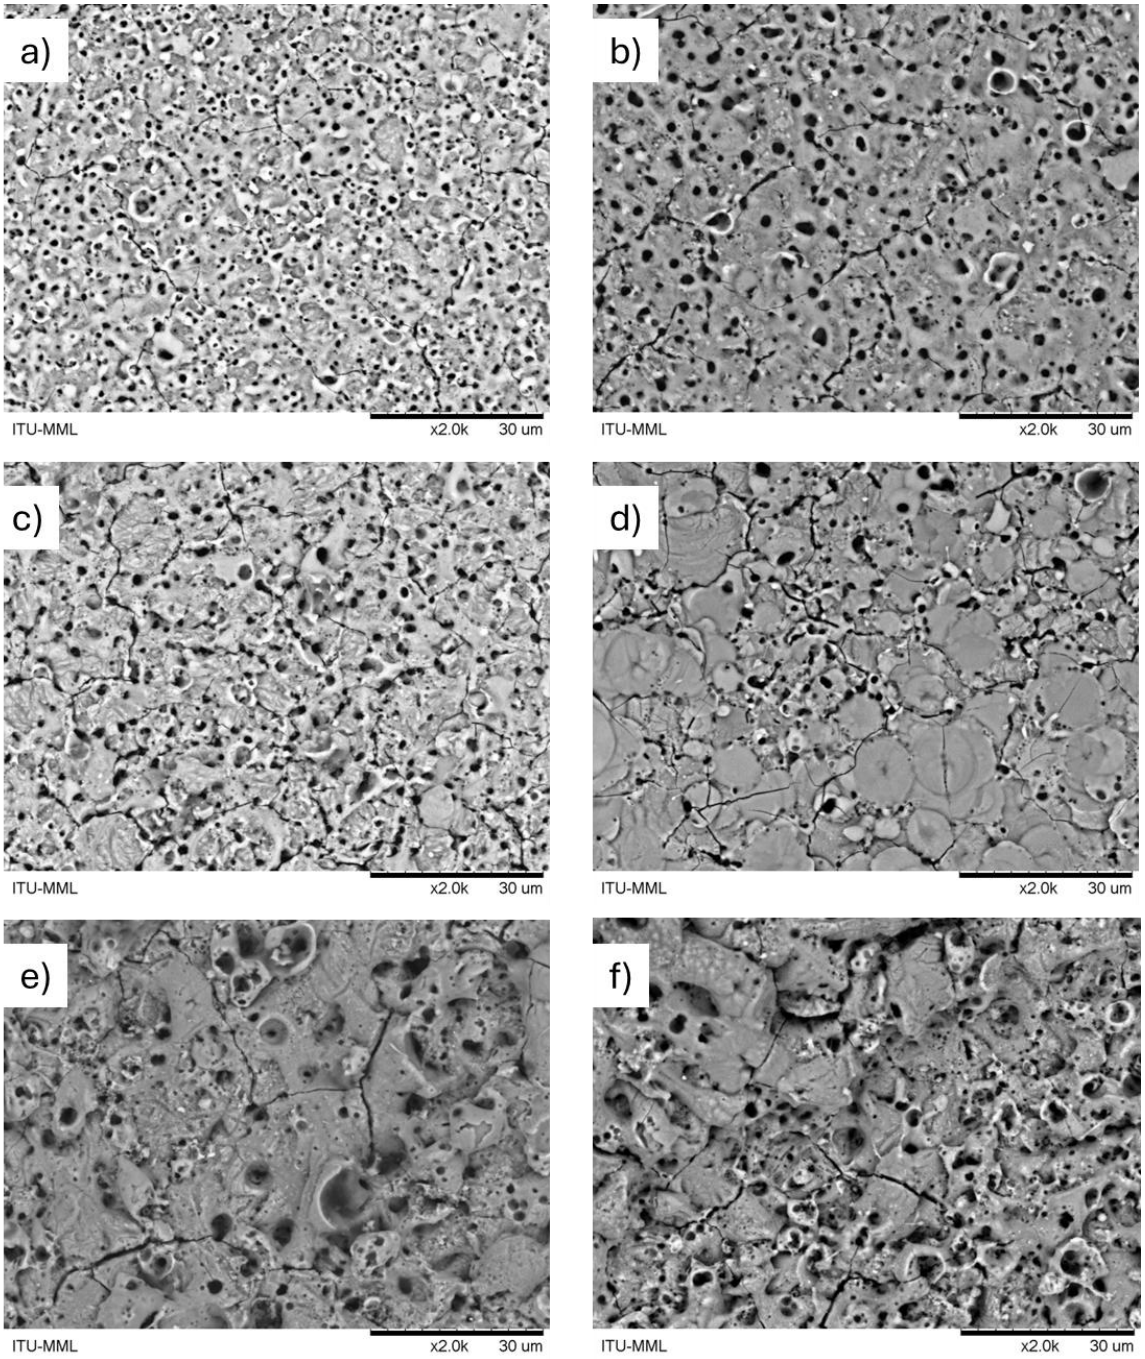

Figure 2. SEM surface images of Samples (a) Sample 1, (b) Sample 2, (c) Sample 3, (d) Sample 4, (e) Sample 5, (f) Sample 6.

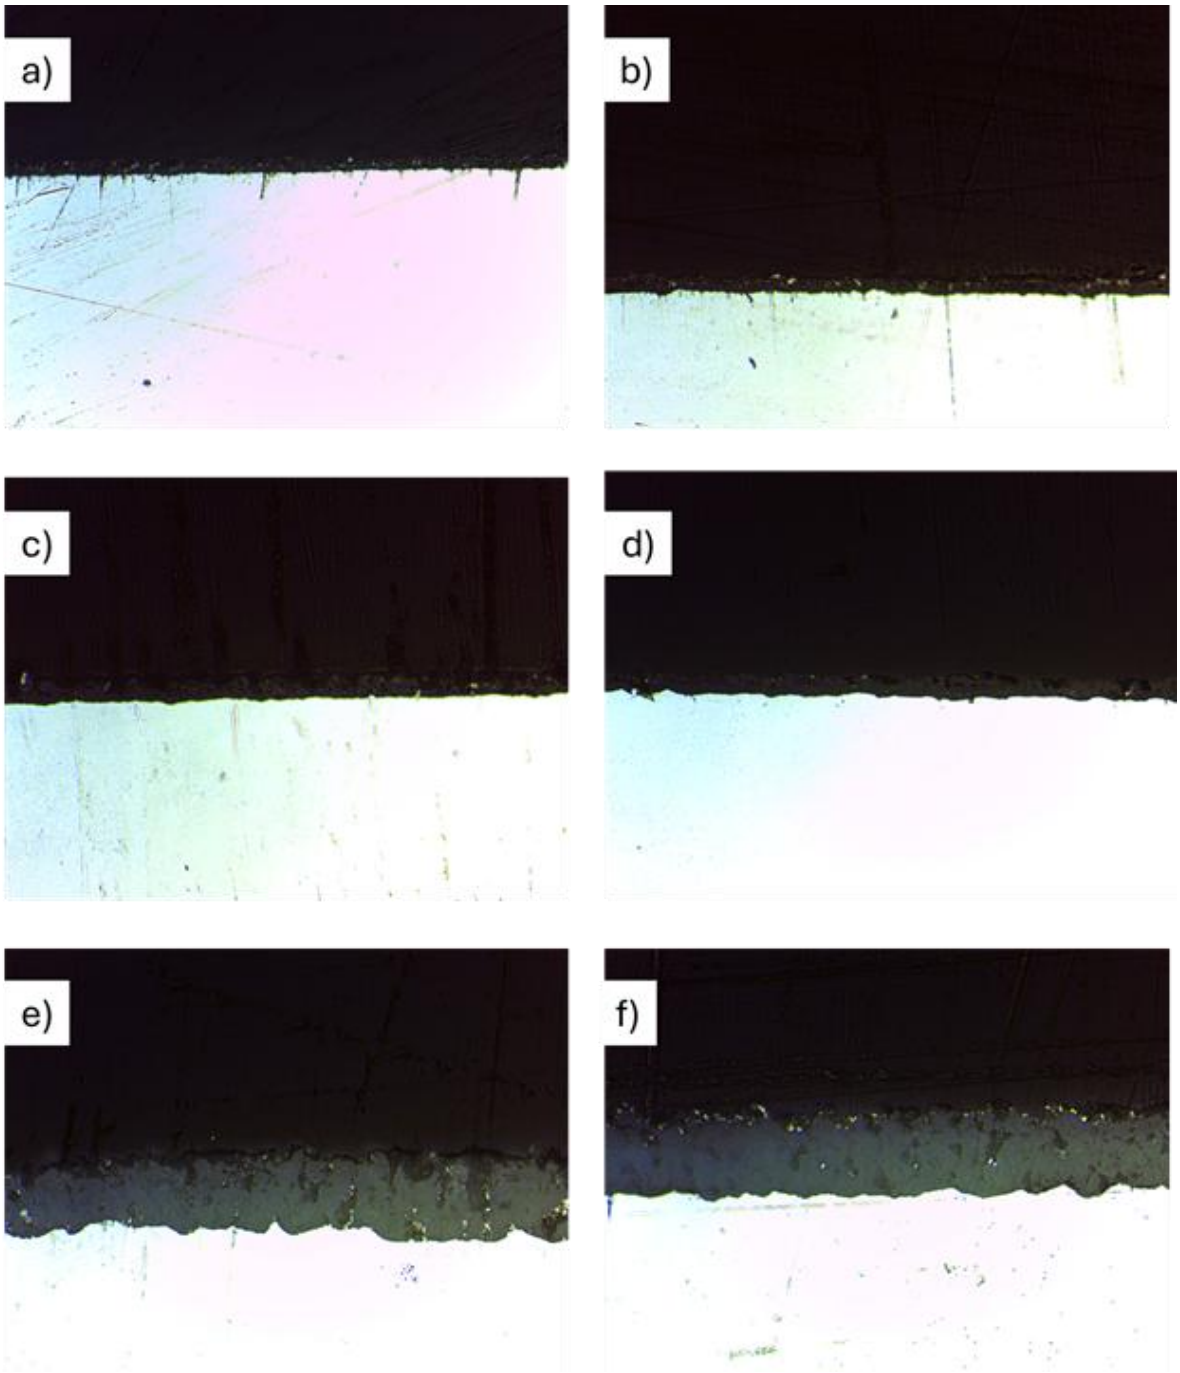

Figure 3. Cross sectional SEM micrographs of the coatings of Samples (a) Sample 1, (b) Sample 2, (c) Sample 3, (d) Sample 4, (e) Sample 5, (f) Sample 6.

The analysis of the XRD results indicates that the Al and Si phases originate from the substrate material. Initially, neither the gamma nor the alpha phases are present; however, these phases emerge as the coating duration increases. In samples 5 and 6, a higher number of peaks corresponding to alpha-alumina and gamma-alumina are observed, suggesting that the $NaAlO_3$ solution positively influences alumina phase formation.

Conclusion

This study demonstrated that micro-arc oxidation (MAO) effectively enhances the surface properties of SLM-produced AlSi10Mg alloys. Increasing the applied voltage duration significantly increased coating thickness. While MAO improved surface durability, it also increased surface roughness, particularly in thicker coatings. SEM

and optical microscope analyses revealed that micropores and cracks, with excessive coating thickness compromising uniformity. XRD analysis indicates that the $NaAlO_3$ solution promotes alumina phase formation and that gamma-alumina and alpha-alumina phases develop more prominently as the coating duration increases. Overall, MAO is a promising surface treatment for AlSi10Mg alloys, but optimizing electrical parameters is essential to balance thickness, porosity, and roughness.

Batman Airport Fog Analysis and The Relationship of Long-Term Fog With Low-Level Jets

Rozerin Koyuncu[a,b], Ali Deniz[a]

[a] İstanbul Technical University, Department of Meteorology, Turkey.
[b] Turkish State Meteorological Service, Batman Airport Meteorology Office, Turkey.
koyuncu15@itu.edu.tr

Keywords : Fog, Metar, Aviation, Low Level Jet, Radiation, Wind.

Aim

This study thesis presents a detailed analysis of fog events observed at Batman Airport between 2010 and 2024 in terms of frequency, duration, and types, and examines the relationship between long-lasting fog events and low-level jets (LLJs), a phenomenon of the atmospheric boundary layer.

Material and Method

In this study, 8,285 observations were evaluated using METAR and SPECI meteorological reports and upper-air radiosonde data. The data were obtained from the Turkish State Meteorological Service (MGM) and the Iowa State University's IEM database.

Findings

A total of 750 foggy days were detected in the 15-year period. The annual average was 50 foggy days. A total of 3829.02 hours of fog occurred. In the 15-year period, prevailing visibility dropped below 1000 meters in 8270 METAR observations. It was detected that fog continued for 24 hours on December 31, 2013, January 1, 2014, December 26, 2014, February 8, 2017 and January 11, 2023 in the 15-year period. The prevailing visibility dropped to 400 meters in 61% of the METAR observations, to 300 meters in 43.63%, to 200 meters in 16.86%, and to 100 meters in 2.28%. Wind directions and speeds of the observations were determined in the 15-year period. The observation frequency of wind blowing from variable directions (VRB) was determined as 29.32%, south-southwest wind (from 180-240 degrees) as 21.15% and north-northeast wind (from 360-060 degrees) as 21.9%. Wind frequency over a 15-year period was determined and in 97.03% of the observations, the wind intensity was between 0-5 knots, and in 2.97% the wind frequency was between 6-10 knots. In 18.4% of the fogs that occurred, pressure values occurred between 1016-1020 hPa, in 47.7% the pressure values occurred between 1021-1025 hPa and in 25.9% the pressure values occurred between 1026-1030 hPa. Fog type was determined according to temperature in the 15-year period by years and months; 67.4% warm fog and 32.6% cold fog were detected. These fogs were classified as radiation fog, cloud base lowering, precipitation fog, advection fog, and unknown fog. It was determined that fog continued for 24 hours on 31 December 2013, 1 January 2014, 26 December 2014, 8 February 2017, and 11 January 2023 within the 15-year period.

Fog classification was made for Batman Airport using the fog classification of Tardif and Rasmussen (2007). These fogs were classified as radiation fog, cloud base lowering, precipitation fog, advection fog and unknown fog. According to their formation types, 52.27% radiation fog, 30.56% cloud base lowering, 2.8% precipitation fog, 3.47% advection fog and 11.07% unknown fog were classified. In addition, fog types and the durations during which they occurred were determined. Radiation fog occurred for 2234.4 hours (%58.35), cloud base lowering for 1170 hours (%30.56), precipitation fog for 140.6 hours (%3.67), advection fog for 95.5 hours (%2.49) and unknown fog for 188.5 hours (%4.92). The dispersion conditions of the fogs differed according to the fog types. Radiation fog generally lost its effect with sunrise, temperature increase and wind. Precipitation fog generally lost its effect with the cessation of rain, decrease in precipitation intensity or change in fog type. The dominant visibility, which decreases with the lowering of the cloud base, lost its effect with the rise of the cloud base. It was observed that radiation fog generally started to form at night.

Low-level jets (LLJs) are wind speed maxima occurring within the boundary layer and can indirectly affect fog formation mechanisms. It was found that LLJs from the southwest transported moisture into fog-prone areas, enhancing fog development and duration, whereas strong northerly LLJs contributed to fog dissipation through turbulence and mixing. In this context, the synoptic analyses of long-duration fog events on January 21, 2013, December 18, 2013, December 28, 2013, and February 8, 2017, were conducted and the effects of LLJs were evaluated with concrete data.

The synoptic analyses identified strong relationships between the direction and altitude of LLJs and fog intensity. Southwesterly jets transported the water vapor required for fog development, increasing its persistence, while strong northerly jets rapidly dissipated fog. Weaker northerly jets could also help maintain fog presence. These findings indicate that LLJs influence not only the formation of fog but also its distribution and duration.

In light of these findings, it is recommended that the effects of LLJs be integrated into operational planning at Batman Airport to enable more accurate forecasting of long-lasting fog events and to prevent disruptions in air traffic. The thesis offers both academic and practical contributions to aviation meteorology, boundary layer meteorology, and synoptic analysis methods.

Conclusion

One of the most important findings of the study is the identification of 751 foggy days over the 15-year period, corresponding to a total duration of 3,834.85 hours. The year with the highest number of foggy days was 2013, while the longest-lasting fog event occurred in 2014. The year with the least fog was 2010. Approximately 75% of fog events occurred during nighttime hours (22:00–06:00 UTC). Winter was by far the season with the most intense fog formation. Fog types were classified as radiation fog, advection fog, low cloud base, precipitation fog, and morning evaporation fog, with radiation fog being the most commonly observed.

Low-level jets (LLJs), which are wind speed maxima within the boundary layer, play an indirect role in fog formation processes. Observations revealed that southwesterly LLJs transported moisture into areas prone to fog, thereby promoting its development and extending its duration. In contrast, strong northerly LLJs contributed to fog dissipation through enhanced turbulence and mixing. In this context, synoptic analyses were carried out for

prolonged fog events on January 21, 2013; December 18, 2013; December 28, 2013; and February 8, 2017, to assess the impacts of LLJs using concrete data.

The synoptic evaluations revealed a strong correlation between the direction and altitude of LLJs and the intensity of fog. Southwesterly jets facilitated the transport of moisture necessary for fog formation, leading to greater persistence, while strong northerly jets dispersed fog more rapidly. Interestingly, weaker northerly jets were also found to contribute to the maintenance of fog under certain conditions. These results demonstrate that LLJs significantly influence not only the initiation of fog but also its spatial extent and duration.

MINERAL PROCESSING ENGINEERING

Critical and Strategic Raw Materials

Industrial Raw Materials

Li Recovery from Clayey Boron Plant Tailings Through Mechanical Activation and Saline Water Leaching

Gülsen Obuz Teker [a], Feridun Boylu [a]

[a] Istanbul Technical University, Faculty of Mines, Mineral Processing Engineering Department, Türkiye
obuz19@itu.edu.tr

Keywords: Mechanical Activation, Lithium Recovery, Salt Leaching, Clay Mineral.

Aim

In this study the recovery of lithium from clayey wastes from Kırka Boron Plant was investigated. As an alternative method proposing selective, economic and environmentally friendly process "mechanical activation followed by saline water" proposed and patented by Tesla was applied on Kırka Boron Plant tailings. Optimizing the mechanical activation and leaching conditions resulted in 60-70 % lithium recovery and 115 ppm lithium concentration in leach solution.

Introduction

The increasing world population, new requirements and technologies developed to meet these, naturally accelerate the studies on the production of new technological raw materials. In particular, the supply or production of these raw materials is extremely important for the economic/technological development of countries. The production of electric vehicle batteries, the production of which has been rapidly increasing in the world and in our country recently, is a very good example of this situation, with minerals such as Lithium, Nickel, Cobalt and Aluminum coming to the forefront as important and critical raw materials. Among these critical minerals, Lithium in particular is of vital importance as an indispensable component/raw material in the production of rechargeable batteries, fuel cells and electronic devices. The interest in electric vehicles in terms of preventing environmental pollution and reducing CO2 emissions and the increasing production of electric vehicles indicate that the demand for lithium resources will potentially increase in the next 10-30 years. For this reason, lithium is included in the critical raw material class for many countries. Lithium is traditionally obtained from salt water (brine), pegmatite lithium mines and sedimentary lithium mines. As a potential lithium source, lithium-containing clay minerals have recently attracted great attention and are of strategic importance to meet lithium demand. There are also lithium-containing resources in our country, and especially the smectite/hectorite clays in Boron wastes appear to have significant potential with their high lithium content. As stated in ETİ Mine reports, the solid waste generated in Kırka Borax facilities within ETİ Mine generally contains lithium-containing clay, marl, calcite and dolomite, and the lithium content varies between 1200-2150 ppm.

Today, direct leaching, chlorination-sulfuration and supported roasting leaching are among the lithium extraction methods from lithium-containing clay minerals. In these conventional methods, high-temperature roasting and acid use are involved, creating significant problems in terms of both economic and environmental impacts. Therefore, it has become essential to develop other alternative methods that are more economical and environmentally friendly.

As stated in the 2020 "Tesla Battery Day" organization, Tesla claims in its patent for the process it developed that lithium-containing clays can be mechanically activated in high-energy mills and the resulting activated powder, referred to as extraction powder, can be selectively taken into solution with high efficiency (70-80%) in hot water (65 °C) with a low-cost agent such as table salt (10% of the clay by weight). Tesla's process is based on the recovery of lithium from lithium-containing clays; (i) taking the lithium between the layers into solution based on the cation exchange principle, (ii) taking the lithium in the cage structure out of the cage using high-energy mills and taking it into solution with mechanical activation (mechano-chemical methods). Although it enables selective lithium recovery with high efficiency without the application of acid and high temperature (roasting), no industrial application of the patent in question or an article confirming the findings has been found in the literature so far. In addition, it has not been stated or presented how the high-energy equipment in the patent in question can be applied

in an industrial sense, what the mechano-chemical activation conditions are, how the possible problems that may be experienced in the discharge of mechano-chemically activated clays from the system will be overcome.
In this study, the applicability of the patent in question to Kırka Boron Plant clayey wastes and the applicability of the Tesla Patented process on this sample were investigated.

Material and Method

The material used in this study is taken from Boron Plant (Penta 4) tailings. The sample was homogenized, dried and crushed down to 2 mm for mechanical activation followed by saline water leaching. The chemical analysis of the used material is given in Table 1.

Table 1. Chemical analysis results of the sample.

Element	Value	Element	Value
Al, %	0.69	Mg, %	10.16
SiO_2, %	16.34	K, %	0.62
Fe, %	0.25	Na, %	2.15
S, %	0.21	Ca, %	11.16
Li, ppm	**900**	**LOI, %**	**34.08**

The mineralogical analysis was carried out through XRD analysis given in Figure 1. XRD analysis illustrated that the tested sample contains dominantly dolomite (>85 %), totally less than 15 % of Illıte, Clinoclor, montmorillonite, clinoptinolite, tincalcoite etc. The existence of dolomite was also highlighted with the Table 1 pointing out the high amounts of Ca and Mg.

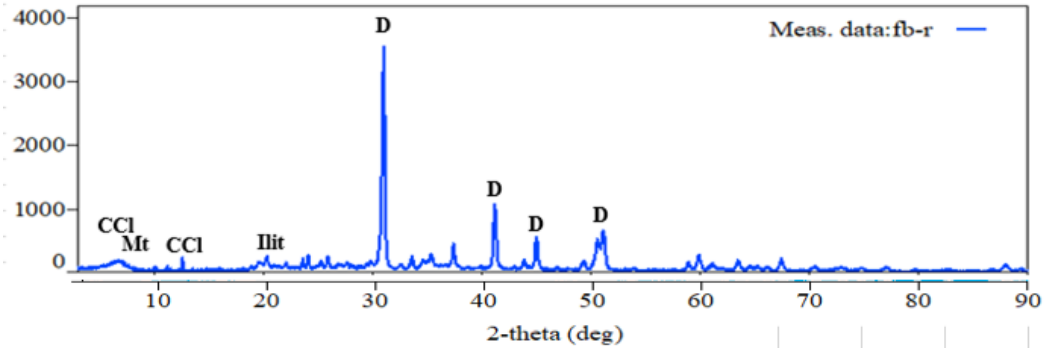

Figure 1. XRD Analysis of Kırka Boron Plant Tailings (Tested Sample) (D: Dolomit, CCI: Clinochlore, Mt: Montmorillonit, Ilit: Illit).

Representative samples in small amounts were used at mechanical activation test through Stirred mill (Fig 2) which is actually an attritor having cell including shaft for mixing and zirconium balls in size of 3 mm.

Figure 2. Stirred Mill used for mechanical activation tests.

The operational parameters for both mechanical activation and leaching process chosen as; Grinding media (ball) volume, cc, Material (Sample) weight, gr, Mechanical activation period, min, Shaft speed, rpm, Salt Addition, %, Leach time, min., Leach Temp., oC and Water/solid ratio.

Findings

In mechanical activation experiments, the grinding conditions were set as a shaft speed of 700 rpm, a liquid/solid ratio of 5, a salt concentration of 10%, a leaching duration of 60 minutes, a leaching temperature of 80°C, and an agitation speed of 520 rpm. In the mechanical activation experiments, the optimum ball amount was found to be 1100 g in a grinding medium ranging between 700 and 1200 g, and the lithium recovery efficiency was 24.00%. As the sample amount decreased, the mechanical activation rate increased, leading to higher lithium recovery efficiencies. When the ground amount was 52 g, the lithium recovery efficiency was 16.94%, whereas it increased to 44.28% when the amount was reduced to 16 g. The effect of the changing grinder shaft speed was observed to increase the recovery efficiency to 51.67% at a rotation speed of 550 rpm. When the grinding duration was 150 minutes, a recovery efficiency of 56.67% was achieved. Figure 3 presents the lithium recoveries (%) and lithium amounts (ppm) obtained with varying activation conditions.

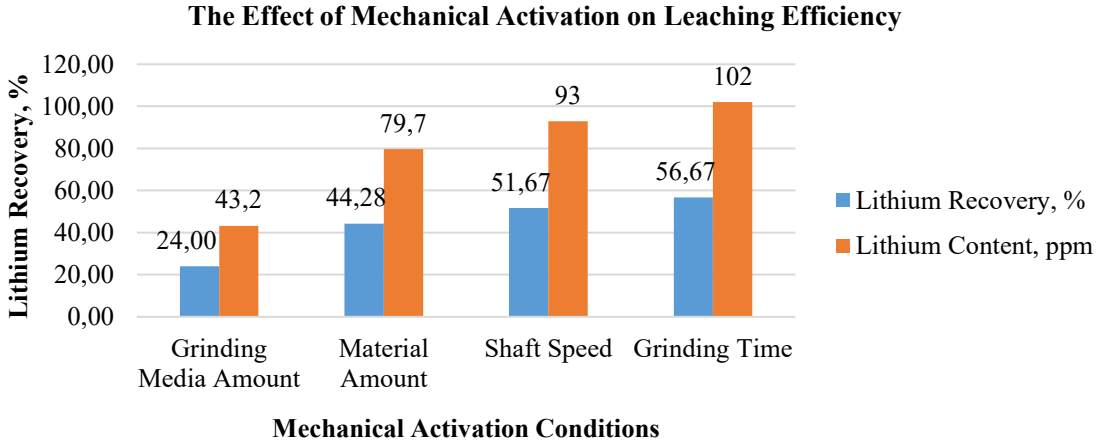

Figure 3. Effects of mechanical activation on lithium recovery.

In mechanical activation experiments, the grinding duration was set to 150 minutes, the grinding medium amount to 1100 g, the shaft speed to 550 rpm, and the sample amount to 16 g. Under these grinding conditions, leaching parameters were studied. The extension of the leaching duration did not have a positive effect on lithium recovery. The values varied approximately between 103 and 109 ppm within a leaching duration range of 5 to 180 minutes, and a 20-minute leaching duration was deemed sufficient, yielding an efficiency of 60.72% with a lithium

concentration of 109.3 ppm. When the temperature ranged between 60 and 80°C, lithium recovery varied between 58% and 61%. At temperatures above and below this range, the efficiency dropped to as low as 44%. The optimum temperature was determined to be 80°C, achieving a recovery efficiency of 60.72%. As the salt concentration increased, the recovery efficiency also improved, reaching 63.67% at a 25% salt concentration. However, when no salt was added to the system, the efficiency was observed to be 54.11%. When the liquid/solid ratio was 100%, the efficiency reached 69.67%. Figure 4 presents the leaching efficiency percentages and lithium ppm contents. Figure 5 illustrates the variation of lithium dissolution efficiency with temperature and time. The highest efficiency was obtained at 50°C, while lower values were observed at 80°C and 25°C.

- At 50°C, lithium recovery started at 59.44%, reaching its maximum at 66.28% at 90 minutes, before slightly decreasing to 60.11%.
- At 80°C, recovery started at 60.22% and remained relatively stable, around 59.78%.
- At 25°C, the initial recovery was 35.67%, increasing over time to 47.33%, before slightly decreasing to 46.22%.

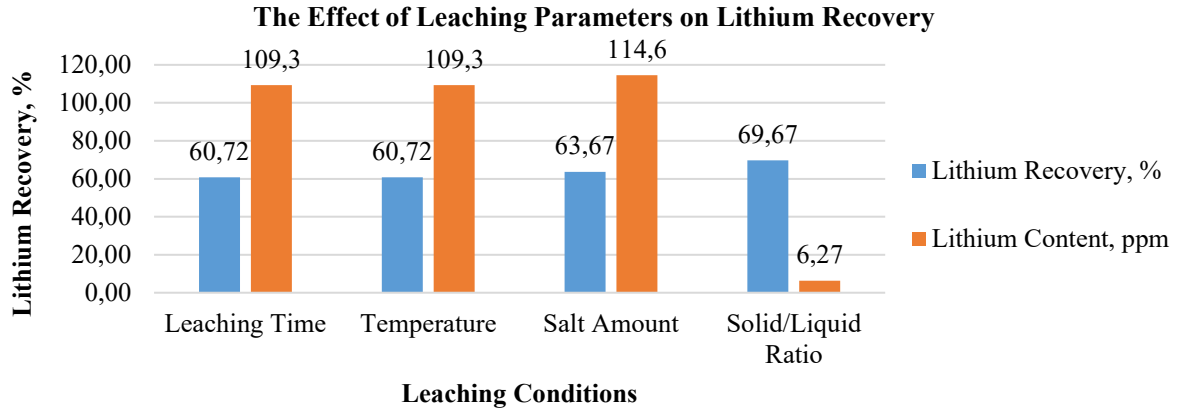

Figure 4. Effects of varying leaching conditions on lithium recovery.

As the leaching time increases, lithium recovery initially rises rapidly, but after a certain point, it reaches a plateau and stabilizes. Although higher temperatures generally enhance reaction rates, the fact that 50°C resulted in the highest efficiency could be related to factors such as solubility equilibrium, re-precipitation, surface passivation, and chemical reaction kinetics. At high temperatures, certain lithium compounds may precipitate instead of remaining in solution, leading to a decrease in efficiency. Additionally, passive layers forming on the surface could hinder further reactions. Furthermore, at 80°C, water evaporation may alter the solution concentration, affecting reaction equilibrium, while the decomposition of some reactive species could further reduce efficiency. Considering these results, 50°C appears to be the optimal temperature for lithium dissolution and effective interaction with the mineral structure. Therefore, chemical equilibrium, surface reactions, and energy efficiency should be considered when selecting the optimum temperature.

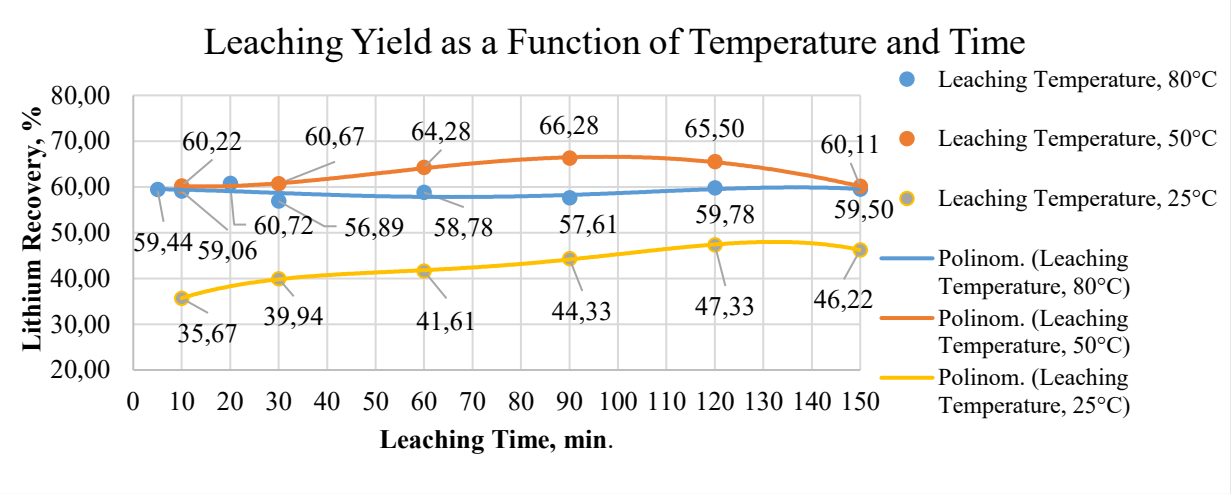

Figure 5. Influence of Temperature on Leaching Kinetics Over Time.

Conclusion

In mechanical activation, the greatest impact was observed with the sample amount and grinding duration. When the sample amount was reduced from 52 g to 16 g, the recovery increased by 27%, while extending the grinding duration from 30 minutes to 150 minutes resulted in a 25% increase in recovery. When the shaft speed was increased from 400 rpm to 700 rpm, the change in recovery was 8%, whereas variations in the grinding medium led to only a 2% difference in recovery.

Among the leaching parameters, salt concentration, temperature, and liquid/solid ratio influenced the leaching kinetics, but the leaching duration had no positive effect. The lithium recovery was 59.44% with a 5-minute leaching time and 60.44% with a 180-minute leaching time. This clearly indicates that with effective mechanical activation, lithium can be easily recovered from the sample in a short time. Another striking result is that due to the presence of dolomite in the sample, lithium can be recovered with approximately 54.11% efficiency without the need for additional salt, thanks to the Mg and Na elements it contains.

Effect of Temperature (Room Temperature-25°C, 50°C, and 80°C) on Leaching Kinetics - Time-Based (from 10 minutes to 150 minutes) has been examined. No significant difference was observed between 50°C and 80°C; however, 50°C yielded more efficient results compared to 80°C. Although an increase in temperature was expected to positively affect the leaching kinetics, the opposite was observed. At 50°C, the recovery reached up to 66%, whereas at 80°C, it could not exceed 66% and only reached a maximum of 60.72%. These results show that temperature increase does not always have a positive effect on solubility and recovery. The optimum temperature at 50°C ensures better dissolution by balancing the reaction rate and preventing surface passivation, providing a more efficient leaching process.

Effect of Particle Size on Obtaining High-Quality Silica by Flotation Method

Yuşa Şahin[a], Gülay Bulut[a]

[a]Istanbul Technical University, Faculty of Mines, Department of Mineral Processing Engineering, Türkiye
sahinyu17@itu.edu.tr

Keywords: Flotation, Impurity, Mineral Processing, Particle Size, Silica Sand.

Aim

This study aims to produce high-quality glass sand using the reverse flotation method in different size ranges with flotation. In addition to the size of the material, the effects of various parameters and methods such as flotation reagents and mechanical scrubbing are also examined in the research. It aims to obtain high-quality silica sand with low iron oxide content and thus reduce the import of silica sand required for areas of use such as solar sand, thus reducing the use of domestic products in the industry and foreign dependency.

Material and Method

In the experimental studies conducted for this thesis, a sample of silica sand from the flotation unit feed of the sand preparation plant was utilized. Following the crushing processes, grinding, and sizing, the material is fed to the flotation unit at the plant. The sieve analysis results of the silica sand sample are presented in Table 1, showing that the portion of the material less than 106 micrometers (µm) constitutes 46.6%. In glass production, a low percentage of the -106 µm particle size is desired because it negatively impacts the furnace operation and increases costs [1]. For instance, in photovoltaic glass production furnaces, the amount of this size should be less than 5%. Therefore, flotation experiments were not conducted on the -106 µm particle size. After sieving the flotation feed sample, which was entirely below 500 microns, flotation test studies were performed on three size groups; (-500+300), (-300+212), and (-212+106) micrometers.

Table 1. Sieve Analysis Results of Silica Sand Sample**.**

Size Fractions	Quantity	Σ Under Screen
(µm)	(%)	(%)
-500+300	7,6	100,0
-300+212	7,6	92,4
-212+150	13,0	84,8
-150+106	25,1	71,7
-106+75	22,0	46,6
-75+53	18,8	24,7
-53+38	4,9	5,8
-38	0,9	0,9
Total	100,0	-

The chemical analysis results for this sample are shown in Table 2. Upon examining these results, it is evident that there is a significant increase in the levels of impurity components such as Al_2O_3, Fe_2O_3, TiO_2, CaO, MgO, Na_2O, and K_2O as the grain size decreases. In the -38 µm size fraction, the impurity levels are as follows: Al_2O_3 1.33%, Fe_2O_3 0.231%, and TiO_2 0.858%. This represents a significant increase compared to coarse size fractions. This trend can be attributed to the finer fractions containing a higher amount of clay minerals, iron oxides, and other impurities.

Table 2. Chemical Analysis Results of Silica Sand Sample.

Size Fractions	SiO_2	Al_2O_3	Fe_2O_3	TiO_2	CaO	MgO	Na_2O	K_2O
(µm)	(%)	(%)	(%)	(%)	(%)	(%)	(%)	(%)
Flotation Feed	99,48	0,30	0,045	0,099	0,01	0,00	0,00	0,07
-500+300	99,20	0,48	0,067	0,095	0,02	0,01	0,00	0,13
-300+212	99,29	0,40	0,073	0,109	0,02	0,01	0,00	0,10
-212+106	99,59	0,22	0,043	0,077	0,01	0,00	0,00	0,06
-106+38	99,54	0,24	0,047	0,097	0,01	0,01	0,00	0,06
-38	96,93	1,33	0,231	0,858	0,13	0,03	0,16	0,33

May apply mechanical scrubbing to the material, to remove the clay minerals found in the fine size fractions [2]. The values for CaO (0.13%), MgO (0.03%), Na_2O (0.16%), and K_2O (0.33%) also peak in the finest fraction, indicating that alkali and alkaline earth oxides tend to accumulate as the grain size decreases. Conversely, in the -500 µm fraction, which was not subjected to the sieving process in the experiments, the levels of Fe_2O_3 are at 0.045%, TiO_2 at 0.099%, and Al_2O_3 at 0.30%. This analysis highlights that to achieve high-purity silica, it is essential to either remove the fine fractions or subject them to purification processes. The increase in iron, titanium, and alkali oxides, in particular, may limit the direct application of the material in glass and solar panel industries. Therefore, flotation or acid leaching processes would be necessary [3].

Literature research predicted that the amount of material and impurities transitioning to fine size would increase by applying mechanical scrubbing processes. Experiments on mechanical scrubbing were conducted in 10, 20, and 30 minutes, and the results of the sieve tests performed on the material are shown in Table 3. Contrary to expectations, the sieve analysis results indicated no transition to fine material.

Table 3. Sieve Analysis Results of Mechanical Scrubbing Applied Material.

Time	10 min	20 min	30 min
Size (µm)	Quantity, %	Quantity, %	Quantity, %
-500+300	8,6	8,1	8,4
-300+212	9,1	10,0	10,0
-212+106	38,1	37,4	37,9
-106+38	42,7	42,7	42,4
-38	1,6	1,9	1,3
Total	100,0	100,0	100,0

Flotation experiments were carried out in the flotation laboratory of the Mineral Processing Engineering Department of Istanbul Technical University, Faculty of Mines. In the experimental studies, the reverse flotation method was utilized to remove iron oxide minerals, such as magnetite and hematite, along with other impurities from silica sand. In the reverse flotation method, iron oxides and other impurities in silica sand are separated using selective reagents. In experiments conducted with different particle sizes, the anionic type collector, which has a

high selectivity to provide a reduction in iron oxide content, was kept constant and the effects of 2 different frothers were investigated. As collector anionic chemical Collector1, Frother1 and Frother2 were used as frothers. In the first experiments, the effect of the parameters was investigated by keeping the number of stages and reagent dosages high to increase the efficiency of the flotation process. The experiments were carried out by adding reactants in 5 stages. A laboratory-type Denver flotation machine was used in the flotation experiments. The machine rotation speed was kept constant at 1150 rpm, the solid ratio in the pulp was 23%, the conditioning time was 5 minutes for the collector, 2 minutes for the frothers, and the flotation time was 2 minutes for each stage. The experiments were carried out in the natural pH range. The obtained products were made using XRF (X-Ray Fluorescence) in the laboratory. Optimization studies were carried out to increase the success of flotation to higher levels in line with the analysis results. Flotation experiments were applied again to optimum conditions.

Findings

In the experiments conducted using Frother2 as a frother, a more selective flotation process was performed compared to the experiments conducted using Frother1, and impurities were collected in the floating product, resulting in both a higher quality product and a higher final product quantity in the sinking product. The images of the products obtained from the experiments conducted at the same size on the microscope are given in Figure 1 and Figure 2. Images A-E are images of products floated using Frother1, and image F is of the sinking final product. In the images of the other experiment, image G is of the floating product using Frother2, and image H is of the sinking product. It was determined that the mechanical scrubbing process also had a no positive effect on the product obtained at the end of the flotation. As a result of the experiments, in studies conducted within the size range of 212-106 microns, the SiO2 content of the obtained material increased to 99.75%, while the Fe2O3 content was reduced to levels of 200 ppm. The high silica content obtained increases the marketable value of the material and makes it suitable for use as a main material in many sectors.

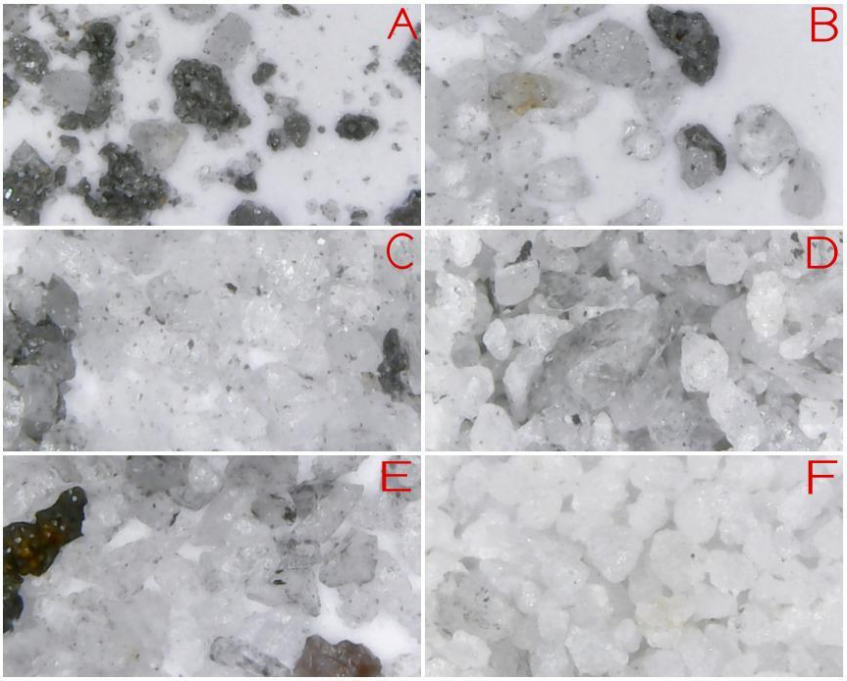

Figure 1. Microscope Image of the Products in the Different stages of the Experiment Performed Using Frother1.

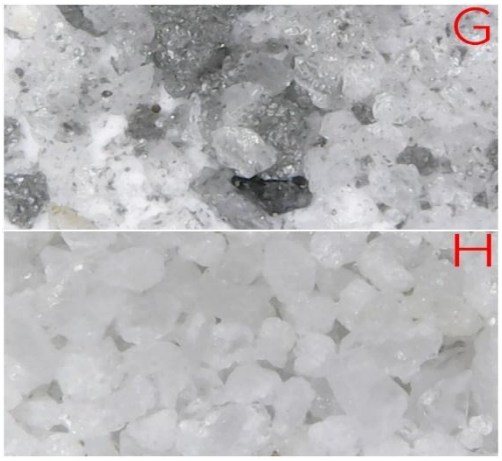

Figure 2. Microscope Image of the Products the Experiment Performed Using Frother2.

Conclusion

As a result, the reverse flotation method stands out as an effective technique for purifying silica sand from impurities and improving quality. This method provides high-purity silica, especially by removing iron oxides and other undesirable components. Thus, its usability in the glass and solar panel industry is increasing.

Keywords: Cells, Deep-learning, Segmentation, Tracking.

Aim

The motility of cells is fundamental for the establishment of organs, the immune system and tissue regeneration [1,2]. Many internal and external factors can affect the pathways that control cell motility. To uncover the regulation of these key elements in detail and their impact on directional changes, state-of-the-art microscopy methods have been applied for high-throughput acquisition of images [3,4]. Despite the recent advances, the lack of automated analysis tools remains as a challenge for the characterization of cell movement [5]. The demand for dynamic programs imposes novel approaches for computing cell tracks and their motility features [6]. While open-source tools are available for the analysis of image data, [7,8] many of the proposed techniques to determine cell paths and lineages are composed of multiple sections. The major weaknesses are the use of various parameters and manual curation, although they are applied to determine the dynamics of cell movement. Additionally, the signal-to-noise ratio (SNR), and confluency of cells lead to a variety of image data. The lack of tuning of these methods reduces the efficiency of the linkage step. There is a need for automated methods to segment cells and find corresponding linkages, thus addressing the current limitations of advanced imaging applications. We introduced the integration of learning-based segmentation with the adaptive tracking [9] and determined the tracking performance for fluorescently labeled cells. This combined approach resulted in improved segmentation efficiency compared to the manual methods based on thresholding/pixel linkage. Moreover, the accuracy of cell association was enhanced when compared to the initial version of the adaptive tracking method. Furthermore, the motility parameters were computed and used to characterize the motility modes of single cells. Briefly, the persistence distribution was computed by using the cell paths obtained by adaptive tracking process. HeLa cells exhibited a random migratory pattern, whereas RPE cells displayed directional movement. In conclusion, the integration of adaptive cell tracking with watershed-based segmentation allowed for the computation of cell tracks and motility parameters.

Material and Method

Preparation of cells and imaging.
For HeLa and RPE cells, they were transfected with GFP plasmid by using FuGENE reagent. They were seeded in tissue culture plates. The epifluorescence imaging was performed on an Olympus inverted microscope. Time-lapse images were captured with 10× air objective.
Segmentation of cells.
We have used a modified version of U-net architecture [10] that is composed of encoder and decoder network sections. All convolution layers use a kernel size of 3x3 with a layer depth from 128 to 16. We used Adam as the optimizer with a learning rate of 0.0005. The annotated images including raw and mask data were prepared and used for the model to learn the output. To increase the variability of annotated image pool, images with different signal-to-noise ratios were inserted into dataset. For the model training, randomly selected 1000 of 256x256 images as a train set. A total of 20 epochs were used in all studies. All codes were implemented through Keras API. To separate the touching cells, watershed method was finally applied to binary images. The centroids and other

features were saved for each cell and transferred as an input for the tracking step. To evaluate the training performance, we used a mean squared error loss function. The cell identity was finally achieved by watershed.

Computation of cell paths with adaptive tracking.

The adaptive tracking method [9] was primarily composed of two sections named node and coupling sections that were used to compute the optimum distance and predict all plausible matches respectively. The workflow of the segmentation and adaptive tracking was shown in Figure 1. Briefly, the lowest distance between cells was determined by computing the Euclidean distance in a given frame. Additionally, the closest distance between cells identified in two consecutive frames was estimated and used to determine the step length. To reduce the mismatch ratio, these values were evaluated to compute the optimum threshold distance. Minimum track length and maximum gap time were 25 and 5 frames respectively.

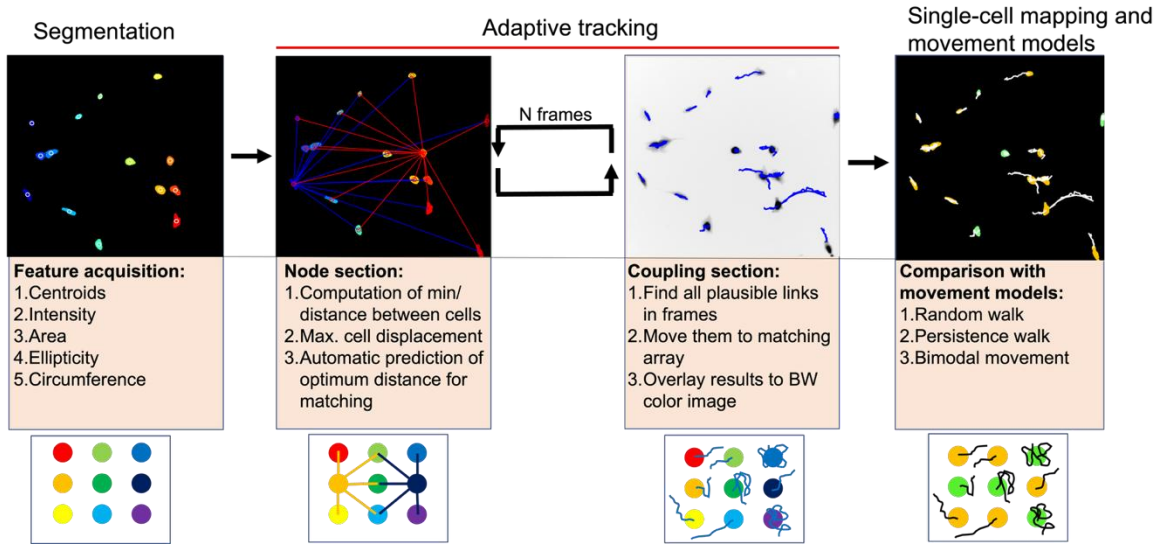

Figure 1. Workflow of adaptive tracking method with CNN based segmentation and characterization of motility dynamics. All raw images were preprocessed before segmentation. The masks of images were prepared for training sample and used to compute the model parameters of U-net. By following the model development, the regions in each image were classified with CNN and later segmented with watershed (First panel). Adaptive tracking modes composed of node and coupling sections were used to determine the optimum matching distance and used to find the cell path (second and third panel). After the trajectories are imported to analysis section, the movement pattern of cells was determined by using the persistence distribution and angular changes of cells.

Computation of persistence.

The descriptors of cell motility such as total displacement, persistence, angular changes were computed and used to determine movement characteristics of each cell type. The module present in adaptive tracking can also overlay each property to the computed trajectories. After reconstructing the cell tracks, the centroids were used to determine the average speed that was computed by the ratio of total distance to elapsed time. The persistence ratio was measured by dividing the ratio of line distance to total cumulative displacement.

Findings

Segmentation with deep learning and comparison with nPixel method

We have used two data sets that demonstrate the HeLa and RPE cells (Fig. 2A). To remove the pixel noise, each video was initially convoluted by using a band-pass filter before segmentation (Fig. 2B). Then, the data sets were separately processed either pixel-based method or U-net-based methods, where the cell and other attributes centroid positions were finally computed. The deep learning with watershed method yielded higher separation efficiency for cells whose boundaries were overlapping. As compared to nPixel, areas of some touching cells in the videos were clearly identified when the watershed transform was applied at the segmentation step (Fig. 2C and Fig. 2D). When the nPixel method was applied, cells with attached boundaries were not completely separated, a

single cell center rather than two was registered at this section. In the presence of high confluency, learning method yielded increased segmentation scores. To evaluate the segmentation efficiency, the results were compared with those obtained from manually annotated images (Fig. 2E). The Jaccard values were high for all sets of segmented images obtained from both methods (Table 1). Although similar scores were observed for all cell types, low number of undersegmented images were obtained when the learning approach was applied. The centroids of touching cells were correctly labeled before the tracking analysis. The learning-based method scored higher than traditional techniques. The increased ratio of true positive cell count can be attributed to the integration of U-Net with watershed segmentation. As a result, a higher separation efficiency was obtained for the cell borders in most videos.

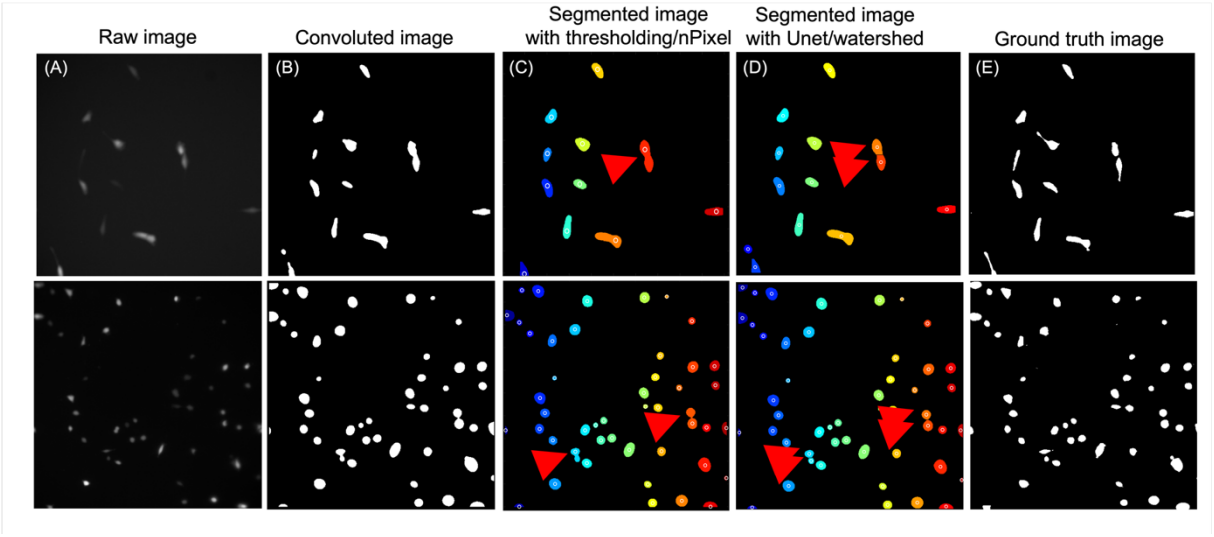

Figure 2. Segmented images for comparison of U-Net like segmentation and pixel linkage methods. Side-by-side comparison of segmentation steps and ground truth images. The representative pictures from left to right represent (A) raw images of RPE and HeLa, (B) convoluted images after background subtraction and band pass filtering, (C) segmentation results obtained from nPixel linkage methods, (D) segmented image with deep-learning/watershed method, (E) manually annotated ground truth images. The color-coded regions represent the total area of each cell. The red arrows indicate the cells whose centroids were correctly labeled when watershed was applied. The cell number was higher for the watershed methods compared to previous method (red arrow).

Table 1. The comparison of thresholding/nPixel linkage and watershed-based segmentation results by using the Jaccard index value. The tracking efficiency is reported in the table.

Name of data set after thresh./Pixel	a. Thresholding with nPixel segmentation	b. DeepLearning segmentation	c. Adaptive tracking	d. Adaptive tracking after DeepLearning segmentation
HeLa	0.7575	0.7732	0.8742	0.9046
RPE	0.8024	0.8195	0.8546	0.8947

The comparison of thresholding/nPixel linkage and watershed-based segmentation results by using the Jaccard index value. Tracking efficiency was reported in the table. A total of 10 video data sets for each cell type were recorded by a live-cell inverted microscope (Olympus IX71). A. The values represent the average Jaccard index values. B. The centroids computed with nPixel or watershed-based method were used for adaptive tracking. C. Tracking efficiency of Adaptive Tracking method. D. Tracking efficiency of Adaptive tracking after Deep-Learning segmentation.

Evaluation of trajectories obtained from adaptive tracking.

The representative trajectories were overlaid over fluorescence images of cells (Fig. 3A). The incomplete trajectories were observed when the areas and centroids obtained from nPixel were used at the tracking section. As described previously, adaptive tracking automatically computes the optimum matching distance for consecutive frames. Threshold distances computed at the node section of the adaptive tracking to match cells were computed

for all cell types (Fig. 3B). The algorithm initially computes the minimum distance between cells (Fig. 3B, black-circles) and maximum displacement (Fig. 3B, black- diamonds). The optimum distance was then determined and used to identify plausible matches of cells in consecutive frames (Fig. 3B, red-square). For most frames, the mean value of adaptive distance was smaller than the minimum distance between cells (Fig. 3B, green-triangle), indicating that the threshold distance was dynamically computed and used to determine the cell trajectories. To evaluate the efficiency, tracked cell ratios compared to total cells were computed by using the centroids and attributes from segmentation section (Fig. 3C). The ratio of tracked to total cells was computed as 0.80 when the centroids from watershed were used at the tracking section. When the centroids from the nPixel method were applied for tracking, the ratio of total tracked cells to all identified cells was computed as 0.71. Total track time was also longer when the centroids from watershed were used at the tracking section. We obtained an average track frame of 38 when the centroids from the watershed were applied at the segmentation section (Fig. 3D). Although we have used a low number of input values, Adtari can correctly determine the cell linkages for most videos.

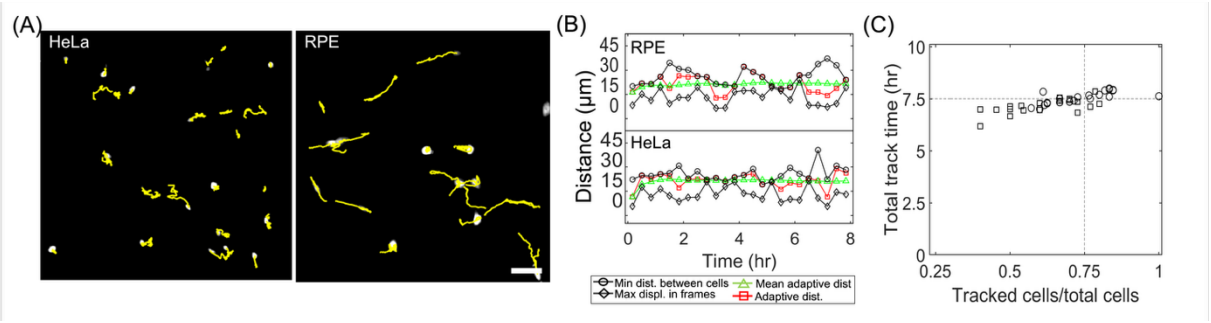

Figure 3. Cell trajectories and evaluation of tracking efficiency. The centroids computed by using nPixel or watershed methods were used to determine the cell paths. (A) Representative cell trajectories of Hela, and RPE and (yellow line). A higher tracking ration was obtained due to the high efficiency of watershed-based segmentation that yields highly accurate centroids. A total of 40 frames were evaluated using both methods. (B) The dynamic computation of threshold distance (red squares) as a function of time. Distance represents the limit of the threshold to determine all plausible matches. Maximum displacement (black diamonds) remained below the threshold distance. The average adaptive distance (green triangles) was lower than the minimum distance between cells (black circles). The overlap of adaptive distance and minimum distance resulted from an increased displacement of cells in frames.

Characterization of RPE, and HeLa cells.

The normalized persistence was computed with an interval of 16 frames for each cell type. The computation of persistence depends on the measurement of centroid positions, however the segmentation methods used to determine cell centers are subject to different errors. Frame rate, distribution of cell intensity, and small displacements between frames affect the accurate estimation of cell centers. Since the tracks can be highly noisy, the total distance was measured at 2-frame intervals. HeLa cells demonstrated low values of persistence ratio (Fig. 4A, left panel), while the RPE cells had high values of persistence, indicating their tendency to move linearly on the substrate (Fig. 4A, right panel). We concluded that these cells demonstrate distinct persistence patterns. To determine peaks and average values of persistence for different states, their distributions were fitted by a single or double Gaussian distribution. The average (Pave) and PL for HeLa cell demonstrating a wide distribution were 0.31 and 0.24 respectively (Fig. 4B). We concluded that HeLa cell movement can be described as random movement. The persistence distribution of RPE cells demonstrates a right-shifted peak with high amplitude and was fitted with the double Gaussian function by using MLE (Fig. 4B). The abundance of a high persistence value (Pave=0.66) with a strong occurrence was an indicator for directional movement for RPE cells. We concluded that both HeLa and RPE cells exhibited different motility patterns, which can therefore be characterized either random or directional.

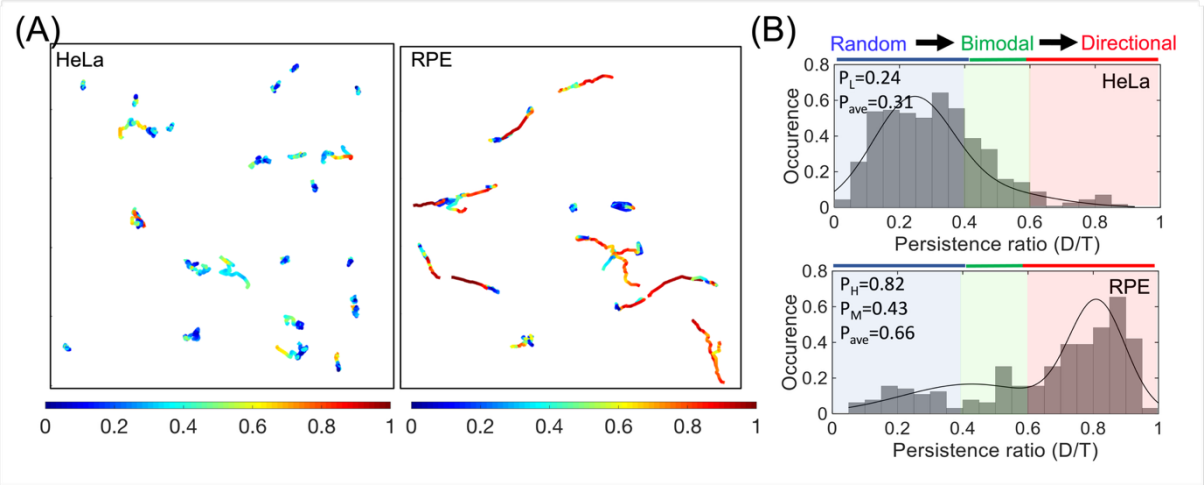

Figure 4. Computation of persistence distribution for different cell types. (A) The collection of representative cell trajectories demonstrating the instant persistence changes for HeLa (left panel), and RPE (right panel). (B) The distribution of persistence was obtained at an interval of 16 frames for HeLa cells (left panel) and RPE cells (right panel). The data was fitted to Gaussian functions (black line) to determine the peak values for different regions. Average persistence (P) values were given for each plot.

Conclusion

As a conclusion, we integrated the adaptive tracking method with CNN-based segmentation. Notably, segmentation errors decreased compared to the previous iteration. We successfully identified the borders of adjacent cells and determined their centroid positions. As a result, our method, which autonomously determines the optimal search radius for identifying potential cell linkages, achieved higher tracking scores across various video datasets. Adtari excels in determining the majority of tracks [5,11–13]. When employing centroids from watershed in the tracking phase, the average tracked time and the ratio of successfully tracked cells to the total were high for different video sets. Our proposed method still has certain limitations, particularly when cell displacement surpasses the minimum distance between cells. These challenges can be addressed either by incorporating more cell features or by modifying the weight of matching parameters.

Vaccinomics to Design Chimeric Vaccine Candidate Against Four *Bordetella* Species

Beyza Uslu[a], Çiğdem Yılmaz Çolak[a]

[a] Istanbul Technical University, Molecular Biology-Genetics & Biotechnology, Türkiye
uslube17@itu.edu.tr

Keywords: Bordetella, Chimeric vaccine, Immunoinformatics, Multi-epitope Vaccine, Vaccinomics.

Aim

Various *Bordetella* species are known to cause respiratory diseases across a range of hosts, affecting both animal and human populations. Besides human pathogens including *B. pertussis* and *B. parapertussis*, animal pathogens such as *B. avium*, *B. hinzii*, *B. bronchiseptica*, and *B. holmesii* have critical importance as they can cause disease in economically important animals and can also be transferred to immunocompromised patients. Using a vaccinomics-based strategy, this study attempts to create a chimeric vaccine that targets conserved antigenic areas across these four species to effectively elicit an immune response.

Members of the *Bordetella* genus are Gram-negative, aerobic coccobacilli that predominantly target the respiratory system.[1] Birds, especially turkeys, are the primary host of *Bordetella avium*, which causes avian bordetellosis, which costs the poultry business money.[2] Because of its great adaptability, *Bordetella bronchiseptica* can infect a variety of species, such as dogs, cats, and pigs, and can linger in the environment. In people with compromised immune systems, it can occasionally result in respiratory infections.[3] Once thought to be a harmless commensal in birds, *Bordetella hinzii* has become an opportunistic pathogen, causing sepsis and bacteremia in immunocompromised people.[4] An emerging pathogen called *Bordetella holmesii* is associated with systemic and respiratory diseases that might be mistaken for pertussis.[5] The virulence, host specificity, and environmental persistence of these *Bordetella* species vary, presenting problems for public health as well as the economy. Their zoonotic potential highlights the necessity of a vaccine to lower the danger of transmission. This work intends to create a chimeric vaccine that can elicit a robust immune response, ultimately assisting in disease control and prevention, by identifying conserved antigenic areas and using a methodical *in silico* methodology.

Material and Method

Proteome Data Retrieval

The complete proteomic datasets of the four *Bordetella* species were downloaded from public repositories such as UniProt and NCBI. In selecting the proteomes, priority was given to sequences from the reference strains of each species to ensure data consistency and reliability.

Sequence Alignment and Homology Analysis

The multiple sequence alignment was performed using Clustal Omega, MEGA, and NCBI BLASTp to identify conserved proteins across the species by aligning entire protein sequences. Four proteins (LolA, LptA, OmpA, and LapB) demonstrating high conservation were marked for further analysis, ensuring the potential for cross-protection.

Subcellular Localization and Transmembrane Domain Analysis

The cellular localization of candidate proteins was determined using the TargetP program. This step was critical as proteins secreted or located on the cell surface are more likely to be immunogenic. The presence of transmembrane domains was evaluated using the TMHMM program. This analysis was performed to determine whether any part of the selected proteins remained intracellular, which could hinder epitope accessibility.

Epitope Prediction and Selection

Both MHC-I and B-cell epitopes were predicted using the IEDB analysis resource. For the MHC epitope predictions, the source species was set to dog to reflect the specific MHC allele data pertinent to the host of interest. Epitopes were selected based on stringent criteria including high binding affinity (evaluated by scoring metrics and percentage rank), robust immunogenicity, and favorable antigenicity. Additional filters, such as toxicity and allergenicity assessments, were applied to eliminate any candidates that might induce adverse reactions.

Multi-Epitope Vaccine Construction and Structural Analysis

The selected epitopes were concatenated to form several multi-epitope vaccine constructs. Various adjuvant sequences, known to enhance immune responses, were appended at the N-terminal of the constructs. Flexible linker sequences were inserted between epitopes to maintain proper folding and optimal epitope presentation. Different configurations were explored to optimize the overall antigenicity and structural integrity of the vaccine construct. The antigenicity scores, solubility, and physicochemical properties of each construct were predicted using VaxiJen, Protein-Sol, and ProtParam servers, respectively, and compared to guide the selection of the most promising candidate.

A three-dimensional structural model of the selected construct was generated using both homology modeling and *ab initio* techniques. The model was then refined using GalaxyRefine server. The ProSA and SAVES tools was used to provide insight into the overall quality of the refined model.

Molecular Docking Analysis

Molecular docking was performed using ClusPro to assess the interaction between the vaccine construct and immune receptors TLR2 and TLR4. The best binding pose was selected based on the lowest energy score. Docking results indicated strong and stable interactions, supporting the potential of the designed construct to activate immune pathways.

Findings

Four conserved proteins, LolA, LptA, OmpA, and LapB were identified across the four *Bordetella* species by looking at multiple sequence alignment results with Clustal Omega and MEGA. After homology analysis, a refined set of epitopes was chosen based on high antigenicity, strong binding affinity, and favorable percentage rank values with IEDB tools. Toxicity and allergenicity filters were applied to ensure immunological safety. 20 selected epitopes were then used to design multiple multi-epitope vaccine constructs with different adjuvant and linker combinations, resulting in 10 different designs. After antigenicity analysis, an about 30-kDa multi-epitope vaccine construct with the highest antigenic profile was obtained. The final vaccine construct was subjected to 3D structural modeling using I-TASSER, generating multiple structural models ranked by confidence scores (C-score, TM-score, and RMSD values). The best model was selected for further refinement. Structural validation was further performed using Ramachandran plot analysis, Ramachandran analysis showed that 92.3% of residues are in the most favored regions, indicating good stereochemical quality. The ProSA tool was used to calculate the Z-score, ensuring that the final selected model was within the range of native proteins and had a realistic 3D conformation. The ProSA Z-score (–2.52) indicates a reliable overall model quality within the range of native protein structures. The physicochemical properties of the vaccine constructs including molecular weight, isoelectric point (pI), instability index, and half-life were evaluated using ProtParam, ensuring the selected construct met the required stability criteria. The physicochemical properties of the vaccine construct including molecular weight, isoelectric point (pI), instability index, and half-life were evaluated using ProtParam, ensuring the selected construct met the required stability criteria. The designed protein is stable (instability index: 39.42), hydrophilic (GRAVY: –0.441), and moderately thermostable (aliphatic index: 49.87). It is suitable for expression in E. coli (half-life >10 h) and shows a high extinction coefficient (14,285 $M^{-1}cm^{-1}$), facilitating purification. After using Cluspro for molecular docking, as seen in figure below, the vaccine construct shows binding interaction with both TLR2 and TLR4.

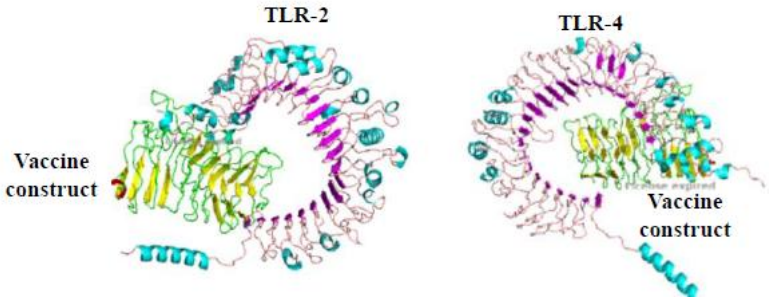

Figure 1. Predicted binding interaction between the vaccine construct and TLR2/TLR4 based on ClusPro docking.

Conclusion

This study presents the computational design of a chimeric multi-epitope vaccine candidate targeting four *Bordetella* species. Immunoinformatics tools were used to select highly immunogenic epitopes while minimizing potential adverse responses. The results indicate promising immunogenic potential. Further validation through in vitro and in vivo studies is needed. Future work may include plasmid-based expression and molecular dynamics simulations to assess structural stability and receptor interactions.

Keywords: *Saccharomyces cerevisiae*, Metabolic Engineering, Evolutionary Engineering, Stress Resistance, Oxidative Stress, Antioxidant, Secondary Metabolites.

Aim

Metabolic engineering involves the improvement of cellular activities by manipulating the enzymatic, transport, and regulatory functions of the cell using recombinant DNA technology (Bailey, 1991). Rational metabolic engineering involves designing a targeted genetic manipulation for the genetic makeup of industrially important microorganisms based on existing knowledge of their metabolic pathways (Bailey, 1999). However, this method faces several limitations. Firstly, extensive biochemical and genetic knowledge of the metabolism or metabolic pathways of the target organism is required. Moreover, cellular responses to interventions are typically complex and unpredictable. For instance, when an existing metabolic pathway is inhibited, cells may activate an alternative metabolic pathway. Consequently, a large number of stimulus-response experiments are necessary to realistically assess the effects of such perturbations. Additionally, the genetic manipulation of industrial strains is considerably challenging due to their complex genetic makeup, such as polyploidy. Furthermore, regulatory issues related to the use of genetically modified organisms in the food industry complicate this process even more. Lastly, the limited availability of suitable vectors and methodologies for genetic modification presents a significant obstacle (Bailey, 1991; Bailey et al., 1996). To overcome all these limitations, a bottom-up approach to metabolic engineering has been developed, called inverse metabolic engineering. This approach begins by first identifying or designing the desired phenotype. The genetic or environmental factors responsible for this phenotype are then identified. Finally, these factors are transferred to the target organism, thereby reproducing the desired phenotype (Bailey et al., 1996). Evolutionary engineering, an inverse metabolic engineering approach, involves the application of continuous cycles of mutation and selection to obtain a desired phenotype in successive generations. Selection pressures may favor the utilization of a particular substrate, the production of a particular product, or resistance to a specific stress factor. Due to its industrial importance, the yeast *Saccharomyces cerevisiae* has been widely used for the improvement and study of stress resistance through evolutionary engineering (Cakar et al., 2012). It is also suitable for studying oxidative stress responses since oxidative stress plays a critical role in various industrial fermentation processes, affecting cellular viability and product yield (Toledano et al., 2002; de Fátima Alves et al., 2023). Secondary metabolites, which are often involved in stress responses, contribute to oxidative stress resistance through their antioxidant activity (Clarkson et al., 1991).

The aim of this study was to investigate the oxidative stress response mechanism of genetically stable and stress-resistant *S. cerevisiae* strains that had been previously developed through evolutionary engineering. The findings of this study are expected to provide insights into the oxidative stress response mechanisms of stress-resistant *S. cerevisiae* strains and elucidate the role of secondary metabolites in these processes.

Material and Method

Strains: In this study, *Saccharomyces cerevisiae* CEN.PK 113-7D was used as the reference strain (provided by Prof. Dr. Jean Marie François and Dr. Laurent Benbadis from the University of Toulouse, France), along with mutant strains developed from this reference strain through evolutionary engineering technique to confer resistance to various stress factors. Previously developed *S. cerevisiae* mutant strains, their characteristics, and sources are given in Table 1.

Table 1. Previously developed *S. cerevisiae* mutant strains, their characteristics, and sources.

Strains	Characteristics	Source
REF (Reference strain)	CEN.PK 113-7D (haploid)	Entian and Kötter (2007)
SRM11	Chronologically long-lived	Çakar's Lab collection
FD11	Propolis-resistant	Çakar's Lab collection
8C	Iron-resistant	Çakar's Lab collection
B2	Ethanol-tolerant	Çakar's Lab collection
R12	Rapamycin-resistant	Çakar's Lab collection
F1	Freeze thaw-resistant	Çakar's Lab collection
ALU10	Aluminum-resistant	Çakar's Lab collection
K1	KCl-resistant	Çakar's Lab collection
H7	Hydrogen peroxide-resistant	Çakar's Lab collection
ANT	Antimycin A-resistant	Çakar's Lab collection
FT9	Freeze thaw-resistant	Çakar's Lab collection
K9	KCl-resistant	Çakar's Lab collection
C9	2-phenylethanol-resistant	Çakar's Lab collection
CAF	Caffeine-resistant	Çakar's Lab collection
B8	Ethanol-resistant	Çakar's Lab collection
2E	Silver-resistant	Çakar's Lab collection

Yeast Culture Conditions: Initially, the reference and mutant strains were revived by inoculating 100 µL from stock cultures into 10 mL of YPD medium (1% w/v yeast extract, 1% w/v peptone, 2.2% w/v glucose monohydrate) in 50 mL culture tubes, followed by overnight incubation at 30 °C and 150 rpm. Subsequently, the reference and mutant strains were pre-cultured in YMM medium (0.67% w/v yeast nitrogen base w/o amino acids, 2.2% glucose monohydrate) at an initial OD_{600} of 0.2 (~2.8 x 10^6 cells/mL) and incubated overnight at 30 °C and 150 rpm. Afterward, the cultures were inoculated into fresh YMM medium at an initial OD_{600} of 0.2 and incubated at 30 °C and 150 rpm for 5 hours and 18 hours.

Secondary Metabolite Extraction: Following incubation for 5 hours and 18 hours, ethyl acetate extraction was performed at a 1:1 ratio on the liquid cultures to isolate secondary metabolites via phase separation. The solvent phase was collected in glass tubes and evaporated at 45 °C under a nitrogen blowdown. After solvent evaporation, the purified extract of secondary metabolites, appearing as an orange-brown residue, was recovered from the bottom of the tubes by dissolving with 70% methanol.

Determination of Antioxidant Activity: The antioxidant activities of the secondary metabolite extracts were evaluated using the 2,2-diphenyl-1-picrylhydrazyl (DPPH) assay and total phenolic content (TPC) assay. The DPPH assay results were expressed as Trolox equivalent antioxidant capacity (TEAC) per gram of cell dry weight. The TPC assay results were expressed as milligrams of gallic acid equivalents per gram of cell dry weight (mg GAE/g cell dry weight).

A schematic representation of the methodology is provided in Figure 1.

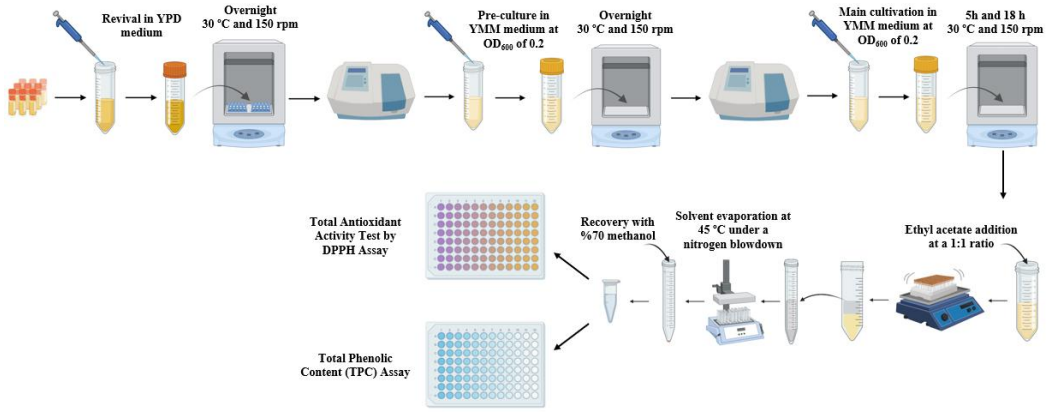

Figure 1. Schematic representation of the methodology.

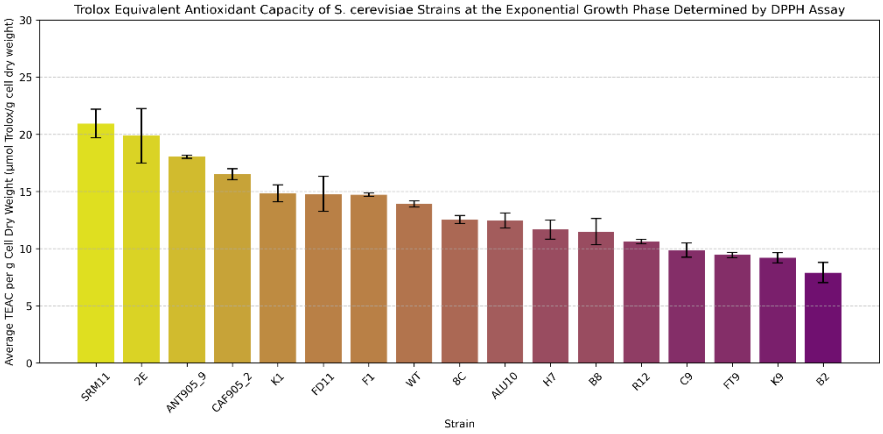
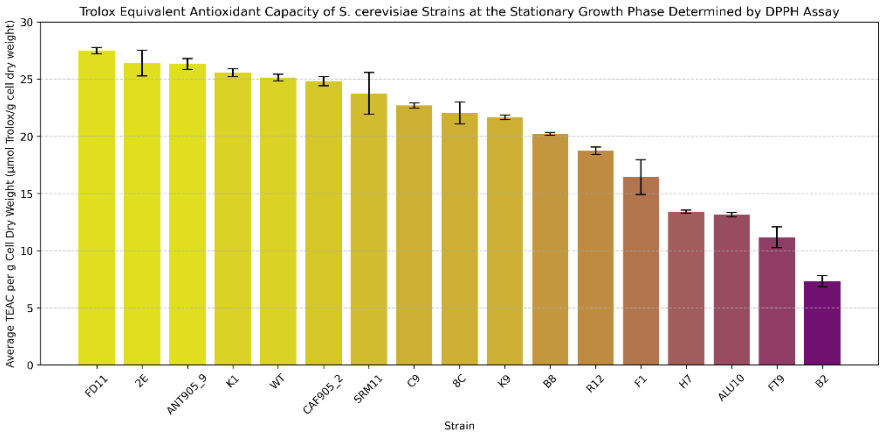
Findings

The antioxidant capacity of secondary metabolites derived from *S. cerevisiae* strains was assessed at both the exponential and stationary growth phases using the DPPH assay (Figure 2). Some of the stress-resistant *S. cerevisiae* strains tested in this study exhibited higher antioxidant activity than the reference strain.



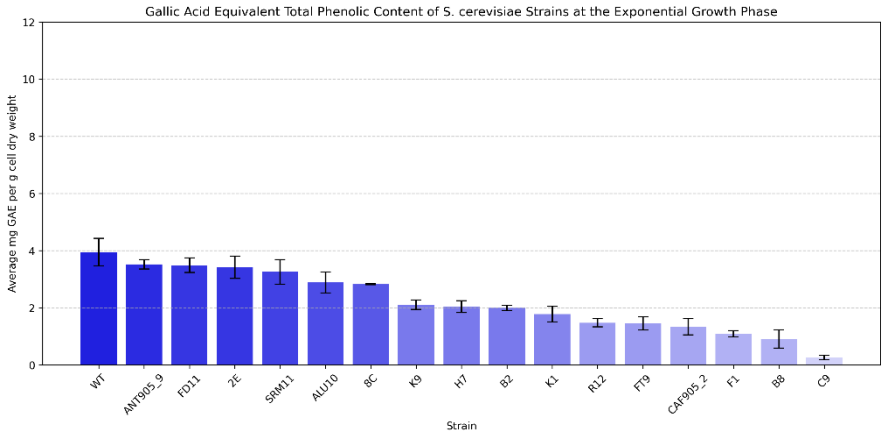
(a)



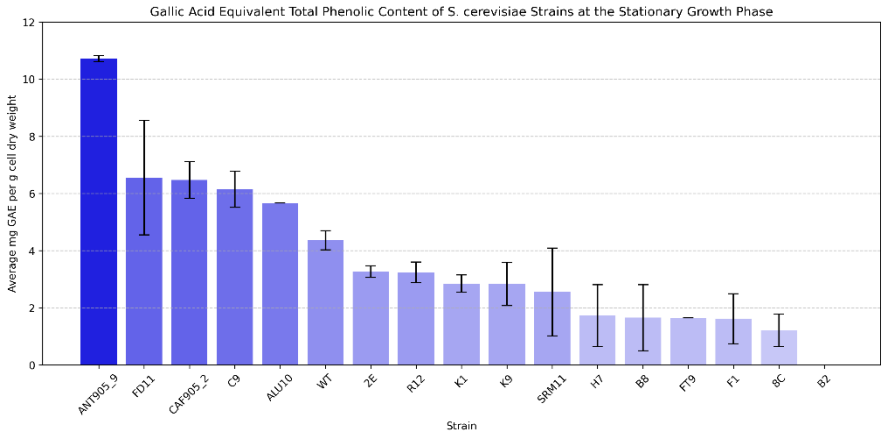
(b)

Figure 2. Trolox equivalent antioxidant capacity (TEAC) per gram of cell dry weight. **(a)** Total antioxidant capacity of *S. cerevisiae* strains measured during the exponential growth phase (5 hours incubation). **(b)** Total antioxidant capacity of *S. cerevisiae* strains measured during the stationary growth phase (18 hours incubation).

The total phenolic content of secondary metabolites derived from *S. cerevisiae* strains was assessed at both the exponential and stationary growth phases using the TPC assay (Figure 3). A few stress-resistant *S. cerevisiae* strains tested in this study exhibited higher phenolic content than the reference strain during the stationary growth phase.



(a)



(b)

Figure 3. Total phenolic content (TPC) expressed as milligrams of gallic acid equivalents per gram of cell dry weight (mg GAE/g cell dry weight). **(a)** TPC of *S. cerevisiae* strains measured during the exponential growth phase (5 hours incubation). **(b)** TPC of *S. cerevisiae* strains measured during the stationary growth phase (18 hours incubation).

Conclusion

Overall, the results indicate that the antioxidant activity of both the stress-resistant *S. cerevisiae* strains and the reference strain was generally higher during the stationary growth phase compared to the exponential growth phase. This suggests that the accumulation of antioxidant metabolites is more prominent as cells undergo a transition into the stationary growth phase. Among the stress-resistant strains tested, only the antimycin A-resistant strain (ANT905_9) exhibited consistently higher antioxidant capacity than the reference strain in both the exponential and stationary growth phases, suggesting that its adaptation mechanism may contribute to its increased antioxidant capacity. In contrast, the ethanol-tolerant strain (B2) showed the lowest antioxidant capacity, implying that its tolerance mechanism is likely independent of oxidative stress pathways. Furthermore, ANT905_9 also showed elevated phenolic content during the stationary growth phase compared to the other strains. The findings of this study highlight potential candidates for further molecular and biochemical characterization of oxidative stress resistance mechanisms in *S. cerevisiae*.

ficici17@itu.edu.tr

Keywords: Caffeine stress resistance , Evolutionary engineering , High-Performance Liquid Chromatography (HPLC) , Metabolic engineering , *Saccharomyces cerevisiae.*

Aim

Caffeine, a widely consumed alkaloid, is primarily known for its antioxidant properties and stimulant effects, making it a crucial component in the food and pharmaceutical industries. However, its biological activity is not limited to beneficial effects, as caffeine has been documented to exert toxic effects on microorganisms. While certain microorganisms exhibit susceptibility to caffeine-induced stress, others have evolved metabolic pathways or resistance mechanisms that enable them to tolerate or even utilize caffeine. Understanding these mechanisms is of significant interest, particularly in eukaryotic systems, as it provides insights into stress adaptation and cellular detoxification pathways that may be relevant to higher organisms, including humans.

Saccharomyces cerevisiae, a eukaryotic model organism, has been extensively used to study genetic and metabolic responses to various stressors. The investigation of caffeine resistance and metabolism in this yeast species not only enhances our comprehension of microbial adaptation but also serves as a model for understanding caffeine metabolism in more complex eukaryotic systems. Furthermore, caffeine metabolism in yeast could offer potential applications in biotransformation and bioremediation strategies, particularly for the degradation and detoxification of caffeine in environmental and industrial settings. Given the widespread presence of caffeine in nature and its impact on microbial ecology, deciphering these mechanisms in *S. cerevisiae* is crucial. Moreover, insights gained from such studies can contribute to biomedical research, as caffeine is known to interact with various metabolic pathways in mammalian systems.

The primary aim of this study was to investigate the metabolism of caffeine in caffeine-resistant *S. cerevisiae* strains CAF905-2, CAF906-11, and CAF906-12 that have been previously developed using an evolutionary engineering approach. By analyzing their growth kinetics and intracellular caffeine accumulation profiles, this research aimed to elucidate the relationship between caffeine metabolism and resistance mechanisms. Another aim of this study was to compare the obtained results with the existing literature to assess similarities, variations, and potential novel findings regarding caffeine metabolism in eukaryotic microorganisms. Understanding these dynamics could provide valuable information on how cells adapt to caffeine exposure over successive generations and whether resistance confers any selective advantage in different environmental conditions.

Material and Method

In this study, previously developed caffeine-resistant *S. cerevisiae* strains CAF905-2, CAF906-11, and CAF906-12 obtained by evolutionary engineering and their reference strain CEN.PK 113-7D were used. The strains were cultivated in both caffeine-containing and caffeine-free yeast minimal media (YMM). In order to compare caffeine response at different growth phases, samples were collected at exponential and stationary phases. The growth kinetics of the strains were monitored using optical density measurements at 600 nm wavelength (OD600) at regular time intervals. Samples were centrifuged at 10,000 g for 5 min to separate cell pellets from the culture

media. Supernatants were collected as an extracellular fraction, and pellets were collected and lysed to analyze the intracellular fraction. The lysis step was performed with an ultrasonic homogenizer.

High-performance liquid chromatography (HPLC) was employed for caffeine quantification in both intracellular and extracellular fractions. C18 reverse-phase column was used, and 3% acetonitrile was used as the mobile phase. Both intracellular and extracellular caffeine amounts were assessed to determine whether resistance mechanisms involved altered uptake, efflux, or degradation of caffeine to its three main metabolites: paraxanthine, theophylline, and theobromine.. The caffeine degradation potential of the strains was analyzed, and comparisons were made to understand how resistance influences caffeine metabolism. Additionally, stress response markers and possible genetic adaptations in resistant strains were considered to further characterize their physiological and metabolic responses.

A schematic representation of the methodology is provided in Figure 1.

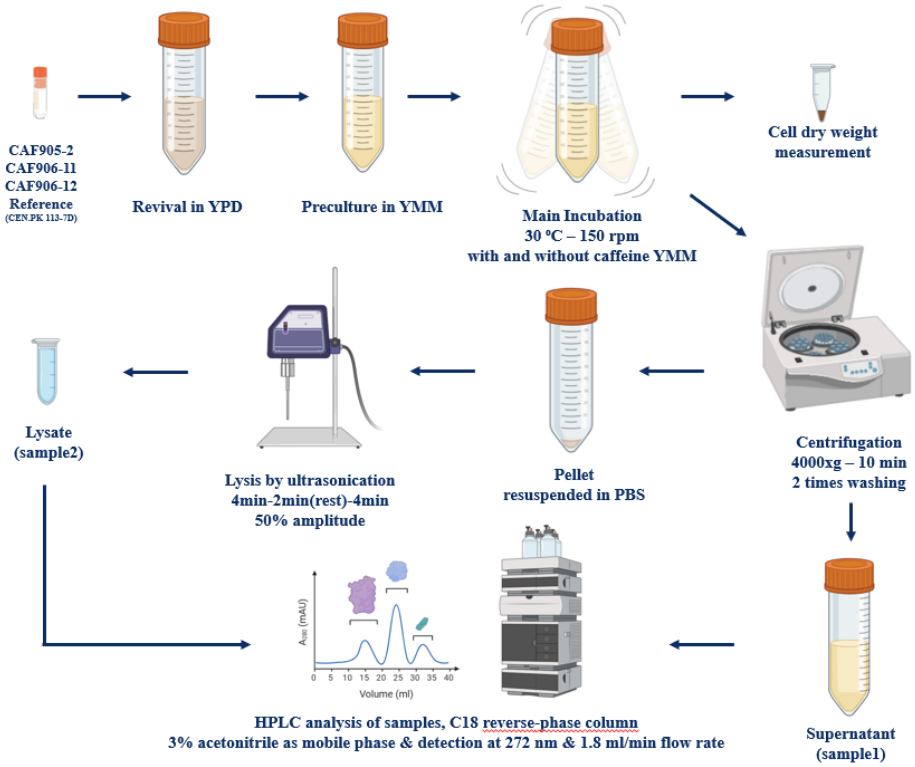

Figure 1. Schematic representation of the methodology.

Findings

Both intracellular and extracellular caffeine accumulation of the mutant strains CAF905-2, CAF906-11 and CAF906-12 were compared against the reference strain (wild type) in Figure 2 and Figure 3. Intracellular levels of caffeine were significantly higher in the mutant strains compared to the reference strain in the exponential phase, while this difference decreased in the stationary phase. Moreover, intracellular levels of caffeine decreased from the exponential phase to the stationary phase for all three mutant strains.

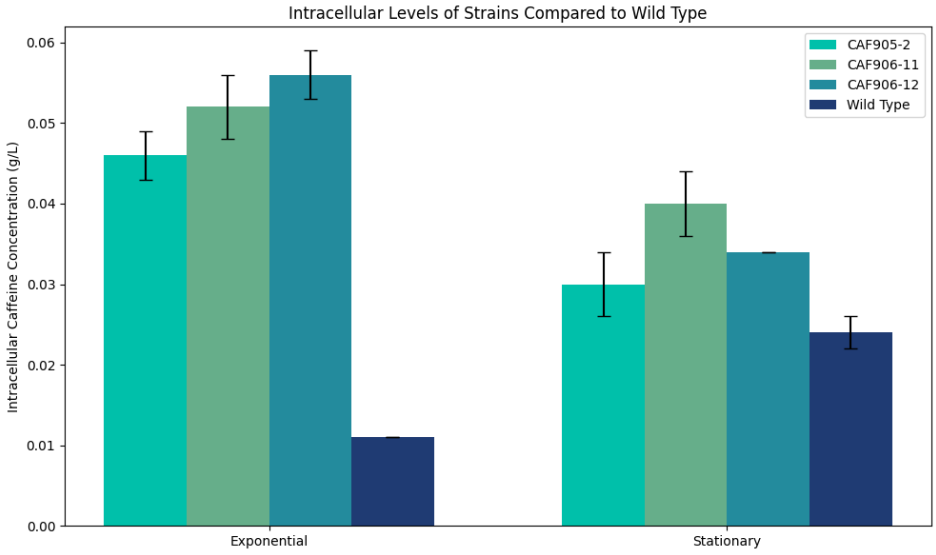

Figure 1. Differences between intracellular level of caffeine for CAF905-2, CAF906-11, CAF906-12 and reference strain in both exponential and stationary phases.

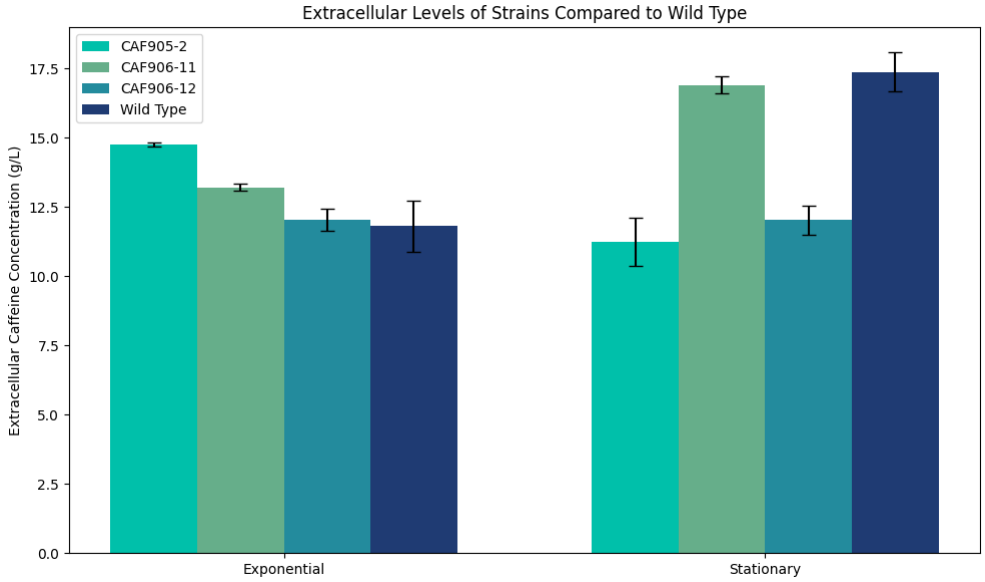

Figure 2. Differences between extracellular level of caffeine for CAF905-2, CAF906-11, CAF906-12 and reference strain in both exponential and stationary phases.

Conclusion

Increase in the extracellular levels of caffeine from the exponential to the stationary phase of growth could imply efflux or pumping out of caffeine. Decrease in both intracellular and extracellular levels of caffeine from the exponential to the stationary phase of growth could be interpreted as metabolizing of caffeine by the cells. Increase in the intracellular levels of caffeine could indicate that cells could tolerate caffeine toxicity by diverse intracellular processes. Further research should be conducted by also analyzing the main metabolites of caffeine, to obtain more detailed results. As a conclusion, all mutant strains could tolerate intracellular caffeine during the exponential phase of growth stronger than the reference strain. During the stationary phase of growth, the caffeine-resistant mutant strains possibly removed intracellular caffeine by metabolizing it or pumping it out of the cell.

Keywords: Saccharomyces Cerevisiae, Metabolic Engineering, Evolutionary Engineering, Stress Resistance, Aluminum Stress, Next-Generation Sequencing.

Aim

Saccharomyces cerevisiae is a widely used eukaryotic model organism in both basic and industrial research due to its genetic tractability and resilience to environmental stressors (Vanderwaeren et al., 2022; Walker, 2009). Aluminum, though abundant, is a toxic and non-essential metal that disrupts key cellular processes, induces oxidative stress, and interferes with DNA and protein function (Kakimoto et al., 2005; Walton, 2013). Evolutionary engineering—based on the principle of adaptive selection under controlled stress—has proven effective for improving microbial tolerance to such toxic compounds (Çakar et al., 2011; Parapouli et al., 2020).

This study aimed to investigate the molecular mechanisms of aluminum-stress-resistance in *S. cerevisiae* by comparative genomic analysis of an aluminum-stress-resistant *S. cerevisiae* strain that was previously obtained by evolutionary engineering which involved chemical mutagenesis by ethyl methane sulfonate followed by 43 successive batch passages at gradually increasing AlCl3 levels. The results of this study may be useful for potential industrial applications that involve aluminum, aluminum bioremediation, and for a better understanding of aluminum-related health issues, including some neurodegenerative diseases. This research was supported by Scientific Research Projects Department of Istanbul Technical University, Project No: TYL-2025-46840.

Material and Method

Strain and Growth Media: The reference strain used was *Saccharomyces cerevisiae* CEN.PK113-7D (named as strain 905), kindly provided by Prof. Dr. Jean-Marie François and Dr. Laurent Benbadis (University of Toulouse, France). Chemical mutagenesis was performed using ethyl methane sulfonate (EMS). Yeast Minimal Medium (YMM) was used during selection experiments.

Mutagenesis and Selection of Aluminum-Resistant Mutants: The reference strain 905 was subjected to EMS mutagenesis to obtain a genetically diverse initial population called 906. Aluminum tolerance was assessed at concentrations ranging from 0.05 to 50 mM $AlCl_3$. Batch selection involved 43 successive passages, by gradually increasing aluminum chloride ($AlCl_3$) concentration to 21.5 mM. After plating, 12 resistant mutants were isolated, with four (Alu9, Alu10, Alu11, Alu12) showing high aluminum resistance. Spot assay and Most Probable Number (MPN) methods confirmed their resistance, and their genetic stability was verified. Cross-resistance tests against various stressors such as lithium chloride, gallium nitrate, ethanol, and silver nitrate were also performed, as described previously (Durmuş-İşleyen, 2015).

DNA Isolation and Whole Genome Sequencing: Yeast cells (the reference strain 905 and the highly aluminum-resistant and genetically stable evolved strain Alu10) were cultured overnight in YMM. Genomic DNA was extracted using the MasterPure DNA Purification Kit (Epicentre) and evaluated using a NanoDrop 2000

spectrophotometer. Whole genome sequencing was conducted using the Illumina NextSeq 550 platform at Gen ERA Diagnostics Laboratory.

Bioinformatics Analysis: The Galaxy Europe platform facilitated sequence data processing. Quality control (using FastQC software), trimming (using Trimmomatic software), genome mapping (BWA-MEM), and variant calling (DeepVariant, BCFtools) steps were performed, as described previously (Demir-Yılmaz et al., 2025). BAM files were visualized using Golden Helix Genome Browser to assess mutation types and genomic positions. VCF filtering was used to isolate strain-specific variants for further analysis.

Data Annotation and Functional Analysis: Mutations specific to the evolved strain Alu10 were classified using the Microsoft Excel software. The Ensembl Fungi Variant Effect Predictor (VEP) tool annotated genetic variants, focusing on EMS-induced point mutations, predominantly missense mutations. The Saccharomyces Genome Database (SGD) was used to investigate phenotypic effects and functional consequences of identified mutations. Cross-referencing with external databases was used for the evaluation of aluminum resistance-related genetic modifications.

Findings

The comparative genomic analysis between the reference strain and the aluminum-resistant evolved strain Alu10 revealed specific genetic alterations associated with the Alu10 strain. When compared to the reference strain, Alu10 exhibited 69 unique genetic variants. Out of a total of 69 observed variants, 67 were GC to AT transitions, a mutation type commonly induced by ethyl methane sulfonate (EMS). These variants were further analyzed using the Ensembl Fungi Portal to assess their functional consequences.

The Variant Effect Predictor (VEP) analysis identified 345 variant consequences specific to the Alu10 strain. Among the coding consequences:

- 70% were missense variants
- 24% were synonymous variants
- 4% were stop-gained mutations
- 2% were start-loss mutations

Missense variants, which result in amino acid substitutions, were the most prevalent. These substitutions are of particular interest as they can impact protein function. Stop-gained and start-loss mutations, though less frequent, may have significant effects by truncating proteins or preventing translation initiation, potentially altering gene expression and cellular function.

Given the known mutagenic properties of EMS, the focus was placed on missense mutations for further analysis. To determine the functional relevance of these variants, the Saccharomyces Genome Database (SGD) was utilized to assess their potential roles in gene function, protein interactions, and cellular pathways.

From this analysis, several genes with mutations were identified as potential contributors to aluminum resistance due to their involvement in oxidative stress and cellular response pathways. The following genes were selected as potential contributors to aluminum resistance:

Oxidative Stress Response:

- *MSH6*: DNA mismatch repair of oxidative lesions
- *ADR1*: Transcriptional activator of antioxidant genes
- *BMH1:* Stress signaling regulator
- *BRO1*: Vacuolar metal detoxification

Cell Wall/Membrane Integrity:

- *BEM2:* Rho1-PKC1 cell integrity pathway
- *IPT1:* Sphingolipid biosynthesis

Metal Ion Homeostasis:

- *PMR1:* Golgi ion transporter (direct Al^{3+} resistance evidence)

Chemical Stress Adaptation:

- *MDS3, PCL8, SRL4:* Stress-responsive regulators

These findings suggest that specific genetic variants within these genes may contribute to the Alu10 strain's enhanced aluminum resistance. The integration of VEP results with functional genomic databases has provided a strong foundation for identifying candidate genes for experimental validation and further research into the mechanisms underlying aluminum resistance in yeast.

Conclusion

Understanding microbial aluminum resistance is critical for industrial and environmental applications. This study explored the molecular mechanisms of aluminum resistance in *Saccharomyces cerevisiae* by analyzing the evolved Alu10 strain. Through comparative genomics, key mutations in genes like *PMR1*, *BEM2*, *MDS3*, *PCL8*, and *SRL4* were identified, linking aluminum tolerance to enhanced cell wall integrity, ion detoxification, stress signaling, and DNA repair. Additional genes (*IPT1*, *MSH6*, *BMH1*, *BRO1* and *ADR1*) further supported resistance via oxidative defense, vacuolar function, and sphingolipid metabolism. The findings reveal a multifactorial adaptation strategy, offering insights for industrial biotechnology (e.g., robust yeast strains) and bioremediation. Future work should validate these targets experimentally. This research highlights the power of evolutionary engineering combined with genomics to decode complex stress resistances.

Keywords: *Saccharomyces Cerevisiae*, Silver Nanoparticles, Green Synthesis, Biosynthesis Optimization.

Aim

Silver nanoparticles (AgNPs) have garnered extensive attention in recent years due to their distinctive physicochemical properties and broad-spectrum antimicrobial activity. These nanostructures possess unique optical, electrical, and thermal characteristics that make them particularly valuable in biomedical, environmental, and industrial applications. Their utility spans a wide range of sectors, including drug delivery, diagnostic imaging, water purification, textile engineering, and food packaging (Rai et al., 2014; Ahmed et al., 2016). However, the conventional methods for synthesizing AgNPs typically rely on chemical and physical processes, which often involve toxic chemicals, high temperatures, and non-renewable energy sources. Such drawbacks pose significant environmental and safety concerns, thereby creating a demand for greener, more sustainable alternatives (Iravani, 2011). In this context, biological or green synthesis has emerged as an eco-friendly and cost-effective method for nanoparticle production. Among biological systems, microorganisms such as bacteria, fungi, and yeast have demonstrated considerable potential in nanoparticle biosynthesis. These organisms can reduce metal ions to their corresponding nanoparticles through enzymatic and non-enzymatic mechanisms. The advantages of microbial synthesis include scalability, low toxicity, mild reaction conditions, and the possibility of precise control over particle size and morphology (Durán et al., 2011; Singh et al., 2015). Among the diverse microbial agents, *Saccharomyces cerevisiae*, commonly known as baker's yeast, represents a promising platform for nanoparticle biosynthesis due to its well-established genetic background, biosafety (GRAS status), and ability to tolerate and interact with metal ions. S. cerevisiae is a eukaryotic model organism that has been widely used in biotechnology, particularly in the production of ethanol, enzymes, and biopharmaceuticals. Its cell wall, composed of polysaccharides and proteins with functional groups such as hydroxyl, amino, and carboxyl moieties, provides a reactive interface for metal ion binding and reduction. Moreover, its intracellular enzymes and metabolites can facilitate the bioreduction of silver ions (Ag^{+}) to elemental silver (Ag^{0}), enabling the formation of stable AgNPs (Bhainsa & D'Souza, 2006; Shahzad et al., 2019).

This study investigates the biosynthetic potential of *S. cerevisiae* for AgNP production under varying experimental conditions, specifically focusing on the influence of yeast cell density and silver nitrate ($AgNO_3$) concentration. The aim was to optimize these parameters to achieve efficient, rapid, and reproducible nanoparticle formation, thereby enhancing the feasibility of yeast-mediated nanoparticle synthesis for practical applications.

Material and Method

S. cerevisiae cells were initially grown in yeast extract peptone dextrose (YPD) medium at 30°C for 18 hours with constant shaking. Then, cells were harvested by centrifugation and washed a few times with sterile deionized water to remove any residual media components that might interfere with nanoparticle formation. Firstly, a set of yeast suspensions were prepared at varying concentrations to assess the effect of cell density on AgNP formation. The washed cells were resuspended in deionized water to achieve different optical densities (OD_{600}) ranging from 0.5 to 5.0, with increments of 0.5. Each suspension (1.5 mL) was transferred into a sterile 2 mL microcentrifuge tube. $AgNO_3$ was added to each tube to a final concentration of 1 mM. To evaluate the impact of $AgNO_3$ concentration,

a separate set of yeast suspensions at a fixed OD_{600} of 2.0 was prepared, and varying concentrations of $AgNO_3$ were added (0.5–5 mM, in 0.5 mM increments). In both experimental sets, 50 mM $AgNO_3$ freshly prepared in deionized water was used. The tubes were incubated in the dark at 30°C for 72 hours to minimize photo-induced reactions. The formation of silver nanoparticles was detected by using a microplate reader, measuring absorbance in the range of 300–700 nm. The presence of a characteristic surface plasmon resonance (SPR) peak around 420–450 nm confirmed the synthesis of AgNPs (Song & Kim, 2009).

Findings

The biosynthesis of AgNPs was found to be significantly influenced by the density of *S. cerevisiae* cells. The most efficient nanoparticle formation, characterized by a strong SPR peak at ~430 nm was observed at an OD_{600} of 2.0. Lower cell densities resulted in weaker SPR signals, likely due to insufficient reducing agents or reactive groups to convert silver ions effectively. Conversely, at higher cell densities, a decline in nanoparticle yield was noted, possibly due to aggregation of particles or metabolic inhibition caused by overaccumulation of silver ions (Gurunathan et al., 2009). These findings highlight the importance of maintaining an optimal biomass concentration to ensure efficient nanoparticle biosynthesis. Varying the concentration of $AgNO_3$ revealed that 1 mM was optimal for AgNP synthesis at OD_{600} = 2.0. At lower concentrations, AgNP formation was slow and incomplete, indicating a threshold concentration is necessary to drive the reduction process. High $AgNO_3$ concentration beyond a limit led to diminished nanoparticle production, possibly due to the cytotoxic effects of silver ions, which interfere with yeast metabolism and viability (Khan et al., 2017). Time-course analysis demonstrated that most nanoparticle synthesis occurred within the first 24 hours of incubation. Absorbance values generally peaked at 24 or 48 hours and plateaued or slightly decreased by 72 hours, indicating a saturation point beyond which no significant synthesis occurred. This observation aligns with previous studies that suggest AgNP formation is typically a rapid process in microbial systems (Ghaffari-Moghaddam & Hadi-Dabanlou, 2014). Extended incubation periods may also promote agglomeration or oxidative dissolution of nanoparticles. The biosynthesis of AgNPs by *S. cerevisiae* likely involves multiple mechanisms. Extracellular enzymes such as reductases may play a role in reducing Ag^+ to Ag^0, while functional groups on the yeast cell surface bind and nucleate the formation of nanoparticles (Kumar et al., 2007). Glutathione, a key antioxidant present in yeast, has also been implicated in redox processes involved in nanoparticle synthesis. The resulting nanoparticles are often stabilized by capping agents derived from cellular proteins or polysaccharides, which prevent aggregation and improve colloidal stability. The interplay between cell wall chemistry, metabolic activity, and environmental conditions determines the size, shape, and dispersion of the synthesized nanoparticles. Understanding and optimizing these variables can lead to more uniform nanoparticle characteristics, which is critical for applications in biomedicine where particle size directly influences cellular uptake and cytotoxicity (Singh et al., 2015).

Conclusion

In conclusion, *Saccharomyces cerevisiae* represents a promising green nanofactory for the synthesis of silver nanoparticles. Our findings demonstrate that both yeast cell density and silver nitrate concentration are critical factors influencing the efficiency of AgNP biosynthesis. Optimal nanoparticle formation was achieved at an OD_{600} of 2.0 and 1 mM $AgNO_3$ concentration after 24 hours of incubation. These results contribute valuable insights into the development of sustainable microbial synthesis protocols and lay the groundwork for further research into the mechanistic and functional properties of biologically synthesized AgNPs. Future works can be done to determine detailed physicochemical characteristics of the synthesized nanoparticles using electron microscopy (TEM/SEM), zeta potential analysis, and X-ray diffraction (XRD).

Keywords: Silver Nanoparticles, Green Synthesis, Antimicrobial Activity, Nanobiotechnology.

Aim

The aim of this project is to systematically investigate the green synthesis of silver nanoparticles (AgNPs) using cinnamon (Cinnamomum zeylanicum), hibiscus (Hibiscus sabdariffa), and green tea (Camellia sinensis) extracts and to evaluate the antimicrobial potential of the synthesized AgNPs. By comparing the reduction and stabilization capacities of these plant extracts, the project seeks to optimize the synthesis parameters, including silver ion concentration and extract type, to obtain the most efficient and stable AgNPs. Furthermore, the study aims to characterize the synthesized AgNPs in terms of size, shape, crystal structure, and surface properties, while assessing their antimicrobial activities against various bacterial strains, including Escherichia coli, Staphylococcus aureus, and Pseudomonas aeruginosa. The project also aims to explore the unique antimicrobial mechanisms of cinnamon AgNPs, particularly those linked to cinnamaldehyde, and to uncover the potential applications of cinnamon, hibiscus and green tea AgNPs in fields such as food safety, sustainable energy, wound healing, and targeted drug delivery. By addressing the gaps in the literature, the results will contribute to the development of plant-based AgNPs as novel antimicrobial agents in the fight against antimicrobial resistance.

Materials and Method

Synthesis process was started with the preparation of plant extracts. First, cinnamon, hibiscus and green tea plant extracts were prepared with the coffee grinder. Solutions of the extract were obtained by mixing the powdered forms of the extracts with distilled water at the specified temperatures and times. Cinnamon was mixed at 100° for 20 minutes; hibiscus and green tea were mixed at 60° for 20 minutes. After that, they were sterilized by filtering with filtration papers and stored at +4°C for use.

Silver nitrate ($AgNO_3$) solutions were prepared at different concentrations (5 mM and 10 mM) for making the synthesis of silver nanoparticles. Extracts from plants and $AgNO_3$ solutions were reacted at the specified temperatures and times in the specified ratios of 1:5 and 1:10 plant solution-silver nitrate. To synthesize the cinnamon-AgNps 90° for an hour was selected. For hibiscus and green tea process were done at 70° for 2 hours. Then, the extracts waited for 24 hours in a dark room. After the waiting process; the progress of the reaction was followed by color change and UV-Vis spectroscopy. The obtained AgNPs were purified again by passing through filtration paper. Then dialysis processes were done to make more stable AgNPs. Measurements were taken for plant extract, silver nanoparticles without dialysis, and silver nanoparticles after the dialysis with UV-Vis. With this application, the purity of the silver nanoparticles was checked. Finally, the antimicrobial activity of the synthesized AgNPs will be evaluated against Escherichia coli bacteria by disk diffusion method, minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) tests. As a result of the antimicrobial tests, the activities of AgNPs synthesized from different plant extracts will be compared.

To control the optical properties and surface plasmon resonance (SPR) peak of the AgNP's UV-Vis spectroscopy is used. Also, to check whether the purification process was successful, SDS-Page method was used. To check the functional groups inside the silver nanoparticles which synthesized from plant extracts, FTIR process was done.

However, there are other techniques and analysis methods that will be planned to be used in this study for the characterization and optimization of the synthesized nanoparticles. The XRD analysis will be used to determine the crystal structure of the nanoparticles. SEM (Scanning Electron Microscope) imaging will be performed to examine the morphology and size distribution of AgNPs (Ahmad et al., 2023). DLS (Dynamic Light Scattering) analysis will be applied to determine the hydrodynamic diameter and stability of the nanoparticles.

Findings

Green synthesis of silver nanoparticles was successfully conducted using cinnamon, hibiscus, and green tea extracts. UV-Vis spectroscopy confirmed silver nanoparticle formation, with 1:5 and 1:10 $AgNO_3$ ratios. Dialysis improved nanoparticle purification, sharpening UV-Vis absorption peaks. After the measurement was taken with UV-VIS and the production of silver nanoparticles was proven, the SDS-Page process was performed for the dialyzed silver nanoparticles. The purpose of this process was to see if the plant extract still remained after dialysis. For every solution, 1:5 and 1:10 ratios' dialysis results are used respectively. No protein from the plant extracts was observed in the SDS-Page result. This shows that the filtration processes were successful. FTIR analyses demonstrate the presence of functional groups on the surface of silver nanoparticles synthesized using Hibiscus, Cinnamon, and Green Tea extracts. The observed –OH, C=O, C–O, and C–N bands indicate that phytochemicals in the extracts acted as reducing and stabilizing agents. Signals detected in the 500–600 cm^{-1} region suggest possible Ag–O or Ag–N bonding on the nanoparticle surfaces

To see the antimicrobial activity of AgNPs Agar Diffusion Test is going to be done with Escherichia coli, Staphylococcus aureus, and Pseudomonas aeruginosa. For characterizing the produced AgNPs; DLS, XRD, SEM tests are also going to be done.

Conclusion

To make a sum up; in this research the aimed silver nanoparticles (AgNPs) were victoriously produced with the use of plant-based extracts from cinnamon, hibiscus, and green tea. Plant-based extracts help to force an eco-friendly green synthesis method. The green synthesis technique escapes the apply of detrimental and hazardous chemicals by depending on organic reducing and stabilizing agents inherent in plant materials (Gudikandula & Charya Maringanti, 2016). The production of AgNPs was established through UV-Vis spectroscopy analysis, where sharp and unique absorption peaks were marked. These results specified that the great fabrication of nanoparticles. Between the three distinct plant extracts chosed in the fabrication of AgNp operation, green tea extract manufactured the nanoparticles with the highest absorbance numbers, proposing that green tea is especially effective in assist the nanoparticle formation.

This study contributes to the area of sustainable nanotechnology by focusing the attention on the utilize of organic resources in nanoparticle production. With the replacement of hazardous chemicals with plant extracts, the technique transforms both safer and more environmentally production (Nasrollahzadeh et al., 2019). More extensive characterization researches utilizing methods such as Dynamic Light Scattering (DLS), X-ray Diffraction (XRD), and Scanning Electron Microscope (SEM) are designed to superior acknowledge the size, shape, and morphology of the produced silver nanoparticles. Later researches will also goal to optimize manufacturing factors and evaluate the antimicrobial effects of these nanoparticles operating the agar diffusion technique. With this research study silver nanoparticles' implementations in the different industries, such as biomedical devices, wound healing and drug delivery applications may be explored in depth (Sahu et al., 2021). Some agricultral and food packaging applications can be done with antimicrobial coating (Herrera-Rivera et al., 2024; RL Manjunatha et al., 2019). In addition, bioenergy production can be done with the nanotechnological processes because of the nanomaterial's specific qualities such as higher surface area and catalytic properties (Kamla et al., 2021).

Keywords: CO2 Reduction, Copper, Phthalocyanine.

Aim

Climate change and global warming are among the biggest problems in ensuring a sustainable world life. CO2 emissions, which increased after the industrial revolution, are one of the main reasons for these problems. For this reason, every step that will reduce emissions is important today.

Although various strategies such as carbon capture and storage have been developed on the subject, these strategies also include various disadvantages such as pollution of groundwater and leaks [1, 2]. For this reason, Electrochemical Conversion of CO2 (CO2RR) is a promising process for a carbon-neutral future. The conversion of CO2 into various liquid and gaseous products such as carbon monoxide, formic acid, ethylene, ethanol and methanol as a result of the reduction reaction not only reduces emissions but also provides economic benefits [3, 4].

CO2RR starts with the absorption of CO2 into the electrocatalysts surface. Firstly, CO2 molecules are converted into HCOO- intermediates, then CO- and H2O through some proton-electron transfers. Further reactions keep happening on the surface of catalysts to create abundant forms of atomic carbon. Controlling intermediate products is a must to control product selectivity. Common intermediate is CO- to produce various products up to C2+ hydrocarbons. Efforts are focusing on adjusting adsorption parameters and modifying surface properties to determine key intermediates like *CO, *COH, and *CH2O to achieve C2+ products [5].

Electrocatalysts are the fundamental factor of reduction selectivity and efficiency. They provide active reaction sites for the adsorption of CO2 and the desorption of the products. Vacant sites on the surface of catalysts facilitate CO2 reduction by stronger bonding [5]. Different pathways for different products require large energy input, mainly activation of CO2. For this reason, design and characterization of exceptional catalysts are one of the important topics. Copper (Cu) is known as the most effective metal catalysts for producing C2+ products with high faradaic efficiency (FE). It has negative adsorption energy for *CO, making it easier to reach a balance with hydrogenation of *CO to enhance hydrocarbon products [6].

To improve catalytic performance and faradaic efficiency of electrocatalysts, molecular catalysts are investigating in addition to bulk form of Cu. For a molecular catalyst, it is important to achieve defined structure and tunable ligands for optimizing structure to enhance catalytic activity. Copper phthalocyanine (CuPc) is one of the molecular Cu-based catalysts that is studied in the literature [7]. For instance, Wang et al. found out that CuPc exhibits good selectivity for methane production [8].

In this study, the electrochemical performances of various copper-based electrocatalysts were tested to determine the best candidate for further studies to be carried out for the electrochemical conversion of CO2.

Material and Method

Cu-foil, Cu-foam and CuPc used in the studies were purchased commercially. Tetrahydrofuran (THF, 99.9%) is used as solvent. Support materials were 300 micron stainless steel fiber, 150 micron %56 porosity titanium fiber, and 200 micron %83 porosity nickel fiber, purchased commercially.

Electrode ink is prepared by 100 mg of CuPc, 202.4 mg of Nafion, 1 ml of DI water and 1399.9 mg of THF. All chemicals added in a container and mixed in an ultrasonic bath. Surface of the support materials (nickel, titanium and stainless steel) were painted. The dyed electrodes were kept at 130°C for 10 minutes, then they were cooled to room temperature and weighed. Support amounts of CuPc electrocatalysts were provided in Table 1.

Table 1. Amount of supports on copper phthalocyanines (CuPc).

Support Materials	CuPc loading (mg/cm^2)
Stainless Steel (SS)	1.3975
Titanium (Ti)	1.1488
Nickel (Ni)	1.1863

All electrochemical tests were carried out in conventional three-electrode cells using Gamry 5000 potentiostat. Cu-foam, Cu-foil, CuPc@Ni, CuPc@SS and CuPc@Ti were used as working electrodes (WE), SCE as reference electrode (RE) and Pt wire as counter electrode (CE). 0.5 M KHCO3 solution was used as electrolyte. Linear sweep voltammetry (LSV) and cyclic voltammetry (CV) tests were carried out at a scan rate of 50 mV/s in the potential range of -0.3 V to -1.3 V vs SCE. For each working electrode, the system was purged with CO2 for 30 min before starting the tests. After each test, gas purging was repeated for 5 min.

Findings

Electrochemical performance of different copper-based electrocatalysts (Cu-foam, Cu-foil, CuPc@SS, CuPc@Ti, and CuPc@Ni) were investigated using Linear Sweep Voltammetry (LSV) and Cyclic Voltammetry (CV) measurements at a scan rate of 50 mV/s within a potential range of -0.3 V to -1.3 V vs. SCE shown in Figure 1 and Figure 2, respectively.

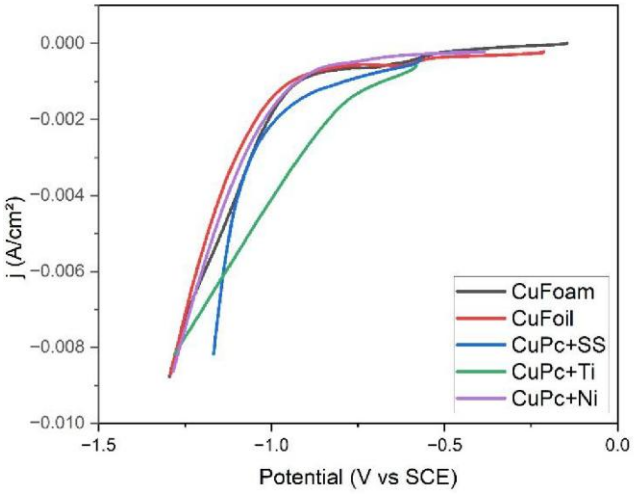

Figure 1. LSV measurements of copper-based catalysts in 0.5 M KHCO3.

As shown in Figure 1, LSV analysis exhibits that foam and foil form of Cu have similar current density trends while foam form shows slightly higher current density values in the more negative potential range (beyond -0.8 V vs. SCE). It can be a result of the porous structure of foam, which improves electrochemical activity by enhancing surface area.

The molecular catalysts, including CuPc@SS, CuPc@Ti and CuPc@Ni displayed different electrochemical behaviors than the bulk forms. While CuPc@SS showed average current densities, CuPc@Ni had the highest current density, particularly at potentials more negative than -0.8 V vs. SCE. CuPc@Ti achieved high current densities at low applied potentials, making it a highly promising candidate for further studies which will be conducted.

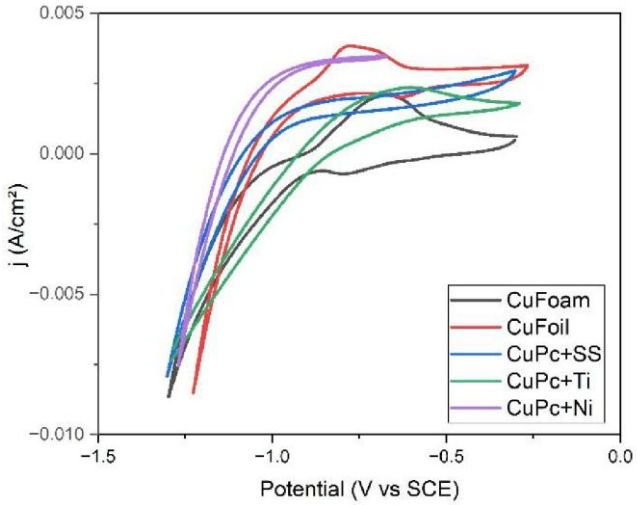

Figure 2. CV measurements of copper-based catalysts in 0.5 M KHCO3.

In Figure 2, CV measurements exhibit that Cu foam shows a superior electrocatalytic performance than foil form with relatively high current density and defined redox peaks. Among the CuPc forms, CuPc@SS and CuPc@Ni displayed less observable peaks than CuPc@Ti, which reveals their slower reaction kinetics.
In summary, CV results showed that foam and CuPc@Ti demonstrated better catalytic performance in CO2 reduction reactions by having high current densities at relatively low potentials in addition to observable well-defined reduction peaks.

Conclusion

Electrochemical performances of bulk and molecular catalysts forms of copper were evaluated by using LSV and CV measurements at 50 mV/s scan rate within -0.3 V to -1.3 V/SCE. Among the tested catalysts, Cu-foam and CuPc@Ti exhibited highest electrochemical activity at relatively low potentials and well-defined peaks in relatively low potentials, which is required for an effective CO2RR electrocatalyst. Therefore, Cu-foam and CuPc@Ti are the most promising candidates for further studies.

NUCLEAR RESEARCH

Radiation Detection and Measurement

Neutron Reflection Method for Element Analysis Using GEANT4

Zehra Güzel[a]

[a] Istanbul Technical University/Energy Institute, Nuclear Researches Division, Radiation Science and Technology, Turkey
guzelz15@itu.edu.tr

Keywords: GEANT4, Neutron Reflection Method, Reflection Cross-Section, Elemental Analysis.

Aim

The study was conducted to investigate the interaction of thermal neutrons with various materials and to develop a material characterization method. The focus is on the concept of the reflection cross-section, a fundamental parameter that defines the neutron reflection properties of different substances. The neutron reflection method can be used for the non-destructive characterization of materials(Csikai & Buczkó, 1999). The aim of applying this method is to improve the analysis of compounds containing elements such as hydrogen, which are difficult to detect. Hydrogen has a high neutron scattering cross-section and a low atomic number. Detecting and quantifying this element is relatively grueling. In this study, the neutron reflection method was also employed to determine the amount of hydrogen in different hydrogen-containing compounds. It is anticipated that this approach could contribute to quality control processes, scientific research, and industrial applications. In this study, analyses were conducted in different experimental geometries and various materials using GEANT4 simulation. The simulation results were compared with experimental data from the literature. The aim of the study was to develop a method in the simulation environment that would increase the accuracy rate in determining the type and quantity of the contents of materials with unknown compositions.

Material and Method

In this study, the dimensions of the experimental setup established in the Csikai and Buczko (1998) paper were used as a reference when defining the geometry in the Geant4 (GEneration ANd Tracking) simulation program, which was employed to apply the neutron reflection method. The simulation setup includes a Pu-Be neutron source and a BF3 proportional counter to detect thermal neutrons. A moderator was used in the geometry to thermalize the neutrons before interacting with the sample, providing an optimal environment for interaction(Csikai, 2001). Polyethylene was chosen as the moderator material. In the simulation developed in Geant4, the interactions of neutrons with various materials have been modeled for this setup. A point-source, isotropic neutron source has been defined in the particle source class of the simulation. Neutrons reaching the experimental geometry from this source are tracked. Nuclear interactions were examined and analyzed using particle tracking methods. The analyses for each event were carried out with ROOT. The neutron reflection method is based on obtaining the relative neutron counting rate measured with (I) and without (I_0) the target sample present. This ratio (R) is related to the composition of the material:

$$R = \frac{(I - I_0)}{I_0} \tag{1}$$

$$R = \sigma_\beta CNd \tag{2}$$

Here, σ_β represents the reflection cross-section, C= 10^{-24} cm2, d is thickness, S is the surface area of the sample, and N is the number of atoms per cm3 (Csikai & Buczkó, 1999).The reflection cross-sections (σ) were determined based on the relationship between neutron counts obtained with the sample, considering material thickness, atomic density, and scattering properties. The neutron reflection method enabled materials to be distinguished based on the reflected neutrons. Additionally, simulations were designed for different target materials to ensure the reliability of the results. The experimental findings from the Csikai and Buczko (1998) study were compared with the simulation data. The Geant4 simulation played a critical role in optimizing the experimental design and interpreting

the neutron reflection data. Thus, performing an initial representation of any experimental setup through simulation will save time and increase accuracy.

The simulation of neutron reflection was carried out using GEANT4 to validate the experimental methodology and characterize neutron-material interactions. By simulating 14 different elements and 16 compounds, the reflection behavior under varying material compositions was analyzed. Furthermore, the average neutron reflection cross section of hydrogen was derived from the reflection cross sections of the compounds. The results were compared with experimental data to validate the approach. The GEANT4 source code includes a plutonium-beryllium source spectrum constructed with literature data, CH2 moderator, samples, and BF3 proportional counter by defining all detailed physical quantities(Figure 1). The meshbox consists of 10 bins along each axis for measuring physical quantities such as neutron flux(Figure 2). Figure 3 presents the simulation output for 50 events, showing neutrons emitted from below the cadmium material within the setup. Geometry involves defining the particle source code with parameters such as the location and type of the neutron source (e.g., angular, point, etc.), the physical parameters of the moderator materials, and the effects of changes in sample thickness on the cross-section. Figure 1 contains a visual of the 3D drawing of the GEANT4 geometry created to apply the neutron reflection method. Figure 3 is an image of 50 neutrons with an energy of 3.25 MeV scattering from the bottom of the Cadmium material. The geometry a cadmium layer around the detector to absorb thermal neutrons. These images are created by using OpenGL.

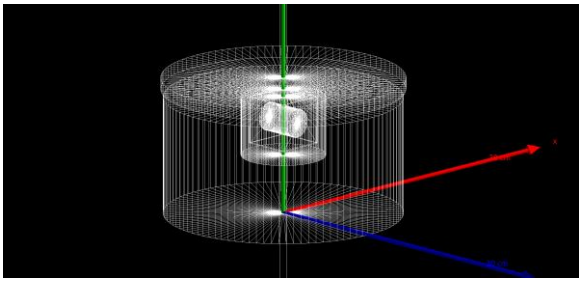

Figure 1. 3D view of the GEANT4 simulation geometry, visualized via Qt.

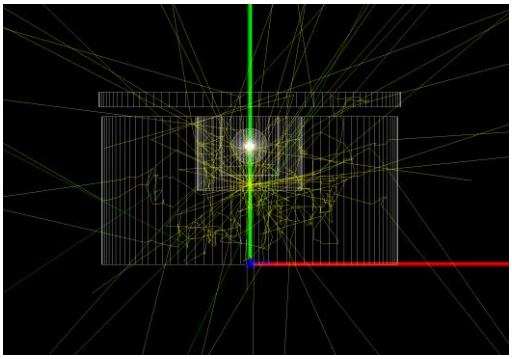

Figure 2. Visualization of the 50 events of 2.5 MeV neutron(yellow), visualized via Qt.

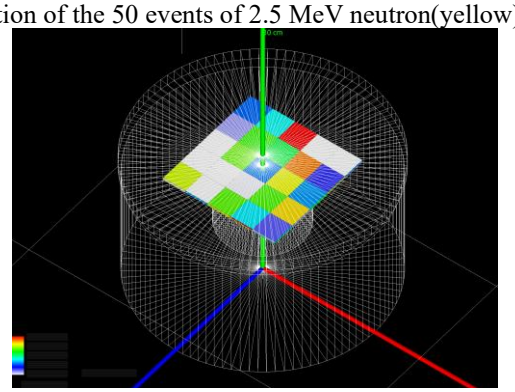

Figure 3. Scoring mesh geometry with thermal filter for counting thermal neutrons (10x10x10), visualized via Qt.

Findings

By simulating neutron reflection for various elements and compounds, the experimental approach was validated, and neutron-material interactions were effectively characterized. Geant4 simulations also allowed the determination of neutron reflection behavior under different experimental conditions, such as changes in material composition or sample geometry. The interaction of 14 different elements and 32 compounds(organics and inorganics) with thermal neutrons was observed, and the reflection behavior under varying material compositions was analyzed. The proposed methodology provided a successful framework for analyzing hydrogen content and other difficult-to-detect elements in complex matrices through Geant4 simulations. The reflection cross-sections calculated from the analyses of different compounds and elements were compared with the experimental reflection cross-section values reported in the literature. For the compounds, this comparison was first made to determine the cross-sections of their elements. The simulation results were also compared with theoretical calculations based on known neutron scattering cross-sections from nuclear data libraries. The combination of simulation and experimental data helped refine the methodology, providing a more robust foundation for future neutron reflection studies. The simulations confirmed that materials with high hydrogen content exhibited strong neutron reflection properties, while metals such as aluminum and lead showed significantly lower reflection cross-sections. To validate the simulation approach, the results were compared with experimental data, yielding a strong correlation coefficient of 0.98, which indicates high reliability(see Figure 4). In the simulation, both elements and molecules were explicitly defined as materials. For molecules, it was assumed that the cross sections are additive—i.e., the total cross section of a compound was calculated as the sum of the cross sections of its constituent elements. This approach produced consistent results, with an overall deviation of 9.09%. However, certain discrepancies were observed in specific compounds such as $Ca(OH)_2$, Fe_2O_3, and CF_2. These deviations may be attributed to uncertainties or inconsistencies in the nuclear data libraries used, or to the sensitivity of these materials to the energy range considered. The simulation exhibited higher accuracy for elemental materials, whereas systematic deviations were more pronounced in organic compounds. When investigating neutron reflection across elements from hydrogen to metals, the reflection cross-section values were found to be reliable. This Geant4 geometry, which produced consistent results, is expected to be particularly useful for evaluating hydrogen content in materials, conducting structural integrity analyses, supporting quality control applications, and detecting hidden substances in security applications. Furthermore, the methodology could be applied to quality control in material production, monitoring moisture content in geological and agricultural samples, and optimizing neutron shielding materials for nuclear reactors.

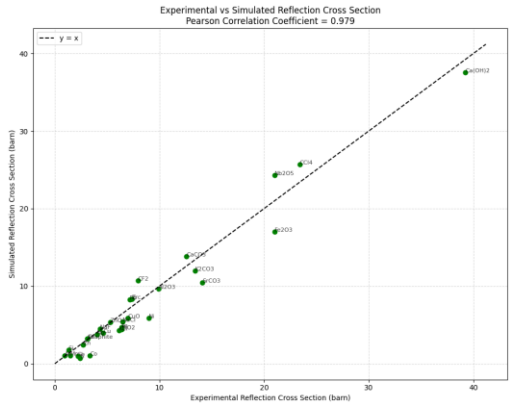

Figure 3. Simulated vs Experimental reflection cross section as a result of 10^6 events.

Conclusion

This study highlights the importance of reflection cross sections in neutron-based material analysis, especially for hydrogen detection and broader compositional studies. The integration of experimental and simulation techniques increases the reliability and applicability of neutron reflection methods. Future work will focus on improving the methodology for greater sensitivity, developing simulation models, and working on a wider range of materials, including elements with high absorption coefficients and complex composite structures.

Two-Body Problem In a Periodic Potential with a Complex Interaction

Koray Hurma[a], Ahmet Levent Subaşı[a]

[a] Istanbul Technical University, Faculty of Science and Letters, Physics Engineering, Istanbul, Türkiye

hurma@itu.edu.tr

Keywords: Bound States, Non-Hermitian Physics, Periodic Potential, Two-Body Problem.

Aim

The formation of Cooper pairs, which are bound-states in the presence of a Fermi sea, is crucial for Bardeen-Cooper-Schrieffer type fermionic superfluidity and superconductivity. In particular, the condensed phase in the strongly interacting limit can be described by the Bose-Einstein condensation of Cooper pairs which behave like tightly-bound dimers. The behavior of such a system in the presence of a periodic potential, which can be realized in the laboratory with ultracold atomic gases in optical lattices, leads to a large effective mass among other effects. [7] The peculiar band structure of the quasiparticle energy spectrum in the lattice can reduce the effects of pair-breaking excitations. [5] Similarly, when the pairing gap is large compared to the strength of the lattice, the effects of the band structure can be suppressed which can play an important role for neutron superfluid density in the inner crust of neutron stars. [8] Therefore, the effects of the periodic potential in superfluid systems are significant for various physical systems with vast differences in their properties such as densities and absolute temperatures. In the presence of inelastic collisions, it has been suggested that the superfluidity in ultracold atoms can show reentrant behavior with increasing dissipation for weak attractive interactions and should be enhanced by dissipation due to an interplay between the BCS-BEC crossover and the quantum Zeno effect. [9] Models with non-Hermitian dynamics on the two particle problem can host bound states in continuum. [2,5,10]

The aim of this work is to investigate the simultaneous effects of a periodic potential and a complex-valued interaction for the two-body problem in a periodic potential. With the gained understanding of the bound-state formation in this problem and the established computational approach, we will be able to attack the Cooper problem in the context described above. This will improve the understanding of superfluid systems in a periodic potential with particle losses.

Material and Method

The standard approach to two-body problems is to use the so-called center-of-mass and relative coordinates instead of the individual particle coordinates. When the problem is separable, the equations decouple and the relative coordinate involving the interaction becomes effectively a one-body problem which is independent of the center-of-mass motion. However, unlike the textbook examples, the two-body problem in a periodic potential is not separable in the center-of-mass and relative coordinates. In addition, the periodic potential leads to a band structure for the one-body problem where stationary states can be labeled by their quasi-momentum k and band index n. In order to simplify the calculations, one can further make a single-band approximation where only one energy band is considered. This allows one to describe the system in terms of a tight-binding Hamiltonian where each unit cell has one orbital. Such a model is described by a hopping matrix element between nearest-neighbor unit-cells and an on-site interaction term on a lattice. The two-body problem within a single-band approximation has been studied. [4] The Cooper problem in a one-dimensional lattice has also been studied with a single band tight-binding approximation. [3] In the lattice, a center-of-mass quasi-momentum K can still be defined as a conserved quantity. It appears in the eigenvalue equation for the relative coordinate in the solution of the energy eigenstates as a constant term. This symmetry consideration leads to smaller problems for each K and all solutions can be obtained in this way avoiding the larger Hilbert space to two-particles. The interaction leads to bound states with both

repulsive and attractive interactions. In this case, the Schrödinger equation for the relative coordinate has to be solved for each value of the center-of-mass momentum.
Our numerical approach involves constructing the Hamiltonian matrix in both position and momentum bases and diagonalizing it. We consider fermionic particles in a spin singlet state so that the spatial wave functions are symmetric under the exchange of particle coordinates. Following the above references, we consider the same problem with a complex-valued interaction. The non-Hermitian Hamiltonian is studied by following the treatment in [1]. Here, we focus on the binding energy of two-particles with an attractive interaction. The complex-valued interaction models the inelastic collision with particle losses. The mechanism for non-Hermiticiy enters in the two-particle problem as opposed to non-Hermitian mechanism acting the on the single particles. [2,5,10]

Findings

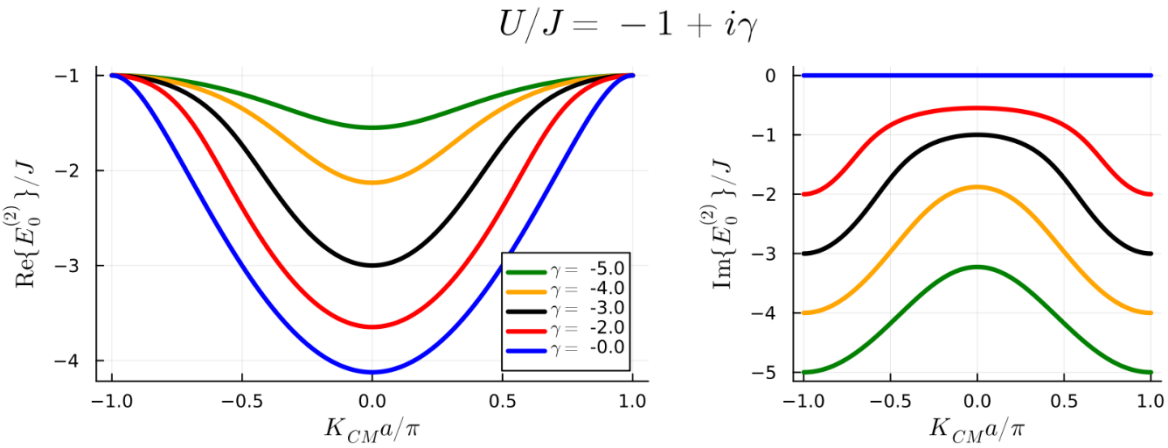

Figure 1. The real (left panel) and the imaginary (right panel) parts of the two-body ground state energies as a function of the center-of-mass momentum of the pair for different values of the collision loss rate.

We study the effects of dissipation on the binding energy as shown in Fig 1. The figure shows the bound state energy as a function of the center-of-mass quasi-momentum for a single band model. The real part of the interaction is negative for attractive interactions. The imaginary part is increased from zero and the results are shown for four non-zero values. It is seen that the global effect of the imaginary part of the interaction increases the (negative) bound state energy which thus decreases the binding energy. In addition, the imaginary part shown on the right panel implies that non-zero values correspond to a finite-lifetime for the bound state. From the shape of the three curves it is seen that the bound state with zero center-of-mass momentum has the longest lifetime and the states with maximum center-of-mass quasi-momentum have the largest decay rate for a given interaction. Finally, looking at the curvature of the real part of the bound state energy curves it is seen that the effective mass of the bound state increases with dissipation. The behavior of the dependence of these quantities on the imaginary part of the interaction is non-monotonic for weak interactions when the bound state band is partly within the continuum of extended two particle states.

Conclusion

The effects of a complex-valued interaction on the bound state energies of two-particles in a periodic potential has been studied within a single band approximation. It is found that the imaginary part of the interaction leads to lower binding energies, finite life-times and increased effective masses for the bound states. The preliminary results indicate a possible non-monotonic dependence on the imaginary part of the interaction, i.e. dissipation. We are ready to study the Cooper problem in a periodic potential with a complex-valued interaction. The inclusion of additional single-particle bands is also possible but becomes numerically more challenging as the number of single-particle bands increases.

Neutrino Particle Direction Estimation Using Transformer-Based Deep Learning

Şevval Coşkun[a], Emre Onur Kahya[a]

[a] Istanbul Technical University, Faculty of Science and Letters, Department of Physics Engineering, Türkiye
coskun21@itu.edu.tr

Keywords: Deep Learning, Neutrino, Transformer.

Aim

Neutrino events come from various processes, including astrophysical and atmospheric neutrinos, and, when studied scientifically, they provide valuable insights into the mechanisms that generate them. In particular, detecting and analyzing neutrinos produced by high energy cosmic phenomena, such as supernova explosions, gamma-ray bursts, and events in active galactic nuclei, offer crucial information about these extreme astrophysical processes [1]. Determining the direction of neutrino events presents a significant opportunity to investigate associated astrophysical phenomena through targeted observations rapidly. Neutrino direction estimation is fundamentally a parameter inference problem, where traditional approaches either struggle to achieve sufficient accuracy or demand significant computational resources [2]. Artificial intelligence offers promising prospects for processing complex event structures, enabling direct parameter estimation, and facilitating rapid inference. The aim of this study is to determine the direction of neutrino arrival by applying deep learning techniques to neutrino event data.

Material and Method

In this study, a Transformer-based deep learning approach is employed to estimate the direction of neutrinos. The study utilizes 117 GB of simulated neutrino event data provided within the IceCube – Neutrinos in Deep Ice competition, hosted by the IceCube Neutrino Observatory on the Kaggle platform from January 19, 2023, to April 20, 2023 [3]. The estimation process focuses on predicting the azimuth and zenith angles of neutrinos using a Transformer-based approach, drawing on the architecture first introduced in the 2017 paper "Attention Is All You Need"[4]. By leveraging the capabilities of deep learning, this study aims to enhance the accuracy of neutrino direction estimation while improving computational efficiency. The IceCube detector at the IceCube Neutrino Observatory is a cubic detection system consisting of a total of 5160 Digital Optical Modules (DOMs) installed in 86 boreholes drilled 2.5 km deep at the South Pole [5]. These DOMs detect the Cherenkov radiation caused by neutrinos, convert it into digital signals, and generate the dataset. The dataset used in the study consists of simulated data generated in parallel with the real data and consists of a train folder with a total of 660 Parquet files named in batch_id format, a sensor_geometry file containing the locations of the sensors in the IceCube detector, and a train_meta file. Due to resource constraints, training was conducted on randomly selected subsets of the dataset using the sub-sample method. As shown in Table 1 with the shared sample data, the train folder's Parquet files contain the event_id representing each neutrino event, the time parameter indicating the relative time in nanoseconds of any neutrino pulse within the event, the sensor_id specifying which sensor the pulse hit, the pulse charge, and an auxiliary flag indicating the fully digitized state with values true or false. The sensor_geometry file, which contains example data as shown in Table 2, provides the x, y, and z coordinates in meters of the DOMs in the IceCube detector. As shown in Table 3, the train_meta file contains the batch_id values of the batch files in the train folder, event_id information, the first and last pulse indices for the respective event, and the azimuth and zenith values used to determine the direction of the neutrinos. The azimuth and zenith values are used as target variables in the training process. A classical transformer architecture was used in the study. Transformer is a deep learning model with high prediction performance despite long training times, which is preferred in many problems today [4]. Python was used as the coding language, and pytorch as the library. The computations were performed as part of a graduate student project on machines provided by the National High Performance Computing Application and Research Center (UHeM) at Istanbul Technical University, which is supported by the Presidency of the Republic of Turkey, Presidency Strategy and Budget Directorate [6]. During data preprocessing, the sensor

position values, time values, and charge values were normalized. Positional encoding was added to the input data to transfer sequential information, and padding was applied to stabilize the sequence length value. The model architecture is a 2-layer Transformer encoder. There are 4 multi-head attention mechanisms in each layer. Different experiments were conducted with various sub-set sizes, evaluating two loss functions: the classical Mean Squared Error (MSE) loss and a custom DirectionMSELoss. While the classical MSE loss computes the squared differences directly between the predicted and target values, the DirectionMSELoss first converts the azimuth and zenith angles into 3D vectors using sine and cosine functions before calculating the MSE, thereby accounting for the spherical nature of the data. The optimizer was chosen as Adam, and the learning parameter value was set to 1e-4. The data set is randomly divided into 70% train, 15% validation, and 15% test.

Table 1. Presents a sample of the parquet data structure read from the train folder.

1	-256.14	-521.08	479.01
2	-256.14	-521.08	461.99

Table 3. Presents a sample from the train_meta parquet file.

Batch_id	Event_id	First_pulse_index	Last_pulse_index	Azimuth	Zenith
1	24	0	60	5.029555	2.087498
1	41	61	111	0.417742	1.549686
1	59	112	147	1.160466	2.401942

Findings

The model's performance was evaluated using two main metrics: the Mean Squared Error (MSE) and the R^2 score, as defined in Equation (1) and Equation (2), respectively.

$$MSE = \frac{1}{n}\sum_{i=1}^{n} \quad (y_i - \hat{y}_i)^2 \tag{1}$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n} \quad (y_i - \hat{y}_i)^2}{\sum_{i=1}^{n} \quad (y_i - \bar{y}_i)^2} \tag{2}$$

In some experiments, the MSE and R^2 were computed directly from the predicted and actual values (classical MSE), while in others, the azimuth and zenith angles were first transformed into 3D vectors before calculating the MSE and R^2 (3D MSE), thereby accounting for the spherical nature of the data. The classical MSE represents the mean square of the differences between the predicted values and the actual values, whereas the 3D MSE considers the spatial orientation of the data. The R^2 score is a statistic that measures the ratio of the difference between the

model's predicted values and the actual values to the total variance in the actual data. For different experiments, the model training durations, the loss function used, batch size, number of epochs, and findings are summarized in Table 4 using abbreviations such as Exp1, Exp2, etc. Additionally, the model outputs for each experiment are visualized in 3D in Figure 1, 2, 3, 4, and 5, where the predicted and actual direction vectors are displayed, as referenced in the table.

Exp5	742.59	0.65(DirectionMSE Loss)	1	5	1000	0.61 (3D MSE)	-0.87	Figure 5

Conclusion

In this study, a Transformer-based deep learning approach was employed to estimate neutrino directions using a simulated dataset from the IceCube – Neutrinos in Deep Ice competition. An examination of the results presented in Table 4 indicates that, in experiments Exp1 and Exp2, increasing the sub-sample size had a positive impact on the loss and evaluation metrics (MSE, R^2). However, due to resource limitations, the batch size could not be increased, leading to longer training times and higher computational costs when dealing with larger datasets. This finding highlights the importance of optimizing data loading and preprocessing strategies. Furthermore, in

experiment Exp3, Exp4, and Exp5 which utilizes a specialized loss function (DirectionMSELoss) that converts azimuth and zenith angles into 3D vectors, promising loss and MSE values were achieved even with fewer data points. Exp 4 and 5 improved the data-loading pipeline and enhanced efficiency by limiting the maximum sequence length. In Exp 5, unlike Exp 4, masking was also applied to the padding positions within each sequence in order to prevent the model from processing the padded elements, thereby aiming to improve performance. On the other hand, although R^2 showed an upward trend in Exp1 and Exp2 as the sub-sample size increased, it did not reach the expected level in Exp3, Exp4, and Exp5. This outcome underlines the need for further research and additional experiments. Overall, these findings underscore the significance of striking a careful balance between model configuration, data preprocessing, and computational resources in neutrino direction estimation. Future work will enhance preprocessing methods, explore various parameter settings, and broaden experimental conditions to achieve more robust and accurate results.

Understanding Epistemic Injustice Through Speech Act Theory

Berfin Eroğlu[a]

[a] Istanbul Technical University Department of Political Studies, Political Studies Program, Türkiye
eroglub21@itu.edu.tr

Keywords: Epistemic Injustice, J. L. Austin, Miranda Fricker, Perlocutionary Silencing, Speech Act Theory.

Aim

This thesis will attempt to establish a connection between Miranda Fricker's epistemic injustice and J. L. Austin's speech act theory. Although the connection between testimonial injustice and non-assertoric speech acts has been made by David C. Spewak (2017, 2021, 2023), I wish to argue that the relationship between hermeneutical injustice and non-assertoric speech acts, especially perlocutionary acts, has been overlooked.

Material and Method

In her book titled Epistemic Injustice: Power and Ethics of Knowing (2007), Miranda Fricker formed a link between social epistemology, virtue ethics and theories of justice. She coined the key term ''epistemic injustice'' in order to illustrate how a person can be epistemically harmed in their capacity as a knower. The term has two sub-categories such as testimonial injustice and hermeneutical injustice. While the former refers to dismissed assertions, not only in testimonial exchanges but also in any sort of action involving telling, the latter is related to the inability of a speaker making themselves intelligible to a hearer due to a gap in the collective hermeneutical resources as a result of the speaker to being hermeneutically marginalised on a systematic basis and excluded from meaning-making and knowledge production process. While the large portion of the book revolves around a detailed discussion on testimonial injustice, taking precisely six chapters, the discussion about hermeneutical injustice is discussed only in the final chapter of the book. For this reason, even though the concept seems intriguing and has piqued the interest of some scholars, there seems to be a need for further exploration. Since Fricker's theory is directly related to language and epistemology, there have been attempts by some scholars such as David Spewak Jr. to correlate epistemic injustice to J. L. Austin's (Austin, 1962) speech act theory in order to gain a better insight on the practical aspect of Fricker's theory. Challenging Fricker's assumption that testimonial injustice involves only assertions, David Spewak Jr. argued that the cases of testimonial injustice are not exclusive to assertions but can also include other speech acts. In his papers, Spewak uses Austin's speech act theory as well as the notion of 'conversational scoreboard' by David Lewis (1979), which is a contextual account of meaning and reference in philosophy of language. With this notion, Lewis argues that conversational dynamics are akin to a baseball game in the sense that each move in the game is recorded, thus, the score of the game/conversation is influenced by what happens within the game/conversation.

Similar to Spewak, I will also take the Lewisian account and argue that if the aim of a conversation is to update its scoreboard by making use of shared meanings and concepts, then the speaker contributes to the conversation in order to influence the scoreboard. A similar idealisation has been made by Rae Langton and Jennifer Hornsby (Hornsby & Langton, 1998) regarding silencing, though their focus was on the illocutionary acts involving assertions. Similarly, Fricker's own notion of testimonial injustice is linked directly to assertions even though Fricker objects to Hornsby and Langton's model of silencing due to the claim that it is not a sufficient account of exploring the epistemic harm as Fricker envisages with her own theory. Correspondingly, Spewak also rejects Langton and Hornby's account on illocutionary silencing as a model to explain testimonial injustice due to his belief that it only illustrates linguistic harm and fails to offer the epistemic harms of dismissed assertions. Thus, this leads Spewak to challenge both Fricker on the grounds that testimonial injustice does not only involve assertions, but also other speech acts such as perlocutionary acts which include directives, commissives, expressives and exercitives. In Austin's theory, perlocutionary acts refer to utterances that are made to influence the hearer whereas illocutionary acts, as argued by Langton and Hornsby, are mainly related to performatives which refers to 'doing by saying' in Austinian terms. To illustrate, a speaker may promise to do a certain act and

by uttering "I promise", he/she performs the very act of promising. Other examples of performatives given by Austin are christening, apologising, warning, declaring and refusing. Thus, Langton and Hornby's model of illocutionary silencing focuses on especially the acts of refusal in the context of women's sexual encounters with men who are misled by pornography and fail to perceive the refusal of real-life women. In this case, since women's capacity as knowers is not harmed on an epistemic level, both Fricker and Spewak reject applying this model of silencing to cases of testimonial injustice.

Findings

As argued above the main difference between Fricker and Spewak is related to which speech acts they believe to be involved in cases of testimonial injustice. It is the purpose of this thesis to add another dimension to this matter and argue that although Spewak's account of non-assertoric speech acts is significant for providing a better understanding of non-assertoric cases of testimonial injustice, both Fricker and Spewak overlook the connection between perlocutionary acts and hermeneutical injustice and how those acts can provide a better understanding of testimonial injustice. For this reason, I aim to offer a theoretical contribution to the issue at hand. In order to link this to both speech act theory and epistemic injustice, I will argue that there are cases of hermeneutical injustice that do not only involve assertions and can directly lead to testimonial injustice. Even though silencing has been equated to illocutionary silencing (assertions) thus far, Spewak's concept of perlocutionary silencing is a step forward in understanding the notion of epistemic injustice. However, Spewak connects perlocutionary silencing to the cases of testimonial injustice, I will argue that perlocutionary silencing can also be connected to hermeneutical injustice which has not been thoroughly discussed by Fricker herself in terms of the speech acts it may involve. The main idea behind my thesis is that if we take the Lewisian account of conversational dynamics, then a speaker uses common meanings and concepts while engaging in a conversation with the aim of updating the scoreboard. This would require the hearer to accept the conversational moves made by the speaker to update the conversational scoreboard. This means that the speaker intends to have the perlocutionary effects on the hearer to accept the moves made. If the speaker's meaning in their utterance is not shared by the hearer, then the speaker is rendered unintelligible and is silenced by the hearer, which leads the speaker to become hermeneutically marginalised. If the speaker is hermeneutically marginalised, they cannot contribute to the meaning-making and knowledge production processes due to failing to achieve their perlocutionary goals and to update the conversational scoreboard. Thus, if there is a case of perlocutionary silencing, then hermeneutical injustice occurs. Even though this argument may seem flawed to some, I will argue that it helps explain what kind of prejudicial dynamics take place even before testimonial injustice occurs. Since conversation revolves around common concepts, the subject of hermeneutical injustice, by definition, is rendered unintelligible due to a gap in common hermeneutical resources. When this is the case, it leads to bias in understanding the subject of hermeneutical injustice in their testimonial exchanges. This means that hermeneutical injustice takes place before testimonial injustice due to the prejudice created by the assumed unintelligibility of the speaker which usually follows certain groups in other aspects of their lives.

Conclusion

As this thesis offers a sequentialist account of epistemic injustice with the integration of speech act theory, it might be argued by some readers that the link between hermeneutical injustice and perlocutionary acts seems to be based on shaky grounds in the sense that hermeneutical injustice may not involve any speech acts at all. Even though this may be a valid concern, Fricker's own gaps in the exploration of the concept and her previous adamancy on assertions in the cases of testimonial injustice point to another assertoric assumption. Furthermore, as I will argue, taking a Lewisian account would require the need for common concepts and when this account is added to Fricker's own argument that hermeneutical injustice takes place before testimonial injustice does, it creates a sequentialist account between the types of epistemic injustice. Therefore, there has to be a previous conversation between two groups/individuals involved in the conversations before testimonial injustice takes place due to identity prejudice. Since Fricker's account fails to explain how this identity prejudice is formed and leads to testimonial injustice, taking hermeneutical injustice proves useful, for in the cases of testimonial injustice that are by definition always based on identity prejudice, there is always a previous stage of hermeneutical injustice that lays the groundwork

for identity prejudice that leads to testimonial injustice. By taking hermeneutical injustice as a preliminary stage, wherein the absence of common concepts leads to the unintelligibility of the speaker and consequently perlocutionarily silencing the speaker who fails to make the conversational moves based on perlocutionary goals that require the hearer to accept the made moves and to be influenced by those moves, the subject of hermeneutical injustice becomes hermeneutically marginalised and cannot contribute to the common meaning-making and knowledge production process, thus becoming a subject of identity prejudice as someone who cannot make what they are and what they know to be heard. By following this logic, before testimonial injustice takes place due to identity prejudice, we can argue that one first becomes hermeneutically marginalised which then leads to the identity prejudice and the testimonial injustice that they face.

Adsorption Performance of Hydrophilic PolyHIPE on Removal of Methylene Blue Dye

Bora Işılgan[a], Büşra Akın Özmen[a], Erdem Yavuz[a]

[a]Istanbul Technical University, Department of Polymer Science and Technology, Polymer Science and Technology Programme, Türkiye
isilgan23@itu.edu.tr

Keywords: Electrostatic Interaction , Emulsion Template , Langmuir Isotherms , PolyHIPE , Pseudo-Second Order Kinetic.

Aim

Methylene blue with environmentally persistent and harmful, toxic, and carcinogenic is one of the widely used cationic dyes that dyeing fabrics in textile industries and also for dyeing papers and leathers are applied in large amount as synthetic dye. That is why, leakage of methylene blue with not biodegradable into the environment as waste necessitates solutions for its removal. Adsorption process is a useful technique for elimination of dyes from wastewater. Thus, by making use of emulsion templating method, which is the polymerized of high internal phase emulsion abbreviated as polyHIPE, for synthesizing adsorbent, methylene blue has been captured from dye solution in a remarkable amount, constituted of the main reason of this study.

This work ascribed to the two properties that electrostatic interaction between methylene blue contained quaternary amine group with porous polymeric material including the potassium salt of sulfonic acid and swelling degree was assessed by terms of the two fundamental approach involved the kinetics and isotherms. The various parameters like pH, ionic strength, dye concentration and adsorbent amount on adsorption kinetics were evaluated as well.

Material and Method

Chemicals;

All starting chemicals utilized for the synthesis of adsorbent and adsorption study were used without any pre-purification. 3-Sulfopropyl methacrylate potassium salt (SPMA), N,N′-Methylene bis(acrylamide) (MBAM), potassium persulfate (KPS), N,N,N′,N′-Tetramethyl ethylenediamine, Toluene, Poly (ethylene oxide)-block-poly(propylene oxide)-block-poly(ethylene oxide), (Pluronic F-127, MW = 12,500 g/mol) provided from Sigma-Aldrich. were used for synthesis of polyhipe. Diethyl ether purchased from Sigma- Aldrich and ethanol with of analytical grade were handled for the purpose of soxhlet extraction. Methylene blue, Rodamine B and Malachite Green Carbinol supplied from Sigma- Aldrich were used to realize the adsorption process.

Synthesis of Sulfonated Based PolyHIPE;

The oil in water (o/w) emulsion composed of 80 % volume fraction oil droplets was prepared as following steps. Initially, surfactant Pluronic F-127 (1g), monomer SPMA (6,12g) cross-linker MBAM (0.154 g), the initiator KPS (0.120 g) were dissolved in water in three neck flask. After that toluene was added drop by drop in a period of two hour. An Overhead stirrer operating at 450 rpm was used to obtain a homogenous emulsion. After the addition of toluene, stable emulsion was achieved and with the addition of the catalyst TEMED(0,1ml), further mixing with approximately one minute was continued. Subsequently, the emulsion was transferred to polypropylene vial and polymerization occurred in a convection oven at 40°C for 24 h. The resulting monolith was purified via Soxhlet extraction with ethanol and diethyl ether, each for 24 h. The polyHIPE was dried under convection oven at 60°C for at least 24 h.

Characterization;

The Attenuated Total Reflectance Fourier Transform Infrared (ATR FT-IR) spectra of samples were recorded on a Thermo Scientific, Nicolet iS20 FT-IR spectrometer equipped with the Platinum diamond ATR module in the range

of 400-4000 cm-1 with a resolution of 4 cm-1.By a double beam UV−vis spectrophotometer (PerkinElmer, Lambda 25) was used to determined for dye concentrations in the adsorption experiments.

Findings

The preparation of polyHIPEs which incorporate the ionically charged functionalities along with the inherent hydrophilic properties and low crosslinking degree that contributes to the improvement of adsorption capacity by swelling in water and thus to the highly effective removal of dyes.

Adsorption Kinetics of Metyhlene Blue

All of the adsorption assays were carried out with plastic vials in magnetic bar and 500, 1000, 2000, 3000, 4000 and 5000 ppm dye solutions, i.e., approximately 7 ml, were used for kinetic experiments. The maximum adsorption capacity was reached to 1483 mg/g after 180 min. A highly efficient adsorption is reflected with in a very rapid decrease of methylene blue dye concentration in aqueous solution during the first 10 min, which is reprepented with Figure 1.

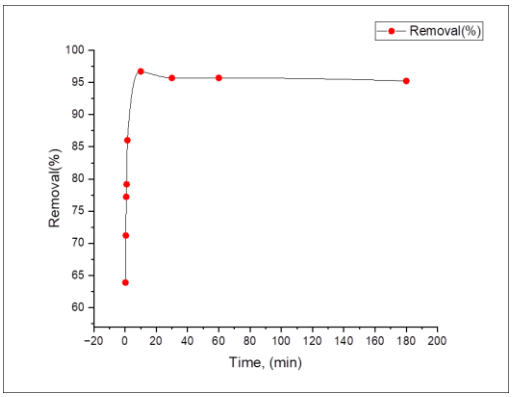

Figure 1. The removal percentage of 5000 ppm methylene blue versus time.

Adsorption kinetics and isotherms demonstrated that the hydrophilic polyHIPE is an effective adsorbent toward methylene blue. Maximum adsorption capacity of this material reached to 1483 mg/g, is intriguing value compared to other scientific articles. Another interesting point is that other cationic dyes, Malachite Green Carbinol and Rodamine B, were removed to 99,15 % and 98,35 % from 1000 ppm dye solution. Evaluating the kinetics and isotherms, as shown Table 1, Table 2 and Figure 2, Pseudo-second order kinetic and Langmuir isotherms are agreed well with experimental datasets which is situation shows that electrostatic interaction are more dominant than other intermolecular forces.

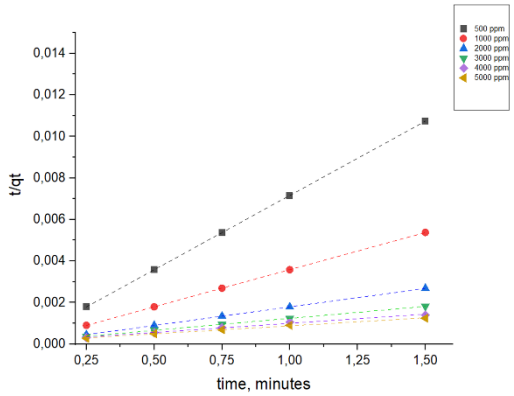

Figure 2. The pseudo-second Order kinetics for different dye concentration.

Water Uptake and Swelling Ratio

Evaluating the kinetics of water uptake, the rapid uptake reaching the equilibrium value in 20 min proved that the high degree of capillary action within the void structure and void expansion of polyHIPE is the main factor. The maximum water uptake was reached to 34,2 g. In other words, as seen in Figure 3, the adsorbent held ,approximately, 3400 percent of its own weight in water.

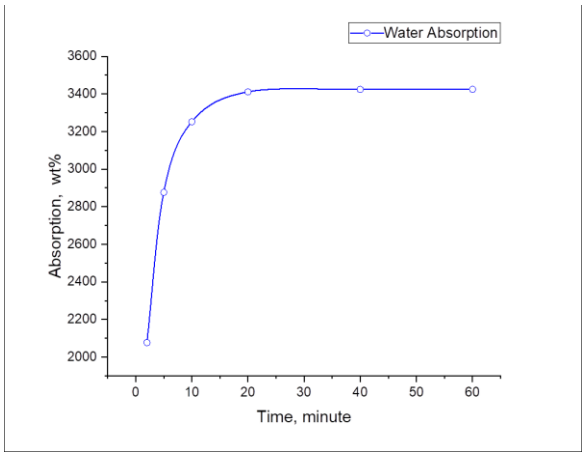

Figure 3. Variation of water absorption with time.

The equilibrium water uptake was calculated with according to the formula shown in Equation 1. The equilibrium water uptake (Ai) was obtained by placing with a known dry mass (m_D) into a sintered glass filter funnel filled with the water until a constant swollen mass (m_{SW}) was reached.

$$A_i = \frac{m_{sw} - m_D}{m_D} \quad \text{(Equation 1)}$$

The Maximum Adsorption Capacity of Adsorbent

To determine of maximum adsorption capacity of adsorbent, dye solutions prepared at various concentrations ranging from 100 ppm to 10000 ppm were adsorbed with adsorbent quantity remained constant. The results show that an adsorption capacity of 1483 mg of dye per 1 gram of adsorbent was achieved.

Demonstration of The Ionic Effect on Adsorption Capacity

The effect on adsorption capacity of ionic strength was determined with 100 ppm dye solution prepared with 0.1, 0.2 and 0.3 M sodium chloride. As can be seen from the Figure 4, the higher salt concentration found in dye solution, the lower adsorption capacity was obtained.

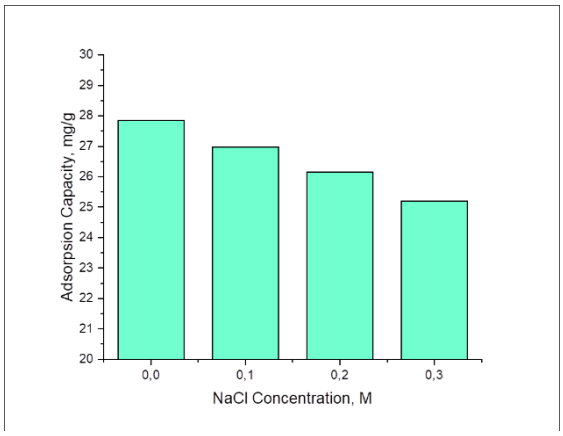

Figure 4. The ionic effect on adsorption capacity.

The Effect on Adsorption Capacity of Buffer Solution

To understand the effect of pH on the adsorption capacity, adsorption assays were taken place in acidic medium prepared with acetate buffer and basic medium obtained from phosphate buffer. As observed in Figure 5, the adsorbent is suitable for dye adsorption in a wide pH range.

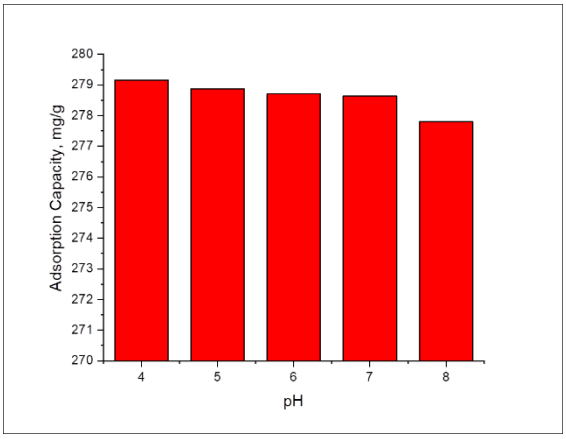

Figure 5. The effect of buffer solutions with different pH values on adsorption capacity.

Conclusion

PolyHIPE based adsorbent bearing sulfonic acid salts which imparts its hydrophilic characters possesses low-crosslinking, which made its good candidate for removing the cationic dyes.

Keywords: Hydrogels, Eco-Friendly Adhesives, Lignin, Polyvinyl Alcohol, Bio-Based Adhesives.

Aim

Adhesives, as an essential supplementary material in several industries, are widely used in medicine, packaging, fabrication, transportation, construction, and renewable energy. Current adhesives, due to their toxicity, negative environmental effects, and non-renewable raw ingredients, have led to attempts to synthesize environmentally friendly and renewable adhesives from bio-based materials and have attracted increasing attention (Huang et al., 2022). Lignin (Lig) is one of the most abundant renewable natural polymers on the planet(Shah et al., 2023). As the only non-petroleum source of renewable aryl compounds in nature, it is an appropriate alternative for phenol because of its phenylpropane units, which are similar to phenol(Gong et al., 2022). Because of their low manufacturing costs, biocompatibility, and biodegradability, as well as their numerous functional groups such as hydroxyl, carboxyl, and aldehyde, Lig can be cross-linked with other polymers, giving them a high potential for use in the synthesis of biodegradable hydrogels and adhesives(Kai Dan et al., 2016).

Tannic acid (TA) is a natural polyphenol, that exists in a wide variety of plants as a colorless to pale yellow solid with an astringent taste. It is also known as a main component of mussel-inspired adhesives(Trimble, 1892),(Yang et al., 2022). TA is composed of pyrogallol and catechol groups with antioxidant, antibacterial, and anti-inflammatory characteristics when interacting with other materials(Trimble, 1892). Polyvinyl alcohol (PVA) is a water-soluble, synthetic, inexpensive, and nontoxic polymer(Ben Halima, 2016). The hydroxyl groups (-OH) on the PVA can connect with multiple functional groups, leading to the formation of crosslinked and water-resistant networks with good mechanical stability(Nagarkar & Patel, 2019),(Pingan et al., 2017). Polyethyleneimine (PEI) is a positively charged hydrophilic polymer with an abundance of amine groups. This crosslinking agent creates a three-dimensional, hydrophobic structure by hydrogen bonding and electrostatic processes (Wang et al., 2022).

According to the mentioned toxicity and limitations in the adhesives sector, lignin-based hydrogels with the adhesion ability to attach to different surfaces are highly required in the modern world. For this aim, we synthesized eco-friendly bioadhesives using Lig, PVA, TA, and PEI by mixing and investigating Lig's effects on characteristics and adhesion properties in both dry and wet environments.

Material and Method

Briefly, the solution of PVA (30% w/v), TA (0.66 w/v), and Lig (15% w/v) was prepared. Then, the determined amounts of PVA, PEI, and TA were added respectively and mixed at room temperature to reach a homogenous mixture. By the addition of 0, 0.4, 0.8, and 1.6 g of Lig in the prepared compound and mixing for another 40 min, the PTPL(PVA+TA+PEI+Lig)0, PTPL0.4, PTPL0.8, and PTPL1.6 formulations were achieved, respectively.

The synthesized hydrogels were characterized by Fourier Transform Infrared (FTIR), scanning electron microscopy (SEM), contact angle, and adhesion strength tests. In order to study the adhesion strength of PTPL hydrogels, the lap shear test was performed on steel substrate under dry and wet conditions using the ASTM (F2255-05) standard method on a Devotrans tensile machine (DVT UZMK).

Findings

The obtained results displayed the successful synthesis of coacervate hydrogels. FTIR spectra indicated resulted functional groups formed through the various interactions between compounds. As shown in Figure 1, the peak at around 1700 cm^{-1} is related to the stretching vibration of aromatic C=O groups in TA, which is seen in all formulas(Mobaraki & Hemmateenejad, 2011). The asymmetric stretching bond of C-H groups of PVA can be seen at 2917cm^{-1} (Hong et al., 2018). The broad peak at 3307 cm^{-1} is attributed to O-H stretching vibrations of Lig, TA, PVA, and all formulas and hydrogen bonding (C. Chen et al., 1998). This peak overlapped with the N-H stretching vibration peak of PEI at 3277cm^{-1} in the prepared adhesives spectra (Z. Chen et al., 2020).

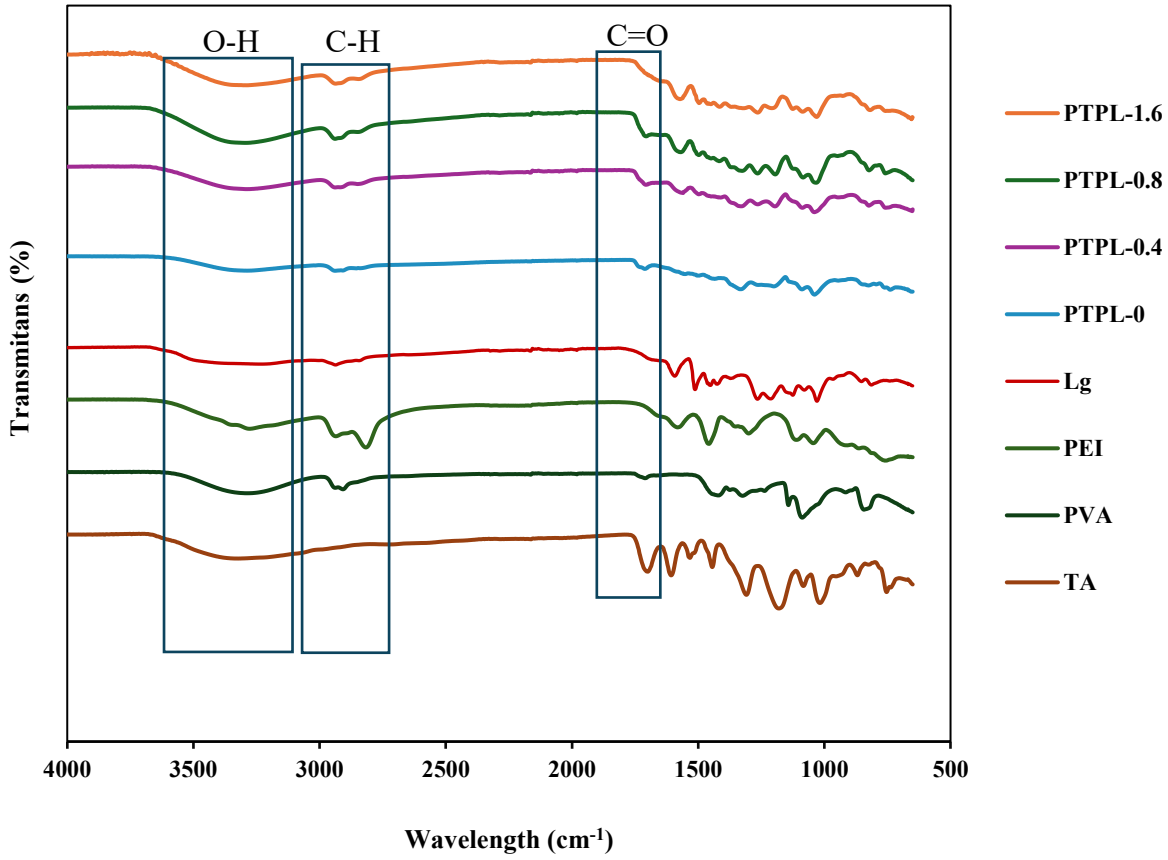

Figure1: FTIR spectra components and prepared hydrogels

The lap shear adhesion test demonstrated a remarkable enhancement in adhesion strength under both dry and wet conditions by the addition of Lig in the formulation. As we can see in Figure 2a and b, the PTPL0.8 adhesive hydrogel showed the highest amount of adhesion strength in both dry and wet conditions with 1753±417 and 2719±634 kPa, respectively, which was attributed to the increase in Lig concentration and strong crosslinking via hydrogen bonding, electrostatic, π-π, and ionic interactions (Benítez-Mateos et al., 2021)·(Xie et al., 2021)·(Qin et al., 2022).

Conclusion

In conclusion, this study successfully synthesized novel, environmentally friendly bioadhesives utilizing Lig, PVA, TA, and PEI. Considering the growing demand for eco-friendly alternatives to traditional toxic adhesives, this research explored the potential of Lig, an available and renewable resource, to enhance adhesive properties. The successful formation of coacervate hydrogels was confirmed through characterization tests, which revealed the presence of functional groups indicative of interactions between the constituent polymers. The lap shear adhesion

test findings suggest that this adhesive holds great promise in dry and underwater applications with increasing Lig concentration. Notably, the PTPL0.8 formulation exhibited the highest adhesion strength, which facilitated effective crosslinking. Future research focuses on optimizing the adhesion strength and rheological properties of lignin-based hydrogels on various substrates, wet environments with acidic and basic pHs, and long-term environmental impact assessment.

Effect of Talc on Carbon Black Reinforced Natural Rubber Compound

Hatay Cöcen[a], Nilgün Kızılcan[b]

Keywords: Carbon Black, Hybrid Filler, Natural Rubber, Talc.

Aim

The unique mechanical properties of rubbers make them suitable for applications in which cyclic loadings are involved. However, due to the high hysteretic losses present in such materials, a significant heat generation occurs. This effect in combination with the low thermal conductivity, leads to a considerable increase in the temperature in the rubber components, which is commonly referred to as heat build-up. (Scihieppati, 2019) High temperatures accelerate the fatigue of rubbers, so it is very important to find proper ways to reduce the heat buildup of rubbers in dynamic applications. Therefore, the formation of thermal conductive pathways in a rubber matrix with a high thermal conductivity can be helpful to attenuate heat build-up. (Weng, 2010)

To improve the thermal conductivity of polymers, fillers with a higher thermal conductivity than the matrix, such as aluminium nitride (AlN), boron nitride (BN), aluminium oxide (Al_2O_3), silicon dioxide (SiO_2), silicon carbide (SiC), silicon nitride (Si_3N_4), carbon nanotubes and nano-diamond, are used to create polymer-based composites with improved thermal conduction (Kochetov, 2011). Using two or more different fillers in the same composite material provides higher enhancements in thermal conductivity. It is caused by the synergetic effect between the particles. (Suplicz, 2012)

The purpose of this research study is to investigate the potential for the use of hybrid fillers by exploiting their various properties, especially thermal conductivity, particle size and shape. With this aim, into the carbon black reinforced natural rubber (NR) based compounds; talc, which is a natural mineral composed of hydrated magnesium silicate with the chemical formula $Mg_3(Si4O_{10})(OH)_2$ (Rothon, 2017), will be added as a second filler. The use of NR as rubber matrix in this research is attributed to its inherent properties making it suitable for dynamic applications, which are excellent mechanical properties and high resilience (lower hysteresis (heat build-up)) compared to other rubber materials (Mathew, 2001). As the main filler, carbon black is chosen due to its high reinforcement, low cost and thermally conductive properties. As a second filler, talc is preferred because of its thermally conductive nature and platelet particle shape in addition to the advantageous price. Moreover, there has been very little previous research on the performance of carbon black and talc filled natural rubber compounds so far. With this aim, carbon black reinforced natural rubber compounds without and with different amounts of talc will be produced keeping other parameters constant at the predetermined values, and the effect of talc amount on mechanical and dynamic properties of compound will be examined. In addition, the effects on their morphological, rheological, physical, and thermal resistance properties will be also analyzed and correlated with the used formulations.

Material and Method

5 different recipes were prepared containing different amounts of carbon black and talc, as seen in Table 1. Imerflex T10C product with median diameter 4.7µ from Imerys was preferred for talc whereas N330 grade carbon black, whose particle size is 28-36nm, from the producer, Kremenchug was used. SEM images of these two filler materials can be seen in Figure 1, showing the spherical shape of carbon black and platelet shape of talc.

Table 1. Recipes of the natural rubber compounds produced.

Materials	CB50	CB50+T5	CB50+T10	CB55+T5	CB60
NR	100	100	100	100	100
Peptizer	0,25	0,25	0,25	0,25	0,25
N330	50	50	50	55	60
Talc	-	5	10	5	-
ZnO	5	5	5	5	5
Stearic acid	2	2	2	2	2
6PPD	2	2	2	2	2
TMQ	2	2	2	2	2
S-80	2	2	2	2	2
TBBS-75	2	2	2	2	2

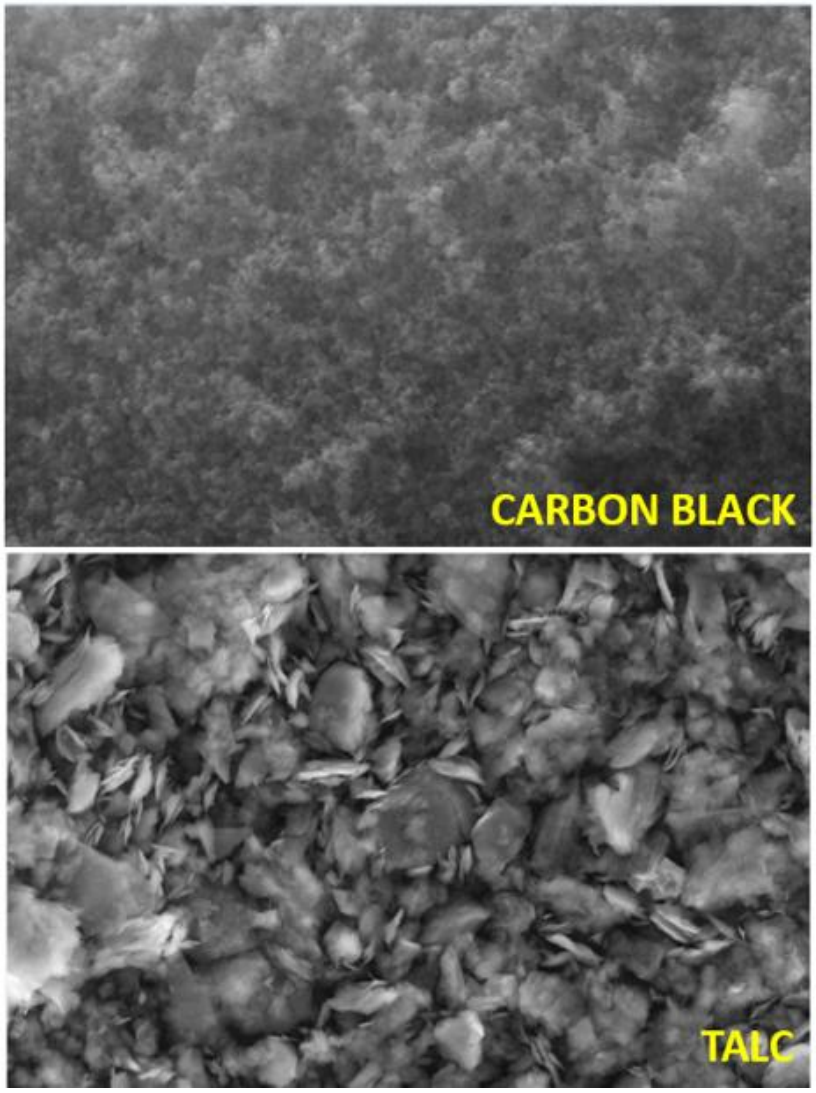

Figure 1. SEM images of carbon black and talc.

The weighed raw materials according to the formulation were mixed, and rubber compounds were produced using a laboratory type mixer and a two-roll mill. All the compounds were prepared by 2-stage mixing. The 1st stage is masterbatch preparation, in which rubbers, fillers, and all chemicals are mixed. The 2nd stage is final mix, where vulcanization agents (sulphur and accelerators) are added.

Findings

Rheological properties:

When the ts_2 (scorch time, the time for the viscosity to increase 2 units above minimum torque) and t_{90} (time at which 90% of crosslinking has been completed) values of the CB50, CB50+T5, and CB50+T10 compounds; in which talc was added as extra amounts to the carbon black, are compared, it can be seen that the results are scattered in a narrow range, as seen in Figure 2. In other words, it can be concluded that talc does not affect the scorch and vulcanization time much. On the other hand, comparison of CB50+T10, CB55+T5, and CB60 compounds shows us that partial replacement of carbon black with talc increases both the scorch and vulcanization time, directly proportional to the talc amount. Also, as realized in Figure 2, the addition of talc decreases CRI (curing rate index, which is equal to $100/(t_{90}-ts_2)$) in both cases, but is more dominant in the partial replacement.

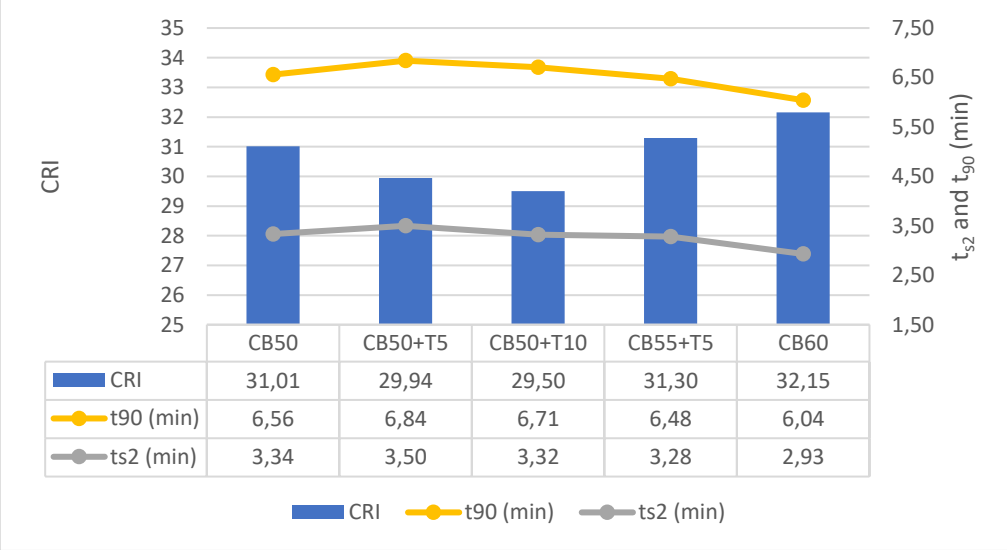

Figure 2. Effect of talc on the curing rate of the compounds.

It is observed in Figure 3, ML (minimum torque), which gives insight into the viscosity, increases as the amount of talc in the compounds increases from CB50 to CB50+T10 because of the reinforcement effect of the talc. On the other hand, while talc amount goes up in the carbon black-replaced compounds, ML goes down because of the higher particle size of the talc than carbon black; as a result less interfacial area and less friction between the rubber and filler. In Figure 3, ML values are also correlated with ML (1+4) values obtained in the Mooney viscosity test at 100˚C. It is observed that the results from both tests are aligned perfectly.

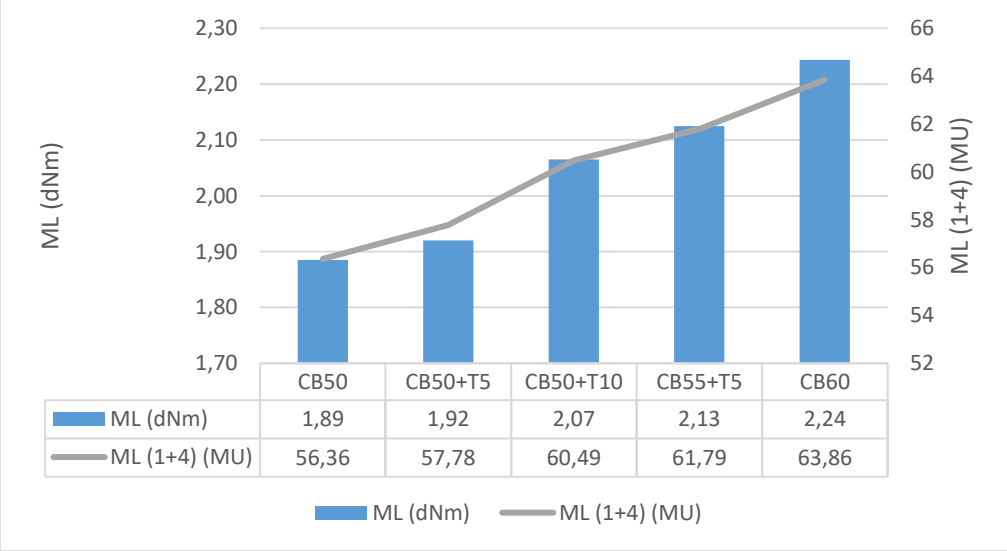

Figure 3. Effect of talc on the viscosity of the compounds.

Morphological properties:

It is seen in Table 2, addition of talc to the compound improves dispersion (X) of carbon black and decreases average agglomerate diameter (AAD) while partial replacement of carbon black does not affect the filler dispersion, which can be concluded from the similar X and AAD values of the CB60, CB55+T5 and CB50+T10 compounds.

Table 2. Morphological properties of the compounds.

	CB50	CB50+T5	CB50+T10	CB55+T5	CB60
X	5,99	6,23	6,63	6,66	6,66
AAD (μ)	10,1	9,65	9,09	9,07	9,14

Physical and mechanical properties:

Physical and mechanical properties of the compounds are summarized in Table 3. The density of the compounds increases with increasing talc amount as expected since talc density is higher than both natural rubber and carbon black. Moreover, the hardness of the compounds, increases with the addition of the talc and decreases with the partial replacement of the carbon black because of its lower reinforcing effect, which stems from both its inorganic structure and higher particle size. In the terms of mechanical properties, it can be concluded that tensile strength and elongation at break values are very close to each other (see Table 3) whereas modulus values of the compounds increase depending on the increasing amount and reinforcement effect of the two fillers, which is in line with hardness results (see Table 3).

Table 3. Physical and mechanical properties of the compounds.

	CB50	CB50+T5	CB50+T10	CB55+T5	CB60
Density (gr/cm_3)	1,1191	1,1388	1,1580	1,1505	1,1431
Hardness (Shore A)	67,0	68,3	69,3	70,3	71,5
Tensile strength (MPa)	27,4	26,9	26,2	26,2	25,4
Elongation at break (%)	483,2	483,2	468,8	466,6	448,2
Modulus 100% (MPa)	3,05	3,28	3,58	3,57	4,03
Modulus 200% (MPa)	8,32	8,42	8,73	9,19	10,72
Modulus 300% (MPa)	14,98	14,98	15,30	15,89	17,40

Thermal aging properties:

In Table 4, change in properties after aging for 72h at 100˚C shows us that compounds containing talc have slightly higher aging resistance, especially when the talc is added as extra like in the compounds CB50+T5 and CB50+T10.

Table 4. Thermal aging performance of the compounds.

Change in properties (%)	Tensile strength	Elongation at break
CB50	-23,46	-30,46
CB50+T5	-20,51	-28,56
CB50+T10	-19,25	-28,71
CB55+T5	-19,16	-28,20
CB60	-16,47	-30,39

Dynamic properties:

In the heat build-up test, it is seen that as the filler amount increases, the heat build-up (temperature rise) increases because of the friction between the rubber and filler, as seen in Figure 4. The results at different loads align well and confirm each other. It is also observed that, although carbon black has a lower particle size and so a higher surface area, it increases the temperature rise less than talc. This is most probably caused by interfacial resistance between organic rubber and inorganic talc.

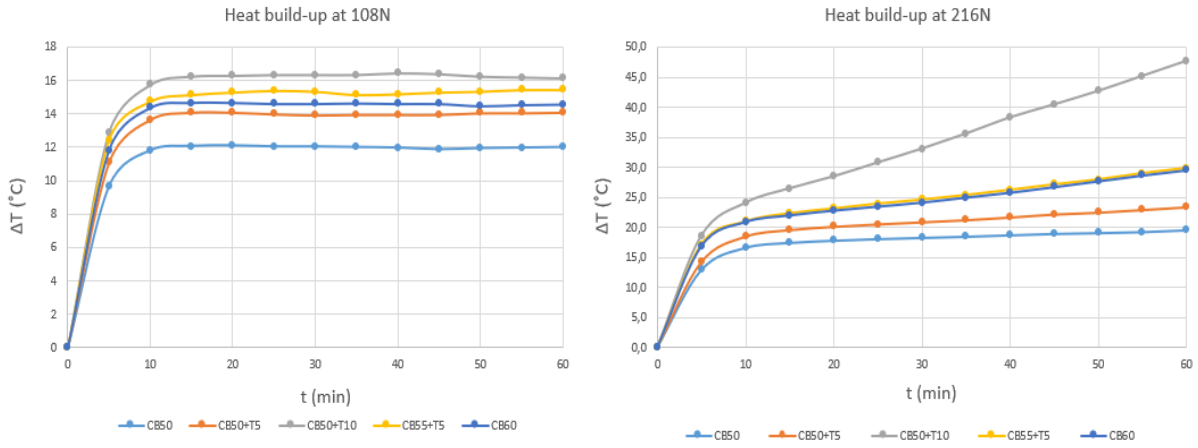

Figure 4. Temperature rise of the compounds at different loadings.

In the tension fatigue test, it is realized that the amount and reinforcement effect of filler impact the fatigue performance negatively (see Figure 5). In other words, the addition of talc or carbon black decreases the fatigue life; however, partial replacement of the carbon black with talc, as in the case of CB55+T5 and CB50+T10 samples improves the compound performance. This result can be attributed to the higher stiffness of the compounds and so lower crack growth resistance with increasing reinforcement.

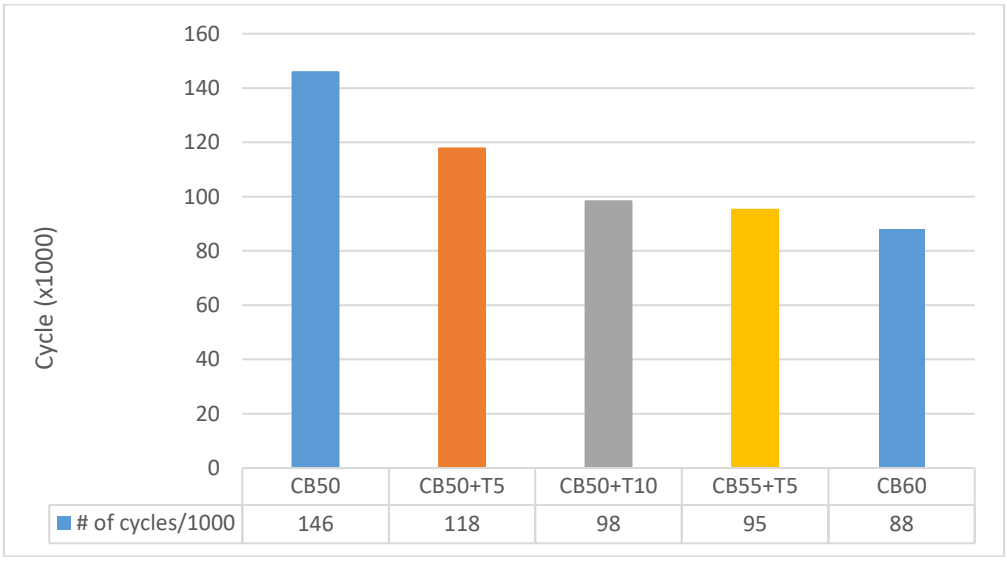

Figure 5. Fatigue lives of the compounds.

Conclusion

To conclude, talc increases the hardness and stiffness of the compounds, but its reinforcing effect is less than carbon black, as expected. It also increases heat aging resistance. When used as a partial replacement of carbon black, it improves tension fatigue performance. On the other hand, talc increases heat build-up of the compounds, even more than carbon black. This negative effect of talc is because of weak physical bonds formed with natural rubber and interfacial resistance at the rubber-filler interface, which are the results of its inorganic nature. It is estimated that this disadvantage will be eliminated via interface functionalization by forming covalent bonds using the silane coupling agent in the next part of the research.

Keywords: Train Localization, Sensor Fusion, FOS (Fiber Optic Sensors), GNSS/IMU Integration, FDI.

Aim

Railway systems are indispensable for modern urban and intercity transportation, offering high capacity, energy efficiency, and robust sustainability (Heirich, 2020; Özgüner et al., 2011). However, guaranteeing operational safety and reliability in these systems requires continuous monitoring of trains and tracks—an endeavor challenged by issues such as electromagnetic interference and GNSS (Global Navigation Satellite System) signal dropouts (Zhou et al., 2022; Emirler et al., 2013).

This document focuses on improving the accuracy, reliability, and safety of railway system localization by leveraging a combination of GNSS, IMU (Inertial Measurement Unit), Radar, LiDAR (Light Detection and Ranging), camera, and other sensor technologies, in addition to more specialized methods such as indoor positioning (IPS) and fiber optic sensing (Özgüner et al., 2011; Heirich, 2020).

Finally, this study explores the strengths and limitations of various sensor types and advanced techniques—such as sensor fusion, machine learning-based fault detection (FDI), and track irregularity-based localization—to address environmental challenges like electromagnetic interference and GNSS signal loss (Akleylek et al., 2021; Emirler et al., 2013). It also evaluates the potential of fiber optic methods such as DOFS (Distributed Optical Fiber Sensors) and FBG (Fiber Bragg Grating) for real-time rail deformity detection and improved train positioning (Sasy Chan et al., 2021). Furthermore, novel approaches like CNN–LSTM (Convolutional Neural Network–Long Short-Term Memory) are considered for enhancing accuracy, lowering maintenance costs, and strengthening early warning systems (Sun et al., 2024; Garramiola et al., 2018). Ultimately, the study proposes an integrated framework that combines GNSS–IMU with next-generation sensing and analytics for precise and reliable train localization.

Material & Method

2.1. Sensor Suite Configuration

An advanced sensor suite provides global position information with GNSS (GPS, GLONASS, Galileo, etc.) but can be affected by signal obstructions and low-signal areas (Akleylek et al., 2021). However, methods like RTK (Real-Time Kinematic) or DGPS (Differential Global Positioning System) enable centimeter-level accuracy (Özgüner et al., 2011). The IMU uses inertial data for position and movement tracking but relies on GNSS corrections to minimize drift (Emirler et al., 2013). Radar offers reliable detection even under poor visibility conditions, while LiDAR facilitates high-resolution 3D mapping (Göhring et al., 2011). Camera-based systems provide detailed scene recognition but are sensitive to varying lighting conditions. In indoor environments, IPS (Indoor Positioning System) technologies using Wi-Fi (RSSI – Received Signal Strength Indicator), BLE (Bluetooth Low Energy), RFID (Radio-Frequency Identification), or UWB (Ultra-Wideband) complement GNSS for positioning when satellite signals are insufficient (Akleylek et al., 2021; Gao et al., 2024).

2.2. Sensor Fusion & Estimation

Combining multiple sensor data enhances system accuracy and robustness. For instance, ETCS (European Train Control System)–level systems use GNSS, IMU, odometer, and balise signals together for train localization (Heirich, 2020; Lundquist, 2011). Variants of the Kalman Filter (standard and extended) reduce noise and compensate for drift. Particle-based or Monte Carlo methods sample possible states, providing estimates resilient to uncertainties (Fox et al., 1999). By merging radar, LiDAR, and camera data, the shortcomings of each sensor are addressed, resulting in a more comprehensive scene perception (Göhring et al., 2011).

2.3. Fiber Optic Integration

Fiber optic solutions, particularly DOFS and FBG technologies, are considered powerful alternatives or complements to conventional sensors. DOFS, which uses Rayleigh/Brillouin scattering, enables wide-area monitoring of temperature, strain, and vibration (Sasy Chan et al., 2021). FBG sensors, capable of detecting local temperature or strain changes while remaining immune to electromagnetic interference, offer advantages in railway safety applications (Zhou et al., 2022). Their insensitivity to electromagnetic noise makes these sensors highly effective for real-time detection of track deformations and anomalies in harsh environments.

2.4. Indoor & GNSS-Denied Environments

In tunnels or environments where GNSS signals are inadequate, indoor positioning methods like Wi-Fi, BLE, and RFID rely on RSSI or fingerprinting, though calibration variability can pose challenges (Akleylek et al., 2021). UWB, which transmits short radio pulses across a wide frequency band, offers centimeter-level accuracy but entails higher infrastructure costs (Gao et al., 2024). Additionally, recording rail geometry deviations (gauge, cross-level, alignment) with an IMU and matching them to a known map helps mitigate drift in the absence of GNSS (Zhou et al., 2022).

2.5. Machine Learning (ML) & Fault Detection (FDI)

FDI: Systems track sensor data in real time, isolating faulty measurements to maintain performance (Garramiola et al., 2018).

Deep Learning (CNN–LSTM): Dynamically updates noise parameters in GNSS–INS (Inertial Navigation System) or multi-sensor scenarios, improving localization resilience when signals degrade (Sun et al., 2024).

2.6. Simulation & Performance Evaluation

To validate system reliability, simulation-based experiments evaluate sensor fusion, Kalman filtering, and advanced ML algorithms on representative datasets before field deployment (Lauer & Stein, 2014). Key metrics include accuracy (deviation from ground truth), error margins (impact of sensor noise), transition times (rate of track segment changes), and uncertainty rate (speed of model convergence under sensor or environment fluctuations). By iteratively refining sensor architecture, data integration, and state estimation, the system targets continuous, high-precision train localization, offering both safety and operational benefits.

Findings

3.1. GNSS and IMU Integration

GNSS systems (GPS, GLONASS, Galileo, etc.) combined with IMU sensors (accelerometers, gyroscopes) provide highly accurate positioning and velocity information for vehicles (Özgüner et al., 2011).

In indoor or tunnel environments where GNSS signals are weak, IMU-based dead reckoning can estimate position but may accumulate bias and drift errors. Therefore, it is important to periodically correct IMU outputs using GNSS data via Kalman filtering or its extended variants (Emirler et al., 2013).

3.2. Indoor (IPS) and Alternative Positioning

Wi-Fi (RSSI) and BLE infrastructures, RFID-tag systems, camera-based SLAM (Simultaneous Localization and Mapping), and UWB technologies provide supplementary positioning data where GNSS is inadequate, both indoors and outdoors (Akleylek et al., 2021; Gao et al., 2024).
Camera-based approaches benefit from low cost and rich data, though performance is directly impacted by lighting conditions and line-of-sight constraints.
Radar and LiDAR offer valuable long-range or high-resolution scans for environment detection and obstacle recognition, yet both face limitations related to cost and field of view (Göhring et al., 2011).

3.3. Sensor Fusion and Error Types

In advanced railway systems such as ETCS, IMU, odometry, balise, and GNSS data are combined to provide reliable train localization (Heirich, 2020).
Errors such as "random noise," "drift," "calibration error," and "multipath effect" are widespread in sensor readings and can be minimized via Kalman filtering, RLS, or machine learning-based corrections (Lundquist, 2011).

3.4. Vision-Based and UWB Positioning

Camera systems are becoming more widespread for detecting environmental markers and recognizing traffic signs, but lighting conditions and occlusions directly affect performance. UWB achieves centimeter-level precision through interference mitigation, though at the expense of higher infrastructure costs (Gao et al., 2024).

3.5. FDI and Machine Learning Applications

By comparing multiple odometers or IMU sensors, faulty data can be swiftly identified (Garramiola et al., 2018). Additionally, CNN–LSTM deep learning models dynamically adjust noise parameters in GNSS–INS fusion, significantly boosting accuracy when GNSS signals are unavailable (Sun et al., 2024). In this way, both sensor failures and environmental challenges (signal outages, wheel slip, etc.) can be more effectively addressed through machine learning techniques.

3.6. Fiber Optic Sensor (FOS) Approaches

Distributed Optical Fiber Sensors (DOFS) exploit Rayleigh/Brillouin scattering techniques to track temperature, strain, and vibration changes over distances of 100–150 km, reducing maintenance costs and improving track safety (Sasy Chan et al., 2021).
Fiber Bragg Grating (FBG) accurately measures local strain and temperature changes, with immunity to electromagnetic interference, making it favorable for track monitoring and train localization systems (Sasy Chan et al., 2021).
FOS methods show promise for continuous monitoring—potentially lessening the need for guide locomotives—and offer early warnings for earthquakes or landslides.

3.7. Track Irregularity–Based Localization

Geometric deviations in track design (e.g., gauge, cross-level, alignment) produce repeated signals during train operation, forming a positioning "fingerprint" (Zhou et al., 2022).
Integrating this approach with INS data enables sufficient accuracy with a low-cost IMU even in the absence of GNSS signals.It proactively enhances track safety, especially in tunnels and other enclosed environments.

Conclusion

Fiber optic-based methods are increasingly important for enhancing positioning and track safety in railway systems. Alongside GNSS, IMU, LiDAR, radar, camera, and UWB, FBG and DOFS provide robust, high-precision alternatives. Their long service life, resistance to electromagnetic interference, and reliable operation in harsh environments make FBG sensors especially promising for improving operational safety and efficiency (Sasy Chan et al., 2021).

Integrating fiber optic sensor data with INS readings mitigates positioning errors in GNSS-denied areas, enabling precise localization and early detection of anomalies like track deformation or vibration. Even a low-cost IMU can achieve high accuracy without GNSS through track irregularity approaches, cutting maintenance costs and preventing accidents (Zhou et al., 2022).

Sensor fusion and FDI (Fault Detection and Isolation) ensure uninterrupted reliability despite faulty measurements, while machine learning and deep learning address noise and modeling limitations beyond those of traditional Kalman filter methods. As a result, continuous monitoring solutions can potentially replace guide locomotives, issue alerts for natural disasters, and detect subtle track issues.

In summary, fortifying GNSS, IMU, and other sensors with FBG technology offers significant potential for proactive safety, lower maintenance costs, and precise localization in railway systems. Ongoing advances in signal processing and sensor design will likely make fiber optic-based solutions a cornerstone of both railway and broader industrial applications.

kirdemir18@itu.edu.tr

Keywords: .NET, Interlocking, MODBUS, PLC, Route.

Aim

Railway systems play a crucial role in contemporary transportation infrastructure, necessitating robust control mechanisms to ensure both safety and operational efficiency (Pachl, 2021). The station areas, particularly those incorporating switch mechanisms, are essential for directing train movements across various tracks (Theeg & Vlasenko, 2017**)**. This project endeavors to enhance safety and operational effectiveness within railway operations by developing a control system specifically designed for a two-switch station area. The proposed system utilizes HIMA Programmable Logic Controllers (PLCs) and integrates them with a .NET-based user interface via the MODBUS protocol. The primary objectives of this project are as follows:

- Design and implement the operational logic for a two-switch station area utilizing both SILworX and .NET development environments.
- Establish reliable communication pathways between HIMA PLCs and the .NET application through MODBUS/TCP protocols.
- Develop an intuitive, user-friendly interface that enables operators to remotely monitor and control the operational status of the station area.
- Create and integrate a routing algorithm specifically tailored to the unique configuration of the two-switch system, thereby ensuring the safe and efficient passage of trains.

This research builds upon the existing single-switch infrastructure at the ITÜ Railway Systems Laboratory, transitioning it to accommodate the complexities associated with a two-switch configuration. By addressing the increasing demands of modern railway operations—characterized by heightened traffic volumes and stringent safety requirements—this project aims to offer a scalable and reliable solution that can serve as a foundation for future advancements in railway automation. The emphasis on safety is aligned with international standards (such as TS EN 50126 and TS EN 50129) (Durmuş et al., 2011), while the focus on efficiency aims to optimize train routing and minimize operational delays. By integrating these elements, the project seeks to contribute significantly to the advancement of railway systems, ultimately enhancing both safety and operational performance within the sector.

Material and Method

1. Materials

The project encompasses a comprehensive integration of hardware and software tools to accomplish its defined objectives:

1.1. Hardware:

The experimental infrastructure is provided by the ITÜ Railway Systems Laboratory, incorporating essential components such as two switches, signaling devices, and an Ethernet network to facilitate effective communication.

- HIMA PLCs: The selection includes two models, specifically HIMatrix F20 01 and HIMatrix F2 DO 16 01, chosen for their reliability and adherence to safety-critical standards pertinent to industrial automation,
- Physical Setup: The ITÜ Railway Systems Laboratory provides the experimental infrastructure, which incorporates essential components such as two switches, signaling devices, and an Ethernet network to facilitate effective communication.

1.2. Software:

SILworX: This programming environment serves as a platform for designing and configuring PLC logic, ensuring compliance with safety regulations.

- .NET Framework: Utilized for the development and integration of the user interface in conjunction with MODBUS communication. The development process leverages Visual Studio as the primary development environment.
- MODBUS/TCP: An open and reliable protocol implemented for data exchange between the PLCs and the .NET application (Swales, 1999).
- Anklaşmatik V2: An existing software application that has been updated to support the functionalities of the dual-switch system.

2. Methods

The methodology adopted for this project adheres to a systematic approach in designing, implementing, and evaluating the control system:

2.1. Logic Design:

The interlocking logic for the dual-switch station area is meticulously developed utilizing SILworX. This process entails creating interlocking tables and safety mechanisms to prevent conflicting routes or hazardous conditions (Dincel & Kurtulan, 2012). The design is structured to ensure compliance with relevant standards such as TS EN 50129 (Durmuş et al., 2011), with an emphasis on fail-safe operations.

2.2. Communication Configuration:

The implementation of MODBUS/TCP facilitates real-time data exchange between the HIMA PLCs and the .NET application. This critical step ensures accurate transmission and reception of switch positions, signal states, and control commands.

2.3. User Interface Development:

A .NET-based application has been meticulously designed to furnish operators with a graphical interface that depicts the operational status of the station area, including switch positions and train locations. This interface supports remote monitoring and control capabilities, thereby enhancing operational flexibility.

2.4. Route Algorithm Development:

A route algorithm has been crafted to manage train movements through the dual-switch system. This algorithm diligently verifies route availability, switch alignments, and signal states prior to authorizing train passage, with a paramount focus on safety and operational efficiency.

2.5. Testing and Validation:

The system undergoes thorough testing within the ITÜ Railway Systems Laboratory using simulated scenarios. The testing protocols are designed to evaluate system functionality, assess safety under fault conditions, and measure performance during the management of simultaneous train movements.

Collectively, these methodologies aim to evolve the existing single-switch system within the laboratory into a dual-switch configuration, ensuring that it fulfills the contemporary operational requirements in railway systems.

Findings

As this project continues to develop, the findings presented herein are preliminary and reflective of current progress. Notably, several significant outcomes have been identified:

1. Communication Success:

The establishment of MODBUS/TCP communication between the HIMA Programmable Logic Controllers (PLCs) and the .NET application has been successfully achieved. Initial testing indicates reliable data transfer, with the application effectively displaying switch states and signal conditions in real time.

2. Logic Implementation:

The interlocking logic for the two-switch system, designed utilizing SILworX, has undergone partial implementation. Simulation results demonstrate the system's capacity to prevent conflicting routes and ensure safe switch operations under standard conditions. However, further testing is imperative to validate the system's behavior during edge cases, such as simultaneous route requests.

3. Route Algorithm Progress:

A prototype route algorithm has been developed and integrated into the Anklaşmatik V2 program. Preliminary tests suggest that the algorithm can effectively manage train movements; however, optimization is necessary to address complex scenarios and mitigate processing delays.

4. User Interface Development:

The .NET interface clearly visualizes the station area, enabling operators to monitor and control switches remotely. Feedback from initial usability assessments indicates that further refinements are required to enhance system responsiveness and operator intuitiveness.

5. Challenges Identified:

Several critical challenges have been recognized, including the necessity of ensuring system scalability for larger station areas and maintaining safety during high-traffic scenarios. Additionally, the integration of fault detection mechanisms is currently being developed to improve overall system reliability.

These findings suggest that the project is progressing toward its goals, with the system showing potential as a safe and efficient solution for two-switch station control. Ongoing work focuses on completing the implementation and conducting comprehensive tests to refine the system further.

Conclusion

This project explores the integration of HIMA PLCs, MODBUS/TCP, and a .NET application to facilitate the effective control of a dual-switch railway station area. Preliminary findings suggest that the proposed system significantly enhances safety by mitigating unsafe conditions and increasing operational efficiency through real-time monitoring and automated route management. The successful establishment of MODBUS communication and the partial implementation of interlocking logic and route algorithms represent substantial progress in this endeavor.

Upon completion, the system is anticipated to minimize human error, enhance response times to operational changes, and provide a scalable framework suitable for managing increasingly complex railway scenarios. Its implications may extend beyond experimental settings, offering a contemporary model for modernizing railway control systems in practical applications. Additionally, this project contributes to academic and industrial advancements in railway automation by demonstrating the effective integration of safety-critical hardware and software solutions. Future efforts will concentrate on the finalization of the system, the resolution of identified challenges, and the validation of its performance across a range of operational conditions. This project demonstrates the potential of integrating HIMA PLCs, MODBUS/TCP, and a .NET application to control a two-switch railway station area effectively. Preliminary results indicate that the system can enhance safety by preventing unsafe conditions and improving efficiency through real-time monitoring and automated route management. The successful establishment of MODBUS communication and the partial implementation of the interlocking logic and route algorithm mark significant steps forward.

Once completed, the system is expected to reduce human error, improve response times to operational changes, and provide a scalable framework for managing more complex railway scenarios. Its impact could extend beyond

the laboratory, offering a model for modernizing railway control systems in real-world applications. The project also contributes to academic and industrial advancements in railway automation by showcasing the integration of safety-critical hardware and software solutions. Future work will focus on finalizing the system, addressing identified challenges, and validating its performance under diverse operational conditions.

Keywords: Fiber Bragg Gratings (FBG), Fiber Optic Sensors (FOS), Railway Monitoring, Signal Processing, Clearance Train.

Aim

Railway systems are essential for urban and intercity transportation, offering high capacity, energy efficiency, and sustainability. Ensuring safety and efficiency requires continuous train and track monitoring. Traditional electronic sensing faces challenges like electromagnetic interference, making fiber optic sensor (FOS) technologies a promising alternative for reliable real-time detection (Hartog, 2017).

This research aims to demonstrate how Fiber Optic Sensors (FOS), particularly Distributed Acoustic Sensing (DAS) and Fiber Bragg Gratings (FBG), can track train positions and assess infrastructure integrity in rail systems. While current implementations operate within 20-50 km, the goal is to extend detection to 75 km and ultimately 500 km, using advanced signal processing and noise suppression to enable early-warning functions and multi-faceted monitoring without electromagnetic or environmental vulnerabilities (Boynukalin et al., 2023).

Furthermore, the aim is to demonstrate the feasibility of replacing or enhancing existing electronic-based secondary warning systems with fiber optic solutions, despite the absence of higher-level safety certifications. This approach supports hybrid applications by enabling real-time detection of track hazards, moving objects, and clearance train functionalities, ultimately encouraging further research and investment in fiber optic-based railway technologies to reduce manual intervention, improve reaction times, and enhance safety and efficiency (Sun et al., 2022).

Material and Method

FOS technologies rely on changes in light signals transmitted through optical fibers to detect external influences such as temperature, stress, and vibration (Agrawal, 2012). The primary advantage is immunity to electromagnetic interference, a key concern in rail environments where traction motors and power lines can disrupt conventional electronic sensors (Asawa & Yao, 1983). Two main FOS approaches are explored:

Distributed Acoustic Sensing (DAS) uses standard single-mode or multimode fibers, which are also common in communication networks; a laser source injects pulses, and variations in Rayleigh backscattering along the fiber reveal acoustic or vibrational changes, which are then processed to locate events (e.g., train wheels passing, track deformation) with a resolution dependent on pulse width, scattering intensity, and signal processing algorithms (He & Liu, 2021; Xiong et al., 2020).

Fiber Bragg Gratings (FBG) incorporate mirror-like gratings inside the fiber core, where mechanical strain, vibration, or temperature shifts alter the fiber's refractive index at the grating locations and change the reflected wavelength, offering higher localized sensitivity and making it suitable for detecting low-intensity events (e.g., minor track cracks) (Werneck et al., 2013; Kinet et al., 2014).

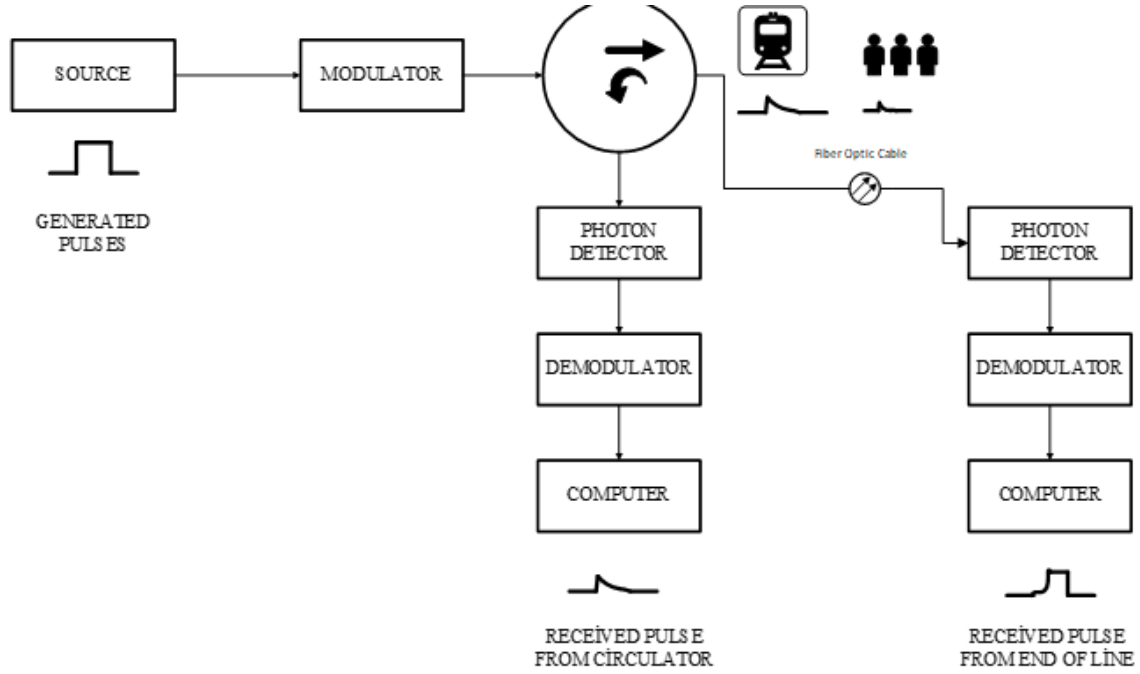

Figure 1: General block diagram of FOS system Adapted from Boynukalin et al. (2023). Copyright 2023 by the authors. Reprinted with permission.

Figure 1 presents a fundamental diagram of a fiber optic sensor application, where enhancements in the source, modulator, fiber link, demodulator, and sensor improve vibration detection, while analyzing transmitted or backscattered signals at specific power and wavelength enables scattering location identification and event detection (Boynukalin et al., 2023).

This work is designed to extend the 20 km detection range of existing systems to 50 km initially, then 75 km, and ultimately 500 km, by optimizing Fiber Bragg Grating (FBG) design, employing Advanced SNR Enhancement techniques such as PN-Codes and cross-correlation, and reducing signal attenuation by operating in the 1550 nm band, where absorption and scattering are minimized. Patent applications have been filed for innovative signal processing and sensor configurations to address randomness in DAS and localized reflection in FBG, ensuring accurate detection of event location, intensity, and direction through a modulated light source and signal analysis (Boynukalin et al., 2023).

Three primary rail categories in Turkey guide the optimal FOS installation:

a.) Intercity High-Speed Trains (YHT): YHT typically has fiber cables running near the ballast or in protective conduits, which provides direct access to track vibrations and anomalies while being crucial for real-time train positioning and early detection of rail deformation (Boynukalin et al., 2023).

b.) Urban Light Rail (Tramway): Urban Light Rail (Tramway) operates at street level, sharing space with vehicles and pedestrians, where fiber optic cables are less common due to minimal dedicated communication ducts, requiring special integration or localized segments for key intersection monitoring, with the potential to improve traffic safety and track boundary detection (Hartog, 2017).

c.) Urban Metro Systems: Urban Metro Systems are typically installed in tunnels with cable trays on the ceiling or walls, offering stable conditions for fiber placement but demanding higher resolution (under 1 meter) for precise position feedback, making them well-suited for continuous structural health monitoring, including tunnel movement and water ingress detection (Kinet et al., 2014).

Fiber optic sensors must contend with Thermal Noise and Shot Noise (inherent in optical sources and detectors), Environmental Noise (mechanical vibrations, temperature fluctuations), and System Noise from splices, connectors, or cable imperfections (Sun et al., 2022).

Filtering is accomplished via High-pass, Low-pass, or Band-pass approaches, depending on target event frequency, Median and Wavelet Filters to suppress outliers and separate noise from actual events, and Cross-correlation using PN-coded signals to boost sensitivity in high-noise conditions (Xiong et al., 2020). A key outcome mentioned is the ability to detect movement with around 1.2 cm accuracy at 50 km, even under significant noise.

Findings

1.) Hybrid System Demonstration: Moving Objects and Track State

A fiber optic system can simultaneously handle vehicle tracking by identifying trains and unauthorized objects on the track and infrastructure monitoring by detecting structural faults such as cracks, ballast shifts, and temperature-induced stress, surpassing the limitations of traditional electronic systems through amplitude and frequency shift analysis in backscattered signals. This approach provides early warnings despite lacking Safety Integrity Level (SIL) certifications, while holding strong potential as a critical secondary safety system to enhance railway monitoring and operational security.

2.) Clearance Train Feature

After maintenance or following a natural disaster, a track may appear structurally intact while still concealing hidden defects. Traditionally, a clearance train is used to verify track integrity; however, the risks associated with this method were highlighted in 2023, when a guide locomotive derailed on the Ankara-Sivas line, emphasizing the need for more advanced and reliable inspection technologies (Boynukalin et al., 2023). Fiber optic–based clearance train approach would provide:

2.a.) Automatic, Real-Time Track Assessment: The FOS continuously monitors the track. If the locomotive encounters a defect or if foreign material is present, the sensor data flags abnormal reflections or frequency shifts (He & Liu, 2021).

2.b.) Reduced Human Dependency: Minimizing the need for personnel to physically inspect the line (Boynukalin et al., 2023).

2.c.) Immediate Feedback: If a section is compromised, the system promptly triggers alarms for remedial action line (Boynukalin et al., 2023).

Simulations show that FBG arrays, placed at intervals along the track, detect variations in reflection levels. Even small anomalies manifest as measurable frequency shifts in the backscattered spectrum (Griffiths, 1987).

3.) Multi-FBG Modeling and Frequency Shift Analysis

Each Fiber Bragg Grating (FBG) reflects a portion of transmitted light at a specific wavelength, and when a train wheel or an external force applies pressure to the rail, the resulting strain alters the reflection profile (Kinet et al., 2014). As the train approaches, the spectrum shifts toward the red or blue range depending on whether the fiber undergoes tension or compression, while as it departs, the spectrum shifts back with a drop in amplitude once beyond the FBG detection zone. Multiple FBG sensors along the track generate distinct signals, allowing precise speed and direction calculations by analyzing frequency shifts. If shifts occur sequentially in consecutive gratings, the train is moving forward, whereas a reversed sequence indicates backward motion. The train's exact location is determined by evaluating the time differences between FBG responses, ensuring accurate real-time monitoring.

4.) Ray Damage Tracking and Early Warning Potential

Another critical finding is the ability to detect rail defects such as cracks or broken rails. Traditional methods may miss sub-millimeter cracks until they become hazardous. Fiber optic cables register the changes in mechanical coupling or acoustic signatures, thereby identifying problems:
4.a.) Micro-Cracks: Cause subtle but detectable shifts in the backscattered signal amplitude and frequency.

4.b.) Ballast Issues: Sinking or washouts generate abnormal vibrations, easily identified under the FOS system's filter algorithms (He & Liu, 2021).

4.c.) Earthquakes or Flash Floods: Instantly produce large spectral anomalies, offering an early warning mechanism (Sun et al., 2022).

Conclusion

The fiber optic sensor (FOS) approach addresses key limitations in rail monitoring by providing long-range, high-resolution detection across 75 km and beyond, with enhanced sensitivity to vibrations, cracks, and structural deformations. It ensures versatility across rail environments, offering tailored solutions for high-speed intercity lines, urban tramways, and metro systems, with adaptable sensor placement in ballast zones, cable trays, or embedded installations.

Robust signal processing against noise is achieved through wavelet transforms, median filters, PN-coded signal transmission, and cross-correlation, enabling precise localization in challenging conditions. The system also supports clearance train automation and disaster preparedness, reducing reliance on manual inspections while providing real-time track assessment and early warnings for natural disasters such as washouts, landslides, and earthquakes, minimizing derailments and disruptions.

This technology lays the groundwork for future SIL (Safety Integrity Level) certifications, as its performance and reliability indicate strong potential for becoming primary safety instruments or secondary warning systems in rail infrastructure. Additionally, FOS developments significantly reduce operational costs by integrating real-time train tracking, infrastructure health monitoring, and environmental impact assessment, with minimal electromagnetic interference, making them superior to traditional electronic solutions.

In conclusion, fiber optic sensors are a transformative technology that can reshape railway safety, maintenance, and operations. The research and prototypes demonstrate how Fiber Bragg Gratings (FBG) and Distributed Acoustic Sensing (DAS), combined with advanced signal processing techniques, overcome range limitations while ensuring high precision and reliability, paving the way for early track anomaly detection, continuous train positioning, and improved clearance train operations, ultimately contributing to a safer, more efficient, and more reliable railway system.

SHIPBUILDING AND OCEAN ENGINEERING

Hydrodynamics of Marine and Offshore Structures

Marine Environmental Impact and Pollution Control

Numerical and Experimental Study of The Effect of The Hull Vane on The Total Resistance of The Catamaran

Rahmi Murat Dural[a], Devrim Bülent Danışman[a]

[a] Istanbul Technical University, Department of Naval Architecture and Marine Engineering, Naval Architecture and Ocean Engineering Program, Turkey
dural22@itu.edu.tr

Keywords: Computational Fluid Dynamics (CFD), Experimental Study, Hull Vane, Hydrodynamics.

Aim

The development of technology affects all branches of industry. The maritime industry is a vital and major sector fueled by advanced technological developments implemented to improve safety, efficiency, cost, etc., on the operating ships. Since the early efforts of sailing, humankind has desired to build less resistant, highly efficient ships. As a result, various innovations have been developed to reach the current level of technological advancement in the maritime industry. One of the innovations to increase the efficiency of the ship by lowering resistance is the Hull Vane technology. A Hull Vane (HV) is a submerged wing (hydrofoil) appendage that is transversely fixed at the vessel's transom. Accelerated flow passing through the suction side of the foil creates negative pressure on the stern of the hull, resulting in reduced stern wave and lifting force created from the foil. This lifting force results in trim correction and additional thrust force. This study aims to study the effect of Hull Vane on total ship resistance of a catamaran after the addition of the Hull Vane by performing an experimental study and computational fluid dynamic (CFD) analysis on OpenFOAM (Open Source Field Operation and Manipulation).

Material and Method

There are two methods used in this research: the experimental method and the CFD method. Foil profile of the Hull Vane is chosen as optimized foil profile of NACA 4412 from the study of (Çelik et al., 2021) for both numerical and experimental study. In this work, the Hull Vane is investigated at different locations with different angles of attack to fully look into the importance of the location of the Hull Vane on the total resistance of the model catamaran. Hull Vane's chord and span lengths are kept constant throughout the study. The Hull Vane chord length ratio is kept the same as the study of (Çelik et al., 2021), which is 2.9% of the waterline length, and the span length is the same as the model breadth. The initial location of the hydrofoil's leading edge is located at a horizontal and vertical distance of 2.33% (LWL/43) and 1.87% (LWL/53) of the transom bottom corner. The position of the Hull Vane is shifted horizontally and vertically. Hull Vane's leading edge is positioned horizontally at 3.23% (LWL/31) and vertically at 2.44% (LWL/41). In addition, the Hull Vane is positioned with a 0-degree and 5-degree angle of attack with respect to the calm waterline. Hence, 8 different configurations are created, as given in Table 1. In addition to the eight Hull Vane configurations, the bare hull is also tested at five different speeds from 1.715 m/s (Fr=0.327) to 4.115 m/s (Fr=0.784). CFD analysis and experimental work are conducted with a scale of 1/9 catamaran model. The main dimensions of the catamaran model are given in Table 2. A wooden model is manufactured at the workshop of İTÜ Ata Nutku Ship Model Testing Laboratory (see Image 1.). The model is CFD analyzed and tested at the towing tank for a loading condition of T = 1.235 meters. For the experimental study, 3D printing is concluded to be a cost-efficient manufacturing method that can fulfill the Hull Vane profile sensitivity. Therefore, two sets of the Hull Vane are printed for 0-degree angle of attack configurations and 5-degree angle of attack configurations. 3D printed 0-degree angle of attack Hull Vane is given with the connection part in Image 2. The connection part is supplementary to the printed Hull Vane to attach the Hull Vane to the transom of the model. The connector part is designed to change the vertical and horizontal locations of the Hull Vane according to the studied configuration. The location of the Hull Vane is fixed by bolts attached to the connection part. For 3D printing parts, PLA material is used. PLA is a cost-effective option for the ABS material. PLA has a very low thermal shrinkage value and does not cause problems when in contact with water. For numerical study, Open FOAM, which is a free, open source CFD software program is used. OpenFOAM can be

used effectively to solve fluid dynamics problems such as laminar, turbulent, multi-phase flows, etc (Url-1). To calculate the hydrodynamic forces acting on the model scale for bare vessel and Hull Vane installed versions, incompressible Navier-Stokes equations are solved by performing the finite volume discretization. Domain dimensions and boundary conditions for the CFD analysis are determined according to the ITTC Practical Guidelines for Ship CFD Applications (Url-2). Inlet, side, and bottom boundaries are located at 2 LBP away, while the top boundary is 1.5 LBP and the outlet boundary is 4.1 LBP away (downstream direction) from the ship model. The boundary condition of the model hull and Hull Vane were stated as a wall function. The sides and bottom boundaries were specified as symmetry conditions. Inlet, outlet, and atmosphere boundary conditions were separately defined in compliance with flow characteristics and turbulence parameters. Around 1.1 million number of mesh is used in the domain, and detailed mesh views are given in Figure 1.

Table 1. Hull Vane configuration table.

HV No.	Angle of Attack	HV Trailing Edge AP (TEAP)	HV Trailing Edge Draft (TED)
1	0	LWL/43	LWL/53
2	0	LWL/31	LWL/53
3	0	LWL/43	LWL/41
4	0	LWL/31	LWL/41
5	5	LWL/43	LWL/53
6	5	LWL/31	LWL/53
7	5	LWL/43	LWL/41
8	5	LWL/31	LWL/41

Findings

Findings of the experimental and numerical analysis show that the Hull Vane attachment is advantageous on the catamaran around 0.35-0.63 Fr, which is in line with the previous studies. It is also found that the Hull Vane provides extra resistance and becomes a disadvantage outside this range. Sinkage data show that when the speed of the model passes around 0.65 Fr, the sinkage of the vessel increases for all Hull Vane appended configurations. Thus, resulting in increased total resistance compared to the bare hull. Among the Hull Vane configurations, the designs with the 0-degree angle of attack gave better results than the designs with the 5-degree angle of attack. In Figure 2., a comparison of the numerical and experimental C_T differences for bare hull vs 0-degree angle of attack HV configurations are given. In Figure 3., a comparison of the numerical and experimental C_T differences for bare hull vs 5-degree angle of attack HV configurations are given. Comparing Figure 2. and Figure 3., the advantage of 0-degree angle of attack HV configurations over 5-degree ones can be seen, and the performance of HV with comparison to the bare hull relative to the speed of the model can be observed. Trim data shows that Hull Vane configurations with a 5-degree angle of attack cause excessive trim compared to the bare hull, causing disadvantages. This occurs because the excessive z-component of the lifting force causes the x-component, which causes thrust to decrease, causing drag and decreased total resistance. Also, it is observed that the configuration named HV3 with a 0-degree angle of attack with LWL/43 vertical and LWL/41 horizontal distance from the trailing edge is found to be the most advantageous design, providing total resistance reduction for a wider speed range with higher percentages (around 0.32-0.62 Fr). HV3 total resistance coefficient reduction peaks at 7.8 % at 2.401 m/s (0.457 Fr) compared to the bare hull total resistance coefficient at the same speed.

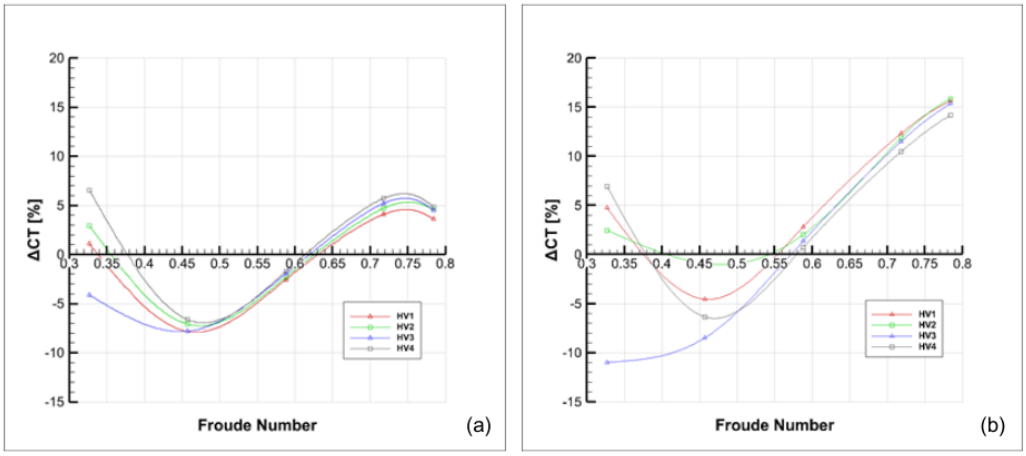

Figure 2. Comparison of the experimental (a) and numerical (b) C_T Differences for Bare Hull (BH) vs Hull Vane Configurations (HV1-HV4).

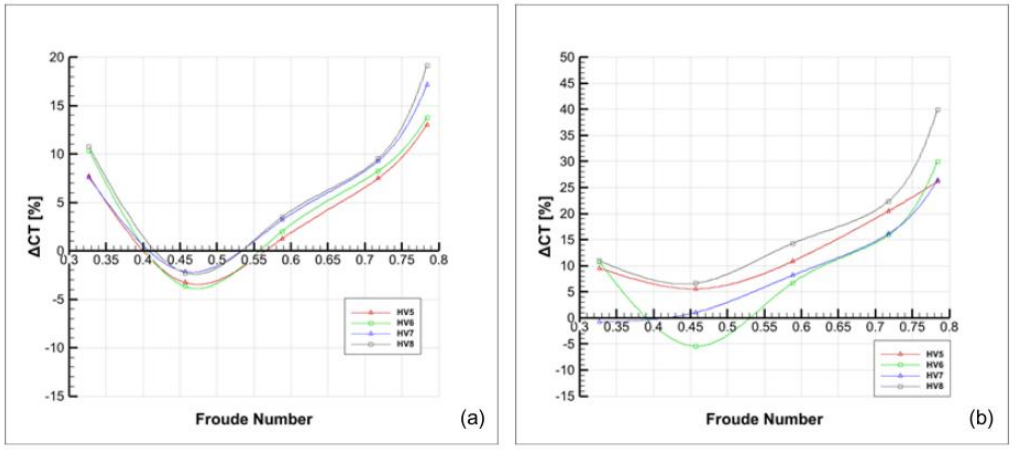

Figure 3. Comparison of the experimental (a) and numerical (b) C_T Differences for Bare Hull (BH) vs Hull Vane Configurations (HV5-HV8).

Conclusion

It is concluded that the Hull Vane is an advantageous appendage for ship operators who want to reduce their ship's fuel consumption by reducing the total resistance of the ship, thus resulting in decreased cost and carbon emission levels that comply with the International Maritime Organization (IMO) regulations. However, this innovation is interesting for vessels that operate at a moderate to high non-planing speed, it is not optimal for all ships and all operating speeds. Therefore, a detailed experimental and numerical investigation should be conducted for the specific ship to better evaluate the applicability of the Hull Vane. This work exhibits that for the studied catamaran vessel, the Hull Vane appendage achieves total resistance reduction at lower speeds (around 0.3-0.6 Fr) and up to around 8 % total resistance reduction. For future work, it is necessary to find the optimal values of the Hull Vane position and the angle of attack by using data-driven optimization techniques applied to an expanded dataset to further increase the advantage of the Hull Vane on the total resistance of the catamaran.

Comparison of Different Methods for Dynamic Earth Pressures on a Retaining Wall

Perim Kılıç[a], Recep İyisan[a]

[a]Istanbul Technical University, Department of Civil Engineering, Soil Mechanics and Geotechnical Engineering, Türkiye
kilicp22@itu.edu.tr

Keywords: Retaining Walls, Lateral Earth Pressures, Dynamic Earth Pressures.

Aim

Retaining walls, like many other structures, have been damaged or destroyed due to devastating earthquakes throughout history. Retaining walls that support important structures such as roads, buildings, bridges and slopes can affect the damage that may occur in these structures. Therefore, the design of retaining walls in earthquake zones is of great importance in terms of usability and safety of the environment (Singh et al., 2023). The seismic behavior of retaining structures is a widely studied topic in geotechnical engineering due to its effects on the safety and stability of structures in earthquake zones. Retaining structures are important because they provide structural support and prevent the movement of the soil mass, especially when the ground elevation or slope geometry changes (Thottoth et al., 2024). Retaining walls are generally under the effect of lateral earth pressures. These earth pressures are static pressures due to gravity and dynamic pressures due to earthquake loads. Dynamic earth pressures acting on retaining walls in earthquake zones differ from static pressures in distribution and magnitude (Kramer & Stewart, 1996). It is observed that a lot of damage occurs in retaining structures as a result of ground movements caused by pressure increases during earthquakes. When designing a retaining wall, the structure must resist static and dynamic lateral earth pressures. At the same time, when constructing a safe retaining wall, care should be taken to design the structure economically. For these reasons, the necessary static and dynamic analyses must be performed to design an optimum retaining wall. To properly design and construct retaining structures, the lateral earth pressures between retaining structures and soil masses must be known in detail. The magnitude and distribution of the lateral earth pressure depend on factors such as the shear strength parameters of the soil, the slope of the backfill surface, the slope and height of the retaining wall on the surface between the wall and backfill, the angle of adhesion and friction on the surface between the wall and backfill (Das, 2010).
This study aims to determine the dynamic earth pressures on retaining walls using different methods and compare the results obtained. It is desired to determine the differences between the methods and their effects on dynamic earth pressures. Lateral dynamic earth pressures will be analyzed for a retaining wall in the same model. In the study, the effects of distributed load and backfill soil properties on dynamic soil pressures will also be investigated. It is aimed to contribute to engineering applications by determining and comparing dynamic earth pressures according to the methods.

Material and Method

This study will determine dynamic lateral earth pressure on the retaining wall according to Mononobe Okabe, Seed & Whitman methods and Türkiye Building Earthquake Code (TBDY-2018). Some parameters were selected as variables to analyze this study in more detail. The shear strength angle (φ), retaining wall length (H) and the distributed load (q) of the backfill soil behind the retaining wall were selected as variables In the calculations, the effects of different methods and the selected variable parameters on the earth pressures were investigated. The selected parameters and their values are given in the Table 1.

Table 1. Selected parameters and their values.

H (m)	ϕ (˚)	q (kPa)
4	25.0	15
5	27.5	30
6	30.0	
7	32.5	
8	35.0	

Findings

As a result of the detailed literature review, it is revealed that there are many studies to determine the earth pressures on retaining walls. Rankine and Coulomb Theory are the most widely used basic methods for determining static earth pressures. It is seen that later-developed methods are based on these theories. In the event of an earthquake, retaining walls are affected by static earth pressures as well as dynamic earth pressures due to ground movements. Dynamic earth pressures can be determined using Mononobe-Okabe, Prakash-Saran, Seed & Whitman, and Steedman-Zeng methods. Together with these methods, there are earthquake codes that countries have created according to their conditions. The methods developed to find dynamic earth pressures are generally based on the Mononobe Okabe method. In the Mononobe-Okabe method, in addition to the forces existing in the static state, lateral and vertical inertial forces due to the earthquake effect are applied to the Coulomb active (or passive) wedge mass. With these forces acting on the wedge, a force polygon is created, and dynamic earth pressure is obtained. Maximum active force is found by drawing different force polygons. TBDY is based on the Mononobe-Okabe method with some differences while determining the earth pressures acting on the retaining structures under earthquake ground motion. In TBDY, the vertical seismic coefficient k_v is acting both downward and upward. Seed and Whitman (1969) use the formulas in the Mononobe-Okabe analysis when determining the active earth pressure coefficient. The Mononobe-Okabe method assumes that the total dynamic earth pressure acts at H/3 from the base of the wall of height H (Kramer & Stewart, 1996). However, Seed and Whitman calculate the point of action of the active earth pressure differently than the Mononobe-Okabe method. In Figure 1. the distribution of earth pressures acting on the retaining wall is shown for static and dynamic lateral loads.

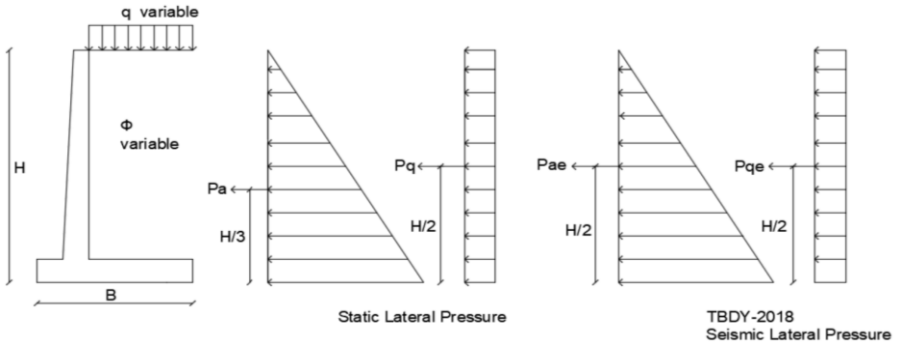

Figure 1. The load distribution of static and dynamic earth pressures on the retaining wall.

The changes in dynamic soil pressures according to the shear strength angle, wall length and distributed load values for three methods are given in Figures 2. 3. and 4.

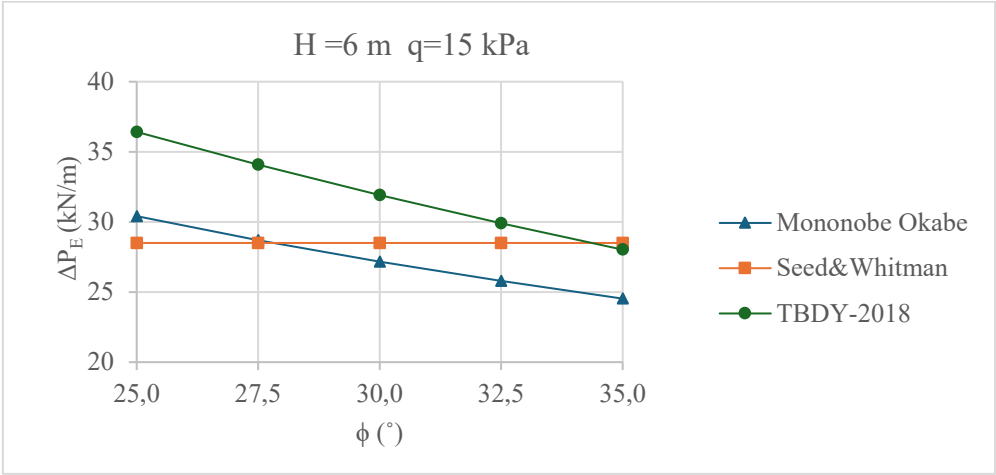

Figure 2. Variation of additional dynamic earth pressure with shear strength angle.

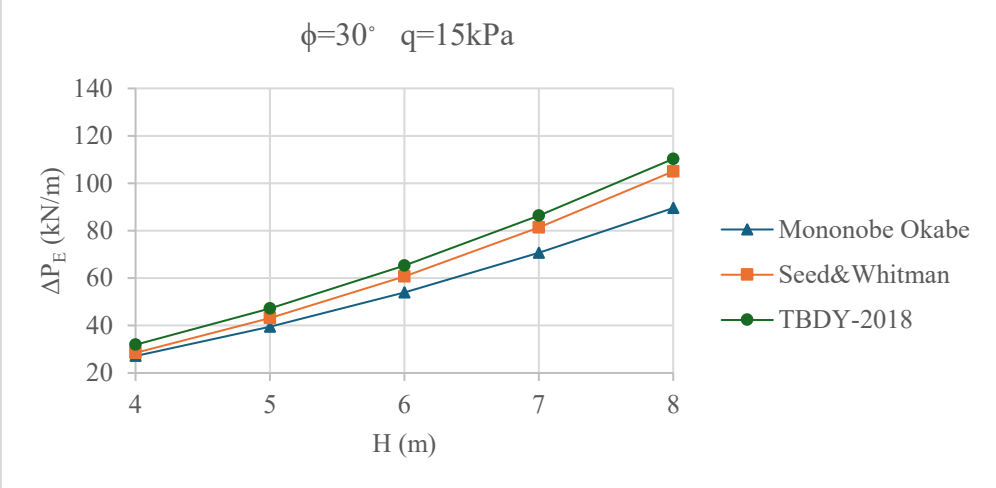

Figure 3. Variation of additional dynamic earth pressure with wall height.

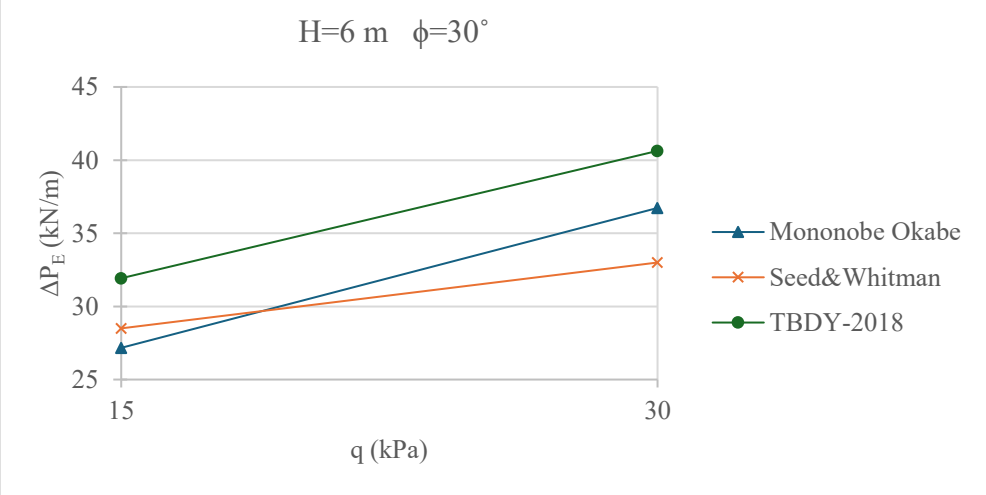

Figure 4. Variation of additional dynamic earth pressure with the distributed load value.

Conclusion

In this study, dynamic soil pressures on the retaining wall were calculated according to Mononobe Okabe, Seed and Whitman and TBDY-2018. The effect of the obtained results on dynamic earth pressures was investigated. The Mononobe-Okabe and Seed-Whitman methods provide simplified approaches. While both are practical for preliminary analyses, they do not fully capture dynamic earth pressures. TBDY-2018 based on current seismic data, considers soil classes and structural response. For this reason, it can be said that it gives more comprehensive results. TBDY-2018 represents a more advanced and regulated methodology aligned with current engineering standards.

Effect of Fly Ash on Chloride Permeability and Sulfate Resistence of Concrete

Hüsnü Kadir Özcan[a], Hasan Yıldırım[a]

[a] Istanbul Technical University, Structural Engineering Program, Türkiye
ozcanhusn@itu.edu.tr

Keywords: Fly Ash, Chloride Permeability, Sulfate Resistance, Concrete Durability, Ultrasonic Pulse Velocity.

Aim

This study aims to investigate the effects of high-volume fly ash (HVFA) usage in concrete production on chloride permeability and sulfate resistance. Portland cement, commonly used in traditional concrete production, is an important topic in the search for sustainable building materials due to its high carbon footprint and environmental impact (Malhotra and Mehta, 2002). Fly ash is a pozzolanic additive used as a replacement for cement, with the potential to improve the mechanical properties and durability of concrete (Bilodeau et al., 1994; Bouzoubaa et al., 2000). In this context, the main objective of the study is to perform a comparative analysis of concrete mixes containing different proportions of HVFA in terms of chloride ion penetration, sulfate resistance, and general mechanical properties. Research by Malhotra (1986) showed that the inclusion of fly ash significantly improved the permeability characteristics of concrete. Similarly, Ramezanianpour and Malhotra (1995) found that fly ash-containing concretes were more resistant to chloride ion penetration, and curing conditions directly influenced this durability. When examining the sulfate resistance of concrete, it was determined that mixes with high-volume fly ash showed resistance to sulfate attack (Sivasundaram et al., 1992). The study aims to improve the long-term durability of concrete by evaluating the potential of fly ash to reduce chloride permeability and increase sulfate resistance.

Material and Method

The materials used in this study include CEM I 42.5 R type cement produced at the Nuh Cement's Hereke factory and fly ash sourced from a single supplier. Concrete samples were prepared by using different amounts of fly ash in the mixtures. The fly ash amounts were determined as K250+70 and K250+90, with 70 kg and 90 kg of fly ash used, respectively. Additionally, a control sample (R001) without fly ash was included in the experiments. The chemical and physical properties of the fly ash, including SiO2, Al2O3, and Fe2O3 contents, are classified as Class C according to ASTM C 618 standard. Experimental methods include the evaluation of the physical and chemical properties of the concrete mixtures, such as chloride permeability, compressive strength, and ultrasonic pulse velocity. The chloride permeability of the concrete samples was measured using the Rapid Chloride Permeability Test (ASTM 1202-10), and the compressive strength of the concrete was tested using the Hardened Concrete Compressive Strength Test (TS EN 12390-3). Additionally, the Ultrasonic Pulse Velocity Test was conducted to assess the internal structure and durability of the concrete samples. These experiments were performed to determine the effects of fly ash on the concrete mixtures and their durability.

Findings

In this study, the performance of different concrete mixtures was examined in terms of compressive strength and chloride permeability. While compressive strength determines the load-bearing capacity of concrete, chloride permeability is a critical factor affecting the structure's resistance to corrosion. Comparisons made by considering various aging processes (7-day, 28-day, and post-sulfate exposure) revealed the performance differences among different concrete codes.

As a result of the experiment, the chloride ion permeability of the reference concrete R300, which does not contain fly ash, was measured as 1402.1 Coulombs, placing it in the high permeability category. Among the mixtures containing fly ash, the K250+70 sample showed a slight reduction in permeability with a value of 1151.4 Coulombs, while the lowest permeability was observed in the K250+90 sample with 621.5 Coulombs. These

results indicate that increasing the amount of fly ash improves the pore structure of the concrete, thereby limiting ion penetration and enhancing resistance to chloride ions. In particular, the K250+90 mixture demonstrated the best performance with its low permeability level (See Table 1).

Table 1. Rapid Chloride Permeability Test Results.

Concrete Code	Passed Charge (Coulomb)
R300	1402.1
K250+70	1151.4
K250+90	621.5

As a result of the experiment, the sulfate resistance compressive strength of the reference concrete R300 was measured as 46.4 N/mm², while this value reached 54.0 N/mm² in the fly ash-containing mixtures K250+70 and K250+90 (See Table 2).

Table 2. Compressive Strengths of Reference and Fly Ash-Containing Concretes (N/mm²).

Concrete Code	7-Day	28-Day	After Sulfate Exposure
R300	33.4	43.0	46.4
K250+70	31.4	42.8	54.0
K250+90	34.3	44.9	54.0

The results obtained from the study demonstrate that the use of fly ash significantly enhances the strength and durability properties of concrete. Notably, the K250+70 and K250+90 specimens exhibited clear improvements in both chloride ion permeability and resistance to sulfate attack with increasing amounts of fly ash. In terms of compressive strength at 7 and 28 days, the mixtures containing fly ash performed similarly to, or even better than, the reference concrete (R300), indicating that fly ash does not negatively affect early or long-term strength and may even improve it under certain conditions (See Figure 1).

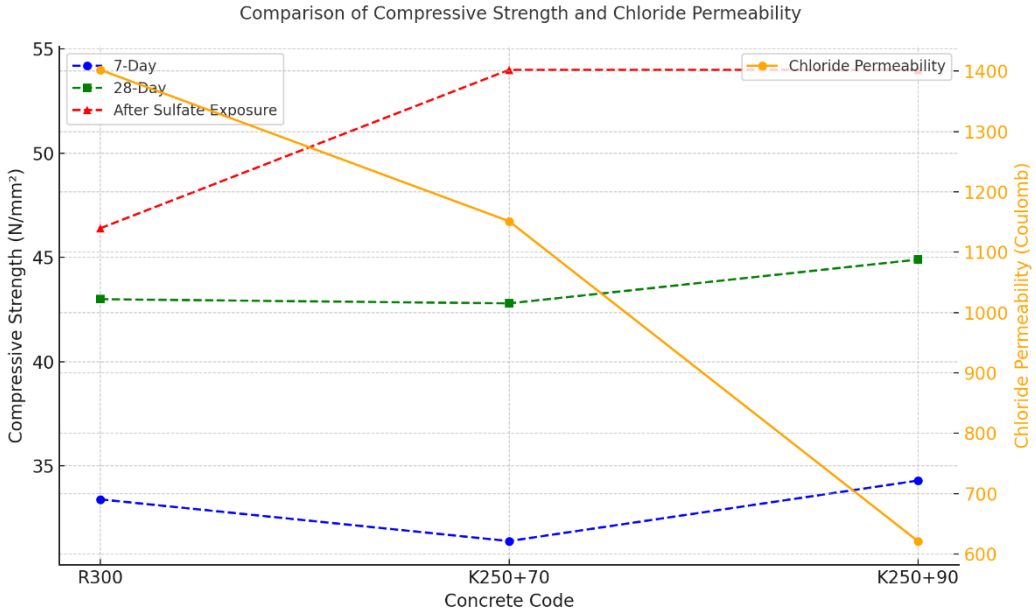

Figure 1. Comparison Of Concrete Strength and Chloride Permeability.

With regard to chloride permeability, the reference sample R300 exhibited a charge passed of 1402.1 Coulombs, whereas the K250+90 sample showed a significant reduction to 621.5 Coulombs. This result indicates that fly ash refines the pore structure of concrete, effectively reducing permeability and enhancing resistance to external

agents. A similar trend was observed in sulfate resistance. While the compressive strength of R300 after sulfate exposure was 46.4 N/mm², this value increased to 54.0 N/mm² in both K250+70 and K250+90 samples. These findings suggest that fly ash forms a protective matrix within the concrete, enhancing long-term durability against sulfate attack. In summary, the inclusion of fly ash in concrete mixtures proves to be an effective strategy for improving durability by reducing permeability and increasing chemical resistance. Among the samples, K250+90 demonstrated the best performance with the lowest chloride permeability and highest sulfate resistance. These findings clearly highlight the potential of fly ash as a strategic additive for producing sustainable, durable, and environmentally friendly concrete.

Table 3 presents the results of the ultrasonic velocity test for the concrete samples. This test is an important parameter for assessing the structural integrity and durability of concrete, and an increase in ultrasonic velocity indicates that the concrete is stronger and more durable. Below are the ultrasonic velocities (in km/s) of each concrete mixture over time:

Table 3. Ultrasonic Velocity Measurements (km/s) for Concrete Samples at Different Ages.

Concrete Code	15 Days	30 Days	45 Days	60 Days	90 Days	156 Days	387 Days	402 Days
R300	4.77	5.11	4.90	5.15	5.00	4.90	5.20	5.05
K250+70	4.87	5.13	4.85	5.23	5.45	4.99	5.27	5.14
K250+90	4.95	5.13	5.01	5.29	5.36	5.09	5.24	5.17

Ultrasonic velocity is an important test used to understand the internal integrity and durability of concrete. An increase in ultrasonic velocity indicates that the concrete is harder and more durable. According to the test results, the ultrasonic velocity of the K250+90 mixture remains more stable and at higher levels compared to the other mixtures. This indicates that with an increase in fly ash content, the structural integrity of the concrete is better preserved and it is more resistant to sulfate effects. Notably, the higher and more stable ultrasonic velocities of the K250+90 mixture after the 90th day demonstrate that fly ash contributes to enhancing the durability of the concrete. In the case of the K250+70 mixture, the ultrasonic velocity shows lower values compared to the K250+90 mixture, and a decline over time is observed. This indicates that the sulfate effect has a greater impact on the K250+70 mixture, and as the fly ash content increases, this effect diminishes. In the R300 mixture, the fluctuation in ultrasonic velocity and generally lower levels suggest that the concrete without fly ash has weaker structural integrity and is less resistant to sulfate effects.The durability and long-term performance of concrete are evaluated using parameters such as chloride permeability and ultrasonic velocity. Chloride permeability indicates the concrete's resistance to harmful ions, while ultrasonic velocity measurements help determine the integrity and density of the concrete's internal structure. In this study, the chloride permeability and ultrasonic velocity values of different concrete mixtures were examined to assess the material's durability (See Figure 2).

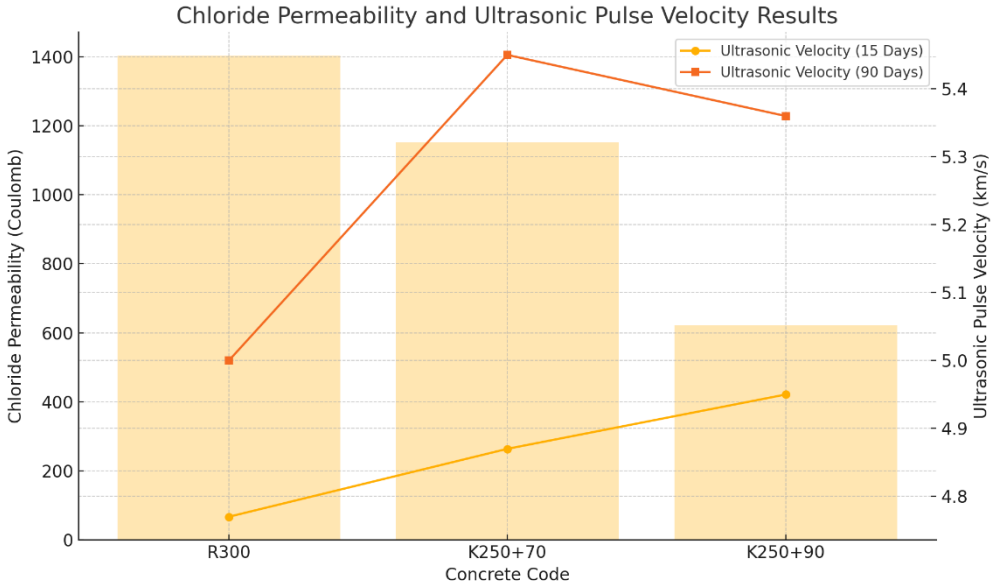

Figure 2. Chloride Permeability and Ultrasonic Pulse Velocity Results.

Conclusion

The increase in fly ash content significantly enhances the chemical durability of concrete. In chloride permeability tests, as the amount of fly ash increases, the chloride permeability of the concrete decreases noticeably. This results in reduced water permeability, making the concrete more resistant to chemical attacks. Fly ash decreases the porosity of the concrete, preventing the passage of water and chloride ions, and thereby contributing to the long lifespan of the concrete. The durability and long-term performance of concrete are evaluated using parameters such as chloride permeability and ultrasonic velocity. Chloride permeability shows the concrete's resistance to harmful ions, while ultrasonic velocity measurements help determine the integrity and density of the concrete's internal structure. In this study, the chloride permeability and ultrasonic velocity values of different concrete mixtures were examined to assess the material's durability. The following findings compare the ultrasonic velocity values and chloride permeability levels of samples with different concrete codes at 15 and 90 days. Under sulfate exposure, the stability of the ultrasonic velocity is an important parameter indicating the concrete's resistance to sulfates. The more stable ultrasonic velocity in the K250+90 mixture indicates that the concrete is more resistant to sulfates. These findings show that fly ash is a factor that enhances the concrete's resistance to sulfates. By maintaining the structural integrity of the concrete, fly ash makes it more resistant to the damage caused by sulfate reactions within the concrete. In conclusion, the addition of fly ash to concrete mixtures increases the concrete's resistance to sulfates, resulting in stronger and more durable structures. Therefore, high fly ash content concrete mixtures should be preferred for constructing structures that are particularly resistant to chemical attacks.

High-Temperature Performance of Concrete Containing Calcium Aluminate and Portland Cements

Halil Gençoğlu[a], Muhammet Tekingündüz[a], Hasan Yıldırım[a]
[a] Istanbul Technical University, Faculty of Civil Engineering, Türkiye
gencoglu19@itu.edu.tr

Keywords: Aggregate, Calcium Aluminate Cement, High-Temperature Resistant Concrete, Mechanical Properties Of Concrete, Portland Cement.

Aim

In today's world, the performance of building material at high temperatures is crucial for both the safety of occupants and the structural integrity of buildings. To avoid the deterimental effects of this environment, many materials have been designed and produced. Concrete is one of them-a material that can be durable at elevated temperatures. However, concrete produced with Portland cement (PC) has some drawbacks in maintaining its mechanical properties at these levels. The compressive strength and other mechanical properties of concrete produced with Portland cement (PC) decline sharply above 400–600°C because the CH ($Ca(OH)_2$) in hydrated Portland cement begins to decompose at these temperature levels. Due to the shortcomings of concrete containing Portland cement (PC), calcium aluminate cement (CAC) was explored as a potential replacement. In contrast to Portland cement, CAC does not contain CH ($Ca(OH)_2$) in its hydrated phase. For this reason, it is considered a more favorable cement type for producing concrete with a service temperature above these levels and is often associated with the refractory concrete— a type of high-temperature-resistant concrete made with calcium aluminate cement (CAC) [1][2]. Despite its superior advantages, concrete containing CAC undergoes a conversion mechanism— a type of recrystallization of certain hydrated compounds — which leads to noticeable proportional decreases in strength. As a result, it is often considered a less preferable material for use in building construction [3].

In spite of the sheer amount of research regarding the performance of building materials, especially concrete, at high temperatures, their scopes and contents resemble one another and do not differ significantly, leading to a deficiency in literature. In the modern academic field and codes, most research discussing the performance of concrete elements at high temperatures involves the aggregates that can withold high temperatures and are conducted at temperatures below 800 ºC. Moreover, although the amount of research related to refractory concrete has significantly increased in recent years, knowledge about calcium aluminate cement (CAC) and the comparison of its performance with Portland cement (PC) at high temperatures is still very limited and most of them are not prepared in detail [4]. In light of these factors, there should be new research in this field. In this research, the main goal is to contribute new and accurate knowledge and data about the high-temperature performance of concrete to the academic field by properly conducting relevant experiments and analyses.

Material and Method

In the research, there are a total of six different types of concrete which will be separated into two main types: those produced with portland cement (PC) and those made with calcium aluminate cement (CAC), resulting in three concrete types for each group. The three types of concrete will be separately produced with three types of aggregates: sandstone, basalt and limestone. The water-to-binder ratio is 0.45 and cement dosage is 400 kg, and both parameters remain same for all concrete.

In the first phase, the concrete was produced and cast into 10x20 cm cylindrical specimens. The fresh state tests such as workability and unit weight will be conducted on the produced concretes. In the end of this phase, standard curing with water will be applied for 28 days to the samples, which will be demolded the day after casting.

Secondly, after 28 days curing of specimens in curing pools, the specimens will be exposed to high temperatures ranging from 200°C to 1000°C for at least two hours, and each specimen will be ovendried at only one temperature level. When the temperature at the core of the specimens reaches the target degree, they will be removed and left

to cool until their temperature equilibrates with the ambient temperature. The central temperature will be measured by using high-temperature resistant thermocouples.

Figure 1. Heating process of specimens made with calcium aluminate cement (CAC) at 800 °C.

Figure 2. Mortars produced with CAC after being held at 800 °C for one hour.

This experiment type is the residual test which is one of the three main types of high-temperature experiments: 'stressed', 'unstressed' and 'residual'. For all methods, the specimen is taken out from the furnace when the temperature at its the center reaches the target temperature. However, there are other factors that vary from one another. In the 'stressed' test, the specimen is subjected to 0.4 f_c stress in the furnace and is immediately subjected to relevant mechanical test upon removal from the furnace. In contrast, there is no such a thing that applying forces to specimen during heating in the 'unstressed' test. For 'residual' test, the specimen needs to be cooled after heating until its core temperature drops to ambient temperature: this process typically takes 24 hours [5].
Finally, the mechanical experiments will be conducted on the cooled samples to measure changes in compressive strength, elasticity modulus and mass. Based on the data obtained at different high-temperature values, the various statistical models will be developed to compare the behavior of these mixtures at ambient temperatures (approximately 23-25°C) with their behavior at high temperatures.

Figure 3. Compression test of unheated sandstone specimen containing CAC.

Figure 4. Cube specimen made with limestone and CAC under compression test after being held at 400 °C.

Findings

So far, the production of all concrete mixtures for this study has been completed, and the heating and mechanical experiments will be performed after the curing of the concrete is complete.
However, as a preliminary preparation for this study, mortars were produced using exactly the same materials as in the main study. There are some differences between the produced concrete and mortars. Instead of using a 0.45 water/binder ratio and casting into cylindrical specimens, the mortars were made with a 0.35 water/binder ratio and poured into prism molds with dimensions of 40×40×160 mm. Later, 40x40x40 mm cube mortars were made by slicing those prisms into cubes. After 14 and 28 days curing, those specimens were exposed to separately exposed at 400°C and 800°C for a hour each. At 400°C, the average relative compressive strength compared to ambient temperature strength for mortars containing fine sandstone, limestone, and basalt is %60.41, %73.45, and %74.18 respectively for those made with Portland cement (PC), and %55.39, %70.11, and %56.69 for those made with calcium aluminate cement (CAC). At 800°C, the results are %26.81, %17.42, and %30.36 for mortars produced with Portland cement (PC), and %50.56, %62.01, and %65.03 for those made with calcium aluminate cement (CAC), following the same aggregate order. Assumptions and conclusions can be drawn from this mortar research, both for general insights and for guiding the ongoing main study.

Firstly, there is a significant decrease in the compressive strength of mortars produced with Portland cement (PC) at 800°C compared to that at 400°C. This phenomenon was also studied for three types of aggregates—gravel, ilmenite, and baryte—by Sakr and El-Hakim [6], showing that concrete containing Portland cement (PC) dramatically loses its strength after 500°C.

In addition, mortar containing calcium aluminate cement (CAC) performed better at 800°C—a high temperature—than those produced with Portland cement (PC). The work by Khan and Khaliq [7] reported similar results at 400°C and 800°C for concrete aggregate produced with separately Portland cement (PC) and calcium aluminate cement (CAC), both containing limestone aggregate. It was stated that the compressive strength of concrete at 400°C, relative to its strength at ambient temperature, was %77 and %76 for mixtures with Portland cement (PC) and calcium aluminate cement (CAC), respectively; and at 800°C, the values were %22 and %29, in the same order of cement types. Furthermore, Koksal et al. [8] studied a similar effect, and their research observed that mortars made from calcium aluminate cement (CAC) withstood further than those with Portland cement (PC) above 600°C.

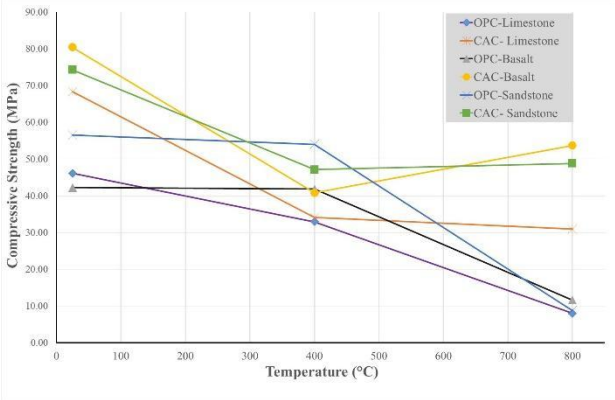

Figure 5. Compressive strength of mortars cured for 14 days as a function of target temperature.

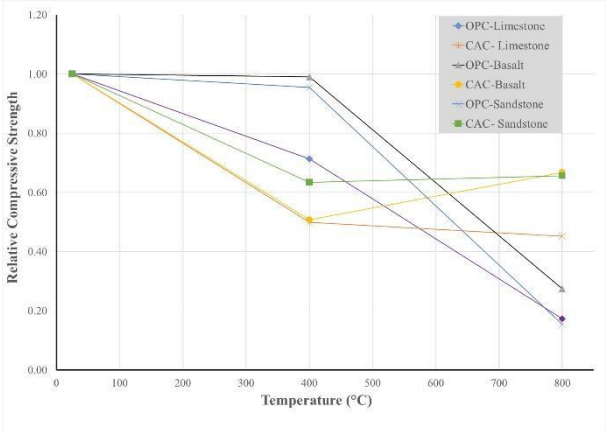

Figure 6. Relative compressive strength of mortars cured for 14 days as a function of target temperature.

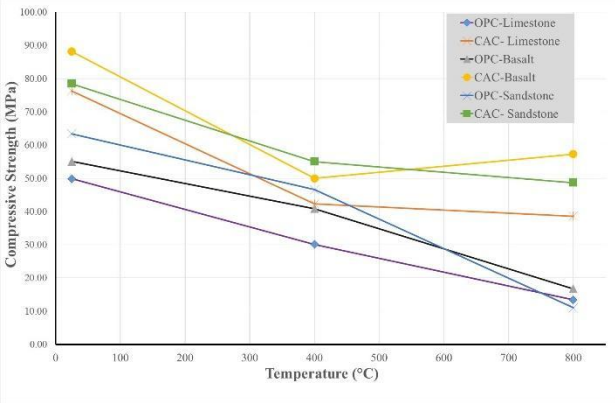

Figure 7. Compressive strength of mortars cured for 28 days as a function of target temperature.

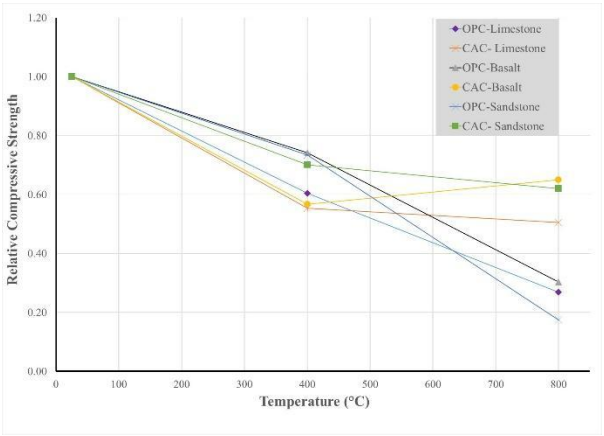

Figure 8. Relative compressive strength of mortars cured for 28 days as a function of target temperature.

Moreover, as shown in our mortar research, the slight decrease—and even increase, as observed in Koksal's study [8]—in the strength of concrete and mortar containing calcium aluminate cement (CAC) above 700°C is likely due to the development of a ceramic bond between the hydrated cement paste and fine aggregates in this type of binder [3]. It was observed that at 600°C and 900°C some mortar produced with calcium aluminate cement (CAC) gained strength ranging from %1.7 to %12.3, depending on the amount of cement and fine aggregate in the mixture [3][9].

Additionally, up to the 400–600°C range—where a dramatic reduction in the strength of concrete produced with Portland cement (PC) begins—concrete containing calcium aluminate cement (CAC) does not retain its strength as well as concrete with Portland cement (PC). In the mortar research, at 400°C, all mixtures with Portland cement (PC) retained more of their strength compared to those made with calcium aluminate cement (CAC). This observation was similarly noted by Newey [3].

Conclusion

In conclusion, at the high temperatures, the performance of concrete can vary depending on the type of cement that concrete contains. With the produced concrete mixtures, the aim is to determine the mechanical and elastic properties of these concretes in their hardened state when exposed to high-temperature.

This study can be beneficial for dealing with certain problems and improving conditions in the construction industry. There are two main area where this research can come in handy.

Firstly, with the infrastructure investments rapidly increasing, a large number of the tunnels are being constructed for railway and highway projects worldwide. When these structures are exposed to fire, the temperature of concrete elements forming the tunnels can swiftly increase. This is because extinguishing the fire could take long time, and the intensity of fire could quickly grow, often causing to structural damages and economic losses. Furthermore, except the tunnels, there is also need high-temperature resistant concrete for the industrial furnaces. As in the tunnels, formal regulations does not present suitable solutions for those furnaces. Since the service temperature is too high in those ovens, the structural elements making up the furnace need to endure these temperature levels. For such situations, modern codes and regulations may be insufficient to overcome them. Therefore, during the construction of these concrete elements, the findings and analyses from this research can help to construct durable and resilient structures.

A Multidisciplinary Approach to Sustainable Agriculture: The Impact of Microbial and Organomineral Fertilization on Soil Bacteria, Crop Yield, and Farmer Adoption

Ceyda Alat Doruk[a], Bülent Arıkan[a]

[a]Istanbul Technical University, Eurasia Institute of Earth Secience, Departmant of Ecology and Evolution, Geoanthropology Program, Türkiye
doruk21@itu.edu.tr

Keywords: Microbial Diversity, Microbial Fertilizer, Organomineral Fertilizer, Sustainable Agriculture.

Aim

Agriculture has long been a cornerstone of human survival, influencing economic and social frameworks of civilizations (Altieri, 1999). Modern challenges like increasing populations, climate change, and soil degradation make achieving agricultural sustainability difficult (Tilman et al., 2011). Soil microbiota plays a crucial role in nutrient availability, organic matter decomposition, carbon storage, and disease resistance (van der Heijden et al., 2008). A diverse microbial community is essential for soil health, as beneficial microbes aid nutrient cycling, suppress diseases, and enhance soil structure (Philippot et al., 2023). Excessive synthetic fertilizer use leads to soil acidification, salinization, and nutrient depletion, affecting microbial communities and diminishing productivity (Vitousek et al., 2009). Alternatives include microbial and organomineral fertilizers. Microbial fertilizers contain beneficial microorganisms promoting plant growth (Rehman et al., 2022). Organomineral fertilizers combine mineral nutrients with organic matter, improving soil structure and microbial activity while supplying nutrients; boost soil fertility by releasing nutrients gradually, reducing leaching losses, and increasing nutrient-use efficiency (Uddin et al., 2025). Despite proven benefits, their use remains limited. Farmers often prefer traditional methods due to economic concerns, market uncertainties, and existing policies (Aghabeygi et al., 2024).

This study hypothesizes that combined microbial and organomineral fertilizers will have a more pronounced impact on soil microbial diversity, plant growth, crop yield, and soil quality than either type alone. It aimed to assess effects of microbial, organomineral, and combined fertilization on soil microbial diversity and composition; evaluate changes in soil physicochemical properties; analyze plant growth and crop yield under different treatments; and explore socioeconomic and policy-related barriers to adoption of these fertilization methods by farmers.

Material and Method

The research occurred in Apa Village, Çumra, Konya, on a 23,394 m^2 plot uncultivated for nearly a decade. The field was divided into three 7,000 m^2 areas, separated by one-acre buffer zones. Beans (*Phaseolus vulgaris L.*) were sown using microbial, combined microbial and organomineral, and organomineral fertilizers. Comprehensive soil physicochemical and metagenomic analyses were conducted pre-planting and post-harvest for each area. Soil samples from a neighboring cultivated field served as a control. Plant parameters were measured monthly on 10 random samples per area. Post-harvest, bean samples' physical properties were examined in triplicate. The study ran from 20.05.2023 to 20.09.2023. Amplicon sequencing of the 16S rRNA gene was performed on the Illumina platform. Raw sequences were filtered using DADA2 package (v1.34.0) (Callahan et al., 2016). OTUs were created and classified using SILVA genus database (v138.2) and Naïve Bayes classifier (99% similarity threshold). Mitochondrial, chloroplastic, and undetermined sequences were removed. Soil microbial community structure was assessed using alpha diversity (Shannon, Chao1, Simpson indices) and beta diversity (NMDS based on Bray-Curtis distance). Relationships between soil properties and microbial diversity were examined using Spearman correlation. Statistical differences were determined by PERMANOVA, Wilcoxon, and Kruskal-Wallis tests. Principal Component Analysis (PCA) visualized major microbial genera distribution. Analyses and visualizations were performed in R (v4.2.2). One-way ANOVA determined significance of differences between treatments.

Multiple comparisons used Tukey's HSD test ($p < 0.05$). Pearson correlation analysis determined relationships between soil properties, microbial activity, and plant growth parameters.

Findings

The soil's organic matter content peaked at 1.90% in areas treated with microbial and organomineral fertilizers, while it was lowest at 1.06% where only organomineral fertilizer was used. Soil pH values varied slightly, ranging from 7.48 to 7.78. There were no notable changes in electrical conductivity and phosphorus levels. Potassium content was highest with microbial fertilizer, whereas lime content was highest with organomineral fertilizer.

Beta diversity analysis using NMDS and PERMANOVA based on Bray-Curtis distance showed that fertilization significantly influenced microbial community composition. PERMANOVA indicated phosphorus concentration significantly impacted microbial community differences ($F=2.086$, $R^2=0.294$, $p=0.0023$) (Delgado- Baquerizo et al., 2017). Considering fertilizer applications and soil pH, 45.8% of microbial community variation was explained ($F=1.69$, $R^2=0.458$, $p=0.033$). However, pH alone was not significant ($p=0.090$) due to the limited pH range. The NMDS graph (Figure 1) showed distinct pre-planting and post-harvest microbial communities, indicating plant growth and fertilizers altered microbial composition over time. Microbial fertilizer and microbial-organomineral treatments showed similarities, while organomineral fertilizer alone resulted in a distinct microbial community. The control group was markedly different from other treatments.

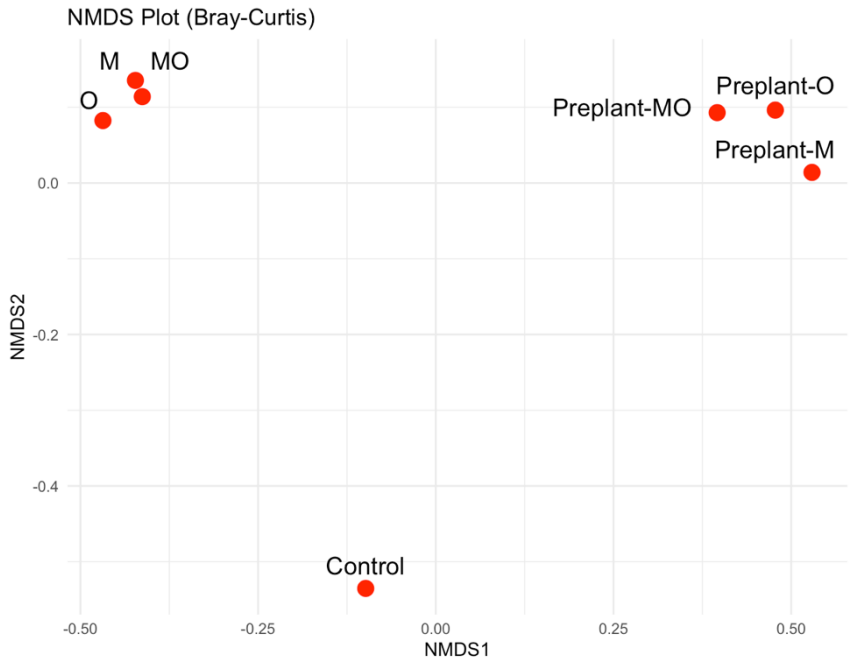

Figure 1. Non-metric Multidimensional Scaling (NMDS) analysis based on Bray-Curtis distances illustrating the impact of different fertilization treatments on soil bacterial community composition.

In alpha diversity analyses, Shannon index values ranged from 3.62 to 4.60, and Simpson index values varied from 0.93 to 0.98, reflecting generally high diversity and balanced species distribution. Chao1 estimated species richness values were between 140 and 395.6. The Kruskal-Wallis test showed no statistically significant differences between treatments in Shannon ($p=0.423$), Simpson ($p=0.512$), and Chao1 ($p=0.297$) indexes. Spearman correlation analysis (Figure 2) evaluated the relationships between alpha diversity indices and soil properties. The Shannon index showed no significant relationship with soil pH ($r=0.037$, $p=0.94$). Although the Chao1 index was negatively correlated with potassium levels, it was not statistically significant ($r=-0.56$, $p=0.19$). The Simpson index had a high positive correlation with phosphorus levels, but this was not statistically significant ($r=0.90$, $p=0.90$). These findings suggest that the observed relationships were not statistically significant, preventing clear biological conclusions. A significant positive correlation was found between potassium and phosphorus levels ($r=0.95$, $p<0.01$), indicating that these elements may jointly influence microbial diversity.

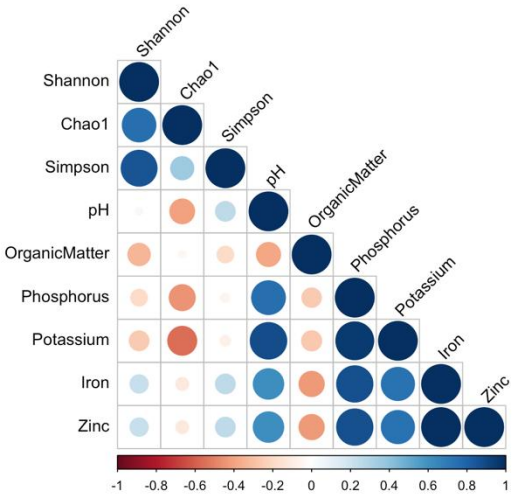

Figure 2. Spearman correlation matrix illustrating the relationships between alpha diversity indices (Shannon, Chao1, Simpson) and environmental factors.

The effects of different fertilization practices on microbial diversity were analyzed at the genus level using 16S rRNA sequencing. In the control area with ongoing agriculture and post-harvest soil samples, *Vibrio* (22.7%) was prevalent, while *Rhizobium* and *Bradyrhizobium* were absent, suggesting long-term cropping may have negatively selected against these symbiotic taxa (Hartmann et al., 2015; Vitousek et al., 2009). In the field with only microbial fertilizer, *Rubrobacter* (25%) and *Microvirga* (12.5%) initially dominated, but post-harvest, *Vibrio* rose (25.4%), and *Rubrobacter* fell to 1.6%. In the field with a microbial-organomineral fertilizer mix, *Rubrobacter* was initially low (10.3%), while *Afipia*, *Microvirga*, and *Pseudomonas* were high. Post-harvest, *Rubrobacter* vanished, *Vibrio* (18.1%) rose, and *Microvirga* and *Pseudomonas* declined. With only organomineral fertilizer, *Rubrobacter* and *Pseudonocardia* (9.4%) initially dominated, but post-harvest, *Vibrio* (11.9%) increased, *Rubrobacter* decreased, *Peredibacter* and *Sandaracinus* rose. PCA results (Figure 3) showed the first component (PC1), accounting for 99.93% of microbial community variation, was marked by aquatic environment-related genera like *Vibrio* and *Catenococcus*. PCA and Wilcoxon tests indicated irrigation impacted microbial composition more than fertilization and pH. Post-irrigation, aquatic genera like *Vibrio*, *Pseudocitrobacter*, and *Catenococcus* increased , while drought-resistant *Rubrobacter* decreased. These results highlight irrigation's greater influence on soil microbial communities than fertilization, underscoring its importance in agricultural management (Naylor et al., 2023).

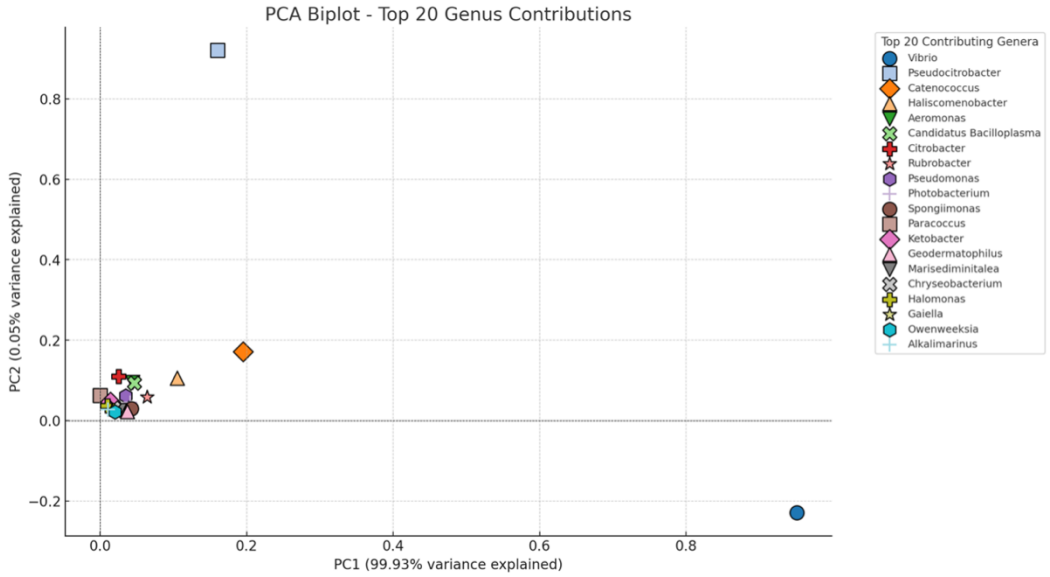

Figure 3. Principal Component Analysis (PCA) biplot of bacterial genus contributions in soil.

The microbial-organomineral fertilizer combination resulted in the most balanced microbial structure, controlling *Vibrio* more effectively than microbial fertilizer alone and ensuring high initial levels of beneficial bacteria (*Afipia*, *Microvirga*, *Pseudomonas*). In the organomineral fertilizer application alone, although *Vibrio* levels were lower, beneficial bacteria were limited. Thus, the microbial-organomineral fertilizer combination is a more sustainable approach supporting beneficial microbial groups. However, optimizing fertilizer application and inoculation strategies is crucial to maintaining beneficial microorganisms (Hartmann et al, 2015).

Although no statistically significant differences were observed in plant growth, plants treated with the microbial and organomineral fertilizer combination showed the highest root length and overall development. Different fertilization strategies did not significantly affect the physical properties of beans, such as wet and dry grain weights and water uptake capacities. ANOVA analysis revealed that plots with a combination of microbial and organomineral fertilizers had significantly higher yields compared to other applications ($p<0.05$) (Silva et al., 2022).

The study identified economic and psychological barriers as the main challenges farmers face in transitioning to sustainable fertilization methods, with economic concerns and uncertainties arising from moving away from familiar chemical fertilizers to alternative options (Aghabeygi et al., 2024). The current situation arises from the elevated costs of biofertilizers and the fact that their anticipated benefits are not immediately apparent. Additionally, farmers' unfamiliarity and lack of experience with these new methods lead them to maintain a psychological distance from adopting them. It has been noted that Türkiye's existing agricultural policies and publication services have a direct impact on farmers' willingness to adopt these practices. Due to insufficient state support and limited access to agricultural publication services, farmers are unable to fully utilize the information and incentives for sustainable practices. Consequently, to enhance the use of microbial and organomineral fertilizers, it is necessary to bolster educational programs, increase economic support, and tailor policies to meet farmers' needs.

Conclusion

This study evaluated the effects of microbial and organomineral fertilizers, both individually and in combination, on soil microbial composition, plant growth, and crop yield. The results indicated that the combination of microbial and organomineral fertilizers led to a more balanced microbial structure in the soil compared to single-type fertilizer applications and significantly boosted crop yield. However, irrigation was found to be a more influential factor in shaping microbial communities than fertilizer applications. It is stressed that reducing economic uncertainties, strengthening comprehensive education programs, and enhancing policy support are crucial to

increasing farmers' adoption of biofertilizers and organomineral fertilizers. Future research should focus on optimizing application methods and ensuring the long-term sustainability of microbial communities.

Life Cycle Assessment in a Zinc Oxide Recovery Plant Using the Waelz Process: Evaluation of Environmental Impacts from a Sustainability Perspective

Cansu Gunes[a], Orhan Ince[b]

[a] Istanbul Technical University/Graduate School, Environmental Sciences, Engineering and Management Program, Türkiye
[b] Istanbul Technical University / Civil Engineering Faculty, Engineering Department, Türkiye
gunesc22@itu.edu.tr

Keywords: Life Cycle Analysis (LCA), Waste Recovery, Waelz Process, Zinc Production, Electric Arc Furnace Dust (EAFD).

The iron and steel industry plays a pivotal role, particularly in developing countries, and is expected to maintain its influence across multiple sectors, including construction, automotive, and machinery manufacturing. The primary inputs of this industry are iron ore or scrap, while its main output is crude steel (Ersöz et al., 2016). Currently, steel production is carried out using various methods, with the Electric Arc Furnace (EAF) and Blast Furnace (BF) being the most commonly employed techniques (Bıyık & Özkale, 2017). According to 2021 data, steel production in facilities utilizing the Electric Arc Furnace method increased by 16.6% compared to previous years (Iron and Steel Sector Report, 2021). In EAF-based steel production, in addition to sludge and slag, Electric Arc Furnace Dust (EAFD) is generated as a by-product (Iron and Steel Industry Waste Management Report, 2014). Due to its zinc content, EAF dust adversely affects the refractory lining of the Electric Arc Furnace and reduces the economic efficiency of the process, thereby preventing its direct recycling into steel production. Consequently, this waste is collected via filtration systems. Approximately 10–15 kilograms of EAFD are generated per ton of steel produced. Owing to its content of heavy metals such as zinc (Zn), cadmium (Cd), lead (Pb), and chromium (Cr), it is classified as hazardous waste by the U.S. Environmental Protection Agency (EPA) (Kalpaklı et al., 2020). In Turkey, EAF dust is likewise regulated as hazardous waste (Iron and Steel Industry Sectoral Waste Guide). Due to the high costs of landfilling, the challenges of managing leachate resulting from heavy metal contamination, and the valuable zinc content of EAF dust, the recovery of zinc from EAFD has gained increasing importance (Kalpaklı et al., 2020). The zinc content of EAF dust varies depending on the quality of the scrap used in the process and generally ranges between 23–26% Zn. This high zinc content is primarily attributed to the presence of galvanized steel scrap in the EAF charge (Antuñano et al., 2019).

Globally, zinc production is carried out through both primary and secondary sources. While primary zinc production involves extraction from ores, secondary production refers to zinc recovery from waste materials. Both approaches employ pyrometallurgical and hydrometallurgical methods (Kania & Saternus, 2023). In hydrometallurgical zinc production, zinc is separated using various leaching solutions, whereas pyrometallurgical production is based on the high volatility of zinc at elevated temperatures (Nair et al., 2022). The most commonly used and historically established pyrometallurgical method for zinc recovery is the Waelz Process. This German-patented method was first implemented in 1925 in Lünen, Germany (Ruetten, 2006). The Waelz Process is recognized as a Best Available Technology (BAT) (Best Available Techniques (BAT) Reference Document for the Non-Ferrous Metals Industries, 2017). In this process, zinc recovery is based on reduction-oxidation principles and involves the use of raw materials (EAF dust), auxiliary substances, and coal (TÜBİTAK, 2023). The output of this process is a Waelz Zinc Oxide Concentrate with a minimum zinc content of 55% (Wang et al., 2021).

The concept of Life Cycle Analysis (LCA) emerged in the 1960s and, with its widespread application beginning in the 1990s, necessitated the establishment of standardized frameworks. Currently, ISO 14040 defines the principles and framework of LCA, while ISO 14044 provides detailed requirements and guidelines (Yıldız & Atış, 2023). Since the industrial advancements of the 19th century, global environmental concerns have intensified. In response, international conferences and agreements have been convened since the 1970s to address these issues.

One of the most significant contributors to environmental degradation is climate change. To ensure a sustainable future and reduce carbon emissions, the Paris Agreement was signed in 2015, with the goal of limiting global temperature rise relative to pre-industrial levels. This agreement necessitates a reduction in fossil fuel consumption and a shift toward renewable energy sources (Ministry of Environment, Urbanization, and Climate Change).

Life Cycle Analysis allows for the identification of the key environmental aspects of a product, the discovery of improvement opportunities, the quantification of the overall environmental burden, and the establishment of fundamental performance indicators. This study aims to conduct a Life Cycle Analysis of Waelz Zinc Oxide Concentrate. The research will evaluate the environmental impacts of replacing fossil fuels with renewable energy sources during production and examine the influence of different renewable energy types on the process and product life cycle. Moreover, the study seeks to explore sustainable and environmentally friendly production strategies and provide recommendations based on these finding.

Aim

Adopting the life cycle methodology within the scope of ISO 14040 and ISO 14044 standards, this study aims to conduct a Life Cycle Analysis of Waelz Zinc Oxide Concentrate, a product of a hazardous waste recovery facility in Turkey. The study will identify key environmental impact points in the life cycle of raw material procurement and production (cradle-to-gate).

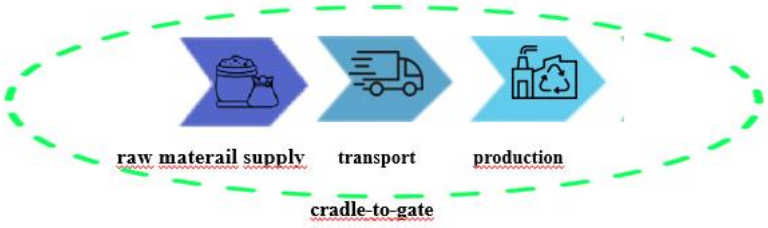
Material and Method

Life cycle assessment calculations were conducted using SimaPro 9.5 software and Ecoinvent LCA Database. It

was developed by PRé Sustainability, a Netherlands based company.Under the ISO 14040 and ISO 14044 standards, the Life Cycle Assessment (methodology primarily consists of four main phases. These standards are internationally recognized references for environmental impact assessment, and the phases are outlined as follows

Goal and Scope Definition: This study aims to identify the environmentally significant aspects of Waelz zinc oxide concentrate through a comprehensive life cycle assessment and to explore potential process improvement opportunities The scope of the study has been defined as cradle to gate.

Table 1: System Boundaries.



Inventory Analysis: Inventory refers to the set of data collection and computation procedures used to quantify the inputs and outputs associated with a product system.

Impact Assessment: The impact assessment was conducted using the Environmental Footprint 3.1 (EF 3.1) method with the Normalization and Weighting Set V 1 01.

Interpretation: This study encompasses a life cycle assessment based on data from a hazardous waste recovery

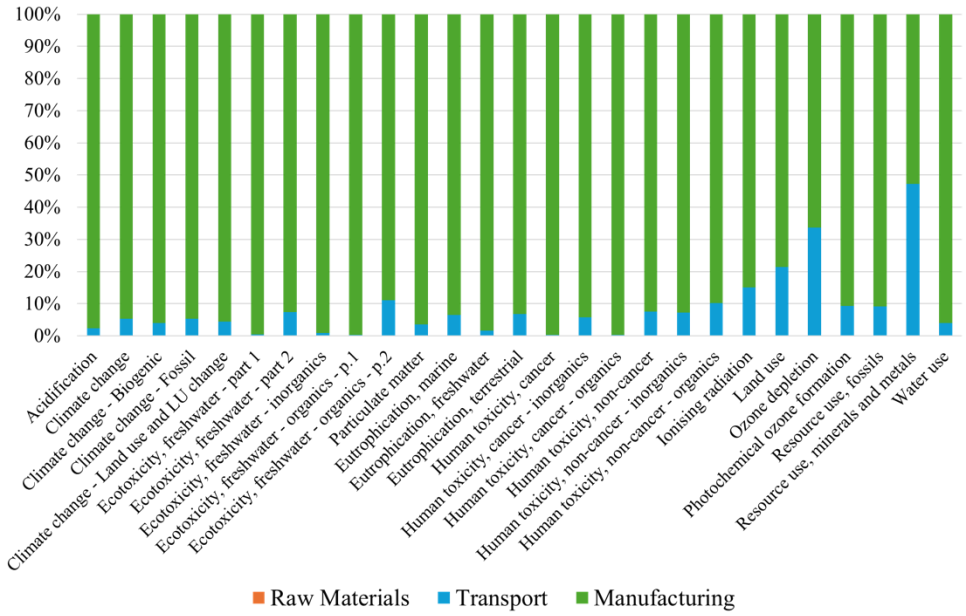
facility located in Turkey.

Findings

The life cycle assessment of Waelz zinc oxide concentrate was conducted using a cradle to gate approach and the

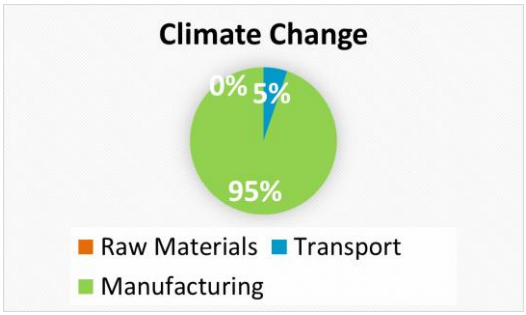
SimaPro 9.5 software, in accordance with ISO 14040 and 14044 standards A total of 27 impact categories were assessed (Table 2).

Table 2: Impact Categories Distribution according to Stage of LCA.



The manufacturing phase has been identified as the dominant contributor across the majority of minimal Greenhouse gas emissions, particularly carbon dioxide are observed to originate predominantly from the manufacturing process This suggests that the energy sources utilized during production are primarily fossil fuel based and/or that the manufacturing operations are highly energy intensive (Table 3).

Table 3: Percentage Distribution of Climate Change Category according to Phases.



Conclusion

The life cycle assessment of Waelz Zinc Oxide production from Electric Arc Furnace Dust reveals that the majority of environmental impact (>90%) is concentrated in the manufacturing phase.This is primarily due to the high energy demand of the Waelz Process and emissions related to heavy metals. To mitigate these impacts, the use of low carbon energy sources and emission control technologies is recommended WZO recovery contributes to resource efficiency and reduces the environmental risks associated with hazardous waste. For more sustainable production, process improvements and alternative methods should be explored.

Keywords: Ski Jumping Suits, Aerodynamics, Air Permeability, Drag Coefficient.

Aim

Ski jumping is a highly demanding winter sport that is gaining increasing popularity over the years. In this discipline, athletes are judged based on the distance traveled and the form maintained during flight and landing. To achieve optimal performance, several important factors regarding the quality of one's performance must be taken into account, as they play a crucial role. Among them, one of the most important factors is the aerodynamic properties of an athlete's equipment and their posture during flight. While numerous studies have examined the aerodynamic effects of jump technique and ski design, relatively little research has focused on the role of ski jumping suits, even though these suits must meet strict regulations. Therefore, the aim of this research is to investigate how different fabric properties, such as air permeability and surface roughness, impact aerodynamic behavior and the overall performance of the athlete.

Material and Method

Ski jumping suits must meet strict regulations according to the International Ski and Snowboard Federation (FIS). All portions of the ski jumping suit must be made of the same material and must exhibit the same air permeability from the outside in and from the inside out. The construction of the suit must be a five-layer laminated fabric, consisting of an outer fabric layer, foam layers, an elastic membrane, and a lining fabric. The outer fabric is a bi-elastic warp-knit fabric, made of 81% Polyamid gloss and 19% Elasthane (Lycra), which weighs 180-190 g/m^2 and has the elasticity 150-160% in length and approx. 85-95% in width. The controlled air permeability of the suit must be a minimum of 40 liters per m^2/sec under 10 mm water pressure, achieved through perforation (FIS Rules). The thickness of the suit may not exceed 6.0 mm nor be less than 4.0 mm. The suit must be close-fitting on any part of the body and must close with a zipper placed at the center of the front part of the suit (Figure 1). No additional chemical or mechanical treatment of the material or suit is allowed. All seams must be inside the suit. (FIS, 2024)

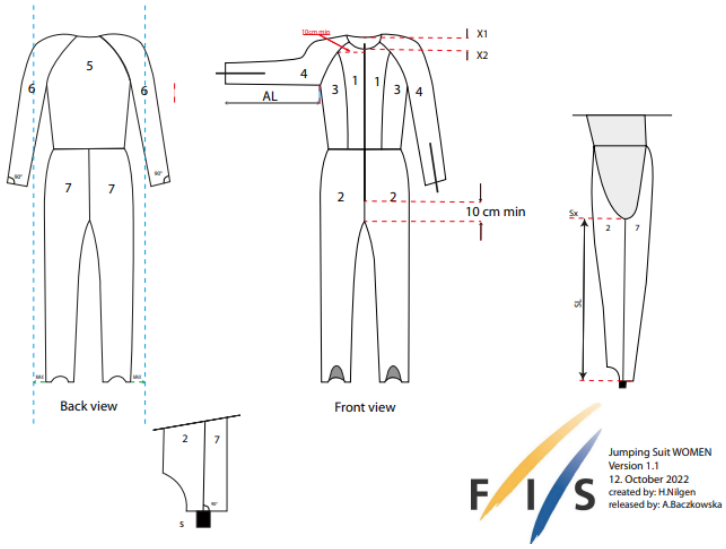

Figure 1. Jumping Suit Women Version 1.1 (FIS, 2024).

Air permeability, which is an important factor in ski jumping suit regulations, is measured using different systems. According to Hasegawa et al., the measurement system used in their study consists of a vacuum pump to provide a constant supply of air through the fabric, a differential pressure gauge, a valve, a measuring cylinder, and a water tank (Figure 2). To measure the flow rate of air passing through the fabric, the differential pressure gauge was used. The air permeability is then calculated based on the pressure difference between the points upstream and downstream of the fabric (Hasegawa, Kawabata, Murakami, Seo, & Obayashi, 2018).

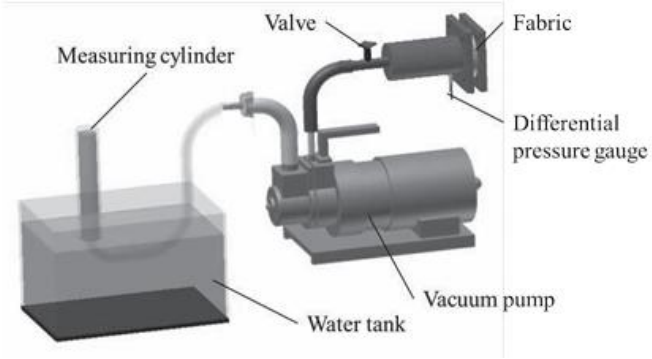

Figure 2. Schematic of air permeability measuring system (Hasegawa, Kawabata, Murakami, Seo, & Obayashi, 2018).

Another important method for investigating aerodynamic properties is wind tunnel testing. According to Chowdhury et al., fabrics are evaluated on various cylindrical arrangements, which are first tested without any fabric covering and then with fabrics wrapped around them (Figure 3). The wind tunnel used in their study is a closed-return circuit with a maximum airspeed of approximately 150 km/h. The drag and lift forces and their moments are computed via purpose-made computer software. The measured aerodynamic forces are later converted to non-dimensional drag and lift coefficients. (Chowdhury, Alam, & Subic, Aerodynamic performance evaluation of sports textile, 2010)

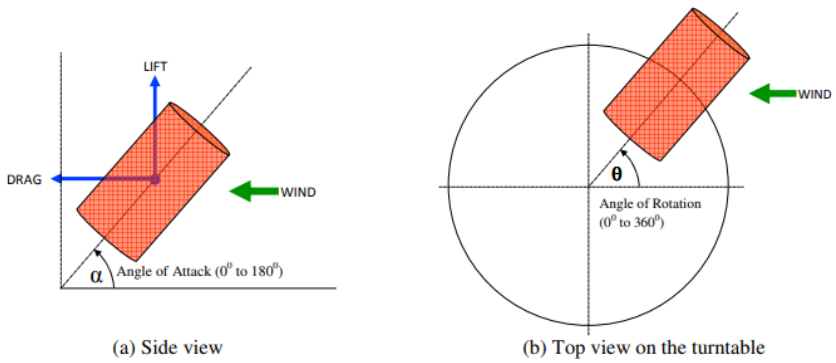

Figure 3. Standard cylinder arrangement for wind tunnel studies (Chowdhury, Alam, & Subic, Aerodynamic performance evaluation of sports textile, 2010).

Chowdhury et al. also designed a robust and safe experimental setup to better investigate aerodynamic properties with minimal interference. This setup can be used to examine a mannequin or athlete with full ski gear, covering most possible variations of an athlete's position in a real ski jump (Figure 4). The system allows adjustments in ski angle relative to the horizontal plane, body position angle, hip angle, and the angle between two skis. The experimental setup was designed to accommodate the athlete/mannequin with all associated equipment (skis, suit, boots, goggles, helmet, gloves, etc.). The mounting device consists of six adjustable circular steel pipe stands connected to a six-component force sensor. This force sensor is linked to a wind tunnel data acquisition computer port, where specialized software captures all six-component forces and moments simultaneously. (Chowdhury, Alam, & Mainwaring, Aerodynamic study of ski jumping suits, 2011)

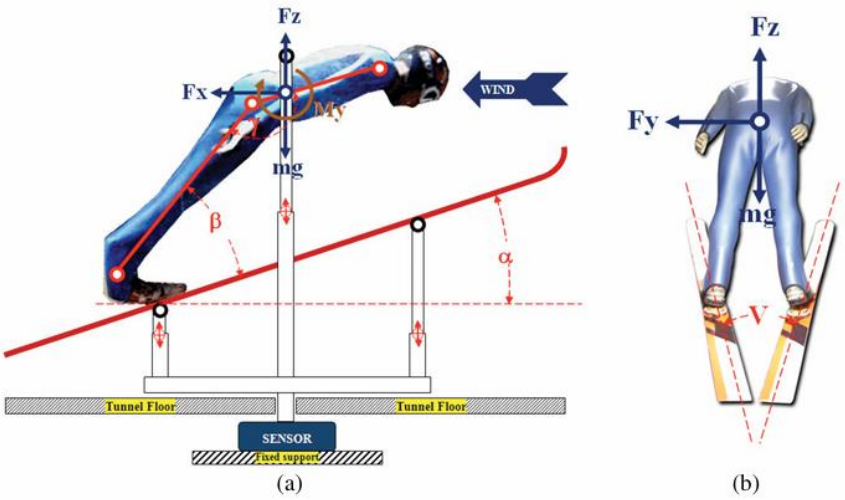

Figure 4. A schematic of experimental setup: (a) side view; (b) rear view (Chowdhury, Alam, & Mainwaring, Aerodynamic study of ski jumping suits, 2011)

More recent studies have also included Computational Fluid Dynamics (CFD) simulations. Liu et al. used a special turbulence model and simulation software to analyze airflow. They set the flight velocity at 29 m/s based on field measurements and tested how different surface roughness values of the suit affect aerodynamic properties. They then calculated lift, drag, and pitching moments and conducted flow field visualizations. Additionally, they examined the effect of surface roughness on different body parts (Figure 5). (Liu, Wang, & Liu, 2025)

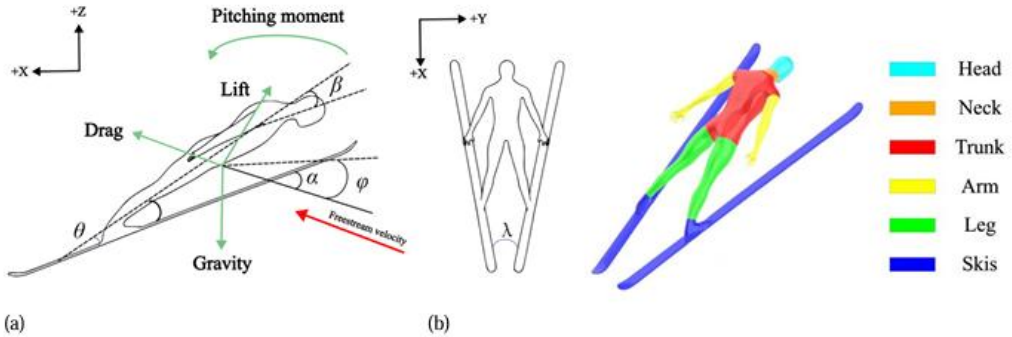

Figure 5. (a) Schematic diagram of posture parameters and force directions during flight; (b) different parts of the multibody system (Liu, Wang, & Liu, 2025).

There is also a growing use of sensor technology to measure aerodynamic forces acting on ski jumpers in real time. These sensors allow the calculation of drag and lift coefficients as well as the lift-to-drag ratio.

Findings

Air permeability is an important factor affecting the aerodynamic properties of ski jumping suits. Hasegawa et al. found that increasing air permeability raises the stall angle and decreases the drag coefficient (Hasegawa, Kawabata, Murakami, Seo, & Obayashi, 2018). Kataoka et. al. carried out wind tunnel experiments to investigate the aerodynamic performances of an elliptic cylinder clothed with fabrics of differing air permeabilities and figured that the stall was delayed by the fabrics with higher air permeabilities. (Kataoka, Hasegawa, Murakami, Seo, & Obayashi, 2020) According to limited studies, jump length can be increased when lift is increased by 1%, whereas jump length decreases when drag is increased by 1%. (Chowdhury, Alam, & Mainwaring, Aerodynamic study of ski jumping suits, 2011)

There is limited information available on full-scale aerodynamic testing methodologies for ski jumping suits. However, Chowdhury et al. developed a reliable full-scale experimental setup, allowing for experimental

evaluation of drag and lift for all types of ski gear, as well as for real athletes and mannequins. Their research concluded that a tight-fitting ski jumping suit provides an aerodynamic advantage over a loose suit. (Chowdhury, Alam, & Mainwaring, Aerodynamic study of ski jumping suits, 2011)

Liu et al. discovered that surface roughness impacts aerodynamic characteristics during the stable flight phase. Their research found that the lift-to-drag ratio peaks at a roughness of 28 μm, making it optimal for maximizing aerodynamic efficiency. However, this roughness also induces significant forward pitching moments. Considering this, roughness values of 8 μm and 11 μm were found to offer commendable aerodynamic performance along with better flight stability. Additionally, the study showed that trunk roughness has the greatest impact on aerodynamic performance, while arm roughness influences the backward shift of the airflow separation point, reducing pressure drag. For leg roughness, when it is small, aerodynamic performance is primarily affected by the position of the separation point, whereas when roughness is higher, frictional drag becomes the dominant factor. (Liu, Wang, & Liu, 2025)

Conclusion

The drag coefficient decreases with an increase in air permeability near the stall angle of attack. Flight distance can be extended by wearing a ski jumping suit made of fabric with higher air permeability.

Wind tunnel testing, with the addition of specialized experimental setups and software, provides a robust method for evaluating drag and lift on various ski gear types.

A tight-fitting suit provides aerodynamic advantages, and in addition, surface roughness plays a significant role in aerodynamic performance, ultimately affecting jump distance and flight stability.

Aim

The textile industry, which is an important part of people's daily lives, has an important place in the global economy. In recent years, the concepts of sustainability and slow fashion have become the agenda of textile designers in order to prevent these industrial processes from posing a threat to the ecosystem [1]. Designers all over the world have turned to different design approaches in order to stop or slow down the rapid pollution of the planet with the fast fashion concept. One of the most important reasons for this is that textiles that are consumed rapidly along with the fast fashion trend create a huge waste burden on the environment. In order to prevent the formation of this waste load, intensive studies are carried out on sustainable approaches such as the use of renewable and environmentally friendly raw materials, reduction of carbon emissions, durability and long life of products. These studies reveal that more than 80% of a product's environmental impact is determined by the design process. For these reason, one of the approaches that should be implemented to achieve sustainable fashion for the consumer and the producer is timeless designs [1-2]. Timeless textiles are the workhorse of slow fashion. Similar to concept of slow fashion, designers work on timeless models with quality materials, in small numbers, and without using current fashion data [3-4]. As the level of awareness of consumers increases, it is seen that their tendency to purchase a design that will never lose its value increases. In this case, they both prefer permanent textiles that will not stand the test of time and also exhibit a more environmentally friendly approach [1,5]. In some of the exemplary studies on these subjects, it is seen that fabrics that have existed throughout history are reinterpreted by taking inspiration from their own historical processes. With vibrant colours and tones that will attract attention, designs that can liberate personal expressions, go beyond time, and have a two dimensional appearance and feel with use of different weaving types and yarn counts together can contribute to the creation of original and distinct styles [6].

The aim of this study was to design woven fabrics by reinterpreting timelessness with a minimalist approach. Thus with timeless designs that were realized, it was tried to obtain fabrics that were both high in design qualities and simple yet functional. The designs, which will bring effortless elegance in every season, are aimed to be woven fabrics that can be worn at any time the day and the year.

Material and Method

Weight, weaving type and blend ratios of the fabric designs are summarized in Table 1. These parameters were determined according to the fabric properties of upper garments that can be basic and timeless.

Table 1. Parameters of designs.

Fabrics	Fabric Weight (g/m²)	Weaving Type	Blend Ratio
Design 1	285	Twill	100 % CO
Design 2	125	Plain	54/40/6 % CO/PA/EL
Design 3	235	Twill	73/25/2 % CO/PES/EL
Design 4	315	Twill	52/46/2 % Organic CO/CO/EL
Design 5	315	Special Dobby	97/3 % CO/EL
Design 6	275	Twill	60/34/4/2 % Recycled PES/CV/PES/EL
Design 7	260	Twill	97/3 % CO/EL
Design 8	285	Special Dobby	56/32/10/2 CV/PES/PAN/EL

The process of realizing designs is divided into two: designing woven fabrics and weaving the designs. In the first step of designing woven fabrics, the screening method, which is a qualitative research method, was used to examine past comments on basic and timeless fabrics. Trend analysis was conducted by following seasonal fashion shows and fashion sites such as WGSN. The findings were reinterpreted according to today's fashion sense using the brainstorming method. The theme is 'timelessness'. Studies have been carried out on the overlap of theme and trend. Drawings, stories and storyboards were created within the scope pf the theme. To ensure consistency and repeatability when making colour selections, eight neutral tones were selected from PANTONE Colour Chart: 14-1217 TCX, 18-0430 TCX, 18-0513 TCX, 19-1034 TCX, 18-4215 TCX, 19-3922 TCX, 19-4122 TCX and 19-3902 TCX. The theme of the study was the main factor in determining the colours. In the weaving process of the designs, plain, twill and special dobby were used as the weave structure. All fabric designs were produced as samples on an eccentric air weaving machine. After additional work on cost and production details, the necessary design revisions were made and the designs were finalized.

Findings

Sample production images of eight designed basic and timeless woven fabrics are presented in Figure 1. Basic and timeless designs were achieved in the works with vague thin or thick lines, denim look and linen look. The fact that the colours chosen were predominantly dark tones supported the timeless design element. At the same time, their combinability has made the designs usable in the production of key textile pieces.

Figure 1. Fabric samples.

The colour fastness to washing test results of the fabrics were carried out in accordance with the method described in ISO 105-C06 (A2S test conditions; 40°C), the colour fastness to rubbing tests were carried out in accordance with ISO 105-X12 and the colour fastness to perspiration tests were carried out in accordance with ISO 105-E04. The Martindale Pilling Tendency tests were applied according to BS EN ISO 12945-2 standard test method for 2000 cycles. When all the test results were evaluated in general, colour fastness washing was staining 4, colour change ¾, colour fastness to rubbing was dry 4, wet 2/3 +, colour fastness to perspiration was acid and alkaline staining 4, acid colour change 4, alkaline colour change ¾ and pilling was 3 +.

Conclusion

In this work, eight basic and timeless woven fabrics were designed. Thanks to the seasonless colour palette and minimalist patterns of the designs, they will appeal to a wide target audience and will be included in both women's and men's collection, regardless of gender. Patterns that are far from sparkle and exaggeration may appeal to those who love the minimal style. In addition, that can also find a place in the quiet luxury trend.

When the technical findings of the designs were evaluated, it was seen that colour fastness and pilling tendencies were generally at acceptable values.

The designs are found to be timeless and minimalist in these aspects, as they enable elegance, comfort and aesthetics to be achieved simultaneously business or social life, depending on the season. It is expected that these woven fabric designs, which will continue to be trendy especially for stylish women in SS25 and 26 globally, will find a response in the fashion industry, with pieces supported by palazzo trousers, midi skirts, tweed jackets and details that can be combined with the quiet luxury trend.

This paper includes the outputs of the project titled '23-24 Simple and Timeless' completed at the Almodo Altunlar Textile Design Center.
