4TH INTERNATIONAL GRADUATE RESEARCH SYMPOSIUM

IGRS'25

BOOK OF **EXTENDED ABSTRACTS**

EDITORS

Fatma Seniha GÜNER, Burçak KARAGÜZEL KAYAOĞLU, Filiz AYAZ

May 12-14, 2025
ITU, Istanbul, Türkiye

4TH INTERNATIONAL GRADUATE RESEARCH SYMPOSIUM

IGRS'25 - E-PROCEEDINGS
May 12-14, 2025 ITU, Istanbul, Türkiye

Editors, Fatma Seniha GÜNER, Burçak KARAGÜZEL KAYAOĞLU, Filiz AYAZ

Istanbul, 2025

e-ISBN 978-975-561-744-2
İTÜ Yayınevi. No: 2025.2/21

PREFACE 37
COMMITTEES 38
SCIENTIFIC PROGRAM 51
EXTENDED ABSTRACTS 71
ORAL PRESENTATIONS 72
AERONAUTICAL AND ASTRONAUTICAL ENGINEERING 73
Aircraft Design, Flight Dynamics And Performance 73
External Store Separation From Fighter Aircraft 74
Sensitivity Analysis of Hypersonic Glide Vehicle Trajectory Under Aerodynamic and Atmospheric Variations 80
Winglet Design, Optimization and Performance Analysis for a Trainer Aircraft 87
Control Systems: Adaptive, Intelligent, Digital, Optimal, Pneumatic-Hydraulic 92
Quadrotor Actuator Fault Detection and Isolation- A Model Based Approach 93
Multi-Agent Reinforcement Learning with Maneuver Primitives for Automatic Ground Collision Avoidance of Fighter Jets 97
Mechanical Vibrations And Structural Dynamics 103
Nonlinear Modeling and Sensitivity Analysis of Oleo-Pneumatic Strut Landing Gear Systems for Aircraft Landing Performance 104
Aeroelastic Optimization with Genetic Algorithm 110
Feed-Forward Neural Network Based Prediction of Flutter Speed of 3 DOF 2D Wing Model 116
Conceptual Modeling of a Multi-Axial Nonlinear Dynamic VibrationAbsorber for Helicopters 124
Rotary Wing Aircraft 130
A Study on Hover and Forward Flight Performance of S70A-28D (UH-60L Black Hawk) Helicopter to Obtain Cruise Chart by Using Momentum and Blade Element Momentum Theory 131
Spacecraft Control, Design And Performance 141
Liquid Propellant Rocket Engine Performance Sensitivity Analysis 142
Theoretical, Computational And Experimental Aerodynamics And Fluid Dynamics 144
A Deep Learning Based Modelling of Axial Turbomachinery 145
Experimental Study on Vortex Gust Encountered by a Flat Plate at 45° Wing Sweep 149
Fully-Coupled k–ω-SST Turbulence Model Implementation for Nonlinear Newton Method in Unstructured Vertex-Based Hemlab Algorithm 153
Digital Twin Approaches in System-Level Modeling for Aerospace and Propulsion Applications of Rocket Engines: A Review 161
Theoretical, Computational And Experimental Structural Analysis And Design 165

Design and Analysis of Isogrid-Stiffened Cylindrical Structures for Launch Vehicles: Mathematical Modelling and Knockdown Factor Correlation with Finite Element Validation 166
Numerical Modeling of Composite Laminates Under Out-of-Plane Impact 169
Investigation Of The Interaction of Carbon Fiber Cylindrical Rocket Bodies With Radial Bolt Joints 176
APPLIED INFORMATICS 183
Computational Electromagnetics 183
Nyström Integral Method for Mode Solving in Optical Waveguides with Arbitrary Geometries 184
Singular Integral Treatment of Nyström Method for Electromagnetic Scattering Problems 189
Data Analysis 194
Optimization Potential of Machine Learning-Based Algorithms in Neonatal Parenteral Nutrition Management: A Systematic Review 195
Medical Image Analysis 201
Deep Learning-Based Breast Tumor Detection in MRI Using Faster R-CNN 202
Prediction of Microsatellite Status Using Deep Neural Network 206
Improving Tumor Segmentation Performance in Breast MRI via U-Net Based Deep Learning Approach 209
ARCHITECTURE 213
Architectural History 213
Spatial Representation In French New Wave Cinema: An Analysis Through Agnès Varda's Cléo De 5 À 7 (1962) Film 214
Legitimisation through Elevation: Romanos' Myrelaion 220
Rural Houses in Renaissance Architecture: Proposals of Sebastiano Serlio According to the Social Hierarchies in his Sixth Book 224
Semi-Open Spaces as a Result of Climate and Culture in Mediterranean Architecture 229
The Historical Layers of Selimpaşa in Constantinople Hinterland Context 232
Furniture Consumption in Istanbul at the Beginning of the 20th Century: The Role of Periodicals 236
Architecture Design Theory 241
The Impact Of Governmental Power On Urban Morphology: A Case Study Of London 242
The Performance of the Archive or Archive as Event: Exhibiting Architecture 249
Typological Transformations and Urban Isolation: Rethinking Architectural Production along Eskişehir Road 252
Conditions of Criticality in Discussions on Architectural Representation 260

Exploring Experiential Learning Design Practices Grounded in Social Responsibility in Mardin 264
Urban Destruction in Malatya's Green Belt Project: A Struggle for Public Space or Capitalist Gain? 266
Reading Architectural Memory Through Cinematic Image: Atatürk Cultural Center 270
Fluid Bodies of Space: Rethinking Architectural Relationality Through The Medusa Head 277
Archival Encounters: Rewriting Istanbul Women's Works Library and its Memory Through Bodily Practices 282
The Potentialities, Displacements, and Spatial Projections of Concepts 289
Soft Matters: (Re)drawing Architecture Through Feminist Material Practices 296
Building Construction Technologies 302
Evaluation of Retrofitting Techniques in Reinforced Concrete Buildings 303
Evaluation of the Seismic Performance of Traditional Akçakese Houses in Relation to Structural Deterioration 306
Evaluation Of Light Steel Structured Housing According To Construction Systems 312
Evaluation of Damage Mechanisms in Stone Structured Houses Due to Earthquakes . 315
Impact of Deterioration Due to Environmental Factors on Seismic Performance of Traditional Timber Buildings in the Historical Peninsula in Istanbul 319
Building Materials and Technologies 323
Developing One-part Geopolymer Binders by Using Ground Granulated Blast-furnace Slag and Ceramic Waste as Precursors 324
Evaluation of Damage Mechanisms of Reinforced Concrete Industrial Structures in Past Earthquakes in Turkey 328
Built Environment Design and Technologies 332
Evaluation of Exterior Cladding Materials in Educational Buildings in Terms of Embodied Energy 333
The Impact of Façade Cladding Materials on Carbon Emissions in Urban Renewal Projects: The Case of Istanbul 337
Conservation and Restoration 341
Ottoman Brick Stamps 342
Examination of the Transformation of Kırklareli Urban Conservation Area and Its Surroundings between 2004 and 2022 in the Context of Conservation and Sustainability 345
The Rural Settlement Structure and the Challenges of Preserving Traditional Housing in Tokat Bağbaşı (İbibse) Village 350
Facade Finishes in Early 20th Century Istanbul: History and State of Conservation ... 356
Environmental Control and Building Technology 361
UrbanReCrete: A Sustainable Approach to Concrete Waste Recycling in Istanbul 362

Reduction of Cooling Loads in Office Buildings in Hot Climates Using Radiant Cooling 365
Multi-Stage Space-Adaptive Shelters: An Alternative to Post-Disaster Shelters 371
Artificial Intelligence in Materials Education for Architecture Opportunities, Challenges and Ethical Considerations..... 381
Project and Construction Management 385
A Literature Review On Organizational Structures In The Construction Industry..... 386
A Systematic Review of BIM and the Circular Economy: Key Research Areas and Findings..... 391
Investigating the Role of Data Management for AI Utilization for Decision-Making in Construction: A Literature Review..... 394
Sustainable Design..... 398
Investigating Circularity in Buildings through Digital Circularity Metric..... 399
ART HISTORY 405
Art and Technology..... 405
The Role of Digital Technologies in Museum Storytelling: Ephesus Experience Museum 406
Art History 409
A Brief Historical Trajectory of Art Collectives as a Commoning Practice in Turkey .. 410
From Functional to Imaginary Forms: Alev Ebüzziya Siesbye's Ceramics..... 413
CHEMICAL ENGINEERING..... 416
Hydrogen Technologies, Fuels Cells, Energy Storage Materials 416
Biomass-Derived Activated Carbon as Electrode Material for Supercapacitors 417
Modelling and Computational Systems..... 420
Machine Learning-Based Prediction of FTIR Spectral Peaks for Biomass Characterization..... 421
CHEMISTRY 424
Inorganic Chemistry 424
The Design And Application of Novel Post-Metallocene Catalysts For Olefin Polymerization..... 425
Nanochemistry..... 428
Investigation of Fluorescence Properties of ZIF-8 Structures Modified with Graphitic Quantum Dots..... 429
Organic Chemistry..... 432
Synthesis Of Polymers Containing Supramolecular Components In The Pendant Or Main Chain 433
Polymer Chemistry..... 437

Dual Radical and Singlet Oxygen Pathways in Polybutadiene Photovulcanization: A Novel Approach Using Phenylacylbromide under UV-A Irradiation for Advanced Crosslinked Films 438
COMMUNICATION SYSTEMS 442
Antennas 442
Design and Inter-Element Spacing Optimization of GNSS Array 443
COMPUTATIONAL SCIENCE AND ENGINEERING 447
Computational Biology 447
Molecular Dynamics Analysis of CHK2 Mutations at the C-lobe of the Kinase Domain 448
Computational Fluid Dynamics 453
Multi-Objective Optimization of Airfoil Geometry for Aerodynamic Efficiency and Noise Reduction Using Bézier Parameterization 454
COMPUTER ENGINEERING 459
Artificial Intelligence 459
An Intelligent Jamming Environment: Reinforcement Learning Approach 460
The Role of Artificial Intelligence in Enhancing Software Quality: A Multivocal Literature Review 469
Multi-Lead ECG Classification Using a Mixture-of-Experts Transformer Model 473
Computer Networks 477
Adaptive Consensus Algorithms for Blockchain Networks 478
Cyber Security 484
Reputation Based Decision Making Consensus Mechanism for UAV Swarms with Ethereum Blockchain 485
Neuromorphic Computing and Memristor-Based Network Attack Detection Systems: New Approaches in Cyber Security 488
Enhancing IoT Botnet Detection: A Streamlined Approach to Feature Selection 495
Embedded Systems 501
Comparison of the Effects of Different Compiler Environments on Communication Signal Detection Software 502
COMPUTER SCIENCE 505
Data Science 505
A Data-Driven Approach to Process Duration Estimation: End-to-End Machine Learning with Process Mining 506
Image Processing 511
PET Image Denoising Using Denoising Diffusion Probabilistic Models (DDPMs) 512
Iterative Reconstruction Applications for Aircraft Image Restoration 514
CONSTRUCTION MANAGEMENT 520

Construction Project Management 520
Inclusion and Gender Equality for Women in the Construction Industry 521
Difficulties Faced by Construction Experts in Construction Sector Cases in the Turkish Justice System 530
Procurement Phases in EPC Projects: A Bibliometric Analysis 533
Determining the Factors Causing Rework in the Turkish Construction Industry 540
IT in Construction 546
Assessing the Level of Digitalization of the Construction Permit Processes in Türkiye 547
Sustainability in Construction 550
Industrialisation of Natural Building Materials for Sustainability in the Built Environment 551
Circular Economy Performance Assessment in Construction: A Critical Review of Firm-Level Models 555
CONTROL AND AUTOMATION ENGINEERING 559
Advances in Automatic Control Engineering 559
Control Surface Failure Management In Dual-System VTOL UAVs 560
4-D Flight Management System Design for the Fighter Jets 563
Lane Change Decision Making For Autonomous Vehicles By Using Adversarial Learning Methods 568
Applications of Control Engineering 571
An Optimization-Based Flight Control Law Design for Fighter Aircraft 572
Enhancing Aircraft Avionics Safety: Integrating STPA With ARP4761 581
Design and Analysis of a Dual Layer Disturbance Observer-Based Controller for Longitudinal Axis in a Fixed Wing Aircraft 585
Fuzzy Gain Decision for Different Types of Aircraft with Dynamic Pitch Control Envelope Cue 591
Enhanced Aircraft Control Throughout Total Energy Control Systems: A Comparative Study with Conventional Autopilots 601
Performance Comparison of Guidance Algorithms for Aerial Vehicles: A Software-In-The-Loop Based Approach 605
Robust Attitude Control of the F-16 Aircraft Using Incremental Nonlinear Dynamic Inversion 610
Adaptive Kalman Filter-Based Gyroscope Error Compensation for IMU Sensors 615
Immersion and Invariance Disturbance Observer-Based Discrete Time Vector Control of BLDC Machines 619
DATA ENGINEERING AND BUSINESS ANALYTICS 628
Big Data Analytics for Decision-Making 628
Automated Plastic Waste Detection on Coastal Areas Using UAVs and Deep Learning 629

Agentic Workflows for Self-Service Analytics Applications in E-Commerce 636
Predictive Analytics and Machine Learning in Business 640
Analyzing Brokerage Firm Trading Behavior via Supervised Learning: A Comparative Study on BIST 10 641
Sentiment Analysis and Opinion Mining 645
Impact of Weekly vs Daily Sentiment Scores on Price Direction Forecast 646
DEFENSE TECHNOLOGIES 649
Remote Sensing 649
A Hybrid Preprocessing Approach Based on Simulation Data for Embedded Object Detection Under an Inhomogeneous Surface 650
Spacecraft Control, Design And Performance 656
Design of a Deployable S-Band Helical Antenna for CubeSats 657
Structural Design and Analysis 661
Optimization and Finite Element Analysis of Metastructures for Vibration Mitigation 662
Parametric Optimization of Semi-Octagon Re-entrant Auxetic Structures for Energy Absorption 667
Finite Element Analysis Of Crack Growth Behavior In The Presence Of Crack-Arresting Holes 672
Design and Modeling of a Nonlinear Bi-Axial Dynamic Vibration Absorber for Helicopter Applications 675
Computational Analysis of Metallic Structures Subjected to Impact Loading Using LS-Dyna 679
Unmanned Vehicles 685
Heuristic Approach to UAV Selection with Fuzzy Logic and MADM Techniques 686
Optimized Visual Odometry and Satellite Image Matching-Based Localization for UAVs in GPS-Denied Environments 689
Comparative Analysis of Object Detection and Tracking Algorithms for UAVs 692
EARTHQUAKE ENGINEERING 696
Artificial Intelligence, Machine Learning, and Deep Learning in Earthquake Engineering 696
Detection of Longitudinal Reinforcement Buckling in Reinforced Concrete Columns by a Deep Learning Method 697
Estimating Equivalent Damping Ratio of Conventional Shear Walls by Machine Learning Methods 702
Experimental Investigation of Reinforced Concrete Building Elements 714
Enhancing Seismic Resilience of Substandard RC Beam-Column Joints with All-Steel Tube-in-Tube Buckling-Restrained Braces: 715
A Shake Table Test 715
Performance-Based Seismic Assessment and Design 719

Seismic Performance Assessment of Irregular RC Structures Using the Extended N2 Method 720
Structural and Geotechnical Earthquake Engineering 725
Seismic Performance Enhancement of RC Coupling Beams Using Shape Memory Alloy Devices 726
Preliminary Study on St. Ilyas Church Damaged in the Kahramanmaraş Earthquakes 732
Design and Comparison of Different Types of Reinforced Concrete Slab Systems for Multi-Storey Buildings 743
ECOLOGY AND EVOLUTION 747
Anthropocene 747
Exploring the Biodiversity Patterns of Anatolia Under Changing Climatic Conditions 748
Defining the Character of Turkey's Biodiversity Policies 752
ECONOMY 755
Financial Crises and Macroprudential Policies 755
Financial Contagion: Dynamic Correlations Approach 756
ELECTRICAL ENGINEERING 762
Electric Power & Energy Systems 762
Techno-Economic Integration of Nuclear Energy Towards Achieving Net-Zero Emissions 763
Electrical Machines 767
Investigation of the Effect of Space Vector PWM Technique on Zero-Sequence Voltage Formation in Open-End Windings 768
Determination of Altitude Dependent Insulation Breakdown of Brushed DC Starter Generators 773
Electrical Vehicles 775
Development And Validation Of A Dynamic Energy Consumption Model For A 12-Meter Electric Bus Using SORT-2 Test Data 776
Power Electronics 779
Three Phase LLC Resonant DC/DC Charger for Railway Applications 780
A Real-Time Resonance Detection and Mitigation Method for Shunt Active Power Filters 784
Smart Grids 786
Adaptation of a Generalized Observer Scheme for False Data Injection Detection in Load Frequency Control Systems 787
Cyber-Resilient Real-Time Transient Stability Prediction for Modern Power Systems 791
ELECTRONICS AND COMMUNICATION ENGINEERING 800
Analog/Mixed-Signal/Microwave Circuits 800

22-nm FD-SOI Internal Power Management Unit for Frequency-Modulated Continuous Wave Lidar 801
Design of a Low-power Phase-Frequency Detector in 65 nm CMOS Technology Suitable for 5G Mobile Applications 804
Bio-Medical, Bio-Inspired Circuits/Systems 812
Thermoplastic Microfluidic Platform for 3D Cell Culturing and Imaging 813
A Deep Learning Network for Automatic Grade Classification of Renal Cell Carcinoma 818
Image Reconstruction and Restoration with Diffusion Network 822
Customizable Fluidic and Anisotropic Vocal Fold Phantom for Biomechanical Analysis 826
Development of Multi-Capsule Endoscopy via Spring-Assisted Distance Control 831
Effect of Wavelength, Intensity, and Eye Color on Pupil Detection in Infrared-Based Eye Tracking Systems 836
Multi-Class Classification for Skin Lesions Using Deep Learning Techniques 844
Digital Circuits and Systems 849
Hardware Implementation of FALCON's ffSampling Algorithm 850
Embedded Systems 853
Design of a Clutchless Automated Gear Control System for Electric Tractors 854
VLSI Systems and Applications 857
Logic Locking-Based FPGA System Design for Third-Party IP Protection 858
ENERGY SCIENCE AND TECHNOLOGY 862
Computational Fluid Dynamics 862
Numerical Investigation of the Effects of Interfacial Contact Resistance in PEM Fuel Cells with Coated Metal Bipolar Plates 863
Computational Heat and Mass Transfer 869
Numerical Investigation of Engine Cooling Using Nanofluids 870
A State-of-Charge Based Experimental and Numerical Investigation of Li-Ion Battery Heat Generation and Temperature Distribution 873
Electrochemical and Thermal Modeling of Lithium Batteries for 878
Temperature Distribution Based on Cathode Materials 878
Flow Control and Thermal Behavior of Bearings Using a Proportional Valve in a Closed-Loop Lubrication System for Turbofan Engines 884
Energy Conversion and Storage Technologies 888
Sustainable GSM Base Station Energizing Using Portable Radioisotope ThermoelectricGenerator (RTG) Design 889
The Lifespan Comparison of an NMC811 Pouch Cell Based High Voltage Battery with Silicone and Polyurethane Foam Usage 892

Energy Conversion and Sustainability 896
Energy Efficiency Potential Analysis of SMEs In Türkiye's Fertilizer Sector 897
Renewable Energy 900
Feasibility Assessment of Hydrogen Fuel Cell Integration in the Dornier 228 Aircraft with the Structural and Operational Considerations 901
Sustainable Energy 905
The Effect Of Seawater On The Electrodecomposition Of Hydrogen Sulfide To Hydrogen And Polysulfides 906
ENVIRONMENTAL ENGINEERING 910
Air Pollution and Control 910
Effects of Air Pollutant Parameters on Respiratory Diseases in Edirne 911
Membrane Technologies 916
Enhancing Reverse Osmosis Performance: A CFD-Based Study of Randomized Feed Spacer Geometries 917
FOOD ENGINEERING 921
Food Bioactive Compounds 921
Extraction of Phenolic Compounds from Grape Pomace; Potential Application Packaging Materials 922
Functional Foods 925
Plant-Based Proteins in Instant Soups: Comparison of Sensory, Functional, and Bioactive Properties 926
Composition and technofunctional properties of Aquafaba from Local Legume 931
Novel Food Processes 933
Effects of Audible-Range Sound Treatment on the Microbiological Quality of Strawberry During Post-Harvest Storage 934
Sustainable Foods 938
Development and Characterization of Biodegradable Films Enriched with Protein Extracted from Agro-Industrial Pea Waste and By-Products 939
GAME AND INTERACTION TECHNOLOGIES 944
AI in Gaming 944
A Comparative Study For Analyzing LLM Performance in Bluff-Based Card Games 945
Preliminary Study on the Feasibility of Neural Network-Based Generative AI Models in Video Game Music Production 948
Game Design 951
Optimizing Level Production in Hidden Object Games Using YOLO Object Detection 952
A Systematic Approach to Ludonarrative Harmony: Methods for Aligning Interactive Gameplay and Storytelling 955

Impossible Spaces in Games: Using Anamorphic Projection in Space Interactions to Explore Possibilities of New Game Mechanics 959
Understanding Player Behavior: The Role of Intrinsic and Extrinsic Motivations in Bartle Player Types 965
Game Production 971
RNBO for Game Development: A Framework for Dynamic and Adaptive Audio Design 972
Gamification 975
Procedural Entity Generation For Simulated Ecosystems 976
Interaction Technologies 979
Naval History Reconstruction Through 3D Modeling and Simulation 980
Series Games 985
Mechanics To Design Virtual Reality Cognitive Training Games 986
User Studies 989
An Analysis of Gaming Behavior Through Bartle's Player Model & Human Psychology 990
GEOGRAPHIC INFORMATION TECHNOLOGIES 993
Artificial Intelligence and Machine Learning in Remote Sensing Analysis 993
Current Challenges in Port Management and Common Approaches from Geographic Information Technologies (GIT) 994
Spatial Data Algorithms and Visualization and 3D GIS Technologies 997
Tactile Map Production Processes And Application Areas For Visually Impaired 998
Spatial Planning and Management with GIS Applications 1002
Analysis of Customer Complaints in Mobile Communication Networks with GIS 1003
City Model Production With LIDAR Technology And Integration Of Urban Transformation With GIT: The Example Of Zeytinburnu District 1006
Mitigating Urban Heat Island Effects through Nature-Based Solutions: The Case of Istanbul 1008
GEOLOGICAL ENGINEERING 1012
Rock Mechanics 1012
Detachments Induced By Thermal Cycling At Grain Boundaries of Fine Grained Marble 1013
GEOMATICS ENGINEERING 1019
Geodesy 1019
On the Role of Earth Observations and Geodetic Data in Environmental and Climate Change 1020
Geographic Information Systems 1023
Spatial Problems And Effective Factors In Hospital Campus Structure 1024

Social Vulnerability Analysis of the Cities Affected by the February 6 Turkey Earthquake 1029
Spatial Analysis and Optimization of E-Commerce Company's Parcel Collection Operations: The Case of Esenyurt, Istanbul 1032
Transformation of Solid Waste Management in Baku: A GIS-Based MCDM Approach to Landfill Site Selection Beyond Balakhani 1040
Natural Hazards 1045
Flood Risk Analysis with Geospatial Artificial Intelligence Techniques 1046
Seismic Hazard Assessment of Kahramanmaraş Region: Analysis of Earthquake Sources and Probabilistic Seismic Risk 1050
Photogrammetry 1057
Generating a High-Definition Map (HD Map) via YOLO (You Only Look Once) Deep Learning-Based Object Detection Model 1058
Remote Sensing 1061
Investigation of Anthropogenic Effects in Protected Wetlands Using Remote Sensing and Geographic Information Systems: A Case Study of Manyas Bird Lake and Bird Paradise National Park 1062
Aircraft Contrails Detection with Deep Learning Methods on Remote Sensing Images 1068
Enhancing Sentinel-1 SAR Geolocation Accuracy: The Impact of DEM on Orthorectification Performance 1071
Offshore Wind Turbine Site Selection in the Aegean Sea 1075
Evaluating The Temporal Consistency Of Sar And Optical Vegetation Indices For Cotton Monitoring Using Sentinel-1 And Sentinel-2 1078
HEAT FLUID 1084
Fluid Mechanics 1084
Generation of Proper Inflow Conditions with Hydrodynamic Stability Approach: A Case Study For An Axially-Rotating Pipe Flow 1085
HISTORY OF SCIENCE AND TECHNOLOGY 1092
History of Engineering 1092
The Transformation of Armored Vehicles as a Response to Amphibious Warfare: A Comparative Analysis of the Dieppe Raid and the Normandy Landings 1093
History of Physics 1095
Scientific Tendencies in Early Nineteenth-Century Britain: William Sturgeon and The Annals of Electricity, Magnetism and Chemistry 1096
History of Sciences 1099
Brief History Of Artificial Intelligence Approaches 1100
HYDRAULICS AND WATER RESOURCES ENGINEERING 1104
Hydrology 1104

Spatio-Temporal Analysis of Long-Term Rainfall Erosivity Trends and Climate Impacts on Erosion Potential 1105
INDUSTRIAL DESIGN 1112
Historical, Cultural and Social Context of Design 1112
Discovering The Choir Members' Practices: An Initial Understanding of The Intersection of Design, Music, and Community 1113
Decoding Toxic Attachment Between Design Products and the Users: Understanding by using Metaphors 1115
Product Design 1119
Testing the Aesthetic Responses to Small Household Appliances in The Context Of Incremental Innovation 1120
Theory and Methodology in Industrial Design 1126
User Narrative as Antenarrative: A Brief Overview 1127
Prompt 'Design the Perfect Product': A Literature Review on AI Incorporation in Industrial Design Processes 1130
Exploring Emotions in Design Research: An Initial Mapping of Emotion-based Concepts 1134
Understanding Creativity: A Survey-Based Investigation into the Psychology of Designers' Creativity during the Ideation Phase 1140
INDUSTRIAL ENGINEERING 1143
Decision Making 1143
Multi Criteria Decision Making For Selecting Best Banking Service Channel 1144
A Comparative Analysis of Machine Learning and MCDM Sorting Methods in Electric Vehicle Selection 1147
A Bayesian Network-Based Approach for Analyzing Railway Accidents 1150
Engineering Management 1154
Impact of Organizational Life Cycle on R&D Project Prioritization Criteria 1155
Structuring Challenges for Textile Industry in Adopting the Digital Product Passport 1160
Sector-Specific Supplier Evaluation Based on LARGS Dimensions 1164
Customer Preferences For Mobile Operating Systems In Smartphones Using Conjoint Analysis 1168
Industrial Data Analytics 1172
Predicting the Closing Time of Debt Files in Legal Stage Using Machine Learning and Deep Learning Methods 1173
Knowledge Management 1175
Understanding University Reputation: A Stakeholder-Centered Model for Reputation 1176
Manufacturing Management 1180

Analysing the Automotive Production: A Bibliometric Analysis on Lean-Green Management 1181
Improvement Study In The Inner Door Production Area With Lean Production Approach 1184
INFORMATICS 1191
Computational Design Tools and Methods 1191
A Decision Support Model Proposal For Urban Green Space Site Selection Problem Based on Multi-Criteria Decision Making 1192
Computational Memorability Model Based on Object Size 1198
INTERNATIONAL MASTER OF INTERIOR ARCHITECTURAL DESIGN 1204
Interior Architecture 1204
Use of Mycelium-Based Materials as an Interior Design Component: A Digital Fabrication Approach 1205
Technology in Interior Design 1211
A Strategy for Dataset Preparation in AI Model Training: The Case of Hotel Room Interiors 1212
LANDSCAPE ARCHITECTURE 1216
Heritage and Identities 1216
From Tradition to Globalization: The Conceptual Transformation of Korean Landscape in Global City Seoul 1217
Innovative Technologies for Landscape Design and Management 1220
The Use of Computer Vision in Observing Human Behavior in Landscape Architecture 1221
Landscape Design 1224
Understanding Play: How Playground Exuipment Shapes Cognitive, Social, and Pyhsical Behaviors in Children Aged 3-12: A Case Study in Maltepe Orhangazi City Park 1225
MANAGEMENT 1228
Economics 1228
Central Bank Digital Currencies (CBDCs): a countermeasure to Anti-Money Laundering (AML) challenges posed by cryptocurrencies? 1229
Finance 1234
Investor Attention and Asymmetric Conditional Volatility: Evidence from GARCH-X and GJR-GARCH-X Models 1235
How Was Financial Performance Affected by ESG In The After- Covid Era? A Global Analysis 1240
Human Resource Management 1246
Remote Work and Virtual Presenteeism: Insights from the Turkish Organizational Context 1247
Marketing 1252

Navigating the Paradox of Connectivity and Isolation: Impacts on Digital Nomads' Psychological Well-Being 1253
Organization 1261
Organizing Through Code: A Bibliometric Review of Algorithms in Organizational Contexts 1262
Production Management 1267
Supplier Performance Evaluation with Balanced Scorecard 1268
Performance Evaluation Model Based on Balanced Scorecard for Industry 4.0 Applications in the Fast Moving Consumer Goods Sector (FMCG) 1272
MANAGEMENT ENGINEERING 1277
Finance 1277
The Effect of ESG Ratings on Firm's Financial Performance in Borsa Istanbul 1278
TEFAS's Effect on the Turkish Mutual Funds Landscape 1281
Marketing 1285
Adoption of Smart Small Home Appliances: An Analysis of Social and Behavioral Factors 1286
Understanding Consumer Acceptance and Purchase Intentions in Unmanned Retail Stores 1289
MARITIME STUDIES 1295
Maritime Human Resources 1295
Importance of Safety Awareness and Safety Culture Onboard with Alternative Fuels 1296
MATERIAL SCIENCE AND ENGINEERING 1300
Ceramics, Glass, Refractory Materials 1300
Improvement of the Selenium Retention and Control of the Color Stability in Selenium Containing Glasses 1301
Nanomaterials 1305
A Study About Tin Nanoparticles and Production of Core-shell Structure 1306
MATHEMATICAL ENGINEERING 1310
Applied Mathematics 1310
Symmetry Analysis on Rosenau Type Equations 1311
Exploring Rayleigh Waves in Layered Media 1314
Understanding Predator- Prey Dynamics Through Equilibrium State Classification. 1317
Effects of Weak Heterogeneity on Nonlinear Love Wave Interactions 1320
Data Science and Machine Learning 1323
A Case Study in Time Series Classification Using Machine Learning and Deep Learning 1324
Mathematical Modeling 1327

Modeling Rare Metal Market Dynamics: A Nonlinear Approach withInvestment and Geopolitical Risk..... 1328
MECHANICAL ENGINEERING 1330
Additive Manufacturing 1330
Evaluation of Mechanical Properties of SLM AlSi10Mg Alloy Produced with Different Production Parameters 1331
Automotive 1335
Optimizing Urban Micro-Mobility: Ergonomic Design, Structural Integrity, and Dynamic Analysis of Electric Kick Scooter 1336
Electrification of Heavy Commercial Truck: Vehicle Modeling with Using MATLAB/Simulink, Energy Efficiency Analysis and Economic Comparison with Conventional Diesel Engine 1346
ANN-Based PID Tuning Mechanism For A Vehicle Control SystemConsidering Improved Path Following 1354
Combustion Model Analysis on Validation Purpose of a Spark Ignition Engine 1358
Computational Fluid Dynamics 1363
Multi-Objective Aerodynamic Shape Optimization of Helicopter Nose..... 1364
Analysis of Effects of Tip Clearance on Axial Pump Performance..... 1369
Aerodynamic Performance Enhancement of a 27-Inch Apc Propeller Through Geometric Modifications 1375
Process Optimization of Polymer Melt Impregnation Systems by Extrusion Method 1380
Investigation of Thermal-Flow Performance in Close Circuit Cooling Towers..... 1388
Computational Solid Mechanics 1396
A Novel Approach for Robust Identification and Characterization of Mechanical Shock Loads for Structural Durability Assessment..... 1397
Modeling Hydrogen-Induced Failure of AISI 4135 Steel by Finite Element Analysis . 1405
A Comparative Modal Analysis of Homogenized and Full-Scale FE Models of Sandwich Composite Structures with Re-entrant Auxetic Core.....1411
Parametric Investigation of Mechanical Properties for Laser Powder Bed Fusion Processed Inco718 Auxetic Metamaterials 1417
Hybrid Optimization Method for I-Section Beams: A Comparative Study with Detailed FEM 1422
Structural Optimization of LPDC Aluminum Wishbone for Sheet Metal Design in Rear Suspension System for Electric C-SUV Vehicles 1426
Post-Buckling Behavior of Metallic Panels 1430
Machine Design..... 1437

PREFACE

Dear Colleagues, Students and Distinguished Participants,

It is a great pleasure and honor for Graduate School of Istanbul Technical University to invite you to the 4th International Graduate Research Symposium: IGRS'25, to be held between 12th and 14th of May 2025, which will be organized as an hybrid event.

The symposium will present the findings of the most recent graduate researches from a diverse range of disciplines from basic sciences, engineering, and architecture to art and social sciences. We aim to bring together students, staff, alumni and industry from a diverse background to foster the interdisciplinary discussions, exchange of ideas, expand the knowledge, construct professional interactions and discuss the future perspectives. The symposium program will feature keynote presentations as well as poster sessions.

This symposium will demonstrate ITU's Graduate School's strategic commitment to innovation, academic excellence and leadership in higher education.

We hope that you will join the symposium and distribute this invitation to the staff and students across your institutions.

Many thanks
Best regards,

Chair of the Organizing Committee
Dean of Graduate School
Istanbul Technical University

Prof. Dr. F. Seniha Güner

COMMITTEES

HONORARY CHAIR

Prof. Dr. Hasan Mandal, Rector of İstanbul Technical University

ORGANIZING COMMITTEE CHAIR

Res. Asst. Ozan Vahit Altınpınar, Istanbul Technical University
Res. Asst. Ömer İmir, Istanbul Technical University
Res. Asst. Özgür Altınışık, Istanbul Technical University
Res. Asst. Seda Tepe, Istanbul Technical University
Res. Asst. Şevki Samet Kaplan, Istanbul Technical University
Res. Asst. Volkan Er, Istanbul Technical University

SCIENTIFIC COMMITTEE

AERONAUTICAL AND ASTRONAUTICAL ENGINEERING

Prof. Dr. İbrahim Özkol, Aeronautical and Astronautical Engineering, Istanbul Technical University
Prof. Dr. Hülya Cebeci, Aeronautical and Astronautical Engineering, Istanbul Technical University
Prof. Dr. Melike Nikbay, Aeronautical and Astronautical Engineering, Istanbul Technical University
Prof. Dr. Metin Orhan Kaya, Aeronautical and Astronautical Engineering, Istanbul Technical University
Prof. Dr. Zahit Mecitoğlu, Aeronautical and Astronautical Engineering, Istanbul Technical University
Prof. Dr. Fırat Oğuz Edis, Aeronautical and Astronautical Engineering, Istanbul Technical University
Prof. Dr. Vedat Ziya Doğan, Aeronautical and Astronautical Engineering, Istanbul Technical University
Prof. Dr. Bayram Çelik, Aeronautical and Astronautical Engineering, Istanbul Technical University
Prof. Dr. Okşan Çetiner Yıldırım, Aeronautical and Astronautical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Özge Özdemir, Aeronautical and Astronautical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Mete Budaklı, Aeronautical and Astronautical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Baha Zafer, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Ali Tatar, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Duygu Erdem, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Saliha Banu Yılmaz, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Oğuzcan İnal, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Demet Çilden Güler, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Barış Başpınar, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Cuma Yarım, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Demet Balkan, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Seher Eken, Aeronautical and Astronautical Engineering, Istanbul Technical University
Asst. Prof. Dr. Ramazan Yeniçeri, Aeronautical and Astronautical Engineering, Istanbul Technical University
Dr. Bülent Tutkun, Aeronautical and Astronautical Engineering, Istanbul Technical University
Dr. Kaan Yıldız, Aviation Institute, Istanbul Technical University

APPLIED INFORMATICS

Prof. Dr. Behçet Uğur Töreyin, Informatics Institute, Istanbul Technical University
Assoc. Prof. Dr. Volkan Müjdat Tiryaki, Informatics Institute, Istanbul Technical University
Asst. Prof. Dr. Mehmet Akif Yazıcı, Informatics Institute, Istanbul Technical University
Azizjon Meliboyev, Digital Technologies and Mathematics, Kokand University

ARCHITECTURE

Prof. Dr. Seden Acun Özgünler, Architecture , Istanbul Technical University
Assoc. Prof. Dr. Francisco Abarca, Urban and Spatial Planning, University of Granada
Prof. Dr. Ozan Önder Özener, Architectural Design, Istanbul Technical University
Assoc. Prof. Dr. Aslıhan Şenel, Architectural Design, Istanbul Technical University
Assoc. Prof. Dr. Bihter Almaç, Architectural Design, Istanbul Technical University
Prof. Dr. Fatih Yazıcıoğlu, Environmental Control and Building Technology, Istanbul Technical University
Assoc. Prof. Dr. Tarık Serhat Bozkurt, Environmental Control and Building Technology, Istanbul Technical University
Assoc. Prof. Dr. Halet Almıla Büyüktaşkın, Environmental Control and Building Technology, Istanbul Technical University
Prof. Dr. Ecem Edis, Building Sciences, Istanbul Technical University
Assoc. Prof. Dr. Caner Göçer, Building Sciences, Istanbul Technical University
Assoc. Prof. Dr. Filiz Akşit, Building Sciences, Istanbul Technical University
Prof. Dr. Elçin Filiz Taş, Project and Construction Management, Istanbul Technical University
Prof. Dr. Hakan Yaman, Project and Construction Management, Istanbul Technical University
Assoc. Prof. Dr. Bahriye Ilhan Jones, Architecture and Built Environment, Northumbria University
Assoc. Prof. Dr. Fatma Pınar Çakmak, Project and Construction Management, Istanbul Technical University
Prof. Dr. Yegan Kahya, Conservation and Restoration, Istanbul Technical University
Assoc. Prof. Dr. Işıl Polat Pekmezci, Conservation and Restoration, Istanbul Technical University
Assoc. Prof. Dr. Umut Almaç, Conservation and Restoration, Istanbul Technical University

Assoc. Prof. Dr. Gül Cephanecigil, Architectural History , Istanbul Technical University
Assoc. Prof. Dr. Bilge Ar, Architectural History , Istanbul Technical University
Assoc. Prof. Dr. Işıl Çokuğraş Bağdatlıoğlu, Architectural History , Yıldız Technical University
Assoc. Prof. Dr. Çağhan Keskin, Architectural History , İstanbul University
Asst. Prof. Dr. Mustafa Kaan Sağ, Architectural History , İstanbul University
Assoc. Prof. Dr. Nisa Semiz, Architectural History , Abdullah Gül University
Asst. Prof. Dr. Mejrema Zatric-Sahovic, Architectural History , International University of Sarajevo
Dr. Ayşe Ercan Kydonakis, Architectural History , Simon Fraser University
Dr. Batu Bayülgen, Architectural History , Istanbul Technical University
Prof. Dr. Mine Özkar Kabakçıoğlu, Building Information Modelling, Istanbul Technical University
Prof. Dr. Figen Gül, Building Information Modelling, Istanbul Technical University
Prof. Dr. Meryem Birgül Çolakoğlu, Building Information Modelling, Istanbul Technical University
Assoc. Prof. Dr. Derya Güleç Özer, Building Information Modelling, Istanbul Technical University
Assoc. Prof. Dr. Lana Kudumovic, Architecture, Istanbul Technical University
Assoc. Prof. Julia Nerantzia Tzortzi, Landscape Architecture, Politecnico di Milano

ART HISTORY

Prof. Dr. Zeynep Kuban, Architecture, Istanbul Technical University
Assoc. Prof. Dr. Aslıhan Erkmen, Graduate School, Istanbul Technical University
Assoc. Prof. Dr. Ebru Yetişkin, Faculty of Science and Letters, Istanbul Technical University
Assoc. Prof. Dr. Fariba Afkari, History of Art, Tahran University

CHEMICAL ENGINEERING

Prof. Dr. Ayşegül Meriçboyu, Chemical Engineering, Istanbul Technical University
Prof. Dr. Ş. Birgül Tantekin-Ersolmaz, Chemical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Neslihan Alemdar, Chemical Engineering, Marmara University
Asst. Prof. Dr. Sadiye Velioğlu, Nanotechnology Institute, Gebze Technical University
Prof. Dr. Begüm Tokay, Chemical and Environmental Engineering, University of Nottingham

CHEMISTRY

Prof. Dr. Turan Öztürk, Chemistry, Istanbul Technical University
Prof. Dr. İsmail Yılmaz, Chemistry, Istanbul Technical University
Assoc. Prof. Dr. Caner Ünlü, Chemistry, Istanbul Technical University
Prof. Dr. Mustafa Gazi, Physics and Chemistry, Eastern Mediterranean University

CLIMATE AND MARINE SCIENCES

Prof. Dr. Hakkı Baltacı, Earth and Marine Sciences Institute, Gebze Technical University
Asst. Prof. Dr. Cihangir Köyceğiz, Civil Engineering, Konya Technical University
Assoc. Prof. Dr. Hu Liu, Northwest Institute of Eco-Environment and Resources, Chinese Academy of Sciences
Asst. Prof. Dr. Semih Sami Akay, Architecture and Urban Planning, İstanbul Topkapı University

COASTAL SCIENCES AND ENGINEERING

Prof. Dr. Şevket Çokgör, Civil Engineering, Istanbul Technical University
Prof. Dr. Mehmet Cüneyd Demirel, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Yavuz Selim Güçlü, Civil Engineering, Istanbul Technical University
Asst. Prof. Dr. Erdal Kesgin, Civil Engineering, Istanbul Technical University
Asst. Prof. Dr. Mehmet Melih Koşucu, Civil Engineering, Istanbul Technical University
Abderrahmane Benabdesselam, Hydraulics, University of Batna
Manousos Valyrakis, Civil Engineering, Aristotle University of Thessaloniki

COMMUNICATION SYSTEMS

Prof. Dr. Erdem Topsakal, Electrical and Computer Engineering, Virginia Commonwealth University
Prof. Dr. Filiz Sertel, Geomatics Engineering, Istanbul Technical University

Prof. Dr. Şinasi Kaya, Geomatics Engineering, Istanbul Technical University
Asst. Prof. Dr. Sebahattin Eker, Informatics Institute, Istanbul Technical University

COMPUTATIONAL SCIENCE AND ENGINEERING

Dr. Birkan Tunç, Computational Science & Engineering in Psychiatry, University of Pennsylvania
Asst. Prof. Dr. Süha Tuna, Computational Science and Engineering, Istanbul Technical University
Prof. Dr. F. Aylin Sungur, Computational Science and Engineering, Istanbul Technical University
Prof. Dr. M. Serdar Çelebi, Computational Science and Engineering, Istanbul Technical University

COMPUTER ENGINEERING

Prof. Dr. Mustafa Kamaşak, Computer Engineering, Istanbul Technical University
Assoc. Prof. Dr. Ahmet Cüneyd Tantuğ, Computer Engineering, Istanbul Technical University
Assoc. Prof. Dr. Yusuf Yaslan, Computer Engineering, Istanbul Technical University
Asst. Prof. Dr. Yaşar Erenler, Computer Engineering, Istanbul Technical University
Asst. Prof. Dr. Tolga Ensari, Computer and Information Science, Arkansas Tech University
Academic Dr. Meriç Yücel, Computer Engineering, Istanbul Technical University
Res. Assis. Dr. Kadir Özlem, Computer Engineering, Istanbul Technical University

COMPUTER SCIENCE

Assoc. Prof. Dr. Sefer Baday, Informatics Institute, Istanbul Technical University
Assoc. Prof. Dr. Volkan Müjdat Tiryaki, Informatics Institute, Istanbul Technical University
Asst. Prof. Dr. Mehmet Akif Yazıcı, Informatics Institute, Istanbul Technical University
Em. Prof. İzzet Kale, School of Computer Science and Engineering, University of Westminster

CONSTRUCTION MANAGEMENT

Prof. Dr. Esin Ergen, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Deniz Artan, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Atilla Damcı, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Onur Tokdemir, Civil Engineering, Istanbul Technical University

CONTROL AND AUTOMATION ENGINEERING

Semih Beyçimen, Control and Automation Engineering, Istanbul Technical University
Asst. Prof. Dr. Erhan Yumuk, Control and Automation Engineering, Istanbul Technical University
Asst. Prof. Dr. Abdurrahman Yılmaz, Control and Automation Engineering, Istanbul Technical University
Dr. İbrahim Beklan Küçükdemiral, Applied Science, Glasgow Caledonian University

DATA ENGINEERING AND BUSINESS ANALYTICS

Assoc. Prof. Dr. Mücahit Çevik, Department of Mechanical, Industrial, and Mechatronics, Toronto Metropolitan University
Asst. Prof. Dr. Mehmet Yasin Ulukuş, Data Science and Analytics, Istanbul Technical University
Asst. Prof. Dr. Mehmet Ali Ergün, Data Science and Analytics, Istanbul Technical University
Assoc. Prof. Dr. Ömer Faruk Beyca, Data Science and Analytics, Istanbul Technical University

DEFENSE TECHNOLOGIES

Dr. Şükrü Akif Ertürk, National Fighter Aircraft Technologies, TUSAŞ
Dr. Tanyel Çakmak, National Fighter Aircraft Product Directorate, TUSAŞ
Dr. Latif Akçay, Electrical and Electronics Engineering, Bayburt University
Prof. Dr. İbrahim Özkol, Aeronautical Engineering, Istanbul Technical University
Prof. Dr. Hülya Cebeci, Aeronautical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Emre Koyuncu, Aeronautical Engineering, Istanbul Technical University
Dr. Alptekin Yıldız, Aviation Institute, Istanbul Technical University
Dr. Kaan Yıldız, Aviation Institute, Istanbul Technical University

Dr. Ramazan Yeniçeri, Aeronautical Engineering, Istanbul Technical University
Dr. Murat Şimşek, Electrical Engineering and Computer Science, University of Ottawa
Dr. Mehmet Akif Özkan, Cadence Design Systems

DISASTER AND EMERGENCY MANAGEMENT

Asst. Prof. Dr. Hikmet İskender, Disaster Management Institute, Istanbul Technical University
Assoc. Prof. Dr. Çağlar Göksu Akkaya, Disaster Management Institute, Istanbul Technical University
Assoc. Prof. Dr. Abdullah Can Zülfikar, Disaster Management Institute, Istanbul Technical University
Mitra Mohammadi, Environmental Science, Kheradgarayn Motahar Institute of Higher Education

EARTHQUAKE ENGINEERING

Prof. Dr. Ufuk Yazgan, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Reşat Oyguç, Civil Engineering, Istanbul Technical University
Prof. Dr. Ercan Yüksel, Earthquake Engineering, Istanbul Technical University

ECOLOGY AND EVOLUTION

Michael Barton, Human Evolution and Social Change, Arizona State University
Isaac Ullah, Anthropology, San Diego State University
Selin Gür, Archaeology, Swiss Archaeological Institute
Assoc. Prof. Dr. Orkan Özcan, Ecology and Evolution, Istanbul Technical University
Prof. Dr. Bülent Arıkan, Ecology and Evolution, Istanbul Technical University

ECONOMICS

Prof. Dr. Ahmet Faruk Aysan, Islamic Economics and Finance, Hammad Bin Khalifa University
Prof. Dr. Bülent Güloğlu, Economics, Istanbul Technical University
Prof. Dr. Resul Aydemir, Economics, Istanbul Technical University
Assoc. Prof. Dr. Aysun Hızıroğlu Aygün, Economics, Istanbul Technical University

ELECTRICAL ENGINEERING

Prof. Dr. Mustafa Bağrıyanık, Electrical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Salih Barış Öztürk, Electrical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Derya Ahmet Kocabaş, Electrical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Duygu Bayram Kara, Electrical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Ramazan Çağlar, Electrical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Suat İlhan, Electrical Engineering, Istanbul Technical University
Asst. Prof. Dr. Lale Erdem Atılgan, Electrical Engineering, Istanbul Technical University
Asst. Prof. Dr. Cavit Fatih Küçüktezcan, Electrical Engineering, Istanbul Technical University
Dr. Ayman El-Hag, Electrical and Computer Engineering, University of Waterloo

ELECTRONICS AND COMMUNICATION ENGINEERING

Prof. Dr. Ender Mete Ekşioğlu, Electronics and Communication Engineering, Istanbul Technical University
Assoc. Prof. Dr. Nil Tarım, Electronics and Communication Engineering, Istanbul Technical University
Assoc. Prof. Dr. Mustafa Berke Yelten, Electronics and Communication Engineering, Istanbul Technical University
Prof. Dr. Edoardo Bonizzoni, Electrical, Computer and Biomedical Engineering, University of Pavia
Prof. Dr. Mattia Frasca, Electrical, Electronics and Computer Engineering, University of Catania
Prof. Dr. Cüneyt Güzeliş, Electrical-Electronics Engineering, Yaşar University
Prof. Dr. Serkan Topaloğlu, Electrical and Electronics Engineering, Yeditepe University
Prof. Dr. Arda Deniz Yalçınkaya, Electrical and Electronics Engineering, Boğaziçi University
Prof. Dr. Günhan Dündar, Electrical and Electronics Engineering, Boğaziçi University
Prof. Dr. Burak Acar, Electrical and Electronics Engineering, Boğaziçi University
Assoc. Prof. Dr. Muhammed Fatih Toy, Electronics and Communication Engineering, Istanbul Medipol University

Prof. Dr. Mustafa Altun, Electronics and Communication Engineering, Istanbul Technical University
Asst. Prof. Dr. Faik Başkaya, Electronics and Communication Engineering, Boğaziçi University
Assoc. Prof. Dr. Yiğit Dağhan Gökdel, Electronics and Communication Engineering, Istanbul Bilgi University
Prof. Dr. Tufan Kumbasar, Electronics and Communication Engineering, Istanbul Technical University
Assoc. Prof. Dr. Tufan Coşkun Karalar, Electronics and Communication Engineering, Istanbul Technical University
Assoc. Prof. Dr. İsa Yıldırım, Electronics and Communication Engineering, Istanbul Technical University

ENERGY SCIENCE AND TECHNOLOGY

Assoc. Prof. Dr. M. Suha Yazıcı, Energy Institute, Istanbul Technical University
Asst. Prof. Dr. Sevan Karabetoğlu, Energy Institute, Istanbul Technical University
Asst. Prof. Dr. M. Berker Yurtseven, Energy Institute, Istanbul Technical University
Prof. Dr. Arjan Korpa, Chemistry, University of Tirana

ENVIRONMENTAL BIOTECHNOLOGY

Prof. Dr. Özlem Karahan, Environmental Engineering, Istanbul Technical University
Prof. Dr. Mahmut Altınbaş, Environmental Engineering, Istanbul Technical University
Assoc. Prof. Dr. Börte Köse Mutlu, Environmental Engineering, Istanbul Technical University
Assoc. Prof. Dr. Mahmut Ekrem Karpuzcu, Environmental Engineering, Istanbul Technical University

ENVIRONMENTAL ENGINEERING

Prof. Dr. Vahid Vatanpour, Chemistry, Kharazmi University
Asst. Prof. Dr. Ramazan Keyikoğlu, Environmental Engineering, Istanbul Technical University
Asst. Prof. Dr. Mehmet Sadık Akca, Environmental Engineering, Istanbul Technical University
Asst. Prof. Dr. Hazal Gülhan Eksin, Environmental Engineering, Istanbul Technical University

FOOD ENGINEERING

Prof. Dr. Pervin Başaran Akocak, Food Engineering, Istanbul Technical University
Asst. Prof. Dr. Evren Demircan, Food Engineering, Istanbul Technical University
Prof. Tuba Esatbeyoğlu, Food Science and Human Nutrition, Leibniz University Hannover
Dr. Francesca Giampieri, Food Science and Human Nutrition, Universita Politecnica delle Marche

GAME AND INTERACTION TECHNOLOGIES

Asst. Prof. Dr. Aslı Kanan, Architecture, Istanbul Technical University
Assoc. Prof. Dr. Gökhan İnce, Computer Engineering, Istanbul Technical University
Asst. Prof. Dr. Mehmet Tahir Sandıkkaya, Computer Engineering, Istanbul Technical University
Asst. Prof. Dr. Ahmet Gün, Architecture, Istanbul Technical University
Prof. Halil Erhan, Interactive Arts & Technology, Simon Fraser University

GEOGRAPHIC INFORMATION TECHNOLOGIES

Dr. Mehmet Furkan Celik, Geomatics Engineering, Twente University
Prof. Dr. Taşkın Kavzoğlu, Geomatics Engineering, Gebze Technical University
Assoc. Prof. Dr. Muzaffer Can İban, Geomatics Engineering, Mersin University
Asst. Prof. Dr. Ozan Öztürk, Civil Engineering, Recep Tayyip Erdoğan University

GEOLOGICAL ENGINEERING

Asst. Prof. Dr. Zeynep Döner, Geological Engineering, Istanbul Technical University
Dr. Alp Ünal, Geological Engineering, Istanbul Technical University
Asst. Prof. Dr. Bala Ekinci Şans, Geological Engineering, Istanbul Technical University
Prof. Dr. Haibo Zou, Geosciences, Auburn University

GEOMATICS ENGINEERING

Prof. Dr. Bihter Erol, Geomatics Engineering, Istanbul Technical University
Assoc. Prof. Dr. Uğur Algancı, Geomatics Engineering, Istanbul Technical University
Assoc. Prof. Dr. M. Oğuz Selbesoğlu, Geomatics Engineering, Istanbul Technical University
Dr. Penjani Hopkins Nyimbili, Geomatics Engineering, The University of Zambia

GEOPHYSICAL ENGINEERING

Prof. Dr. Hülya Kurt, Geophysical Engineering, Istanbul Technical University
Prof. Dr. Doğa Doğan, Geophysical Engineering, Istanbul Technical University
Asst. Prof. Dr. Ümit Avşar, Geophysical Engineering, Istanbul Technical University
Dr. Nordiana Binti Mohd Muztaza, Geophysics, Universiti Sains Malaysia

HEAT FLUID

Prof. Dr. Ayşegül Abuşoğlu, Mechanical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Sertaç Çadırcı, Mechanical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Abdussamet Subaşı, Mechanical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Amjad Anvari-Moghaddam, Mechanical Engineering, Aalborg University

HISTORY OF SCIENCE AND TECHNOLOGY

Prof. Dr. Aytekin Çökelez, Humanities and Social Sciences, Istanbul Technical University
Prof. Dr. Tuncay Zorlu, Humanities and Social Sciences, Istanbul Technical University
Assoc. Prof. Dr. Burak Barutçu, Renewable Energy, Istanbul Technical University
Asst. Prof. Dr. Mehmet Ali Doğan, Sociology, Istanbul Technical University
Darina Martykanova, Contemporary History, Universidad Autónoma de Madrid

HYDRAULICS AND WATER RESOURCES ENGINEERING

Prof. Dr. Şevket Çokgör, Civil Engineering, Istanbul Technical University
Prof. Dr. Mehmet Cüneyd Demirel, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Yavuz Selim Güçlü, Civil Engineering, Istanbul Technical University
Asst. Prof. Dr. Erdal Kesgin, Civil Engineering, Istanbul Technical University
Asst. Prof. Dr. Mehmet Melih Koşucu, Civil Engineering, Istanbul Technical University
Abderrahmane Benabdesselam, Hydraulics, University of Batna
Dr. Manousos Valyrakis, Civil Engineering, Aristotle University of Thessaloniki

INDUSTRIAL DESIGN

Prof. Dr. Gülay Hasdoğan, Industrial Design, Middle East Technical University
Assoc. Prof. Dr. Aykut Coşkun, Media and Visual Arts, Koç University
Prof. Dr. Piera Maresca, Industrial Design, Universidad Politécnica de Madrid
Prof. Dr. Ahmet Zeki Turan, Industrial Design, Mimar Sinan Fine Arts University

INDUSTRIAL ENGINEERING

Prof. Dr. Mehmet Güray Güler, Industrial Engineering, Istanbul Technical University
Assoc. Prof. Dr. Hatice Tekiner Moğulkoç, Industrial Engineering, Istanbul Technical University
Asst. Prof. Dr. A. Elvan Bayraktaroğlu, Industrial Engineering, Istanbul Technical University
Assoc. Prof. Dr. Çağatay İris, Management, University of Liverpool
Assoc. Prof. Dr. Velichka Traneva, Natural Sciences, Assen Zlatarov University
Assoc. Prof. Dr. Stoyan Tranev, Social Sciences, Assen Zlatarov University
Assoc. Prof. Dr. Venelin Todorov, Mathematics and Informatics, Assen Zlatarov University
Asst. Prof. Dr. Slavi Georgiev, Mathematics and Informatics, Assen Zlatarov University

INFORMATICS

Asst. Prof. Dr. Benay Gürsoy, Architecture, Pennsylvania State University
Prof. Dr. Özgür Ediz, Architecture, Bursa Uludağ University
Prof. Dr. Neşe Çakıcı Alp, Architecture, Kocaeli University
Asst. Prof. Dr. Gamze Gündüz, Architecture, Istanbul Bilgi University

INSTRUMENT - VOICE

Prof. Dr. Cihat Aşkın, Instrumental Performance, Istanbul Technical University
Prof. Dr. Tolgahan Çoğulu, Instrumental Performance, Istanbul Technical University
Prof. Kandemir Basmacıoğlu, Instrumental Performance, Istanbul Technical University
Dr. Reuben de Lautour, Music Technology, Istanbul Technical University
Prof. Dr. Münir Nurettin Beken, Instrumental Performance, University of California

INTERNATIONAL MASTER OF INTERIOR ARCHITECTURAL DESIGN

Prof. Dr. Suzie Attiwill, Interior Design, RMIT University
Prof. Dr. Özge Cordan, Interior Architecture, Istanbul Technical University
Prof. Dr. Banu Garip, Interior Architecture, Istanbul Technical University
Assoc. Prof. Dr. Demet Arslan Dinçay, Interior Architecture, Istanbul Technical University

LANDSCAPE ARCHITECTURE

Prof. Dr. Hayriye Eşbah Tunçay, Landscape Architecture, Istanbul Technical University
Prof. Dr. Elif Kutay Karaçor, Landscape Architecture, Istanbul Technical University
Assoc. Prof. Dr. Melih Bozkurt, Landscape Architecture, Istanbul Technical University

MANAGEMENT

Prof. Dr. Suat Teker, Management, Işık University
Prof. Dr. Nimet Uray, Management, Kadir Has University
Prof. Dr. Gül Tekin Temur, Industrial Engineering, Bahçeşehir University
Prof. Dr. Ephraim Clark, Management, Middlesex University

MANAGEMENT ENGINEERING

Assoc. Prof. Dr. Fuat Kosanoğlu, Management Engineering, Istanbul Technical University
Assoc. Prof. Dr. Ahmet Göncü, Management Engineering, Istanbul Technical University
Assoc. Prof. Dr. Ayşe Aylin Bayar, Management Engineering, Istanbul Technical University
Assoc. Prof. Dr. Ahmet Atıl Aşıcı, Management Engineering, Istanbul Technical University
Assoc. Prof. Dr. Adnan Veysel Ertemel, Management Engineering, Istanbul Technical University
Assoc. Prof. Dr. Öznur Özdemir Akyıldırım, Faculty of Management, University of Bradford
Assoc. Prof. Dr. Tuncay Özcan, Management Engineering, Istanbul Technical University
Assoc. Prof. Dr. Kaya Tokmakcıoğlu, Management Engineering, Istanbul Technical University
Prof. Dr. Elif Karaosmanoğlu, Management Engineering, Istanbul Technical University
Prof. Dr. Raziye Selim, Management Engineering, Istanbul Technical University
Prof. Dr. Oktay Taş, Management Engineering, Istanbul Technical University
Prof. Dr. Hür Bersam Bolat, Management Engineering, Istanbul Technical University
Asst. Prof. Dr. İdil Vedia Evcimen, Management Engineering, Istanbul Technical University
Prof. Dr. Mehmet Erçek, Management Engineering, Istanbul Technical University
Prof. Dr. Ferhan Çebi, Management Engineering, Istanbul Technical University

MARITIME STUDIES

Assoc. Prof. Dr. Pelin Bolat, Maritime, Istanbul Technical University
Prof. Dr. Levent Kırval, Maritime, Istanbul Technical University
Prof. Dr. Funda Yercan, Maritime, Piri Reis University

Dr. Christos Kontovas, Engineering and Technology, Liverpool John Moore University
Dr. George Gabedeva, Management, Batumi Navigational Teaching University

MARITIME TRANSPORTATION ENGINEERING

Prof. Dr. Yasin Arslanoğlu, Basic Sciences, Istanbul Technical University
Assoc. Prof. Dr. Burak Zincir, Marine Engineering, Istanbul Technical University
Asst. Prof. Dr. Gizem Kayışoğlu, Maritime Transportation and Management Engineering, Istanbul Technical University
Asst. Prof. Dr. Onur Yüksel, Faculty of Engineering and Technology, Liverpool John Moores University

MATERIAL SCIENCE AND ENGINEERING

Asst. Prof. Dr. Erçin Çağan Duran, Metallurgical and Materials Engineering, Istanbul Technical University
Asst. Prof. Dr. Faiz Muhaffel, Metallurgical and Materials Engineering, Istanbul Technical University
Assoc. Prof. Dr. Aytekin Uzunoğlu, Metallurgical and Materials Engineering, Istanbul Technical University
Prof. Dr. Ahmet Alpas, Mechanical, Automotive & Materials Engineering, University of Windsor

MATHEMATICAL ENGINEERING

Asst. Prof. Dr. İzzet Göksel, Mathematics Engineering, Istanbul Technical University
Prof. Dr. Seher Melike Aydoğan, Mathematics Engineering, Istanbul Technical University
Prof. Dr. Murat Sarı, Mathematics Engineering, Istanbul Technical University
Prof. Dr. Nigar Aslanova, Vice-Rector for Science and Innovation Issues, Azerbaijan University of Architecture and Construction

MECHANICAL ENGINEERING

Prof. Dr. Aliihsan Koca, Mechanical Engineering, Istanbul Technical University
Prof. Dr. Senem Kurşun, Mechanical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Raşit Ahmet Yıldız, Mechanical Engineering, Istanbul Technical University
Asst. Prof. Dr. Akif Yavuz, Mechanical Engineering, Istanbul Technical University
Prof. Dr. Özgen Akalın, Mechanical Engineering, Istanbul Technical University
Prof. Dr. Mesut Kırca, Mechanical Engineering, Istanbul Technical University
Prof. Dr. Erkan Günpınar, Mechanical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Sertaç Çadırcı, Mechanical Engineering, Istanbul Technical University

MECHATRONICS ENGINEERING

Prof. Dr. Volkan Sezer, Robotics and Autonomous Systems Engineering, Istanbul Technical University
Assoc. Prof. Dr. Zeki Yağız Bayraktaroğlu, Mechanical Engineering, Istanbul Technical University
Asst. Prof. Dr. Kerem Altun, Automation and Control Engineering, Yıldız Technical University
Assoc. Prof. Libor Pekař, Automation and Control Engineering, Tomas Bata University

METALLURGY AND MATERIALS ENGINEERING

Assoc. Prof. Dr. Billur Deniz Karahan, Metallurgical and Materials Engineering, Istanbul Technical University
Assoc. Prof. Dr. Aytekin Uzunoğlu, Metallurgical and Materials Engineering, Istanbul Technical University
Assoc. Prof. Dr. Yakup Yüretürk, Metallurgical and Materials Engineering, Bursa Technical University
Prof. Dr. Süleyman Can Kurnaz, Metallurgical and Materials Engineering, Sakarya University
Dr. Łukasz Maj, Metallurgy and Materials Science, Polish Academy of Sciences

METEOROLOGICAL ENGINEERING

Assoc. Prof. Dr. Bahtiyar Efe, Meteorological Engineering, Istanbul Technical University
Prof. Dr. Anthony Lupo, Environmental Sciences, Missouri University
Prof. Dr. Barış Önol, Meteorological Engineering, Istanbul Technical University
Assoc. Prof. Dr. Elçin Tan, Meteorological Engineering, Istanbul Technical University

MINERAL PROCESSING ENGINEERING

Prof. Dr. Feridun Boylu, Mineral Processing Engineering, Istanbul Technical University
Prof. Dr. Fırat Burat, Mineral Processing Engineering, Istanbul Technical University
Asst. Prof. Dr. Ş. Beste Aydın, Mineral Processing Engineering, Istanbul Technical University
Dr. Behzad Vaziri Hassas, Earth and Environmental Engineering, Columbia University

MINING ENGINEERING

Assoc. Prof. Dr. Cüneyt Atilla Öztürk, Mining Engineering, Istanbul Technical University
Assoc. Prof. Dr. Muhammet Mustafa Kahraman, Mining Engineering, Istanbul Technical University
Asst. Prof. Dr. Emre Avunduk, Mining Engineering, Istanbul Technical University
Dr. Özge Akyıldız, Geoscience, Norwegian University of Science and Technology

MOLECULAR BIOLOGY - GENETICS AND BIOTECHNOLOGY

Prof. Dr. Bahtiyar Yılmaz, Visceral Surgery and Medicine, University of Bern
Prof. Dr. Gamze Torun Köse, Genetics and Bioengineering, Yeditepe University
Prof. Dr. Ayten Karataş, Molecular Biology and Genetics, Istanbul Technical University
Asst. Prof. Dr. Abdulhalim Kılıç, Molecular Biology and Genetics, Istanbul Technical University

MUSIC

Assoc. Prof. Dr. Taylan Özdemir, Turkish Music State Conservatory, Istanbul Technical University
Asst. Prof. Dr. Emmanouil Ekmektsoglou, Turkish Music State Conservatory, Istanbul Technical University
Dr. Paul Whitehead, Centre for Advanced Studies in Music, Istanbul Technical University
Dr. Alexandros Charkiolakis, Friends of Music Society, Ionian University
Asst. Prof. Dr. Ozan Sarıer, Music, Istanbul Technical University

MUSICOLOGY AND MUSIC THEORY

Prof. Dr. Nilgün Doğrusöz Dişiaçık, Turkish Music State Conservatory, Istanbul Technical University
Prof. Dr. Burcu Yıldız, Turkish Music State Conservatory, Istanbul Technical University
Prof. Dr. Ozan Baysal, Turkish Music State Conservatory, Istanbul Technical University
Assoc. Prof. Eliot Bates, Music, City University of New York

NANOSCIENCE AND NANOENGINEERING

Prof. Dr. Nilgün Baydoğan, Energy Institute, Istanbul Technical University
Prof. Dr. Nilgün Karatepe Yavuz, Energy Institute, Istanbul Technical University
Assoc. Prof. Dr. Birgül Benli, Mineral Processing Engineering, Istanbul Technical University
Asst. Prof. Dr. Abdulhalim Kılıç, Molecular Biology and Genetics, Istanbul Technical University
Asst. Prof. Dr. Elif Öztürk Er, Chemical Engineering, Istanbul Technical University

NAVAL ARCHITECTURE AND MARINE ENGINEERING

Prof. Dr. Şakir Bal, Naval Architecture and Marine Engineering, Istanbul Technical University
Prof. Dr. Ahmet Ergin, Naval Architecture and Marine Engineering, Istanbul Technical University
Prof. Dr. Gökdeniz Neşer, Marine Sciences and Technology, Dokuz Eylül University
Dr. Tahsin Tezdoğan, Ship Science, Southampton University

NUCLEAR RESEARCH

Assoc. Prof. Dr. Tayfun Akyürek, Energy Institute, Istanbul Technical University
Prof. Dr. Üner Çolak, Energy Institute, Istanbul Technical University
Prof. Dr. Nilgün Baydoğan, Energy Institute, Istanbul Technical University

PETROLEUM AND NATURAL GAS ENGINEERING

Prof. Dr. Ö. İnanç Türeyen, Petroleum and Natural Gas Engineering, Istanbul Technical University
Prof. Dr. Gürşat Altun, Petroleum and Natural Gas Engineering, Istanbul Technical University
Asst. Prof. Dr. Şenol Yamanlar, Petroleum and Natural Gas Engineering, Istanbul Technical University
Prof. Dr. Murat Çınar, Petroleum and Natural Gas Engineering, Istanbul Technical University
Assoc. Prof. Dr. Hasan Özgür Yıldız, Petroleum and Natural Gas Engineering, Istanbul Technical University
Asst. Prof. Dr. Burak Kulga, Petroleum and Natural Gas Engineering, Istanbul Technical University
Asst. Prof. Dr. Emine Didem Korkmaz Başel, Petroleum and Natural Gas Engineering, Istanbul Technical University

PHYSICS ENGINEERING

Prof. Dr. Ahmet Levent Subaşı, Physics Engineering, Istanbul Technical University
Prof. Dr. Oğuzhan Gürlü, Physics Engineering, Istanbul Technical University
Prof. Dr. Hakan Özgür Özer, Physics Engineering, Istanbul Technical University

POLAR SCIENCES

Assoc. Prof. Dr. Bilge Tutak, Shipbuilding and Ocean Engineering, Istanbul Technical University
Assoc. Prof. Dr. Fatma Elif Genceli Güner, Chemical Engineering, Istanbul Technical University
Assoc. Prof. Dr. Deniz Bozkurt, Climate Science and Meteorological Engineering, Universidad de Valparaíso (Chile)

POLITICAL STUDIES

Assoc. Prof. Dr. Ayşe Serdar, Political Studies, Istanbul Technical University
Prof. Dr. Gürcan Koçan, Political Studies, Istanbul Technical University
Res. Asst. Dr. Görkem Giray, Political Studies, Istanbul Technical University
Dr. Yufei Xu, School of Marxism, Xihua University

POLYMER SCIENCE AND TECHNOLOGY

Dr. Natasha Shirshova, Engineering, Durham University
Assoc. Prof. Dr. Nesrin Köken, Chemistry, Istanbul Technical University
Prof. Dr. Ahmet Akar, Chemistry, Istanbul Technical University
Prof. Dr. Nilgün Kızılcan, Chemistry, Istanbul Technical University

RAILWAY SYSTEMS ENGINEERING

Asst. Prof. Dr. S. Ergün Bozdağ, Mechanical Engineering, Istanbul Technical University
Dr. Serhat Boynukalın, Rail Systems Engineering, Istanbul Technical University
Assoc. Prof. Dr. Hüseyin Onur Tezcan, Civil Engineering, Istanbul Technical University
Dr. Tarık Dündar, Transportation Engineering, Istanbul Technical University

REAL ESTATE DEVELOPMENT

Dr. Christopher Hannum, Global Economics, University of Central Asia
Prof. Dr. Ali Hepşen, Finance, İstanbul University
Prof. Dr. Evren Özus, Industrial Product Design, Beykent University
Prof. Dr. Mehmet Topçu, Urban and Regional Planning, Konya Technical University
Prof. Dr. Şevkiye Şence Türk, Urban and Regional Planning, Istanbul Technical University
Assoc. Prof. Dr. Kerem Yavuz Arslanlı, Urban and Regional Planning, Istanbul Technical University

SCIENCE, TECHNOLOGY AND SOCIETY

Assoc. Prof. Dr. Aslı Öğüt Erbil, Science and Letters, Istanbul Technical University
Assoc. Prof. Dr. Ebru Yetişkin Doğrusöz, Science and Letters, Istanbul Technical University

Asst. Prof. Dr. Sevil Hatice Baltalı Tırpan, Science and Letters, Istanbul Technical University
Asst. Prof. Alessandra Cenci, IT and Design, Aalborg University Copenhagen

SHIPBUILDING AND OCEAN ENGINEERING

Asst. Prof. Dr. Bilge Baş, Civil Engineering, Bilgi University
Assoc. Prof. Dr. Emre Peşman, Naval Architecture and Marine Engineering, Karadeniz Technical University
Asst. Prof. Dr. Ahmet Gültekin Avcı, Naval Architecture and Maritime, Yıldız Technical University
Dr. Bülent Düz, Maritime Research Institute Netherlands
Assoc. Prof. Dr. Sevil Deniz Yakan Dündar, Shipbuilding and Ocean Engineering, Istanbul Technical University
Assoc. Prof. Dr. Ceren Bilgin Güney, Shipbuilding and Ocean Engineering, Istanbul Technical University
Assoc. Prof. Dr. Şafak Nur Ertürk Bozkurtoğlu, Shipbuilding and Ocean Engineering, Istanbul Technical University
Asst. Prof. Dr. Burak Karacık, Shipbuilding and Ocean Engineering, Istanbul Technical University

SOIL MECHANICS AND GEOTECHNICAL ENGINEERING

Prof. Dr. Musaffa Ayşen Lav, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Müge Balkaya, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Ece Bayat, Civil Engineering, Istanbul Technical University
Prof. Dr. Erol Tutumluer, Civil Engineering, University of Illinois

SOLID EARTH CHAIR

Prof. Dr. Gültekin Topuz, Eurasia Institute of Earth Sciences, Istanbul Technical University
Prof. Dr. Tolga Görüm, Eurasia Institute of Earth Sciences, Istanbul Technical University
Prof. Dr. Oğuz Göğüş, Eurasia Institute of Earth Sciences, Istanbul Technical University
Dr. Jiamin Wang, Geology & Geophysics, Chinese Academy of Science

STRUCTURAL ENGINEERING

Prof. Dr. Bülent Akbaş, Civil Engineering, Gebze Technical University
Prof. Dr. Bilge Doran, Civil Engineering, Yıldız Technical University
Prof. Dr. Serdar Soyöz, Civil Engineering, Boğaziçi University
Prof. Dr. Özkan Şengül, Civil Engineering, Istanbul Technical University
Prof. Dr. Yılmaz Akkaya, Civil Engineering, Istanbul Technical University
Prof. Dr. Yasin Fahjan, Civil Engineering, Istanbul Technical University
Prof. Dr. Nihal Eratlı, Civil Engineering, Istanbul Technical University
Prof. Dr. Hakan Nuri Atahan, Civil Engineering, Istanbul Technical University
Prof. Dr. Ünal Aldemir, Civil Engineering, Istanbul Technical University
Prof. Dr. Kutlu Darılmaz, Civil Engineering, Istanbul Technical University
Prof. Dr. Tülay Aksu Özkul, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Kadir Özakgül, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Osman Bulut, Civil Engineering, Istanbul Technical University
Asst. Prof. Dr. Cem Demir, Civil Engineering, Istanbul Technical University
Asst. Prof. Dr. Tuba Gürbüz Büyükkayıkçı, Civil Engineering, Istanbul Technical University
Asst. Prof. Dr. Ayda Şafak Ağar Özbek, Civil Engineering, Istanbul Technical University
Asst. Prof. Dr. Hasan Nuri Türkmenoğlu, Civil Engineering, Istanbul Technical University
Assoc. Prof. Dr. Kadir Özakgül, Structural Engineering, Istanbul Technical University

SUSTAINABILITY

Prof. Dr. Fatoş Germirli Babuna, Environmental Engineering, Istanbul Technical University
Prof. Dr. Emrah Acar, Architecture, Istanbul Technical University
Asst. Prof. Dr. Emrah Çoraman, Eurasia Institute of Earth Sciences, Istanbul Technical University
Assoc. Prof. Anders Damgaard, Environmental and Resource Engineering, Denmark Technical University
Asst. Prof. Dr. Ebru Acuner Türet, Sustainability, Istanbul Technical University
Assoc. Prof. Dr. Başak Demires Özkul, Sustainability, Istanbul Technical University

Prof. Dr. İsmail Koyuncu, Sustainability, Istanbul Technical University
Assoc. Prof. Dr. Göksenin İnalhan, Architecture, Istanbul Technical University

TEXTILE ENGINEERING

Prof. Dr. Nazan Okur, Textile Engineering, Istanbul Technical University
Assoc. Prof. Dr. Ali Kılıç, Textile Engineering, Istanbul Technical University
Asst. Prof. Dr. Pelin Altay, Textile Engineering, Istanbul Technical University
Prof. Dr. Yordan Kyosev, Assembly of Textile Products, Dresden Technical University

TRADITIONAL DANCES

Paul-Alexandru Remeş, Romanian Academy, Institute Archive of Folklor and Babeş, Bolyai Üniversity from Cluj- Napoca
Prof. İlknur Bektaş, Turkish Music State Conservatory, Turkish Folk Dance Department, Istanbul Technical University
Prof. Eyüp Uzunkaya, Turkish Music State Conservatory, Turkish Folk Dance Department, Istanbul Technical University
Prof. Nihal Cömert, Turkish Music State Conservatory, Turkish Folk Dance Department, Istanbul Technical University
Prof. Dr. Mehmet Öcal Özbilgin, State Turkish Music Conservatory, Turkish Folk Dance Department, Ege University
Prof. Dr. Kamil Perçin Akgül, Turkish Music State Conservatory, Turkish Folk Dance Department, Gaziantep University

URBAN AND REGIONAL PLANNING

Prof. Dr. Tüzin Baycan, Urban and Regional Planning, Istanbul Technical University
Assoc. Prof. Dr. Eda Yücesoy, Urban and Regional Planning, Istanbul Technical University
Assoc. Prof. Dr. Gülden Demet Oruç Ertekin, Urban and Regional Planning, Istanbul Technical University
Prof. Dr. hab. Jadwiga Biegańska, Urban Studies and Sustainable Development, Nicolaus Copernicus University

URBAN DESIGN

Assoc. Prof. Dr. Eren Kürkçüoğlu, Urban and Regional Planning, Istanbul Technical University
Assoc. Prof. Dr. Melih Bozkurt, Landscape Architecture, Istanbul Technical University
Assoc. Prof. Dr. Ozan Önder Özener, Architecture, Istanbul Technical University

SCIENTIFIC PROGRAM

12.05.2025 | MONDAY | ONLINE

MAIN HALL

10:00 – 11:00

Opening Remarks:
Prof. Dr. Fatma Seniha GÜNER , Institute Director, Istanbul Technical University
Prof. Dr. Hasan MANDAL, Rector, Istanbul Technical University
KEYNOTE SPEAKER: "An Academic Journey From Chemical Engineering to Robotics and Multidisciplinary Impressions of a Scientist"
Prof. Dr. Berna ÖZKALE EDELMANN, Technical University of Munich

11:00 – 12:00

Chair: Assoc. Prof. Dr. Abdullah Aydoğan

CHEMISTRY
Inorganic Chemistry
"The Design and Application of Novel Post-Metallocene Catalysts For Olefin Polymerization"
Önder Güneş, Ozan Sanlı Şentürk - Istanbul Technical University
Nanochemistry
"Investigation of Fluorescence Properties of ZIF-8 Structures Modified With Graphitic Quantum Dots"
Hilal Nazan Ağar, Caner Ünlü- Istanbul Technical University
Organic Chemistry
"Synthesis Of Polymers Containing Supramolecular Components In The Pendant Or Main Chain"
Hafize Reva Bayraktar, Abdullah Aydoğan -Istanbul Technical University
Polymer Chemistry
"Dual Radical and Singlet Oxygen Pathways in Polybutadiene Photovulcanization: A Novel Approach Using Phenylacylbromide under UV-A Irradiation for Advanced Crosslinked Films"
Ragib Talha Uzun, Barış Kiskan - Istanbul Technical University

13:00 – 14:00

Chair: Asst. Prof. Dr. Berna Doğan, Asst. Prof. Dr. Hüseyin Enis Karahan

CHEMISTRY
Drug Design & Drug Delivery (Computational and Experimental)
"Exploring New MAO-B Selective İnhibitors Through in-silico Methods"
Ali Aksu, Mine Yurtsever, Fethiye Aylin Sungur - Istanbul Technical University
CHEMICAL ENGINEERING
Hydrogen Technologies, Fuels Cells, Energy Storage Materials
"Biomass-Derived Activated Carbon as Electrode Material for Supercapacitors"
Damla Kökmen , Anıl Yılmaz, Nahid A. Keshtiban, Ali Gelir, Nil Özbek, Hanzade Açma, Serdar Yaman - ITU
Modelling and Computational Systems
"Machine Learning-Based Prediction of Ftir Spectral Peaks for Biomass Characterization"
Talha Sağiş, Anıl Yılmaz, Hanzade Haykırı-Açma, Serdar Yaman - Istanbul Technical University

14:00 – 15:00

Chair: Assoc. Prof. Dr. Ahmet Gün, Asst. Prof. Dr. Süha Tuna

INFORMATICS
Computational Design Tools and Methods
"A Decision Support Model Proposal For Urban Green Space Site Selection Problem Based on Multi-Criteria Decision Making"
Erdal Kondakcı, Gülen Çağdaş - Istanbul Technical University
"Computational Memorability Model Based on Object Size"
Fatma Seven, Sema Alaçam - Istanbul Technical University
COMPUTATIONAL SCIENCE AND ENGINEERING
Computational Fluid Dynamics
"Multi-Objective Optimization of Airfoil Geometry for Aerodynamic Efficiency and Noise Reduction Using Bézier Parameterization"
Ali İhsan İşgüder, Baha Zafer, Melike Nikbay - Istanbul Technical University
Computational Biology
"Molecular Dynamics Analysis of CHK2 Mutations at the C-lobe of the Kinase Domain"
Cihan Uğur Otçu, Clara Xazal Buran, Gizem Dinler Doğanay, Levent Doğanay, Mert Gür - Istanbul Technical University

15:00 – 16:00

Chair: Assoc. Prof. Dr. Volkan Müjdat Tiryaki

APPLIED INFORMATICS
Medical Image Analysis
"Improving Tumor Segmentation Performance in Breast MRI via U-Net Based Deep Learning Approach"
Alptuğ Şeref Ayyıldız,İbrahimAkduman, AleksandarJanjic-Istanbul Technical University
"Deep Learning-Based Breast Tumor Detection in MRI Using Faster R-CNN"
Şeyma Nur Tufan, Aleksandar Janjic, İbrahim Akduman - Istanbul Technical University
"Prediction of Microsatellite Status Using Deep Neural Network"
Fatma Vildan Engin, Ender Mete Ekşioğlu - Institute of Science and Technology
Data Analysis
"Optimization Potential of Machine Learning-Based Algorithms in Neonatal Parenteral Nutrition Management: A Systematic Review"
Sümeyye Nalbat, Mustafa Alpkan Çiçek, Serkan Türkeli, Mustafa Doğan - Istanbul Technical University

16:00 – 17:00

Chair: Asst. Prof. Dr. Mehmet Akif Yazıcı

APPLIED INFORMATICS
Computational Electromagnetics
"Singular Integral Treatment of Nyström Method for Electromagnetic Scattering Problems"
Faik Yaman, Mehmet Çayören - Istanbul Technical University
"Integral Equation based Eigenmode Solution of Optical Waveguides with Arbitrary Cross Section"
Mücahit Hüseyin Özdilekler, Mehmet Çayören - Istanbul Technical University
Cybersecurity
"Usability of Token-based and Remote Electronic Signatures: A User Experience Study"
Ömer Ege, Kemal Bıçakcı - Istanbul Technical University

12.05.2025 | MONDAY | ONLINE

HALL - I

Chair: Dr. Demet Aydoğmuş

METALLURGY AND MATERIALS ENGINEERING

Composite and Polymer Materials

11:00
12:00

"Thermal and Mechanical Properties of Reduced Graphene Oxide Reinforced Polypropylene Composites"
Cemile Gürer, Yeliz Köse, İrem Düzenli, Fatma Seniha Güner - Istanbul Technical University

"Characterization of Talc and Reduced Graphene Oxide Reinforced Polypropylene Composites: Thermal, Mechanical and Structural Properties"
İrem Düzenli , Yeliz Köse, Cemile Gürer, Yavuz Emre Yağcı, Fatma Seniha Güner - Istanbul Technical University

Extractive Metallurgy

"Investigation of Reduction of Chromite Ore with Hydrogen"
Ayse Deniz, Çağdaş Ekin Zöhra, Selçuk Kan, Ceren Imer, Gökhan Basman, Yavuzhan Kaya, Onuralp Yücel - Istanbul Technical University

"Production and Characterization of Lanthanum Hexaboride Powder"
Deniz Nalcı, Mehtap Arslan-Kaba, Güldem Kartal Şireli, Kürşat Kazmanlı - Istanbul Technical University

---

Chair: Dr. Yonca Alkan Göksu

METALLURGY AND MATERIALS ENGINEERING

Metals and Alloys

13:00
14:00

"Precious Metal (Au, Pd, Pt, Rh) Recovery Using Torrefied Biomass Species Such As Forest, Marine And Agricultural Biomass"
Cansu Kargı, Mahmut Ercan Açma, Hanzade Haykırı Açma, Nil Özbek, Serdar Yaman - Istanbul Technical University

"Effect of Niobium Addition on the Microstructural Features of Titanium Alloys for Dental Implants"
Sena Burcu Hayırcı, Faiz Muhaffel, Hüseyin Çimenoğlu- Istanbul Technical University

"Effect of Heat Treatment on Inconel 718 Superalloy Produced by Cold Spray Additive Manufacturing"
Serra Bayram, Erdem Balcı, Aptullah Karakaş, Murat Baydoğan - Istanbul Technical University

"Recycling-Driven Variations in Mechanical Properties and Weldability of 6XXX Series Aluminium Alloys for Electric Vehicle Structural Parts"
Zeynep Tutku Özen, Necip Ünlü - Istanbul Technical University

---

Chair: Asst. Prof. Dr. Cevat Fahir Arısoy

METALLURGY AND MATERIALS ENGINEERING

Surface Treatment and Coatings

14:00
15:00

"Enhancing CMAS and Hot Corrosion Resistance of YSZ Thermal Barrier Coatings via Aluminium Cold Spray"
Ahmed Emin Tok, Faiz Muhaffel, Muhammed Karabaş - Istanbul Technical University

"Effect of Pack Aluminizing on Hydrogen Charging Behavior of Ti6Al4V Alloy Fabricated by Selective Laser Melting"
Belgin Ataman, Burak Bayram, Erdem Balcı, Murat Baydoğan - Istanbul Technical University

"Comparative Evaluation of Surface Treatments: Anodizing and Micro-Arc Oxidation for Al-Si Cast Alloys"
FurkanTezer, Faiz Muhaffel- Istanbul Technical University

"A Comparative Study of Ni-SiC and Micro-Arc Oxidation Coatings Produced on the Al-Si Casting Alloy"
Özkan Karaman, Faiz Muhaffel - Istanbul Technical University

Chair: Asst. Prof. Dr. Erçin Çağan Duran

METALLURGY AND MATERIALS ENGINEERING

Corrosion and Wear

15:00
16:00

"Fabrication of Al Matrix MMC Cold Spray Coatings on Magnesium Alloy AZ31"
Efecan Madazlı, Hüseyin Çimenoğlu, Sezgin Cengiz, Faiz Muhaffel, Erdem Balcı - Istanbul Technical University

Mechanical Metallurgy

"Effects of Stress Relief Annealing Time on Mechanical Properties and Operating Cost in Lamellar Graphite Cast Iron Engine Blocks"
Furkan Üstün, Ali Kalyon - Yalova University

MATERIAL SCIENCE AND ENGINEERING

Nanomaterials

"A Study About Tin Nanoparticles and Production of Core-shell Structure"
Ayşe Zuhal Karakaş, Ş. Samet Kaplan, M. Şeref Sönmez - Istanbul Technical University

Ceramics, Glass, Refractory Materials

"Improvement of the Selenium Retention and Control of the Color Stability in Selenium Containing Glasses"
Elif Fagiye Yaylacı, Merve Akdemir Kutluğ, Ahmet Caner Kayaalp, Reha Yavuz - Istanbul Technical University

---

Chair: Prof. Dr. Barış Kışkan, Assoc. Prof. Dr. Birgül Benli

POLYMER SCIENCE AND TECHNOLOGY

Material Science

16:00
17:00

"Preparation and Characterization of Sulfonated Polysulfone for Proton Exchange Membrane Fuel Cells"
Turan Can Özmen - Istanbul Technical University

NANOSCIENCE AND NANOENGINEERING

Nanoparticles

"Radiation Attenuation of MWCNT and Magnetic Nanoparticle Reinforced PMMA Comparative Analysis of Coefficient"
Deniz Hande Aydın, Nilgün Baydoğan - Istanbul Technical University

Polymer and Nano Composites

"Thermo-responsive Pnipaam Based Hydrogels with Bio-inspired Additives for Biomedical Applications"
Rabia Yılmaz, Özgür Yılmaz, Birgül Benli - Istanbul Technical University

12.05.2025 | MONDAY | ONLINE

HALL - II

11:00 - 12:00

Chair: Asst. Prof. Dr. Saeed Tasouji Hassanpour

MANAGEMENT ENGINEERING

Marketing

"The Adoption of Smart Small Home Appliances: An Integrated Model of Consumer Acceptance and Behavior"
Betül İmamoğlu, Huriye Şebnem Burnaz - Istanbul Technical University

"Understanding Consumer Acceptance and Purchase Intentions in Unmanned Retail Stores"
Gözde Erdoğan - Istanbul Technical University

Finance

"The Effect of ESG Ratings on Firm's Financial Performance in Borsa Istanbul"
Alper Ataker, Oktay Taş - Istanbul Technical University

"TEFAS's Effect on the Turkish Mutual Funds Landscape"
Mehmet Sami Boz - Boğaziçi University

13:00 - 14:00

Chair: Asst. Prof. Dr. Saeed Tasouji Hassanpour

Economics

"Central Bank Digital Currencies (CBDCs): a countermeasure to Anti-Money Laundering (AML) challenges posed by cryptocurrencies?"
Albina Gaisina, Matthias Finger - Istanbul Technical University

Finance

"Investor Attention and Asymmetric Conditional Volatility: Evidence from E-GARCH-X and GJR-GARCH-X Models"
Müge Özdemir, Oktay Taş - Istanbul Technical University

"Return Predictability and Attention-Based Trading Strategies: Casual and Time-Varying Volatility Dynamics in Borsa Istanbul"
Müge Özdemir, Oktay Taş - Istanbul Technical University

"How Does Firm Esg Impact Financial Performance After Covid-Era? A Worldwide Analysis"
Sırma Şeker, Cumhur Ekinci - Istanbul Technical University

14:00 - 15:00

Chair: Asst. Prof. Dr. Saeed Tasouji Hassanpour

MANAGEMENT

Human Resource Management

"The Impact of Remote Work on Presenteeism During the COVID-19 Pandemic"
Deniz Mat Artun, Fatma Küskü - Istanbul Technical University

Marketing

"Navigating the Paradox of Connectivity and Isolation: Impacts on Digital Nomads' Psychological Well-Being"
Mahin Farshbaf Maherian, Adnan Veysel Ertemel - Istanbul Technical University

Organization

"Organizing Through Code: A Bibliometric Review of Algorithms in Organizational Contexts"
Hakan Sarı - University of Glasgow

15:00 - 16:00

Chair: Asst. Prof. Dr. Saeed Tasouji Hassanpour, Asst. Prof. Dr. Umut Kuruüzüm

MANAGEMENT

Production Management

"Performance Evaluation Model Based on Balanced Scorecard for Industry 4.0 Applications in the Fast Moving Consumer Goods Sector (FMCG)"
Ceren Dilbaz, Hür Bersam Sidal Bolat - Istanbul Technical University

"Supplier Performance Evaluation with Balanced Scorecard"
Hanife Özcan, Hür Bersam Sidal - Istanbul Technical University

"A Quantitative Approach To Sustainability: Applying Multi-Criteria Decision-Making Techniques And Data Envelopment Analysis Models"
Musa Aktaş, Ferhan Çebi - Istanbul Technical University

ECONOMY

Financial Crises and Macroprudential Policies "Financial Contagion: Dynamic Correlations Approach"
Esra Çakır - Istanbul Technical University

16:00 - 17:00

Chair: Prof.Dr. Şevkiye Şence Türk, Prof. Dr. Levent Kırval, Assoc. Prof. Dr. Ceren Bilgin Güney

REAL ESTATE DEVELOPMENT

Geospatial Analysis in Real Estate

"A Spatial and Investment-Oriented Site Selection Model for EV Charging Stations: The Case of Istanbul"
Handan Kaplan,Kerem Yavuz Arslanlı-IstanbulTechnicalUniversity

Real Estate Development

"An Event-Driven Architecture In Real Estate Development"
Özlem Sertbaş, Hakan Yaman - Istanbul Technical University

MARITIME STUDIES

Maritime Human Resources

"Importance of Safety Awareness and Safety Culture Onboard with Alternative Fuels"
Aysel Camci, Firat Bolat - Istanbul Technical University

SHIPBUILDING AND OCEAN ENGINEERING

Marine Environmental Impact and Pollution Control "The Penglai 19-3 Incidents: Failures, Response, And Regulatory Lessons"
Gulled Makaran, Ceren Bilgin Güney - Istanbul Technical University

12.05.2025 | MONDAY | ONLINE

HALL - III

Chair: Assoc. Prof. Dr. Sefer Baday

DATA ENGINEERING AND BUSINESS ANALYTICS

Predictive Analytics and Machine Learning in Business

"Analyzing Brokerage Firm Trading Behavior via Supervised Learning: A Comparative Study on BIST 10"

Kubilay Karaçam - Istanbul Technical University

11:00

Sentiment Analysis and Opinion Mining

"Impact of Weekly vs Daily Sentiment Scores on Price Direction Forecast"

12:00

Ahmet Berkay Gültekin, Alp Üstündağ -Istanbul Technical University

Big Data Analytics for Decision-Making

"Automated Plastic Waste Detection on Coastal Areas Using UAVs and Deep Learning"

Hesam Hatamzadeh Khanghahi, Şule Itır Satoğlu - Istanbul Technical University

"Agentic Workflows for Self-Service Analytics Applications in E-Commerce"

Taylan Yurtsever - Istanbul Technical University

Chair: Prof. Dr. Seher Melike Aydoğan

MATHEMATICAL ENGINEERING

Applied Mathematics

"Effects of Weak Heterogeneity on Nonlinear Love Wave Interactions"

13:00

Berna Yavaş, Semra Ahmetolan, Ali Demirci-Istanbul Technical University

"Understanding Predator- Prey Dynamics Through Equilibrium State Classification"

14:00

Kerime Nur Kavadar, Ali Demirci - Istanbul Technical University

"Exploring Rayleigh Waves in Layered Media"

Tuğçe Sezer, Semra Ahmetolan, Ayşe Peker Dobie, Ali Demirci - Istanbul Technical University

"Symmetry Analysis on Rosenau Type Equations"

Tuğçe Sezer, Cihangir Özemir - Istanbul Technical University

Chair: Prof. Dr. Seher Melike Aydoğan

MATHEMATICAL ENGINEERING

Data Science and Machine Learning

14:00

"A Case Study in Time Series Classification Using Machine Learning and Deep Learning"

15:00

Barış Küçük, Atabey Kaygun - Istanbul Technical University

Mathematical Modeling

"Modeling Rare Metal Market Dynamics: A Nonlinear Approach with Investment and Geopolitical Risk"

Furkan Emre Işık, Ali Demirci- Istanbul Technical University

Chair: Prof. Dr. Esra Özkan Zayim

PHYSICS ENGINEERING

Optics and Photonics

"Imaging Ellipsometry for Material Characterization and Defect Analysis"

Furkan Yıldız, Esra Zayim, Muharrem Aşar - Istanbul Technical University

15:00

High Energy and Particle Physics

"Dynamo Process in Proto-Neutron Stars"

16:00

İrem Bakır, Kazım Yavuz Ekşi - Istanbul Technical University

"Constraints On New Physics With Light Mediators And Generalized Neutrino Interactions Via Coherent Elastic Neutrino Nucleus Scattering"

Sevgi Karadağ, Muhammed Deniz, Henry T. Wong - Istanbul Technical University

Mathematical Physics

"Investigation of Structural and OptoelectronicProperties ofmetal/ZnS Junction under Density Functional Theory (DFT)"

Haris Kulosmanovic, Murat Çalışkan - Yıldız Technical University

---

Chair: Prof. Dr. Nazan Okur

TEXTILE ENGINEERING

Textile Clothing and Fashion Design

16:00

"Real Time Production Management in Garment Manufacturing Using IoT-Based Process Monitoring Devices (PMDs)"

17:00

Bülent Koç, Selin Hanife Eryürük - Istanbul Technical University

Sustainability in Textile and Fashion Industries

"Statistical Analysis of Short Fiber Content and Tenacity Using Exponential Regression"

Çağdaş Aslan,Selin Hanife Eryürük,Michael Will-Istanbul Technical University

12.05.2025 | MONDAY | ONLINE

HALL - IV

Chair: Asst. Prof. Dr. Ayşe Elvan Bayraktaroğlu

INDUSTRIAL ENGINEERING

Decision Making

11:00
12:00

"A Bayesian Network-Based Approach for Analyzing Railway Accidents"
Derya Cephe, Umut Asan - Istanbul Technical University

"A Comparative Analysis of Machine Learning and MCDM Sorting Methods in Electric Vehicle Selection"
Mehmet Demir, Umut Asan - Istanbul Technical University

"Multi Criteria Decision Making for Selecting Best Banking Service Channel"
Mustafa Akça - Istanbul Technical University

Engineering Management

"Customer Preferences For Mobile Operating Systems In Smartphones Using Conjoint Analysis"
Cansu Aksu - Istanbul Technical University

Chair: Assoc. Prof. Dr. Umut Asan

INDUSTRIAL ENGINEERING

Engineering Management

13:00
14:00

"Impact of Organizational Life Cycle on R&D Project Prioritization Criteria"
Furkan Yasin Taksim, Cafer Erhan Bozdağ - Istanbul Technical University

"Sector-Specific Supplier Evaluation Based on LARGS Dimensions"
Gözde Çinkay, Şeyda Serdarasan - Istanbul Technical University

"Structuring Challenges for Textile Industry in Adopting the Digital Product Passport"
Sena Nur Dursun, Şeyda Serdarasan- Istanbul Technical University

Knowledge Management

"Understanding University Reputation: A Stakeholder-Centered Model for Reputation"
Orhan Dursun, Çiğdem Altın Gümüşsoy - Istanbul Technical University

---

Chair: Assoc. Prof. Dr. Seda Yanık

INDUSTRIAL ENGINEERING

Industrial Data Analytics

14:00
15:00

"Predicting the Closing Time of Debt Files in Legal Stage Using Machine Learning and Deep Learning Methods"
Şeyda İrem Bilgehan, Başar Öztayşi - Istanbul Technical University

Manufacturing Management

"Analysing the Automotive Production: A Bibliometric Analysis on Lean-Green Management"
Ayşe Melissa Ergün, Hür Bersam Sidal Bolat - Istanbul Technical University

"Improvement Study In The Inner Door Production Area With Lean Production Approach"
İsa Emre Gül, Seda Yanık - Istanbul Technical University

Chair: Asst. Prof. Dr. Saltuk Duran

HISTORY OF SCIENCE AND TECHNOLOGY

History of Engineering

15:00
16:00

"From Dieppe to Normandy: Technological Innovations and the Reclamation of Offensive Initiative in World War II"
Göktuğ Berk Çakı - Istanbul Technical University History of Sciences

"Brief History of Artificial Intelligence Approaches"
İlkem Ahu Şahin, Aytekin Çökelez - Istanbul Technical University

History of Physics

"Scientific Tendencies in the Context of the Annals of Electricity, Magnetism, and Chemistry (1836-1843) in England"
Tuğçe Esenduran - Istanbul Technical University

12.05.2025 | MONDAY | ONLINE

HALL - V

Chair: Asst. Prof. Dr. Murat Yeşiloğlu

CONTROL AND AUTOMATION ENGINEERING

Advances in Automatic Control Engineering

11:00
12:00

"Lane Change Desicion Making for Autonomous Vehicles By Using Adversarial Learning Methods"
Aytuğ Onurhan Efil, Mustafa Doğan - Istanbul Technical University

"Control Allocation Strategies for Dual-System VTOL UAVs Under Control Surface Failures: Enhancing Fault Tolerance and Flight Stability"
Bilal Badur, Fikret Çalışkan - Istanbul Technical University

"New Generation 4-D Flight Management System Design for the Fighter Jets"
Kaan Tellioğlu, Fikret Çalışkan - Istanbul Technical University

Applications of Control Engineering

"Fuzzy Gain Decision for Different Type Aircrafts with Dynamic-pitch-control Envelope Cue"
Ali Karaduman, İlker Üstoğlu - Istanbul Technical University

Chair: Asst. Prof. Dr. Erhan Yumuk

CONTROL AND AUTOMATION ENGINEERING

Applications of Control Engineering

13:00
14:00

"Performance Comparison of Guidance Algorithms for Aerial Vehicles: A Software-In-The-Loop Based Approach"
Alper Makaraç, Mustafa Doğan- Istanbul Technical University

"An Optimization Based Flight Control Law Design for Fighter Aircraft"
Bora Akaryıldız, Yaprak Yalçın - Istanbul Technical University

"Adaptive Kalman Filter-Based Gyroscope Error Compensation Using Magnetometer and Accelerometer Data for IMU Sensors"
Mehmet Eren Savaştürk, Mustafa Doğan - Istanbul Technical University

"Design and Analysis of a Dual Layer Disturbance Observer Based Controller for Suppressing Internal and External Disturbances for Longitudanel Axis in a Fixed Wing Aircraft"
Merve Demiroğlu, İlker Üstoğlu, Yusuf Sıncak - Istanbul Technical University

---

Chair: Assoc. Prof. Dr. Ahmet Onat

CONTROL AND AUTOMATION ENGINEERING

Applications of Control Engineering

14:00
15:00

"Enhanced Aircraft Control Through Total Energy Control Systems: A Comparative Study with Conventional Autopilots"
Rumeysa Kökoğlu, Müjde Güzelkaya - Istanbul Technical University

"Enhancing Aircraft Avionics Safety: Integrating STPA with ARP4761 Analysis"
Şükrü Can Sulak - Istanbul Technical University

"Robust Attitude Control of the F16 Aircraft Using Incremental Nonlinear Dynamic Inversion"
Yasin Şahin, İlker Üstoğlu- Istanbul Technical University

"Immersion and Invariance Disturbance Observer based Discrete Time Vector Control of BLDC Machines"
Ziya Cem Salış - Istanbul Technical University

Chair: Asst. Prof. Dr. Ali Yeşilyurt

EARTHQUAKE ENGINEERING

Artificial Intelligence, Machine Learning, and Deep Learning in Earthquake Engineering

15:00
16:00

"Detection of Longitudinal Reinforcement Buckling in Reinforced Concrete Columns by a Deep Learning Method"
Bahadır Güleşmen, Ömer Tuğrul Turan - Istanbul Technical University

"Estimating Equivalent Damping Ratio of Conventional Shear Walls by Machine Learning Methods"
Siamak Tahaei Yaghoubi, Zeynep Tuna Deger - Istanbul Technical University

Performance-Based Seismic Assessment and Design

"Seismic Performance Assessment of Irregular RC Structures Using the Extended N2 Method"
Zekeriya Semih Aygün,Reşat Atalay Oyguç - Istanbul Technical University "Seismic Performance of Irregular RC Frames Retrofitted with TnT BRBs"
Zeynep Orman, Resat Oyguc - Istanbul Technical University

Chair: Res. Asst. Mustafa Mert Eyüpgiller

EARTHQUAKE ENGINEERING

Experimental Investigation of Reinforced Concrete Building Elements

16:00
17:00

"Enhancing Seismic Resilience of Substandard RC Beam-Column Joints with All-Steel Tube-in-Tube Buckling Restrained Braces: A Shake Table Test"
Evrim Oyguç, Abdul Hayır, Reşat Oyguç, Onur Şeker, Bülent Akbaş - Istanbul Technical University

Structural and Geotechnical Earthquake Engineering

"Design and Comparison of Different Types of Reinforced Concrete Slab Systems For Multi-storey Buildings"
Ahmet Jabban, Kadir Güler - Istanbul Technical University

"Seismic Performance Enhancement of RC Coupling Beams Using Shape Memory Alloy Devices"
Ali Attariyan, Beyza Taşkın, Kıvanç Taşkın - Istanbul Technical University

"Preliminary Study on St. İlyas Church Damaged in the Kahramanmaraş Earthquakes"
Kerem Kurnaz, Yunus Arca, Elif Durgut, Sinan Acikgöz, Medine İspir Arslan - Istanbul Technical University

12.05.2025 | MONDAY | ONLINE

HALL - VI

Chair: Prof. Dr. Sevinç Asilhan, Asst. Prof. Dr. Emre Avunduk

METEOROLOGICAL ENGINEERING

Atmosphere, Meteorology

"Heatwave Analysis Approach"

Anıl Eken, Sevinç Asilhan - Istanbul Technical University

11:00
12:00

Renewable Energy

"Repowering at Türkiye's Leading Power Plant: An Analysis of Energy Production Increase"

İpeknur Hazar, Mehmet Özkan Başar, Elçin Tan - Istanbul Technical University

MINING ENGINEERING

Excavation Mechanics

"Machine Learning-Based Prediction of Thrust Force in Tunnel Boring Machines"

Hadi Alizadeh, Ömür Acaroglu - Istanbul Technical University

Chair: Asst. Prof. Dr. Ramazan Yeniçeri

DEFENSE TECHNOLOGIES

Structural Design and Analysis

"Finite Element Analysis Of Crack Growth Behavior In The Presence Of Crack-Arresting Holes"

Buse Yaşın Aydın, İbrahim Özkol, Mustafa Tolga Yavuz - Istanbul Technical University

13:00
14:00

Unmanned Vehicles

"Heuristic Approach to UAV Selection with Fuzzy Logic and MADM Techniques"

Emre Yüksek-Istanbul Technical University

"Comparative Analysis of Object Detection and Tracking Algorithms for UAVs"

Merve İsmailvelioğlu, Mustafa Doğan - Istanbul Technical University

"Optimized Visual Odometry and Satellite Image Matching-Based Localization for UAVs in GPS-Denied Environments"

Ömer Sefa Öztürk, Alptekin Yıldız - Istanbul Technical University

---

Chair: Asst. Prof. Dr. Ramazan Yeniçeri

DEFENSE TECHNOLOGIES

Structural Design and Analysis

"Optimization and Finite Element Analysis of Metastructures for Vibration Mitigation"

Elif Nur Yaşar, Kaan Yıldız - Istanbul Technical University

14:00
15:00

"Parametric Optimization of Semi-Octagon Re-entrant Auxetic Structures for Energy Absorption"

Şenay Yener, Kaan Yıldız - Istanbul Technical University

"Design and Modeling of a Nonlinear Bi-Axial Dynamic Vibration Absorber for Helicopter Applications"

Resmiye Ağan, Vedat Ziya Doğan, Halit Süleyman Türkmen, Ali Tatar - Istanbul Technical University

"Computational Analysis of Metallic Structures Subjected to Impact Loading Using LS-Dyna"

Ümran Türkan, Vedat Ziya Doğan- Istanbul Technical University

---

Chair: Asst. Prof. Dr. Ramazan Yeniçeri, Dr. Abdülkadir Ünal

DEFENSE TECHNOLOGIES

Remote Sensing

"A Hybrid Preprocessing Approach Based on Simulation Data for Embedded Object Detection Under an Inhomogeneous Surface"

Ali Batuhan Bağcacier, Ali Yapar - Istanbul Technical University

15:00
16:00

RAILWAY SYSTEMS ENGINEERING

Railway Systems Engineering

"Fiber Bragg Grating Sensor: Principles, Applications, and Emerging Trends"

Serhat Boynukalın, Kemal Atakan Kırca - Istanbul Technical University

Signaling Systems in Railways

"A Safety-Critical Railway InterlockingArchitecture Based on SCADE and HIMA PLCs with Python-Driven Simulation and Control"

Serhat Boynukalın, Feride Berra Köseoğlu, Erdem Kısaç - Istanbul Technical University

"Energy Efficiency Optimization through Metro Scheduling: Mixed-Integer Linear Programming (MILP) and Genetic AlgorithmApproaches"

Mustafa Karaipek, Abdurrahman Yılmaz - Istanbul Technical University

---

Chair: Asst. Prof. Dr. İhsan Burak Kulga

PETROLEUM AND NATURAL GAS ENGINEERING

Geothermal Engineering

"Utilization of Carbon Dioxide Gas (CO2) for Gas Lift Systems in Geothermal Wells"

Force Lugembe Ndege, Ömer İnanç Türeyen - Istanbul Technical University

16:00
17:00

Natural Gas Engineering

"Natural Gas Hydrate Modelling" Devrim Başar Han - Istanbul Technical University

Reservoir Engineering

"A Machine Learning Approach to Forecast Production Performance of Hydraulically Fractured Horizontal Wells in Tight Oil Sandstone Reservoirs"

Ferhat Yurttagül, Burak Kulga - Istanbul Technical University

"Comparison of Thermophysical Gas Properties"

Nariman Valiyev, Ömer İnanç Türeyen - Istanbul Technical University

13.05.2025 | TUESDAY | ONLINE

MAIN HALL

09:00 - 10:00

Chair: Asst. Prof. Dr. Recep Gül

MUSICOLOGY AND MUSIC THEORY

Music Theory

"Exploring Perde-Çeşni Transformations in Tanburi Cemil Bey's Instrumental Works within Nikriz Makam"
Burak Kesgin - Istanbul Technical University

"Analysis Of Vertical Structures In The Context Of Set Theory In Ivan Wyschnegradsky's 24 Preludes In Quarter Tone System For Two Pianos, Op. 22"
Selçuk Canberk Dağtekin - Istanbul Technical University

"Folk Music And Classical Composition: A New Framework in Scottish Music Based on Bartok's Three Folk Music Categorizations"
Senay Yilmaz - Istanbul Technical University

"Harmony in Brouwer's Late Period: Use of Extended Tonality in the First Movement of Del Pensador"
Tamer Çelik, Recep Gül - Istanbul Technical University

10:00 - 11:00

Chair: Prof. Dr. Burcu Yıldız

MUSICOLOGY AND MUSIC THEORY

Popular Music

'It's Corn': From Everyday Life's 'Sound' to Viral Musical Meme"
Cevher Sarıgül - Istanbul Technical University

"The Issue of "Originality" in Arabesk Music: Analysis of Musical Borrowings, Similarities, and Production Practices from Arab Music"
Yiğit Sarıgül - Istanbul Technical University

Historical Musicology

"Analysis Of Some Makams FromThe Arabic Music Conference 1932"
Mohamed Mostafa Ahmed Mohamed - Istanbul Technical University

"Music as 'Refuge' From Reality: Schopenhauerian Aesthetics Revisited"
Selim Güre - Istanbul Technical University

11:00 - 12:00

Chair: Prof. Dr. Burcu Yıldız

MUSICOLOGY AND MUSIC THEORY

Ethnomusicology

"Evaluating Sounds on the Water from an Ecomusicological Perspective: The Case of Haliç"
Semin Tunalı-Istanbul Technical University

13:00 - 14:00

Chair: Assoc. Prof. Dr. Gökhan Deneç

MUSIC

Sound Engineering and Design

"Transformation of Digital Audio from Metaverse to Web3"
Günsel Işık Gruson, Taylan Özdemir - Istanbul Technical University

"Methodology on Participatory Media Analysis: Insights from Audio Modding Scene on Nexus Mods"
Başar Ünder, Taylan Özdemir-Istanbul Technical University

"Spatial Auditory Masking in 3D Audio: Challenges, Experimentation and Implications for Immersive Sound"
Emre Tenker - Istanbul Technical University

Music Business and Management

"Music Memes and the Relationship Between Music Marketing and Humor in Turkey: The Past, Present, and Future"
Alp Timuçin Bulut - Istanbul Technical University

14:00 - 15:00

Chair: Dr. Jane Harrison

MUSIC

Music Theory

"Effects of Performance Space on Free Improvisation Practices"
Aslıhan Adlin - Istanbul Technical University

"Cyclic Unity and Romantic Expression in Robert Schumann's {Fantasiestücke}, Op. 12: A Schenkerian Perspective"
Doğucan Temizel - Istanbul Technical University

Ethnomusicology

"Sonified Memory of the 2020 Aegean Sea Earthquake"
Doruk Başoğlu - Istanbul Technical University

Music Performance

"Challenging Conventions: Clara Wieck's Op. 20 and the Gendered Landscape of 19th-Century Music"
İrem Hayrioğlu-Istanbul Technical University

15:00 - 16:00

Chair: Dr. Robert Oliver Beahrs

MUSIC

Music Performance

"Messiaen as Liturgist: A ContextualReadingofthe Vingt Regards sur l'Enfant-Jésus"
Robert McDonald - Istanbul Technical University

"The Relentless Clash of Dissonant Harmonies and Lyric Melodic Lines… An Extensive Look into the Sound of Sergei Prokofiev"
Selçuk Ener-Istanbul Technical University

Sonic Arts

"Exploring Dance Floor Tactility: Sonic Ethnography and Artistic Inquiry through Audio Paper"
Gazele Aydın- Istanbul Technical University

16:00 - 16:45

KEYNOTE SPEAKER

"*Reconstructing A Turkish Identity in Boston: Jazz, Mehter, Byzantine Music and the Process of Internalization*"
Prof. Dr.Mehmet Ali SANLIKOL, New England Conservatory - Boston

17:00 - 18:00

Chair: Prof. Dr. Kamile Perçin Akgül, Dr. Görkem Giray

TRADITIONAL DANCES

Dance, Traditional Dances in terms of its role in interdisciplinary interaction in performance areas

"The Reinterpreting Choreographic Art Through Traditional Dances in Turkey: The Shaman Dance 'JEDI' Project"
Gülce Su Gümüş - Istanbul Technical University

POLITICAL STUDIES

Political and Social Thought

"State's Construction of "Othering" Mechanisms: Stigmatization and Discrimination Processes"
Ela Gülboy - Istanbul Technical University

Political Philosophy

"An Evaluation of Socrates, Plato and Aristotle Regarding Their Conceptualizations of Political Legitimacy"
Giray Çavdar- Istanbul Technical University

13.05.2025 | TUESDAY | ONLINE

HALL - I

09:00 - 10:00

Chair: Assoc. Prof. Dr. Umut Almaç

ARCHITECTURE
Conservation and Restoration
"The Rural Settlement Structure and the Challenges of Preserving Traditional Housing in Tokat Bağbaşı (İbibse) Village"
Eva Köker, Zeynep Eres Özdoğan - Istanbul Technical University
"Examination of the Transformation of Kirklareli Urban Conservation Area and Its Surroundings between 2004 and 2022 in the Context of Conservation and Sustainability"
Zeynep Gökçen, Zeynep Eres Özdoğan - Istanbul Technical University
"Facade Finishes in Early 20th Century Istanbul: History and State of Conservation"
Berru Çelik, Işıl Polat Pekmezci - Istanbul Technical University
"Ottoman Brick Stamps"
Nevriye Öztürk, Gülnin Tanyeli - Istanbul Technical University

10:00 - 11:00

Chair: Dr. Görkem Günay

ARCHITECTURE
Architectural History
"Rural Houses in Renaissance Architecture: Proposals of Sebastiano Serlio according to the Social Hierarchies in his Sixth Book"
E. Merve Aksoy Oral, Aygül Ağır - Istanbul Technical University
"Spatial Representation in French New Wave Cinema: An Analysis Through Agnès Varda's Cléo De 5 À 7 (1962) Film"
Mivaç Kaykılı, Demet Arslan Dinçay - Istanbul Technical University
"Legitimisation through Elevation: Romanos' Myrelaion"
Ömer Faruk Ulusoy, Bilge Ar - Istanbul Technical University
"Furniture Consumption in Istanbul at the Beginning of the 20th Century: The Role of Periodicals"
Sezin Dirihan, V. Gül Cephanecigil - Istanbul Technical University

11:00 - 12:00

Chair: Dr. Ebru Şevkin

ARCHITECTURE
Architectural History
"The Historical Layers Of Selimpaşa In Constaninople Hinterland Context"
Nil Ceren Karagülle, Bilge Ar - Istanbul Technical University
"Semi-Open Spaces As A Result of Climate And Culture in Mediterranean Architecture"
Furkan Sağdıç - Istanbul Technical University
Building Materials and Technologies
"Developing One-part Geopolymer Binders by Using Ground Granulated Blast-furnace Slag and Ceramic Waste as Precursors"
İlar Berfin İlbeyi, Ünal Anıl Doğan - Istanbul Technical University

13:00 - 14:00

Chair: Assoc. Prof. Dr. Bihter Almaç

ARCHITECTURE
Architecture Design Theory
"Soft Matters: (Re)Drawing Architecture Through Feminist Material Practices"
Beyza Nergis Özbek, Sıdıka Aslıhan Şenel -Istanbul Technical University
"Fluid Bodies of Space: Rethinking Architectural Relationality Through the Medusa Head"
Esra Yüksek, Sıdıka Aslıhan Şenel - Istanbul Technical University
"Urban Destruction in Malatya's Green Belt Project: A Struggle For Public Space Or Capitalist Gain?"
Furkan Evliyaoğlu, Nurbin Paker Kahvecioğlu - Istanbul Technical University
"Archival Encounters: Rewriting Istanbul Women's Works Library and Its Memory Through Bodily Practices"
Seray Rusçuklu, Sıdıka Aslıhan Şenel - Istanbul Technical University

14:00 - 15:00

Chair: Prof. Dr. Ozan Önder Özener

ARCHITECTURE
Architecture Design Theory
"The Performance of the Archive or Archive as Event: Exhibiting Architecture"
Derya Yıldız, Funda Uz - Istanbul Technical University
"Reading Architectural Memory through Cinematographic Image: Atatürk Cultural Center"
İsmail Gökkaya , Funda Uz - Istanbul Technical University
"Conditions of Criticality in Discussions on Architectural Representation"
Burçe Karadağ, Nurbin Paker Kahvecioğlu - Istanbul Technical University
"The Impact of Governmental Power On Urban Morphology: A Case Study of London"
Hande Nur Çalışkan Yüksel, Tan Kamil Gürer - Istanbul Technical University

15:00 - 16:00

Chair: Assoc. Prof. Dr. Aslıhan Şenel

ARCHITECTURE
Architecture Design Theory
"The Potentialities, Displacements, and Spatial Projections of the Concept"
Umran Aydın-Beykoz University
"Typological Transformations and Urban Isolation: Rethinking Architectural Production along Eskişehir Road"
Ahmet Günel, Celal Abdi Güzer - Middle East Technical University
"Exploring Experiential Learning Design Practices Grounded in Social Responsibility in Mardin"
Betül Toy, Yüksel Demir - Istanbul Technical University
"A Comparative Study on the Physical Quality of Başakşehir Deprem Konutları (Başakşehir Earthquake Housing) and Metrokent Site"
Sena Betül Demircan, Şayeste Tülin Görgülü-Istanbul Technical University

17:00 - 18:00

Chair: Asst. Prof. Dr. Ecem Tezel

ARCHITECTURE
Project and Construction Management
"A Literature Review On Organizational Structures In The Construction Industry"
Ece Gamze Sentuna, F. Pınar Çakmak - Istanbul Technical University
"Investigating the Role of Data Management for AI Utilization for Decision-Making in Construction: {A Literature Review}"
Hansa Eusmanaga, Fatma Pınar Çakmak - Istanbul Technical University
"A Systematic Review of BIM and the Circular Economy: Key Research Areas and Findings"
Merve Cellek, Fatma Pınar Çakmak -Istanbul Technical University
Sustainable Design
"Investigating Circularity in Buildings through Digital Circularity Metric"
Burcu Kumet , Meryem Birgül Çolakoğlu - Istanbul Technical University

18:00 - 19:00

Chair: Assoc. Prof. Dr. Orkan Zeynel Güzelci

INTERNATIONAL MASTER OF INTERIOR ARCHITECTURAL DESIGN
Interior Architecture
"Use of Mycelium-Based Materials as an Interior Design Component: A Digital Fabrication Approach"
Müge Özkan, Orkan Zeynel Güzelci - Istanbul Technical University
Technology in Interior Design
"A Strategy for Dataset Preparation in AI Model Training: The Case of Hotel Interiors"
Yaren Cengiz, Orkan Zeynel Güzelci, Derya Göleç Özer, Koray Kutlu - Istanbul Technical University

13.05.2025 | TUESDAY | ONLINE

HALL - II

09:00 - 10:00

Chair: Assoc. Prof. Dr. Almula Büyüktaşkın

ARCHITECTURE

Building Construction Technologies

"Impact of Deterioration Due to Environmental Factors on Seismic Performance of Traditional Timber Buildings in the Historical Peninsula in Istanbul"
Abdüllatif Sarıkaya, Caner Göçer - Istanbul Technical University

"Evaluation Of Damage Mechanisms Of Reinforced Concrete Industrial Structures In Past Earthquakes In Turkey"
Bahar Şevli, Caner Göçer - Istanbul Technical University

"Evaluation of Light Steel Structured Housing According to Construction Systems"
Burçin Fırtına, Caner Göçer - Istanbul Technical University

"Evaluation of Damage Mechanisms in Stone Structured Houses Due to Earthquakes in Turkey and Surrounding Areas"
Sarvin Iravani Ghadim, Caner Göçer - Istanbul Technical University

---

10:00 - 11:00

Chair: Assoc. Prof. Dr. Tarık Serhat Bozkurt

ARCHITECTURE

Building Construction Technologies

"Evaluation of Retrofitting Techniques in Reinforced Concrete Buildings"
Sinan Sarvan, Caner Göçer - Istanbul Technical University

"Evaluation of the Seismic Performance of Traditional Akçakese Houses in Relation to Structural Deterioration"
Zeynep Dikyer, Caner Göçer - Istanbul Technical University

Built Environment Design and Technologies

"Evaluation of Exterior Cladding Materials in Educational Buildings in Terms of Embodied Energy"
Dilfuruz Kara, Caner Göçer - Istanbul Technical University

"The Impact of Façade Cladding Materials on Carbon Emissions in Urban Renewal Projects: The Case of Istanbul"
Ikranur Sena Akkaya, Caner Göçer - Istanbul Technical University

---

11:00 - 12:00

Chair: Assoc. Prof. Dr. Feride Şener Yılmaz

ARCHITECTURE

Environmental Control and Building Technology

"MUrbanReCrete: A Sustainable Approach to Concrete Waste Recycling in Istanbul"
Başak Akarsu Akdemir, Fatma Sultan Bozkurt, Gizem Aluçlu Armutcu - Istanbul Technical University

"Multi-Stage Space-Adaptive Shelter: An Alternative for Post-Disaster Shelters"
Furkan Berke Çileziroğlu, Oğuz Cem Çelik - Istanbul Technical University

"Integration of Artificial Intelligence into Materials Education in Architecture: Opportunities, Challenges and Future Perspectives"
Peyam Başer, Seden Acun Özgünler, Mine Topçubaşı - Istanbul Technical University

"Reduction of Cooling Loads in Office Buildings in Hot Climates Using Radiant Cooling"
Yasemin Kılıçoğlu, Gülten Manioğlu - Istanbul Technical University

---

13:00 - 14:00

Chair: Prof. Dr. Hatice Ayataç

URBAN AND REGIONAL PLANNING

Transportation Planning and Urban Infrastructure

"Towards Walkable and Green University Campuses: Observational Assessment of ITU Maslak Campus forAdvancing the Sustainable Development Goals"
Amira Maway, Hatice Ayataç - Istanbul Technical University

"Determination of Saturation Flow Rate Right-Turn Adjustment Factor for Large Radii in Istanbul"
Ozan Emekter, Kemal Selçuk Öğüt - Istanbul Technical University

Sustainability, Ecology, and Energy in Planning

"Rethinking Heritage-Tourism Relations: Critical Perspectives and Sustainable Futures for Cultural Sites"
Büşra Yalçın, Turgay Kerem Koramaz - Istanbul Technical University

---

14:00 - 15:00

Chair: Assoc. Prof. Dr. Başak Demirez

URBAN AND REGIONAL PLANNING

Smart Cities, Digitalization, and Data Science

"City Information Modeling: Identifying Knowledge Gaps and Research Priorities"
Abdalrahman T. Y. Alashi, Özhan Ertekin - Istanbul Technical University

"Deprivation Analysis In Turkey And It's Provinces: a Study Based On English Index Of Deprivation And Turkish Statistical Institute"
Abdalrahman T. Y. Alashi, Özhan Ertekin - Istanbul Technical University

Climate Change and Planning

"Climate Change Adaptation in Urban Heritage Sites: The Case of Istanbul Historic Peninsula"
Turgay Kerem Koramaz, Tugce Turk - IstanbulTechnicalUniversity

---

15:00 - 16:00

Chair: Prof. Dr. Hayriye Eşbah Tunçay

LANDSCAPE ARCHITECTURE

Innovative Technologies for Landscape Design and Management

"The Use of Computer Vision in Observing Human Behavior in Landscape Architecture"
Gizem Yağmur Gölbaşı, Melih Bozkurt - Istanbul Technical University

Landscape Design

"Understanding Play: How Playground Equipment Shapes Cognitive, Social and Physical Behaviors in Children Aged 3-12: A Case Study in Maltepe Orhangazi City Park"
İçim Gündoğan Ata - Istanbul Technical University

Heritage and Identities

"From Tradition to Globalization: The Conceptual Transformation of Korean Landscape in Global City Seoul"
Mülkiye Kurt, Ebru Erbaş Görler - Istanbul Technical University

---

17:00 - 18:00

Chair: Assoc. Prof. Dr. Merve Tomaç

FOOD ENGINEERING

Food Bioactive Compounds

"Production of Phenolic Compounds from Grape Pomace by Enzyme-Assisted Extraction"
Ayşe Nilay Yıldırım, Derya Kahveci Karıncaoğlu - Istanbul Technical University

Functional Foods

"Composition and Technofunctional Properties of Aquafaba from Local Legume"
Nurullah Zekeriya Akar, Meral Kılıç Akyılmaz- IstanbulGelisimUniversity

"Plant Based Proteins In Instant Soups: Comparison of Sensory, Functional and Bioactive Properties"
Ceren Çakır - Istanbul Technical University

18:00 - 19:00

Chair: Prof. Dr. Neşe Şahin Yeşilçubuk, Asst. Prof. Dr. Çiğdem Yılmaz Çelak

FOOD ENGINEERING

Sustainable Foods

"Development and Characterization of Biodegradable Films Enriched with Proteins Extracted from Agro-Industrial Fes Waste and By-Products"
Nihal Sultan Bayar, Neşe Şahin Yeşilçubuk, Hande Yenipazar, Ayşe Saygün - Istanbul Technical University

Novel Food Processes

"Effects of Audible-Range Sound Treatment on the Microbiological Quality of Strawberry During Post-Harvest Storage"
Deniz Çavdar,Gürbüz Güneş-Istanbul Technical University

MOLECULAR BIOLOGY - GENETICS AND BIOTECHNOLOGY

Metagenomics and Protein Engineering

"Site-directed mutagenesis oninactive CYP102A178 fromhydrothermalhot spring Hisaralan-Balıkesir"
Elif Mehvej Özer, Başak Birdal, Kaan Dizer, Hande Mumcu, Nevin Gül Karagüler - Istanbul Technical University

"Recombinant Production of Two Novel Ferredoxin-NADP Reductases from {Pseudomonas mandelii} KGI_MA19"
Kaan Dizer, Hande Mumcu, Elif Mehvej Özer, Nevin Gül Karagüler-Istanbul Technical University

13.05.2025 | TUESDAY | ONLINE

HALL - III

09:00 - 10:00

Chair: Assoc. Prof. Dr. Özge Özdemir

AERONAUTICAL AND ASTRONAUTICAL ENGINEERING

Aircraft Design, Flight Dynamics And Performance

"External Store Separation From Fighter Aircraft"
Ahmet Kutsay Dere, Hayri Acar - Istanbul Technical University

"Winglet Design, Optimization and Performance Analysis for a Trainer Aircraft"
Çağlar Yakın, Hayri Acar, Serhat Yılmaz- Turkish National Defence University

"Sensitivity Analysis of Hypersonic Glide Vehicle Trajectory Under Aerodynamic and Atmospheric Variations"
Ekin Gözükaya, Halil Ersin Söken - Middle East Technical University

Rotary Wing Aircraft

"A Study on Hover and Forward Flight PerformanceofS70A-28D(UH-60L Black Hawk) Helicopter to obtain Cruise Chart by using Momentum and Blade Element Momentum Theory"
Mehmet Tayfun Ülbegi, Özge Özdemir - Turkish National Defence University

---

10:00 - 11:00

Chair: Assoc. Prof. Dr. Emre Koyuncu

AERONAUTICAL AND ASTRONAUTICAL ENGINEERING

Control Systems: Adaptive, Intelligent, Digital, Optimal, Pneumatic-Hydraulic

"Multi-Agent Reinforcement Learning with Maneuver Primitives for Automatic Ground Collision Avoidance of Fighter Jets"
Fatih Erol, Hayri Acar, Emre Koyuncu - Istanbul Technical University

"Quadrotor Actuator Fault Detection and Isolation. A Model-Based Approach"
Muhammed Arslan, Gökhan Inalhan- Istanbul Technical University

Spacecraft Control, Design And Performance

"Design of a Deployable S-Bant Helical Antenna for Cubesats"
Rümeysa Üstüncan -Istanbul Technical University

"Liquid Propellant Rocket Engine Performance Sensitivity Analysis"
Turan Copuroglu, Fırat Oğuz Edis - Istanbul Technical University

---

11:00 - 12:00

Chair: Asst. Prof. Dr. Ali Tatar

AERONAUTICAL AND ASTRONAUTICAL ENGINEERING

Mechanical Vibrations And Structural Dynamics

"Aeroelastic Optimization With Genetic Algorithm" Ahmet Güver, Seher Eken - Istanbul Technical University

"Feed-Forward Neural Network-Based Prediction of Flutter Speed of 3 DOF 2D Wing Model"
Osman Dağlı, Metin Orhan Kaya- Istanbul Technical University

"Conceptual Modeling of a Multi-Axial Nonlinear Dynamic Vibration Absorber for Helicopters"
Özkan Karayiğit, Ali Tatar, Vedat Ziya Doğan, Halit Süleyman Türkmen -Istanbul Technical University

"Nonlinear Modeling and Sensitivity Analysis of Oleo-Pneumatic Strut Landing Gear Systems for Aircraft Landing Performance"
Sadık Utku Gulek, Kaan Yıldız - Istanbul Technical University

---

13:00 - 14:00

Chair: Prof. Dr. Mehmet Şahin

AERONAUTICAL AND ASTRONAUTICAL ENGINEERING

Theoretical, Computational And Experimental Aerodynamics And Fluid Dynamics

"Fully-Coupled k–ω-SST Turbulence Model Implementation for Nonlinear Newton Method in Unstructured Vertex BasedHEMLABAlgorithm"
Atakan Okan, Mehmet Şahin - Istanbul Technical University

"Ground Wind Loads on Launch Vehicles"
Ece Saykan, Fırat Oğuz Edis -Istanbul Technical University "

A Deep Learning Based Modelling of Axial Turbomachinery"
Mehmet Fatih Reyhan, Yavuz Selim Mehel, Baha Zafer - Istanbul Technical University

"Experimental Study on Vortex Gust Encountered by a Flat Plate at 45° Wing Sweep"
Ozan Ibrahimagaoglu, Oksan Cetiner- Istanbul Technical University

---

14:00 - 15:00

Chair: Asst. Prof. Dr. Saliha Banu Yılmaz

AERONAUTICAL AND ASTRONAUTICAL ENGINEERING

Theoretical, Computational And Experimental Aerodynamics And Fluid Dynamics

"Digital Twin Approaches in System-Level Modeling for Aerospace and Propulsion Applications of Rocket Engines: A Review"
Yasir Şimes, İbrahim Özkol - Istanbul Technical University

Theoretical, Computational And Experimental Structural Analysis And Design

"Design and Analysis of Isogrid-Stiffened Cylindrical Structures for Launch Vehicles: Mathematical Modelling and Knockdown Factor Correlation with Finite Element Validation"
Hakan Atkan, Atkan Altınkaynak - Istanbul Technical University

"Investigation of the Interaction of Carbon Fiber Cylindrical Rocket Bodies with Radial Bolt Joints"
Kubilay Sazan - Istanbul Technical University

"Numerical Modeling of Composite Laminates Under Out-of-Plane Impact"
Vuslat Sena Avcı - Istanbul Technical University

15:00 - 16:00

Chair: Assoc. Prof. Dr. Ramazan Çağlar

ELECTRICAL ENGINEERING

Smart Grids

"Adaptation of a Generalized Observer Scheme for False Data Injection Detection in Load Frequency Control Systems"
Arslan Mete Baybars, Fikret Çalışkan, Istemihan Genç - Aselsan Inc., Istanbul Technical University

"Cyber-Resilient Real-Time Transient Stability Prediction for Modern Power Systems"
Kemal Aygül,Anurag K.Srivastava, Mostafa Mohammadpourfard, Istemihan Genç - IstanbulTechnicalUniversity

Power Electronics

"Three Phase LLC Resonant DC/DC Charger for Railway Applications"
Murat Gümüş, Abdulkadir Balıkçı - Gebze Technical University Electrical Vehicles

"Development And Validation Of A Dynamic Energy Consumption Model For A 12-Meter Electric Bus Using SORT 2 Test Data"
Mehmed Demirtaş, Mehmet Onur Gülbahçe - Istanbul Technical University

---

17:00 - 18:00

Chair: Assoc. Prof. Dr. Salih Barış Öztürk

ELECTRICAL ENGINEERING

Electric Power & Energy Systems

"Techno-Economic Integration of Nuclear Energy Towards Achieving Net-Zero Emissions"
Serdar Hudayberdiyev, Lale Erdem Atılgan - Istanbul Technical University

Power Electronics

"A Real-Time Resonance Detection and Mitigation Method for Shunt Active Power Filters"
Ramazan Berkan Tut, Veysel Tutku Buyukdegirmenci, Mustak Erhan Yalçın-Istanbul Technical University

Electrical Machines

"Investigation of the Effect of Space Vector PWM Technique on Zero-Sequence Voltage Formation in Open-End Windings"
Arda Tüfekçi, İlker Şahin, Derya Ahmet Kocabaş- Aselsan Inc., Istanbul Technical University

"Determination of Altitude Dependent Insulation Breakdown of Brushed DC Starter Generators"
Ayşe Nur Köklü Ulusoy - Istanbul Technical University

13.05.2025 | TUESDAY | ONLINE

HALL - IV

09:00 - 10:00

Chair: Prof. Dr. Mehmet Murat Monkul

SOIL MECHANICS AND GEOTECHNICAL ENGINEERING

Geotechnics

"Modelling of Lateral Spreading of Sandy Soils"
Hamed Feizollahzadeh Arabili - Istanbul Technical University

Environmental Geotechnics

"Evaluation of Geotechnical Characteristics of Recycled Concrete Aggregate-EAF Slag Mixtures"
Seyedsina Norouzian, Bilal Korkmaz, Aslı Yalçın Dayıoğlu - Istanbul Technical University

Geotechnical Earthquake Engineering

"Dynamic Site Response Analyses for A Site with A Deep Cut"
Yusuf Şahin, Gürkan Özden - Istanbul Technical University

10:00 - 11:00

Chair: Assoc. Prof. Dr. Deniz Artan

CONSTRUCTION MANAGEMENT

Construction Project Management

"Difficulties Faced by ConstructionExperts in Construction Sector Cases in the Turkish Justice System"
Bekir Haktanır, Murat Kuruoğlu, Onur Behzat Tokdemir - Istanbul Technical University
"Determining The Factors Causing Rework in Turkish Construction Industry"
Eda Nur Erdem, Gülden Gümüşburun Ayalp - Adana Alparslan Türkeş Science and Technology University
"Inclusion and Gender Equality for Women in the Construction Industry"
Elif Kılıç, Fatma Pınar Irlayıcı Çakmak - Istanbul Technical University
"Procurement Phases in EPC Projects: A Bibliometric Analysis"
Hasan Utku Uygun, Zeynep Işık - Yıldız Technical University

11:00 - 12:00

Chair: Assoc. Prof. Dr. Onur Behzat Tokdemir

CONSTRUCTION MANAGEMENT

Construction Project Management

"The Role of Cloud-Based Construction Management Software in Enhancing Project Efficiency"
Hazal Tokdemir, Deniz Artan - Istanbul Technical University

IT in Construction

"Assessing the Level of Digitalization of Construction Permit Processes in Türkiye" Gamze Nur İşeri Çetin, Esin Ergen Pehlevan - Istanbul Technical University

Sustainability in Construction

"Industrialisation of Natural Building Materials for Sustainability in the Built Environment"
Merve Guven, Deniz Artan - Istanbul Technical University
"Circular Economy Performance Assessment In Construction: A Critical Review Of Firm-Level Models"
Mohammed Alhallaq, Deniz Artan - Istanbul Technical University

---

13:00 - 14:00

Chair: Asst. Prof. Dr. Ömer Tuğrul Turan

STRUCTURAL ENGINEERING

Steel Structures

"Seismic Performance of Gravity Frames with Flush End-Plate Beam-to-Column Connections"
Alper Demir, Cüneyt Vatansever - Istanbul Technical University
"Effect of initial imperfections in short link beams on frame behavior"
Bünyamin Mutlu, Cüneyt Vatansever - Istanbul Technical University
"Blast-Resistant Steel Modular Structures Design with the Comparison of Dynamic Analysis Methods: SDOF and MDOF Systems"
Nur Doger, Barlas Ozden Cağlayan - Istanbul Technical University

Structural Damages

"Vibration Fatigue-Based Optimization of Open Hole Design in Stiffened Panels "
Görkem Aşçı - Istanbul Technical University

14:00 - 15:00

Chair: Assoc. Prof. Dr. Murat Yılmaz

STRUCTURAL ENGINEERING

Finite Element Methods

"Finite Element Analysis of Symmetrical Laminated Sandwich Plates with Stress Singularities Using Gradient Elasticity Theory"
Azir Mert Yavuz, Ülkü Hülya Çalık Karaköse - Istanbul Technical University
"Effect of Strut Shape and Relative Density on the Homogenized Material Properties and Anisotropy of Octet Truss Unit Cell"
Soheil Gholibeygi, Hale Ergün,Bahar Ayhan- Istanbul Technical University
"Artificial Intelligence Based Surrogate Models for Stiffened Plate Buckling Analysis"
Hasan Kıyık, Metin Orhan Kaya - Istanbul Technical University

Bridges

"Investigation of the Effects of Vibration Dampers Positioned on Hanger Cables of an Existing Suspension Bridge"
Muhammed Emin Demir, Kadir Özakgül - Istanbul Technical University

---

15:00 - 16:00

Chair: Assoc. Prof. Dr. Enes Zengin

STRUCTURAL ENGINEERING

Reinforced Concrete Structures

"A Preliminary Comparison of Turkish Seismic Design Code and the Draft Seismic Design Communiqué based on the Outputs of Structural Analyses of Mid-Rise RC Buildings"
Halit Emre Uygun, Çağlar Göksu Akkaya, Alper İlki - Istanbul Technical University
"Using Parametric Design Software to Optimize Hyperbolic Paraboloid Reinforced Concrete Shells in an Example Model"
İzel Ece Yılmaz, Kutlu Darılmaz - Istanbul Technical University
"Effect of Elevated Temperature on the Compressive Behavior of PET FRP Confined Low Strength Concrete Columns"
Mirsaeid Razavi, Birdal Koçak, Medine Işpir Arslan, Korhan Deniz Dalgıç , Alper İlki - Istanbul Technical University
"Effects Of Using Waste Glass Powder And Rice Husk Ash As A Partial Replacement With Cement In Mortar Productions"
Mohamad Alaa Shurbaji, Özgür Ekincioğlu - Istanbul Technical University

---

17:00 - 18:00

Chair: Assoc. Prof. Dr. Enes Zengin

STRUCTURAL ENGINEERING

Seismic Performance

"Seismic Performance Evaluation and Comparison of Different Structural Systems Using Nonlinear Time History Analysis"
Volkan İygen, Konuralp Girgin - Istanbul Technical University

HYDRAULICS AND WATER RESOURCES ENGINEERING

Hydrology

"Spatio-Temporal Analysis of Long-Term Rainfall Erosivity Trends and Climate Impacts on Erosion Potential"
Ahmet Faruk İpek, Ercan Kahya - Istanbul Technical University

GEOLOGICAL ENGINEERING

Rock Mechanics

"Detachments Induced By Thermal Cycling At Grain Boundaries of Fine Grained Marble"
Dilek Karapınar, Yılmaz Mahmutoğlu, Orhan Apaydın - Istanbul Technical University

13.05.2025 | TUESDAY | ONLINE

HALL - V

09:00 - 10:00

Chair: Prof. Dr. Üner Çolak

ENERGY SCIENCE AND TECHNOLOGY

Computational Heat and Mass Transfer

"A State-of-Charge Based Experimental and Numerical Investigation of Li-Ion Battery Heat Generation and Temperature Distribution"
Barış Işıklar, Ceyda Kök, Nergiz Gürbüz Karslıoğlu, Hasan Celal Malkoç, Sevan Karabetoğlu, Senem Şentürk Lüle, Rahim Jafari, Tuba Okutucu Özyurt - Istanbul Technical University

"Numerical Investigation of Engine Cooling Using Nanofluids"
Metehan Duman, Tuba Okutucu Özyurt, Zafer Dursunkaya - Istanbul Technical University

"Electrochemical and Thermal Modeling of Lithium Batteries for Temperature Distribution Based on Cathode Materials"
Sıdıka Vişne, Tuba Okutucu Özyurt, Sevan Karabetoğlu, Rahim Jafari - Istanbul Technical University

"Flow Control and Thermal Behavior of Bearings Using a Proportional Valve in a Closed-Loop Lubrication System for Turbofan Engines"
Yasin İnce, İlhan Kocaarslan - Istanbul Technical University

10:00 - 11:00

Chair: Asst. Prof. Dr. Sevan Karabetoğlu

ENERGY SCIENCE AND TECHNOLOGY

Energy Conversion and Storage Technologies

"Sustainable GSM Base Station Energizing Using Portable Radioisotope Thermoelectric Generator (RTG) Design"
Erdem Hayat, İskender Atilla Reyhancan - Istanbul Technical University

"The Lifespan Comparison of an NMC811 Pouch Cell Based High Voltage Battery with Silicon and Polyurethane Foam Usage"
Serhat Soyer - Istanbul Technical University

Energy Conversion and Sustainability

"Multi Criteria Decision Analysis For The Selection Of Alternative Marine Fuels In The Shipping Industry"
Emre Uz- Istanbul Technical University

"Energy Efficiency Potential Analysis of SMEs In Türkiye's Fertilizer Sector"
Sude Karabağ, Ebru Acuner - Istanbul Technical University

11:00 - 12:00

Chair: Asst. Prof. Dr. Sevan Karabetoğlu, Prof. Dr. Hakan Ali Çırpan

ENERGY SCIENCE AND TECHNOLOGY

Renewable Energy

"Feasibility Assessment of Hydrogen Fuel Cell Integration in The Dornier 228 Aircraft with the Structural and Operational Considerations"
Caner İlhan, Mehmet Suha Yazıcı - Istanbul Technical University

Sustainable Energy

"The Effect of Seawater on The Electrodecomposition of Hydrogen Sulfide to Hydrogen And Polysulfides"
Faezeh Nazari, Alper Sarioglan, Mehmet Suha Yazıcı - Istanbul Technical University

Computational Fluid Dynamics

"Numerical Investigation of Interfacial Contact Resistance in PEM Fuel Cells with Coated Metal Bipolar Plates"
Özgün Önen, Mehmet Suha Yazıcı, Dilek Kumlutaş, Utku Alp Yücekaya - Istanbul Technical University

COMMUNICATION SYSTEMS

Electrical Vehicles

"Design and Inter-Element Spacing Optimization of GNSS Array"
Muhammed Yusuf Şahin, Meave Kartal - Istanbul Technical University

---

13:00 - 14:00

Chair: Assoc. Prof. Dr. Onur Ferhanoğlu

ELECTRONICS AND COMMUNICATION ENGINEERING

Bio-Medical, Bio-Inspired Circuits/Systems

"Customizable Fluidic and Anisotropic Vocal Fold Phantom for Biomechanical Analysis"
Afarin Sarrafzadeh, Onur Ferhanoğlu, Ahmet C. Erten - Istanbul Technical University

"Development of Multi-Capsule Endoscopy via Spring-Assisted Distance Control"
Erfan Parsaei, Furkan Peker, Ali Fuat Ergenç, Onur Ferhanoğlu - Istanbul Technical University

"Effect of Wavelength, Intensity, and Eye Color on Pupil Detection in Infrared-Based Eye Tracking Systems" Murat Teksin, Onur Ferhanoğlu - Istanbul Technical University

"Image Reconstruction and Restoration with Diffusion Networks"
Onur Parapan, Ender Mete Ekşioğlu - Istanbul Technical University

---

14:00 - 15:00

Chair: Prof. Dr. Ece Olcay Güneş

ELECTRONICS AND COMMUNICATION ENGINEERING

Bio-Medical, Bio-Inspired Circuits/Systems

"Thermoplastic Microfluidic Platform for 3D Cell Culturingand Imaging"
Özlem Koçoğlu, Umut C. Coşkun, Berna Morova, Alper Kiraz, Kemal Baysal, Ahmet C. Erten - Istanbul Technical University

"A Deep Learning Network for Automatic Grade Classification of Renal Cell Carcinoma"

External Store Separation From Fighter Aircraft

Ahmet Kutsay Dere[a], Hayri Acar[b]

[a] Istanbul Technical University, Graduate School, Aeronautical and Astronautical Engineering Program, Turkiye
[b] Istanbul Technical University, Faculty of Aeronautics and Astronautics Department of Aeronautical Engineering, Turkiye
derea15@itu.edu.tr

Keywords: Safe Separation, Eglin Test Case, F-22, Fifth Gen Aircraft, Grid Method, Simulation.

Aim

Developing a new aircraft consists of many challenging topics including carrying and employing of stores. Aircraft must be designed to enable safe seperation of new designed or currently used stores. Designed store must be certified to demonstrate that it is suitable for effective separation. Store separation can be tested in three different ways. First one is the flight test which is highly risky for manned flight and it is expensive. Second way is wind tunnel testing which is also expensive and time consuming. The most cheapest and safest method is using store separation simulations.
The stores can be divided into two categories: bombs and missiles, and differ in their release mechanisms. The stores can be carried in internal stations or external stations which are under the wings. In this study safe separation of Eglin store geometry from a fifth generation fighter aircraft modelled and tested for different flight conditions. The ultimate goal of the fighter jet and store development projects is to hit a targeted point in the most effective way. In order to hit the target accurately, the flight conditions and the aerodynamic and inertial properties of the store must be taken into consideration and the release must be made in the most suitable position and flight conditions. An important criterion in determining the release moment is to prevent the store from collision to the aircraft during its separation. For this purpose, maneuvering the aircraft during the release moment can be a solution. A more effective one is to decide on the correct release moment with simulations to be performed before the flight.
The store examined in this study is an uncontrolled (free-falling) bomb and will be dropped from external stations (under the wing). The aim is to determine the correct release moment for the store to be safely separated from the aircraft. Also ejector force profile will be determined for safe separation.
Separation from inner stations is more challenging than separation from outer stations. Aerodynamic phenomena are more effective in separation from inner stations due to the unsteady characteristics of the flow inside the cavity. Cavity flow is not the subject of this study.

Material and Method

In this study, releases will be performed under different flight conditions using the Eglin store geometry and a generic 5th generation fighter jet (similar to the F-22 geometry)[3]. The correct release points will be determined based on the scenarios where safe separations occur. The 6-DOF model used for the simulations to be performed was verified using the Eglin test case and the verification results were given in Figure 1.
Then, the pylon and store geometries of the Eglin test case were placed under the wing of the generic fighter jet and aerodynamic analyses were performed. The aerodynamic data obtained using the grid method gives the aerodynamic effects that the store will be exposed to during separation from the aircraft. (The aerodynamic analyses obtained with the grid method used in this study were provided by TUSAS and were obtained using open-source geometries that are not subject to any restrictions. For this contribution, I would like to thank my company.)
Another force that the store will be exposed to during separation from the aircraft is the ejector forces. Due to limited data, the ejector forces given in the Eglin test case were used as ejector forces. While ejector profile of the Eglin test case is 2400-

9600 lbf on the forward and aft ejector, in this study different profile will be attempted.

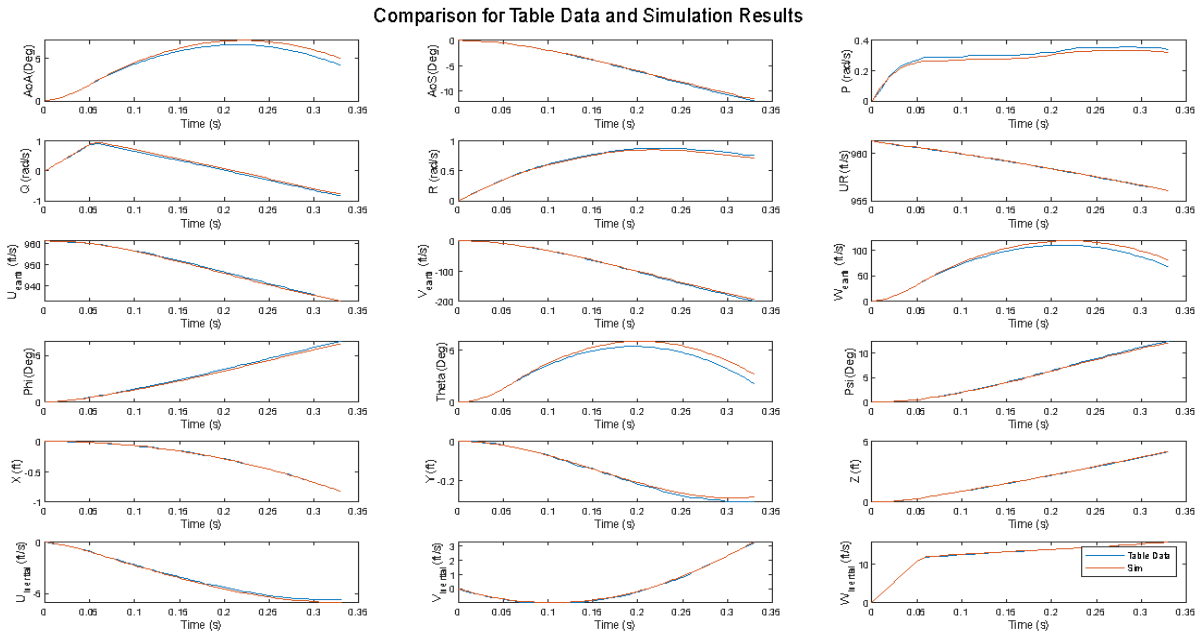

Figure 1. Comparison of simulation results and experimental CTS data on literature [2].

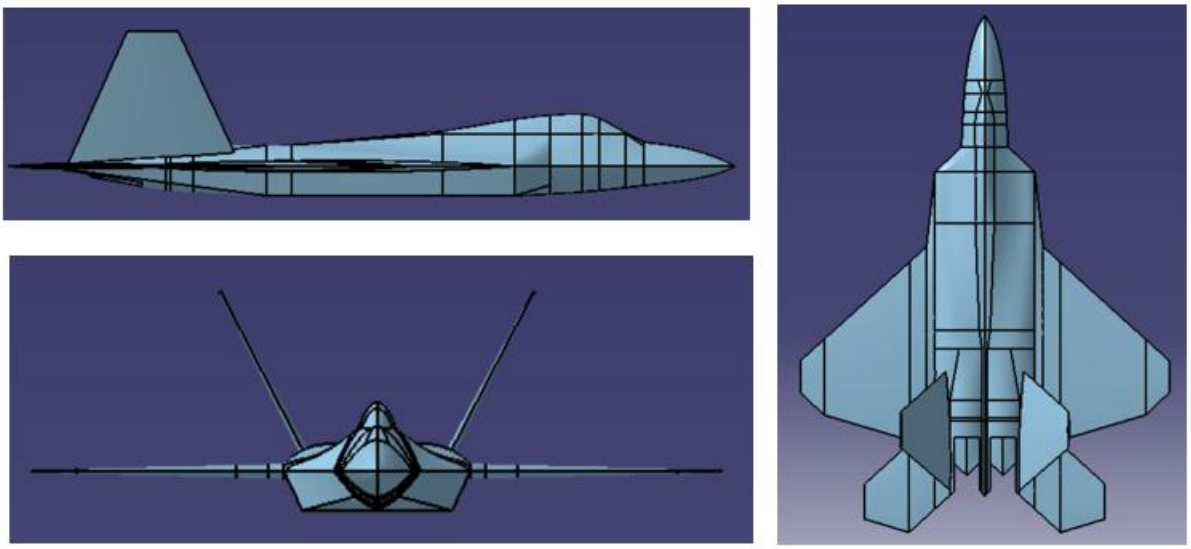

Figure 2. Fifth-Generation High-Performance Aircraft [3].

Degree Of Freedom Equations Of Motions

Store separation equations of motions are very similar to the conventional aircraft equations of motion. Equations of motion for store separation can be found in the literature. For this study equations of motions are derived by using [2].

1. Translational Kinematics

(Equation 1)
(Equation 2)

(Equation 3)

2. Rotational Kinematics

$$\dot{\phi} = p + (qsin(\phi) + rcos\phi)tan(\theta) \quad \text{(Equation 4)}$$

$$\dot{\theta} = qcos(\phi) - rsin(\phi)$$

$$\dot{\psi} = (qsin(\phi) + rcos(\phi))sec(\theta) \cdot \cos(\psi)\sin(\phi)\sin(\theta)) + w(\sin(\phi)\sin(\psi) + \cos(\phi)\cos(\psi)\sin(\theta))$$

$$\dot{y} = v(\cos(\phi)\cos(\psi) + \sin(\phi)\sin(\psi)\sin(\theta)) - w(\cos(\psi)\sin(\phi) - \cos(\phi)\sin(\psi)\sin(\theta)) + u\cos(\theta)\sin(\psi) \quad \text{(Equation 5)}$$

$$\dot{z} = w\cos(\phi)\cos(\theta) - usin(\theta) + v\cos(\theta)sin(\phi) \quad \text{(Equation 6)}$$

3. Translational Kinematics

$$\dot{u} = F_x/m \ - gsin(\theta) - qw + rv \quad \text{(Equation 7)}$$

$$\dot{v} = F_y/m \ + pw - ru \ + gcos(\theta)sin(\phi) \quad \text{(Equation 8)}$$

$$\dot{w} = F_z/m \ - pv + qu \ + gcos(\phi)cos(\theta) \quad \text{(Equation 9)}$$

4. Rotational Dynamics

$$\dot{p} = (I_{xx}I_{zz} - I_{xz}^2)^{-1}[\mathrm{I_{xz}M_z} + \mathrm{I_{zz}M_x} + (\mathrm{I_{yy}I_{zz}} - \mathrm{I_{xz}^2} - \mathrm{I_{zz}^2})\mathrm{qr} + (\mathrm{I_{xx}I_{xz}} - \mathrm{I_{xz}I_{yy}} + \mathrm{I_{xz}I_{zz}})\mathrm{pq}] \quad \text{(Equation 10}$$

$$\dot{q} = I_{yy}^{-1}[M_y - I_{xz}p^2 + I_{xz}r^2 - I_{xx}pr + I_{zz}pr] \quad \text{(Equation 11)}$$

$$\dot{r} = (I_{xx}I_{zz} - I_{xz}^2)^{-1}[I_{xz}M_x + I_{xx}M_z + (I_{xz}I_{yy} - I_{xx}I_{xz} - I_{xz}I_{zz})qr + (I_{xx}^2 + I_{xz}^2 - I_{xx}I_{yy})pq] \quad \text{(Equation 12)}$$

Findings

The separation analysis was performed under the conditions shown in the Table 1 and the effect of the application rates of the ejector forces on the separation analysis was investigated. The results given in the literature [3] give a ratio of 1/4 (2400-9600 lbf) between the forward and aftward ejector forces. It should be noted that this ratio may change since the Eglin pylon and store geometries were installed on another aircraft in this study.

Table 1. Performed Store Separation Conditions.

Mach	Altitude (kft)	Ejector Profile 1	Ejector Profile 2	Ejector Profile 3
0.8	10-20-30	9600-4800 lbf	4800-4800 lbf	4800-9600 lbf

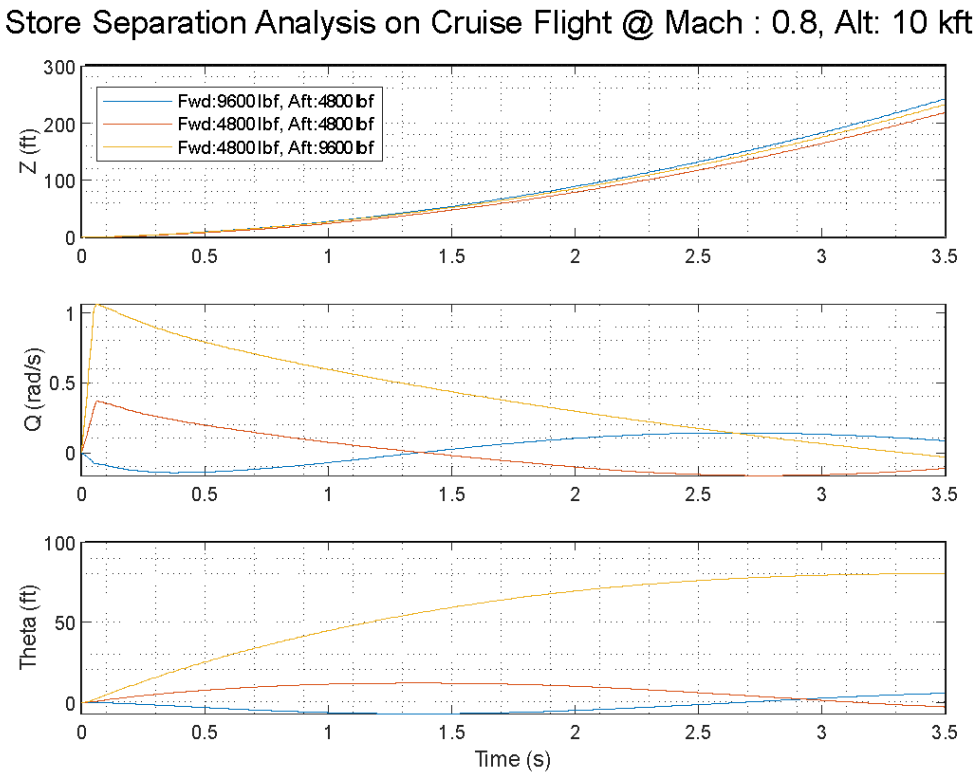

Figure 4. Store Separation Analysis Result on Mach: 0.8, Alt: 10 kft.

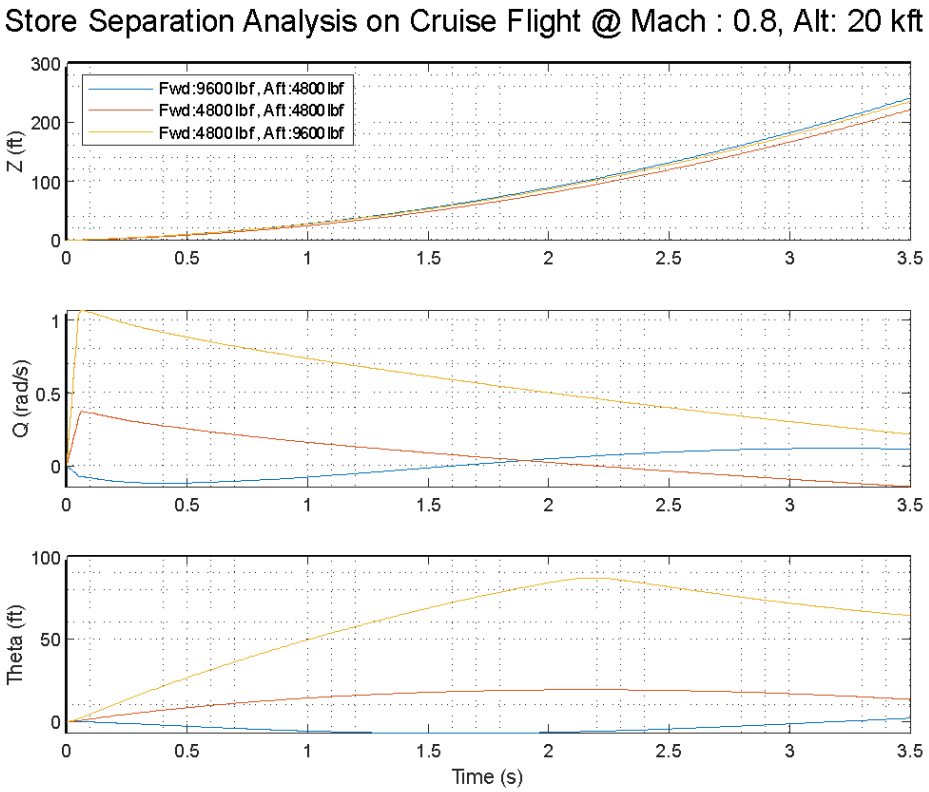

Figure 5. Store Separation Analysis Result on Mach: 0.8, Alt: 20 kft.

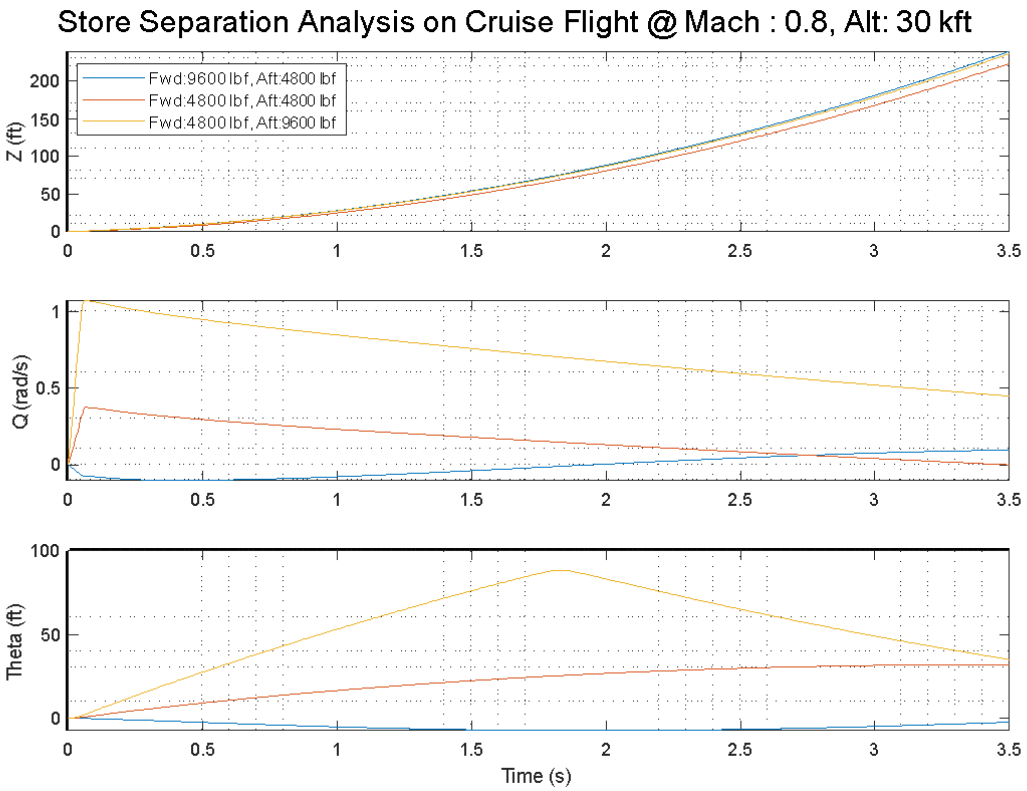

Figure 6. Store Separation Analysis Result on Mach: 0.8, Alt: 30 kft.

Conclusion

In order to test whether the separation was carried out safely, it was decided that the store should not make a pitch up moment until a certain altitude change. This altitude change was determined to be approximately 50 ft (15 m). When the figures above are examined, it is seen that the store reaches the safe distance in approximately 1.5 seconds. When ejector profile 1 is applied for all 3 altitudes, it is seen that the store has a pitch down moment up to 1.5 seconds and the pitch angle is negative. For ejector profile 2 and ejector profile 3, it is seen that it makes a pitch up before 1.5 seconds and the pitch angle is positive. Based on these results, it was decided that the ejector profile to be applied should be ejector profile 1.

Keywords: HGV, Trajectory Optimization, Sensitivity Analysis.

Aim

Hypersonic glide vehicles (HGVs) are aerial vehicles which glide at hypersonic speeds toward their destination after being launched by a rocket into extreme velocities and high altitudes. HGVs have attracted significant interest both in the military field (e.g., strategic strike weapons) and in civilian applications (e.g., intercontinental passenger or cargo transport). However, HGVs' extremely high speeds and complex, unpredictable aerodynamic environments make sensitivity analysis critical, especially for parameters such as heat transfer rate, dynamic pressure, and load factor. These quantities are highly sensitive to variations in aerodynamic coefficients and atmospheric conditions, significantly affecting performance, vehicle safety, and structural integrity. These sensitivities necessitate statistical analysis for mission-level reliability. In this study, sensitivity of the main parameters of HGVs (flight time, terminal velocity, maximum heat flux, maximum dynamic pressure) for the uncertainties of aerodynamic coefficients and environmental parameters are investigated. A Monte Carlo-based statistical analysis is conducted to evaluate the influence of these uncertainties on trajectory performance and to highlight the most critical parameters for robust design considerations.

Hypersonic glide vehicles (HGVs) are primarily accelerated to high speeds and to space by boosters after that the booster is released. Then the HGV re-entries into the atmosphere and glides through the desired destination while satisfying the constraints and accomplishing mission requirements. In the gliding phase these vehicles have speeds around Mach 5-20 which causes extreme heat transfer rates and structural loads. Moreover, the effects of extreme shock waves, plasma formation, and ionization of air causes severe uncertainties in the aerodynamic coefficients and atmospheric parameters (Lampis, 2024). Therefore, it is critical to analyze the effect of these uncertainties on trajectory parameters, structural and thermal loads. The aim of this study is to analyze the sensitivity of hypersonic glide vehicle trajectory parameters (range, flight time, heat transfer exposure, dynamical pressure etc.) to the changes, uncertainties in the aerodynamic coefficients (lift, drag coefficients) and atmospheric uncertainties (density, temperature). Moreover, to provide a statistical representation of deviations in trajectory, identifying the most influential uncertainty sources on flight time, altitude, range, thermal loads and structural loads. The results are beneficial to be used in robust trajectory optimization strategies.

Material and Method

In this study to evaluate the uncertainties in aerodynamic coefficients and atmospheric properties on the HGV dynamics, a 3-DoF dynamic model of a HGV used together with a trajectory optimization tool. The state variables for 3-DoF dynamic model are latitude (φ), longitude (λ), and altitude (h), and the control inputs are angle of attack (α) and bank angle (σ). The equations of motion are given below (Zhou et al. 2019).

$$\frac{dr}{dt} = V sin\gamma$$

$$\frac{d\theta}{dt} = \frac{V cos\gamma sin\psi}{r cos\phi}$$

$$\frac{d\phi}{dt} = \frac{V cos\gamma cos\psi}{r}$$

$$\frac{dV}{dt} = -\frac{D}{m} - gsin\gamma$$

$$\frac{d\gamma}{dt} = \frac{1}{V}[\frac{Lcos\sigma}{m} + \left(\frac{V^2}{r} - g\right)cos\gamma]$$

$$\frac{d\psi}{dt} = \frac{1}{V}[\frac{Lsin\sigma}{mcos\gamma} + \frac{V^2}{r}cos\gamma sin\psi tan\phi]$$

Where r is the distance from the center of the Earth to the vehicle, θ is the latitude angle, ϕ is the azimuth angle, V is the magnitude of velocity, D is drag force, L is lift force, γ is flight path angle, ψ is the heading angle, σ is the bank angle, g is the gravity constant and m is mass of HGV. For trajectory optimization, the angle of attack and bank angle are used as control inputs. Even though, angle of attack does not exist in the equations of motion, it affects the lift and drag forces since the lift and drag coefficients are functions of angle of attack. The definition of aerodynamic forces is given below.

$$L = \frac{1}{2}\rho V^2 S_{ref} C_L(\alpha, M)$$

$$D = \frac{1}{2}\rho V^2 S_{ref} C_D(\alpha, M)$$

The mass, reference area, C_L and C_D coefficients are dependent on the vehicle geometry. The geometry used in the analysis is CAV-H. The physical parameters for CAV-H are given in Table 1.

Table 1. Physical Parameters of CAV-H adopted from Duan et al. (2010).

Parameter	Unit	Value
Diameter/Width	(m)	1.2192
Weight	(kg)	907.2
Reference Area	(m²)	0.4839

The lift and drag coefficient of CAV-L is modeled as a function of angle of attack and Mach (Duan et al., 2010). The relations are given below.

$$C_L = C_{L1}\alpha + C_{L2}\ exp\ exp\ (C_{L3}M)\ + C_{L0}$$

$$C_{L1} = 0.0513, C_{L2} = 0.2945, C_{L3} = -0.1028, C_{L0} = -0.2317$$

$$C_D = C_{D1}\alpha^2 + C_{D2}\ exp\ exp\ (C_{D3}M)\ + C_{D0}$$

$$C_{D1} = 7.24e-4, C_{D2} = 0.406, C_{D3} = -0.323, C_{D0} = 0.024$$

Where C_L is lift coefficient, and C_D is drag coefficient. The atmosphere model used in analysis is COESA standard atmosphere model, and the gravitational acceleration is assumed to be constant and equal to 9.81 m/s^2.

To obtain an optimal trajectory, the Sequential Convex Programming (SCP) method is applied because this method is capable of obtaining feasible solutions even when the initial trajectory and control input guesses are inaccurate (Malyuta et al. 2022). By this approach, the originally non-convex trajectory optimization problem is converted into a series of convex subproblems to obtain a solution. The SCP method iteratively solves convex approximations of the non-convex problem until convergence is reached.

To analyze the effects of atmospheric uncertainties, a Monte-Carlo simulation framework is implemented. Uncertainty is introduced in C_L, C_D and density. The nominal values are multiplied by a gain which is determined using gaussian distributions. Used distributions are given in Table 2. 400 simulations are completed for the same mission and according to the resultant trajectories of these simulations the heat transfer rate, dynamic pressure, normal accelerations, maximum

altitude and flight time are obtained. Then the effect of C_L, C_D and density on these parameters are compared, analyzed and statistically evaluated.

Table 2. Distributions in C_L, C_D and Density.

Parameter	Range	Distribution
Density	±%10	Gaussian [1σ=%3]
C_D	±%30	Gaussian [1σ=%10]
C_L	±%30	Gaussian [1σ=%10]

Findings

400 Monte-Carlo simulations with perturbations on CL, CD and density are completed using the mission stated in Table 3. For all the simulations the flight time is minimized when satisfying the given final conditions. The resultant states are presented in Figure 1. As can be seen most trajectories closely follow the nominal (red) path, maintaining feasibility throughout the glide phase. Velocity generally decreases smoothly with time and the altitude profiles varies. In some cases, jumps in the altitude profiles are observed, however mostly the altitude decreased with a stable flight path angle. To further examine how variations in aerodynamic coefficients affect trajectory feasibility, Figure 2 illustrates the distribution of feasible and non-feasible (final conditions could not be satisfied) simulations in the CD–CL parameter space. This visualization enables a clearer understanding of which combinations of lift and drag gains lead to mission failure, offering insight into the bounds of aerodynamic robustness for the vehicle. According to this graph, over 85% of the simulations resulted in feasible trajectories, indicating strong robustness under moderate variations in aerodynamic parameters. Infeasibility arises predominantly in cases with low CL and high CD, due to insufficient lift and excessive drag, preventing the vehicle from reaching the desired range. Conversely, high CL with low CD can lead to insufficient energy dissipation during flight, preventing the vehicle from descending effectively and reaching the destination altitude.

Table 3. Mission Boundary Conditions and Objective.

Parameter	Value
Initial Altitude	60 km
Initial Latitude	0 deg
Initial Longitude	0 deg
Initial Velocity	6000 m/s
Initial Flight-Path Angle	-2 deg
Initial Heading Angle	0 deg
Final Altitude	Sea Level
Final Latitude	12 deg
Final Longitude	75 deg
Objective	Minimize Time

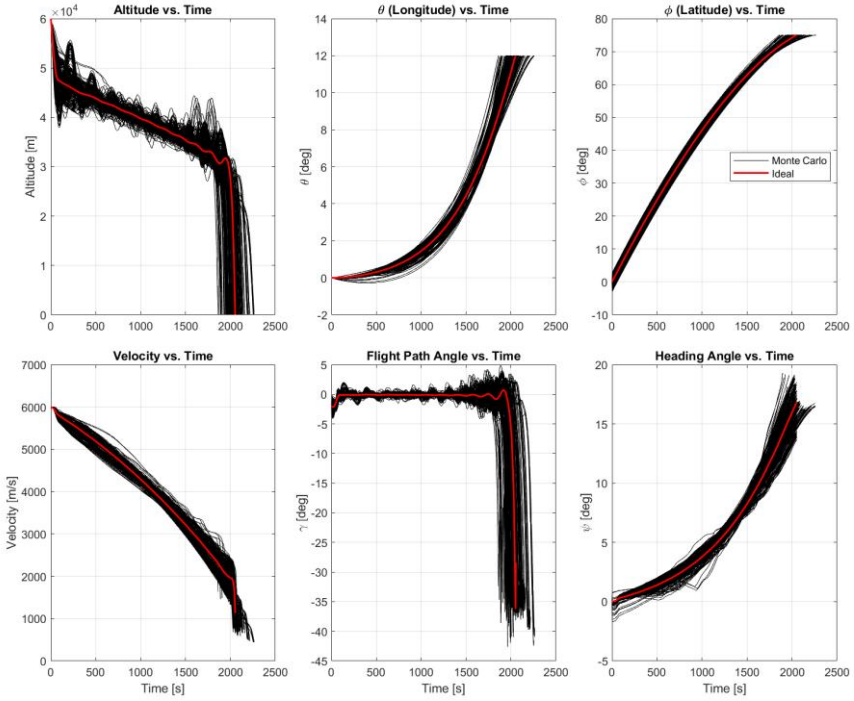

Figure 1. Monte-Carlo Trajectory Results.

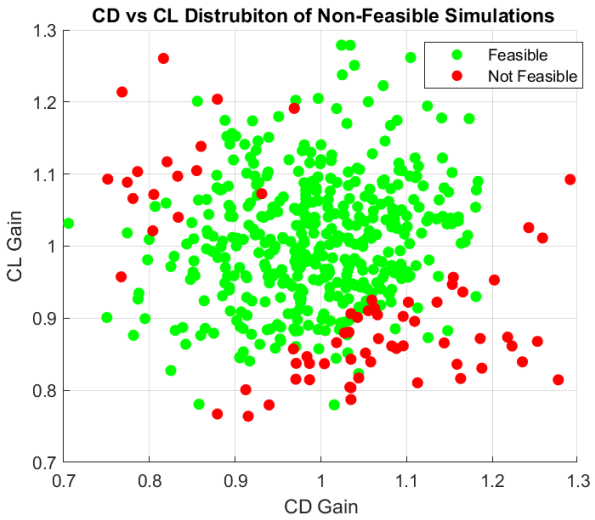

Figure 2. Effect of Aerodynamic Perturbations on Feasibility.

After determining the effect of perturbations on feasibility, the effect of perturbations on flight time, terminal velocity, maximum heat flux and maximum dynamic pressure (above 20 km) are obtained. The effect of perturbations on flight time and terminal velocity are given in ***Figure 3***-***Figure 4*** and the effect of perturbations on heat flux and dynamic pressure are given in ***Figure 5***. In the figures, the x-axis represents the gain applied to each respective parameter, and the y axis represents the value of the parameter which was examined for sensitivity analysis. Each dot represents one simulation, and the black dashed lines show the linear trend (fit) across all simulations for each parameter. According to these results, for flight time it is noteworthy that increasing lift (CL) and density (ρ) tends to reduce final time by enabling more control in trajectory. On the other hand, changes in drag (CD) have an insignificant impact on flight time. Final velocity is strongly influenced

by aerodynamic coefficients, higher CD leads to greater deceleration and lower final speeds, while higher CL helps the vehicle maintain altitude and speed, resulting in higher final velocities. Increased atmospheric density (ρ) also slightly increases final velocity due to greater dynamic pressure enhancing lift generation. Maximum heat flux is most sensitive to the drag coefficient CD, as CD increases the vehicle decelerates rapidly, leading to lower velocities and consequently reduced heat flux. Moreover, a slight downward trend with increasing CL is observed, due to improved altitude control which reduces exposure to denser atmospheric layers. Atmospheric density (ρ) shows a minimal effect on maximum heat flux, indicating that aerodynamic properties dominate heat flux variation for this scenario. Lastly for the dynamic pressures above 20 km, higher CD values lead to significantly lower maximum dynamic pressures due to earlier deceleration in less-dense atmospheric layers. Conversely, increasing CL and ρ both correlate with higher maximum dynamic pressures, due to decreased energy dissipation.

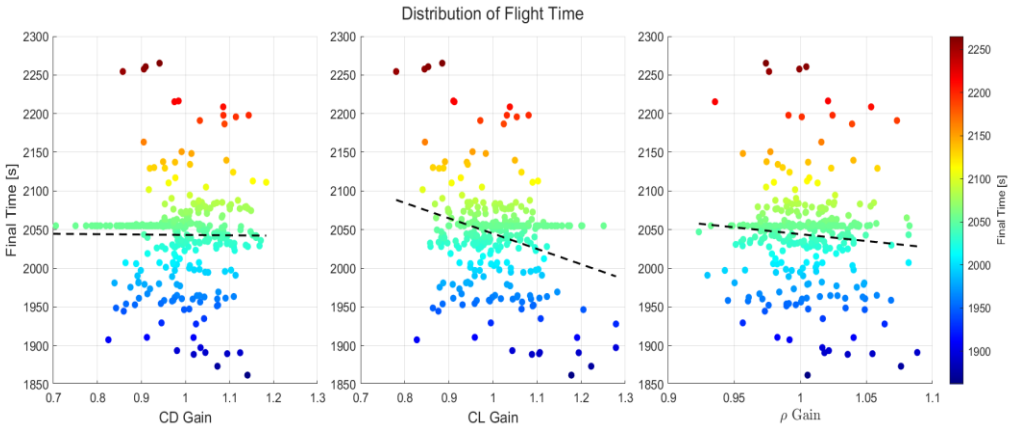

Figure 3. Effect of Perturbations on Flight Time.

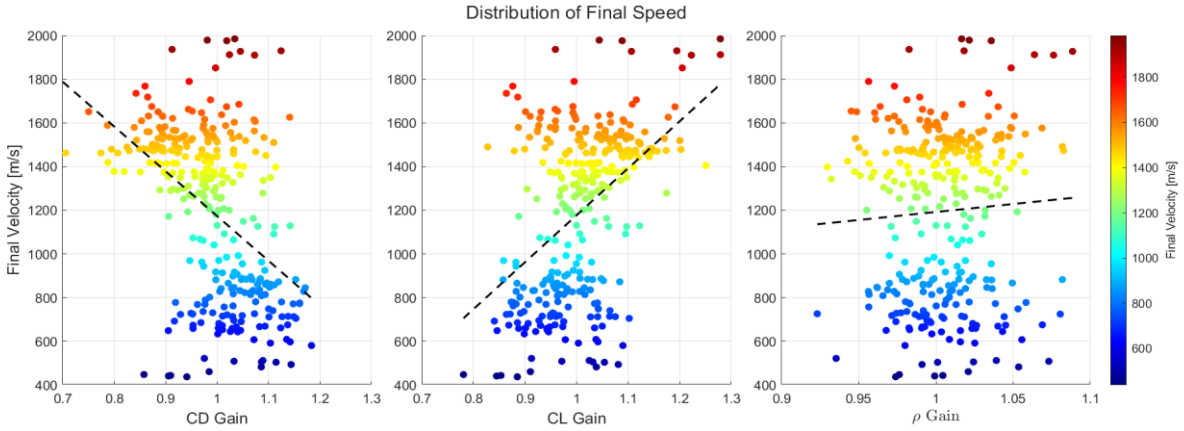

Figure 4. Effect of Perturbations on Terminal Speed.

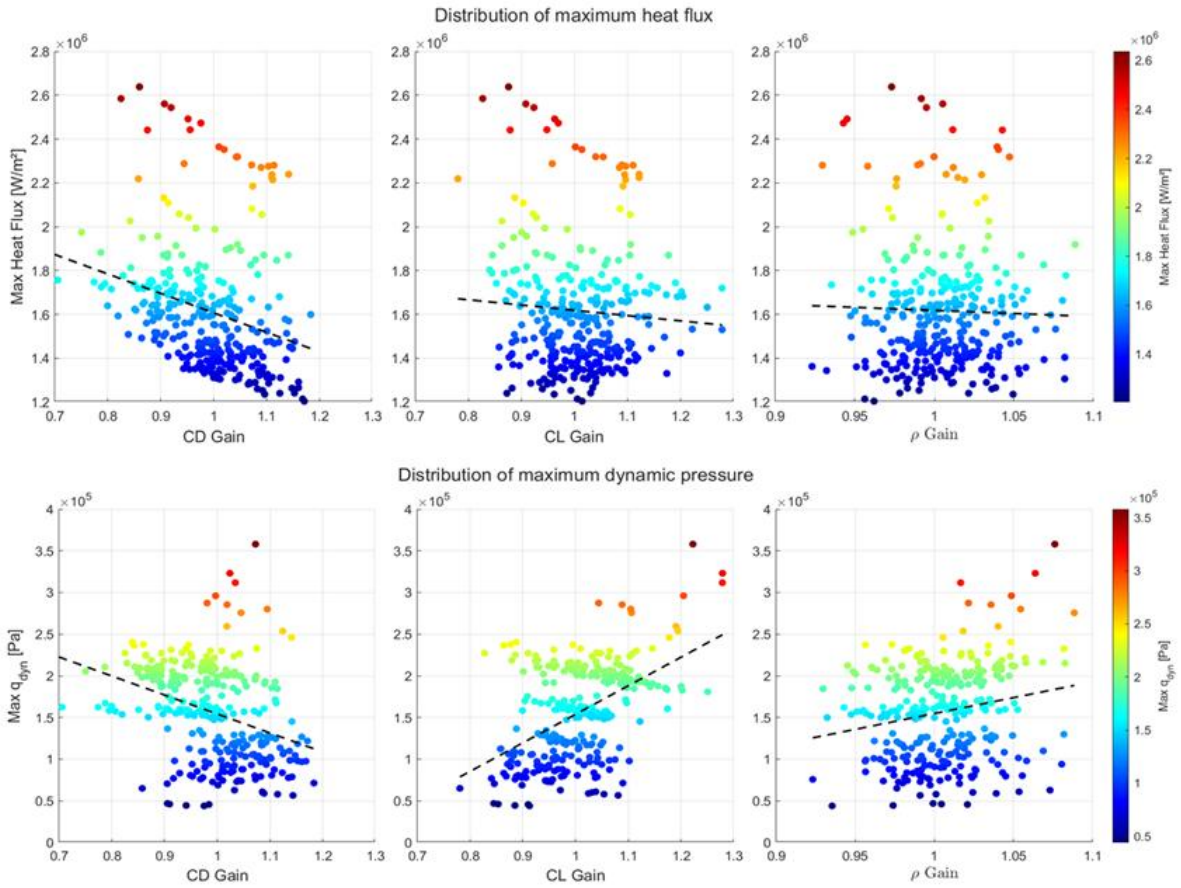

Figure 5. Effect of Perturbations on Dynamic Pressure (Above 20 km) and Maximum Heat Flux.

Conclusion

Sensitivity analysis on the trajectory performance of a hypersonic glide vehicle (HGV) under parametric uncertainties in aerodynamic coefficients and atmospheric density is performed. A total of 400 Monte Carlo simulations were conducted by perturbing drag coefficient (CD), lift coefficient (CL), and atmospheric density (ρ) to assess their impact on key performance indicators such as flight time, final velocity and heat flux, and dynamic pressure. Results demonstrate that approximately 85% of the simulations remained feasible under uncertainty. Infeasible cases were mainly concentrated in scenarios with low CL and high CD—leading to insufficient range—or with excessively high CL and low CD, which hindered energy dissipation and descent. Among the perturbed parameters, CL and ρ had the most significant influence on flight time and thermal loads, while CD showed a relatively minor effect on timing but contributed notably to the reduction of heat flux and dynamic pressure due to earlier deceleration. Maximum heat flux and dynamic pressure distributions reveal that increasing CD reduces aerodynamic loads effectively, whereas increased CL and ρ lead to higher thermal and structural stress. These findings highlight the critical importance of accounting for aerodynamic and environmental uncertainties in trajectory planning and provide guidance for future robust optimization strategies in hypersonic vehicle design.

Keywords: Optimization, Tornado VLM, Winglet Design.

Aim

This study has been conducted to design, optimize, and analyze the performance of winglets for the MFI-395 Super Mushshak military training aircraft, which is recorded in the inventory of the Turkish Air Force. The primary objective of the study is to enhance aerodynamic efficiency, reduce drag, and improve overall flight performance of the aircraft. Within the scope of the research, an optimized winglet design will be developed using a computational method Vortex Lattice Method (VLM). Additionally, the impact of different winglet configurations on aircraft performance parameters has been evaluated.

Material and Method

Winglets are aerodynamic surfaces installed at the wingtips of fixed-wing aircraft to reduce induced drag (D_i) caused by wingtip vortices. By mitigating these vortices, winglets increase lift-to-drag ratio, improve fuel efficiency, increase range, and contribute to lower emissions, making them crucial for both economic and environmental performance. The main geometric parameters considered in winglet design are winglet length, cant angle, toe angle, sweep angle, and taper ratio. The parameters are illustrated schematically in Figure 1 [1].

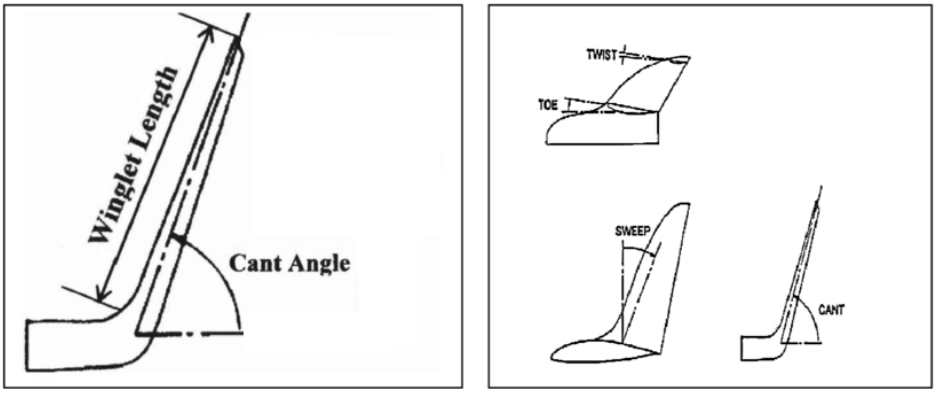

Figure 1. Winglet geometry parameters.

MFI-395 Super Mushshak has been derived from MFI-17 Mushshak military trainer aircraft; however, main updates have been made in engine performance, avionics systems, and missile integration systems [2]. Therefore, geometric properties have been obtained from MFI-17 Mushshak due to data accessibility considerations. The aircraft has a wingspan of 8.85m, root chord length of 1.5m, taper ratio of 1, negative sweep angle of 5°, incidence angle of 0°, dihedral angle of 0° and twist angle of 0° [3]. Main wing airfoil of the aircraft is "NACA23012MOD" with thickness ratio of 10% [4]. The airfoil has been illisturated in Figure 2.

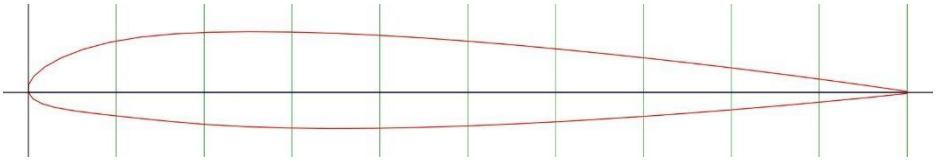

Figure 2. NACA23012MOD airfoil.

In this study, the Vortex Lattice Method (VLM) has been preferred due to its efficient, low-order computational analysis, which makes it both quick and cost-effective. It has been widely used in aerodynamic modeling, offering advantages in design optimization and multi-objective studies. Compared to conventional CFD, VLM is faster, cheaper, and ideal for preliminary aerodynamic analysis [5]. Tornado VLM, which is an open-source code implemented in MATLAB and developed by Tomas Melin, has been used for winglet performance analysis [6]. Tornado VLM code has a user-friendly interface. The code prompts the user for the geometry parameters, sends them to the solution function and presents the results to the user as tables and graphs in separate pop-up windows.

Before the winglet design studies, the main wing geometry without winglet has been analyzed using the Tornado VLM code. The results of this analysis are presented in Table 1. All analyses have been conducted under the MFI-17 Mushshak cruise flight conditions, corresponding to a speed of 210 km/h and an altitude of 4100 meters [3]. The angle of attack was set to 6° to ensure sufficient lift generation during cruise. Winglet optimization studies have been carried out based on these results.

Table 1. Main wing results.

Lift Force (N)	Induced Drag Force (N)	Lift Coefficient (C_L)	Induced Drag Coefficient (C_{Di})	L/D_i
9237	255	0.5105	0.0141	36.21

The geometry of the wing without winglet is illustrated in Figure 3.

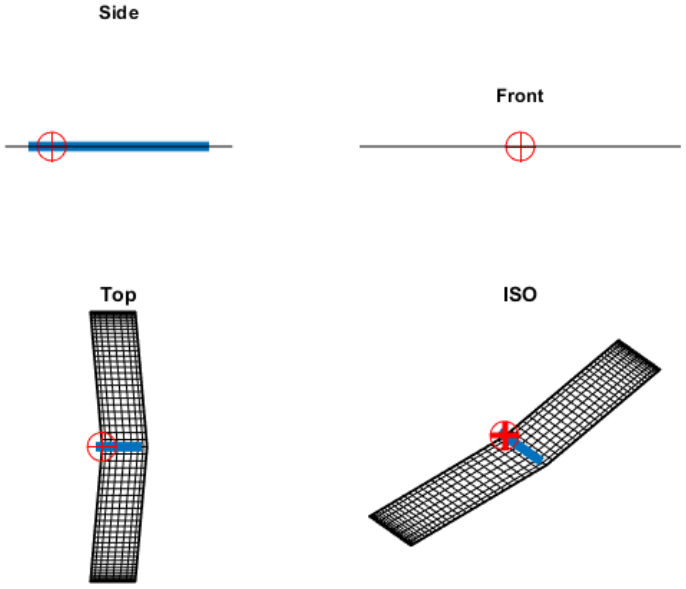

Figure 3. Main wing geometry.

The Tornado VLM code has a user interface. The code prompts the user for the geometry parameters. To accelerate the winglet analysis process, the Tornado VLM code has been modified and automated. The functions within the code have

been regenerated, and all the input functions have been removed. This modification has been made it possible to computationally generate results by varying the winglet parameters within the desired ranges. In this study, toe and twist angles have been assumed to be zero, and the other parameters along with their value ranges have been specified in Table 2. The airfoil of the winglet has been assumed to be the same as that of the main wing, "NACA23012MOD".

Table 2. Winglet geometry parameters.

Parameters	Lower Limit	Upper Limit	Step Size
Cant Agle (deg)	0	90	10
Length (m)	0.1	1	0.1
Sweep Angle (deg)	0	60	10
Taper Ratio	0.1	1	0.1

To obtain consistent and realistic results in VLM, it is required to determine the number of panels both for the main wing and the winglet. The number of panels in the Vortex Lattice Method strongly affects aerodynamic accuracy; higher panel density improves flow representation but increases computational cost [7]. The code has been run multiple times with different panel configurations, and the results have been analyzed. The most consistent panel configuration, considering computational cost, with minimal data noise has been identified and presented in Table 3. Panel distributions of the main wing and the winglet are shown in figure 3 and figure 4.

Table 3. Panel configuration.

Wing Section	Chordwise Panel	Spanwise
Main Wing	10	30
Winglet	10	5

Findings

The results have been exported to Excel and analyzed. Many winglet configurations in which the lift-to-induced drag ratio increases have been identified in the analysis results. In most of the configurations, the improvement in the lift-to-induced drag ratio has been attributed to an increase in lift rather than a reduction in induced drag. Therefore, it has been necessary to apply filtering to the analysis results. In this context, based on the main wing analysis results presented in Table 1, The primary objective of this study is to reduce the induced drag force. Significant increases in lift are not desired; however, increases comparable to the approximate structural weight added by the winglets are considered acceptable. Based on the analysis results, the top three most efficient winglet configurations have been identified and shown in Table 4.

Table 4. Winglet optimization results.

Cant Angle (deg)	Length (m)	Sweep Angle (deg)	Taper Ratio	L (N)	D_i (N)	C_L	C_{Di}	L/D_i	Increment of L/D_i (%)
0	0.3	20	0.3	9327	225	0.5154	0.0124	41.45	14.46
0	0.4	50	0.4	9412	232	0.5201	0.0128	40.59	12.10
0	0.3	50	0.1	9320	231	0.5151	0.0128	40.29	11.27

According to the results, the most efficient winglet configurations have the cant angle of zero. It has been observed that an increase in winglet length leads to a higher lift force. The wing geometry with the highest lift-to-drag ratio is illustrated in Figure 4. This configuration enables 14.46% improvement in the aerodynamic efficiency of the wing.

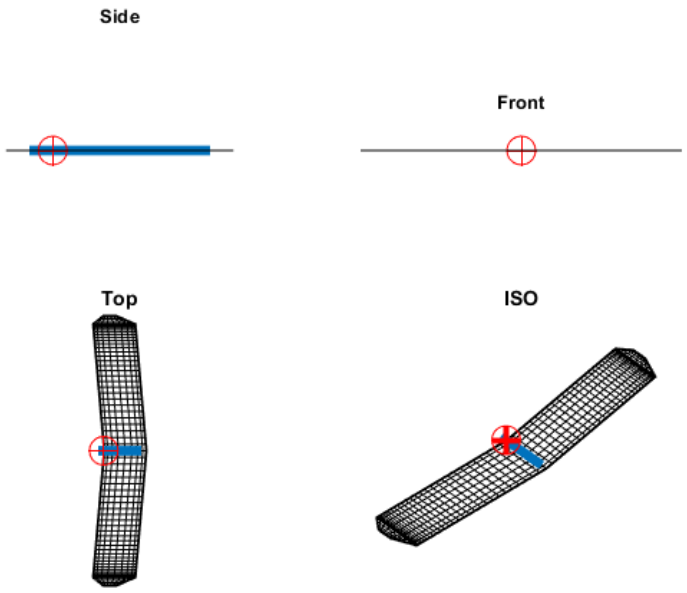

Figure 4. The most efficient winglet configure.

Conclusion

In this study, winglets have been designed, optimized, and analyzed for the MFI-395 Super Mushshak military trainer aircraft in order to improve its aerodynamic performance. The main objective has been to reduce induced drag and increase the lift-to-drag ratio (L/D), contributing to more efficient flight. Various winglet configurations have been tested using the Vortex Lattice Method (VLM), and their impacts on performance have been evaluated. It has been observed that several configurations have provided significant improvements in aerodynamic efficiency. The most efficient design has achieved

a 14.46% increase in L/D_i ratio. Winglets with a cant angle of 0°, short length, and specific sweep angles have been found to be the most effective. The results have demonstrated that well-optimized winglets can lead to enhanced flight performance, reduced fuel consumption, extended range, and lower environmental impact. The potential of winglet applications on trainer aircraft like the MFI-395 has been clearly shown.

Future work may focus on experimental validation, further refinement using high-fidelity CFD methods or wind tunnel testing and exploring additional improvements through detailed aerodynamic studies.

Quadrotor Actuator Fault Detection and Isolation- A Model Based Approach

Muhammed Arslan[a], Gokhan Inalhan[a]

[a] Istanbul Technical University, Aerospace Department, Aerospace, Turkey
darwish16@itu.edu.tr

Keywords: Control, FDI, Quadrotor, UAV.

Aim

Unmanned Aerial Vehicles (UAVs), particularly quadrotors, are increasingly integrated into various fields, including surveillance, agriculture, inspection, and delivery services, due to their vertical take-off and landing (VTOL) capabilities and mechanical simplicity. Their dynamic nature, however, makes them highly susceptible to actuator faults—failures in any of the four motors can lead to loss of stability, degraded control authority, or total mission failure. Various Fault Detection and Isolation (FDI) methods have been developed to address this vulnerability, which are typically categorized into three main approaches: data-driven methods (e.g., machine learning), model-based approaches (e.g., observers and parity space methods), and feedback-based methods. While data-driven techniques are effective in handling complex environments, they often require large amounts of labelled data and are difficult to interpret in real-time safety-critical systems. On the other hand, hardware that includes feedback systems increases system cost, which may not be practical or cost-effective for compact UAV platforms.

Model-based observers offer a good compromise by using a mathematical model of the system to detect inconsistencies between expected and measured outputs. However, many of the existing model-based approaches in the literature depend on linearization approaches. Linearizing the system around an operating point may not be efficient in a naturally unstable system like the quadrotors. Furthermore, several existing FDI strategies show limitations in detecting time-varying actuator degradations or a lack of robustness against disturbances. In this research, we address actuator fault detection in quadrotor UAVs through a model-based approach that does not require feedback from actuators or redundant sensors.

The primary objective of this study is to develop, implement, and validate a robust non-linear model-based fault detection and isolation (FDI) method for actuator/motor faults in quadrotor Unmanned Aerial Vehicles (UAVs) without requiring actuator feedback or redundant sensors. A nonlinear Thau observer-based method is proposed for the detection and isolation of actuator faults. This observer leverages the quadrotor's nonlinear dynamics to track time-varying LOE faults, improving upon traditional observers' static detection limits. The approach prioritizes robustness against noise and unmodeled dynamics. Additionally, this research explores combining this observer with dynamic inversion residual analysis to enhance fault-type identification under realistic conditions, validated through simulations.

Material and Method

Simulation Environment and Platform

The simulation was conducted in MATLAB/Simulink using a fixed-step solver (ode3). The study uses a standard X-configuration quadrotor UAV with a total mass of 2.3 kg. Its inertial properties are as follows: Ixx = 0.0088 kg.m2, Iyy =0.0125 kg.m2, and Izz = 0.0122 kg.m2. The quadrotor has the X configuration with four DC motors, where motors 1 and 3 rotate clockwise, and motors 2 and 4 rotate counterclockwise, as shown in Figure 1.

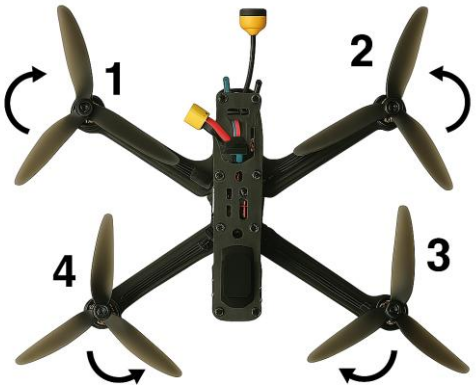

Figure 1. Quadrotor configuration.

System Dynamics

The quadrotor's dynamics are modelled using the Euler-Lagrange formalism as a nonlinear 6-degree-of-freedom system (assuming rigid body, rigid propeller, and symmetric design) with 12 states as shown in Equation 1.

$$x = \left[x, y, z, v_x, v_y, v_z, \phi, \theta, \psi, p, q, r \right]^T$$

The translational dynamic of the system is modelled as shown in Equation 2. While the rotational dynamics is modelled as shown in Equation 3.

$$m\,\ddot{x} = R * [0;\ 0;\ T]^T - [0;\ 0;\ mg]^T + F_{ext}$$

$$I\ \dot{\omega} + \omega \times (I\ \omega) = \tau$$

R is the Direction Cosine Matrix (DCM) mapping body frame to inertial frame. The thrust is the total vertical thrust generated by all four rotors. The Euler angle kinematics are as shown in the following equation

$$\dot{\phi} = p + q\ sin(\phi)\ tan(\theta) + r\ cos\ (\phi)\ tan\ (\theta)$$

$$\dot{\theta} = q\ cos\ (\phi) - r\ sin\ (\phi)$$

$$\dot{\psi} = (q\ \ sin\ sin\ (\phi\ ) + r\ \ cos\ cos\ (\phi\ ))\ cos\ cos\ (\theta)$$

Control Strategy

A model-based cascaded control architecture is employed to ensure the stability and robustness of the system. The outer loop of the controller controls the position (x, y, z) by generating desired accelerations based on a second-order system response with required damping ratio and natural frequency. These accelerations are mapped to reference angles (phi, theta) for stabilization. The inner loop controls the attitude angles, generating a moment command which being transferred to motor angular velocity commands. The overall control strategy is illustrated in in Figure 2.

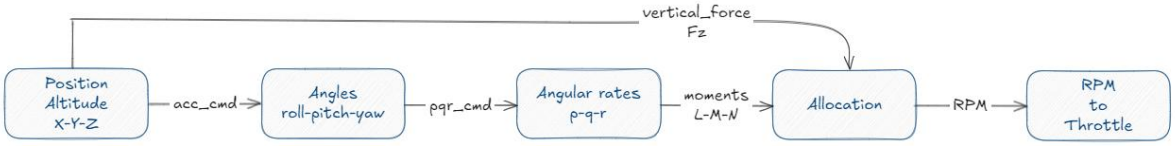

Figure 2. Controller Architecture.

Observer Design

A nonlinear Thau observer-based method is proposed for the detection and isolation of actuator faults. The observer mathematical model is illustrated in the following equation

$$\hat{\dot{x}} = f(\hat{x}, u) + K(y - \hat{y})$$

Where r(t) is the residual vector representing the discrepancy between measured and estimated outputs. The f(xhat,u) function describes the system's full nonlinear dynamics. Observer equations are derived from the same translational and rotational equations described above. The gain K is computed via the Lyapunov equation, ensuring stability.

$$A^T P + P A = -Q$$

Residuals are generated for outputs x,y,z,ϕ,θ,ψ. The residuals are being evaluated continuously, comparing them to thresholds. Faults are detected when residuals exceed thresholds. Then comes the process of isolating the faulty actuator. The overall observer structure is illustrated in Figure 3.

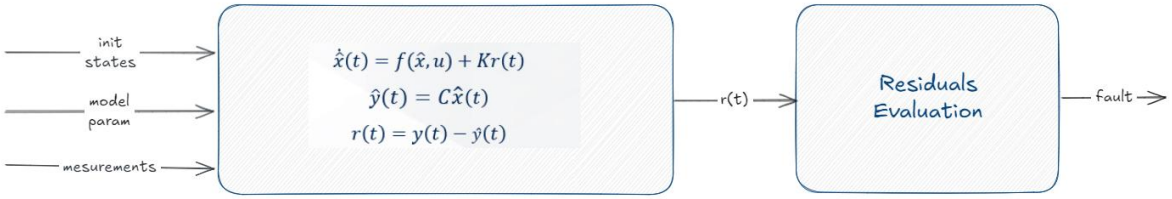

Figure 3. Observer Structure.

To enhance the performance, we implement a dynamic inversion-based complementary observer based assuming that the moments and forces are directly related to the linear and angular acceleration, as illustrated in the equations

$$\tau_{est} = I\dot{\omega}_{meas}$$

$$F_{est} = m\, a_{meas}$$

$$RPM_{est} = [F\ L\ M\ N]^T\ x\ A$$

The residual of this complementary observer is being generated by comparing the estimated motor RPM with the desired motor RPM, assuming the motors are able to generate the desired RPM, as well as neglecting the model uncertainties. When the residuals exceed a specific threshold, the motor fault is detected.

Findings

The proposed fault detection system was successfully integrated into a high-fidelity nonlinear quadrotor simulation built in MATLAB/Simulink. Through a series of test cases, including nominal flight and fault injection scenarios, the system demonstrated high sensitivity to actuator degradations and disturbances. Under fault-free operation, the residual signal remained close to zero, with minor fluctuations due to model uncertainties and unmodeled external disturbances. The observer successfully tracked all 6 measurements, demonstrating rapid convergence and numerical stability under a wide range of flight conditions.

The fault scenarios introduced a sudden partial loss of efficiency or a time-varying degradation in one of the motors. In both cases, the fault detection mechanism triggered a noticeable increase in residuals, allowing for successful detection. The observer remained robust even when small parameter mismatches (in mass and inertia) were introduced and was able to detect the fault with acceptable delay.

The complementary dynamic inversion module played a crucial role. By estimating the actuator torque vector using the measured angular acceleration, and reconstructing motor RPMs through the relationship mentioned before. it was possible to cross-validate the controller's motor commands against the expected actuator performance. This dual detection

mechanism, based on both state residuals and actuator-level discrepancies, enhanced the system's ability to distinguish between modelling errors, sensor noise, and true actuator faults.
The observer was further evaluated under multiple simulation runs with varying levels of input noise and uncertainties in model parameters.
, the observer system was capable of:

- Detecting and isolating single actuator effectiveness loss (LOE).
- Estimating the direction and type and magnitude of fault through combined state and actuator residuals.
- Responding rapidly to fault initiation without additional sensor feedback.

Conclusion

This work demonstrates a robust and practical model-based fault detection system for quadrotor UAVs, leveraging a nonlinear Thau observer and a complementary dynamic inversion observer. The simulation results confirm that the detection system estimates system states and identifies actuator degradations under various conditions, including parameter uncertainties and external disturbances.
The dual-residual approach improves both detection speed and fault interpretability by combining state estimation discrepancies with actuator-level analysis. The observer operates effectively without the need for motor feedback, which is valuable for lightweight UAV platforms. These findings indicate that the proposed method can offer a solution for fault detection in real-world UAV applications and pave the way for future development of fault-tolerant control strategies.
Future work includes implementing the system in a real-time embedded environment, testing with more complex multi-fault scenarios, and exploring adaptive gain tuning to further improve robustness.

Multi-Agent Reinforcement Learning with Maneuver Primitives for Automatic Ground Collision Avoidance of Fighter Jets

Fatih Erol[a], Hayri Acar[a], Emre Koyuncu[a]

Keywords: Multi Agent, Reinforcement Learning, Maneuver Primitive, Ground Collision Avoidance, Fighter Jets.

Aim

Current automatic ground collision avoidance (AGCAS) systems rely on executing a zero-wing-level maneuver followed by a 5G pull-up when a collision is detected (Swihart, et al., 2011). However, this approach is not always optimal, particularly in challenging terrain with significant elevation changes, such as mountainous regions or canyons, where leveling the wings before pulling up could be counterproductive. In such cases, a lateral maneuver may provide a more effective solution for avoiding ground collisions (Neidhardt, 2021).To account for this, recent methods employ predefined maneuver sets, evaluating whether a pull-up at different roll angles can successfully mitigate terrain impact (Kirkendoll, 2021). However, this process requires extensive computational power and multiple trajectory estimations, making real-time implementation challenging.

We aimed to develop an intelligent collision detection and avoidance framework capable of performing collision checking with a single simulation run and autonomously taking control upon detecting a potential collision, even in highly rough environments such as canyons or Cont. In contrast to prior methods that require multiple simulation runs to evaluate predefined maneuver sets for collision avoidance, our approach enables intelligent, sequentially executed evasive maneuvers within a single simulation run.

The intelligent collision detection framework begins with predicted states 0.5 seconds ahead, assuming the real aircraft continues its current behavior during that interval like previous methods (Swihart, et al., 2011). It runs the intelligent simulation using these initial conditions and output the resulting trajectory to the real aircraft. If a collision is detected, it indicates that no viable avoidance trajectory will remain available after 0.5 seconds. Under such circumstances, the AI takes control of the aircraft to execute an evasive maneuver and prevent the collision.

The multi-agent framework facilitates the decomposition of the problem into simpler sub-problems by assigning different tasks to each agent, while the maneuver primitive structure enables the generation of meaningful and interpretable maneuver sequences.

In this study, we aimed to develop intelligent automatic ground collision avoidance (AGCAS) strategies that can handle challenging terrain environments. Our approach enables more effective ground collision avoidance unpredictable conditions, making automatic ground collision avoidance systems more adaptable and efficient.

Material and Method

In Multi-Agent Reinforcement Learning, we aimed to replicate how pilots execute maneuvers sequentially, first adjusting the roll angle, followed by a pull-up maneuver (Kirkendoll, 2021), as illustrated in Figure 1. In this framework, we utilize two distinct agents: the first agent controls the roll angle, while the second agent controls vertical velocity. Both agents operate at a 1 Hz frequency, with the vertical velocity controller agent incorporating a 0.5 second phase shift relative to the roll angle selector agent, enabling sequential decision making.

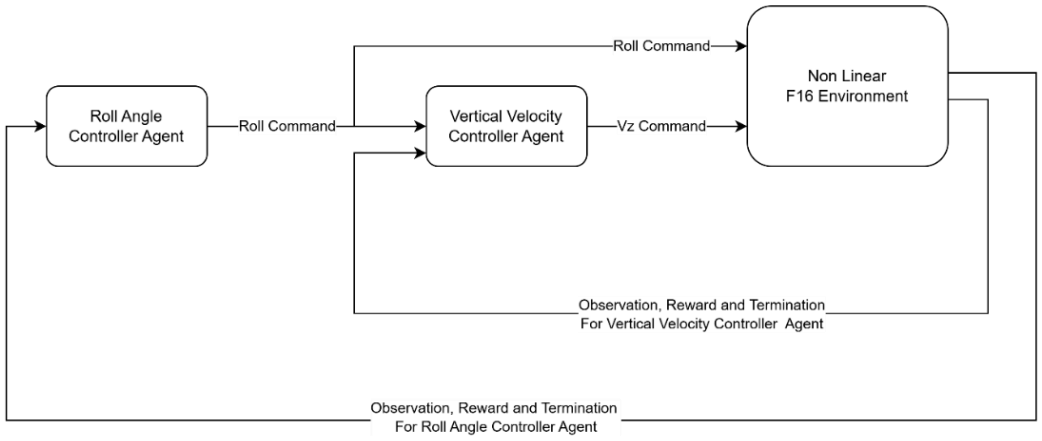

Figure 1. Sequential multi-agent reinforcement learning scheme.

The Multi-Agent framework enables more goal-oriented improvements by allowing each agent to be updated with different observations and rewards. For instance, angle of attack exceedance is primarily the responsibility of the vertical velocity controller agent. This approach prevents unnecessary parameter increases for the roll angle controller agent, ensuring a more efficient and structured learning process.

The Non-Linear F-16 is used as the environment. This model includes post-stall characteristics and features an incremental nonlinear dynamic inversion-based (INDI) autopilot, which controls rotation rates (p, q, r) through an inner loop, while an outer loop manages roll and vertical velocity control. For reinforcement learning (RL), the primary control inputs are the roll angle command and the vertical velocity command.

The action space consists of a discrete set of commands for roll angle ϕ and vertical velocity. Specifically:

- The roll angle command set includes −75°, 0°, and +75°.
- The vertical velocity command set consists of 0 m/s, 20 m/s, and 50 m/s.

The observation space is largely shared between the two agents, with slight variations. The common observations include:

- The loiter point's spherical coordinates in the body-fixed frame shown in Figure 3,
- The lengths of the lidar rays shown in Figure 3,
- Fundamental states of aircraft which are angle of attack, sideslip angle, roll angle, pitch angle, and body angular rates. (α, β, ϕ, θ, p, q, r)

In addition to these, the vertical velocity controller agent has an extra observation: vertical velocity.

To ensure numerical stability, all distances are normalized to the [0,1] range, and angles are expressed in sine and cosine form to prevent discontinuities.

The reward function is composed of two main components: global and local rewards. This structure is one of the key advantages of Multi-Agent RL, as each agent can have distinct reward function. For instance: terrain collision penalty affects both agents, while angle of attack exceedance penalty impact only vertical velocity controller agent.

The total instantaneous reward for the roll controller agent is given by r_{roll} as shown in Equation (1) where $r_{collision}$ penalizes terrain collisions, r_{alive} rewards survival, and r_{ϕ} penalizes excessive roll angles.

$$\begin{aligned} r_{roll} &= r_{collision} + r_{alive} + r_{\phi} \\ r_{collision} &= -1 \\ r_{alive} &= 0.1 \\ r_{\phi} &= \begin{cases} -1, & if\ |\phi| \geq 0.1 \\ 0, & otherwise \end{cases} \end{aligned} \tag{1}$$

The total instantaneous reward for the vertical velocity controller agent is given by r_{VCC} is shown in Equation (2) where $r_{collision}$ penalizes terrain collisions, r_{alive} rewards survival, and r_{G} penalizes excessive load factor and r_{α} penalizes excessive angle of attack.

$$\begin{aligned} r_{VVC} &= r_{collision} + r_{alive} + r_{G} + r_{\alpha} \\ r_{collision} &= -1 \end{aligned} \tag{2}$$

$$r_{alive} = 0.1$$

$$r_G = \begin{cases} -1, & if\ G \geq 5 \\ 0, & otherwise \end{cases}$$

$$r_\alpha = \begin{cases} -1, & if\ \alpha \geq 15° \\ 0, & otherwise \end{cases}$$

Agents are trained using Proximal Policy Optimization (PPO) (John Schulman, 2017) with synchronized update intervals. Both the actor and critic networks are designed with two hidden layers comprising 400 neurons in the first layer and 300 in the second with each layer using the Rectified Linear Unit (ReLU) activation function. The critic network produces a single output value, while the actor network ends with a softmax layer that outputs a probability distribution over the available actions. The PPO parameters for Multi-Agent RL are shown in Table 1.

Table 1. PPO parameters for multi agent RL.

Throughout the training process, a consistent increase in cumulative reward can be observed in Figure 2.

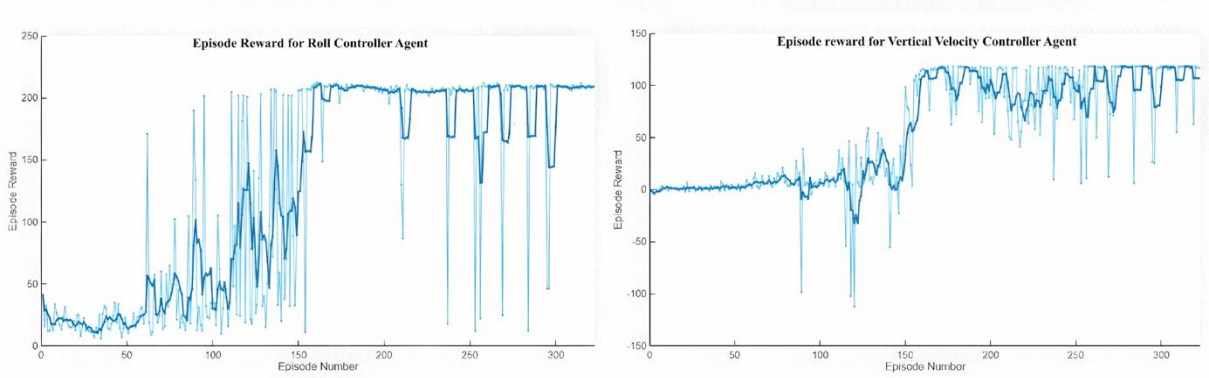

Figure 2. Training results.

All computations, including the nonlinear F-16 model, autopilot, and agent training, are conducted in Matlab Simulink. For visualization, Unity is utilized, as shown in Figure 3, to enable real-time rendering of the aircraft, terrain, LIDAR rays, loiter positions, and trajectory visualization.

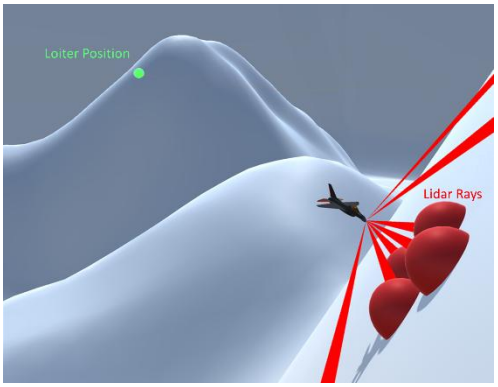

Figure 3. Visualization with Unity.

Terrain generation is achieved by processing digital terrain elevation data (DTED) (Agency, 2022) in MATLAB and meshing it within Unity, or alternatively, by generating procedural terrains using Blender.
Since both methods allow for terrain generation, they provide the flexibility to create diverse environments for RL training, enhancing the model's adaptability and robustness.

Findings

The proposed Multi-Agent RL approach was evaluated across multiple terrain environments with varying elevation profiles and demonstrated successful performance in all tested scenarios.
The RL-based system significantly outperformed traditional AGCAS in highly variable terrains, particularly in regions with steep elevation changes and narrow canyon-like formations. Unlike conventional systems that rely on fixed maneuvers, the RL-based approach adapted dynamically, selecting maneuvers based on the terrain profile as shown in Figure 4, Figure 5 and Figure 6.

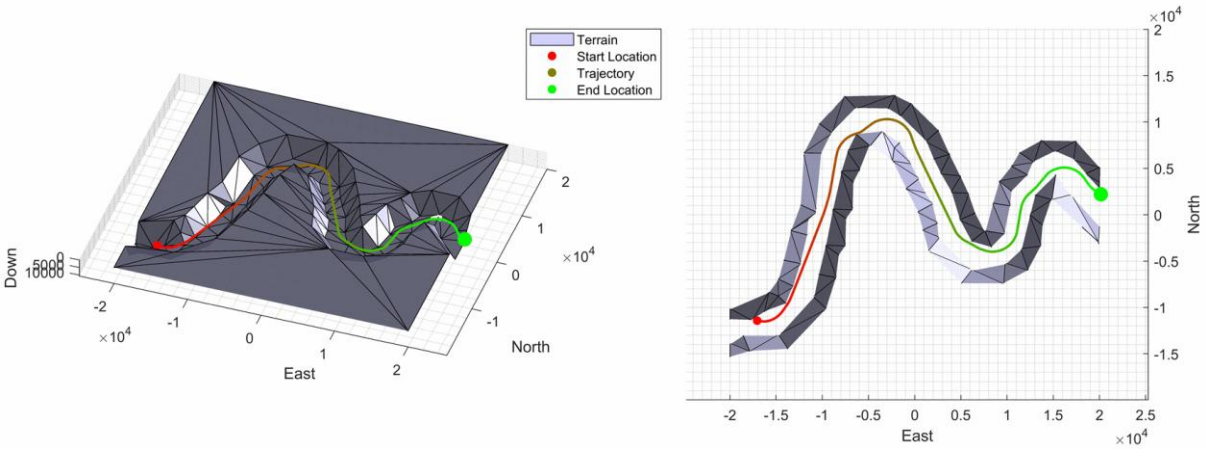

Figure 4. Canyon scenario 1 of multi-agent RL.

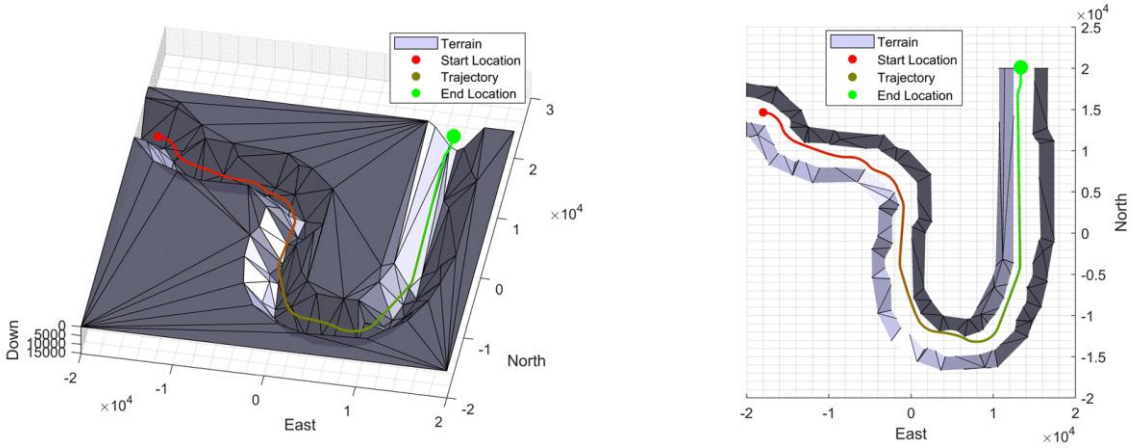

Figure 5. Canyon scenario 2 of multi-agent RL.

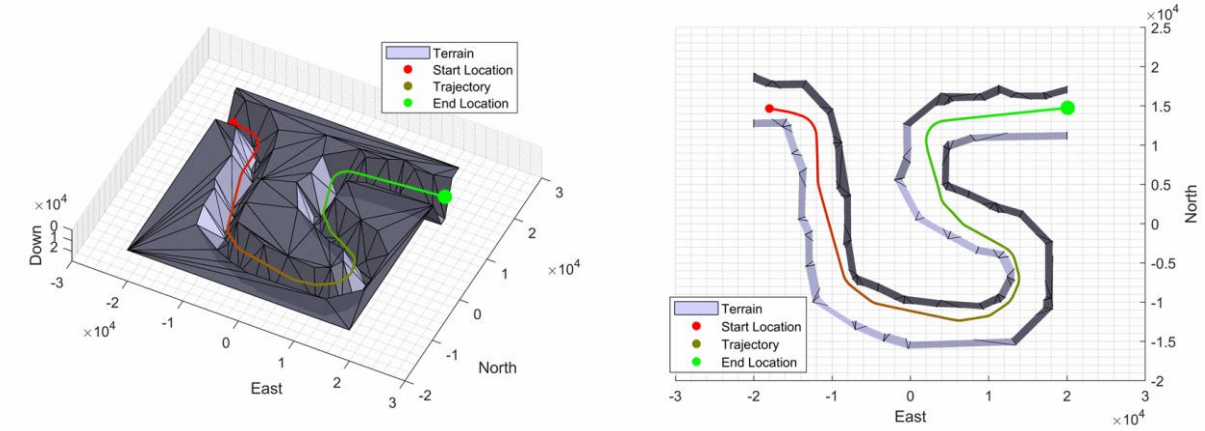

Figure 6. Canyon scenario 3 of multi-agent RL.

The proposed single-pass decision-making approach eliminated the need for multiple trajectory estimations, reducing computational complexity by approximately 80% compared to deterministic predefined maneuver sets. The system successfully delayed intervention until the last feasible moment, allowing the pilot to retain control longer while ensuring safety. This behavior closely mimics human pilot decision-making, providing a more natural and efficient AGCAS response.

Conclusion

This study introduces a novel Multi-Agent Reinforcement Learning approach for AGCAS, addressing the limitations of traditional deterministic maneuver-based methods. Unlike predefined AGCAS techniques that rely on fixed trajectory estimations, our approach enables adaptive, significantly enhancing ground collision avoidance in complex and unpredictable terrain environments. This method offers several key advantages, including a significant reduction in computational complexity, making real-time implementation feasible, improved collision avoidance success rates, particularly in scenarios where traditional pull-up strategies are ineffective, and minimized unnecessary pilot intervention, ensuring that AGCAS decision-making aligns with human pilot strategies, resulting in a more natural and effective safety system. These findings indicate that the Multi-Agent Reinforcement Learning approach provides substantial advancements over conventional AGCAS methodologies, especially in cases where terrain variations necessitate more adaptive and non-traditional avoidance strategies with intelligent, sequentially executed evasive maneuvers within a single simulation run can be seen in Figure 7.

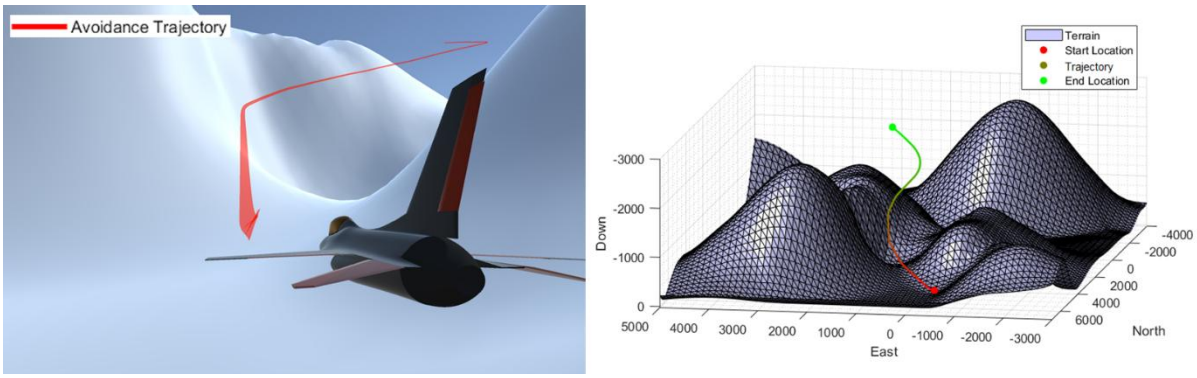

Figure 7. Proposed intelligent avoidance trajectory (with single simulation run).

Keywords: Aircraft Landing Gear Touchdown Dynamics, Landing Gear Systems, Non-Linear Mass-Spring-Damper Dynamic System, Oleo-Pneumatic Strut, Simulink Model.

Aim

Landing gear systems support the aircraft throughout ground operations and play a crucial role in absorbing impact forces at touchdown. In today`s modern landing gears, mostly oleo-pneumatic struts are utilized as the shock-absorber component in the landing gear system since it has the maximum efficiency to weight ratio of about 80% among all the conventional landing gears [1]. The aim of this study is to conduct a sensitivity analysis to evaluate the effects of oleo-pneumatic strut landing gear design parameters on the key performances such as energy absorption capacity and aircraft maximum vertical acceleration.

Material and Method

The vertical motion of a landing gear system can be analytically modeled as a double mass-spring-damper system as shown in Figure 1 [2], capturing the dynamics of both the aircraft and the landing gear system as separate masses: upper or sprung mass and lower or unsprung mass respectively. The upper and lower masses are connected to each other with the oleo-pneumatic strut that can be modeled as one spring and one damper, and the tire-ground interaction can be modeled as one spring. Also, the lift acts on the aircraft wings because of the horizontal speed during the aircraft landing operation. The lift is usually taken equal to the total weight of the aircraft at touchdown. After touchdown, the lift decreases as the horizontal speed decreases during the landing operation [3,4]. The equations of motion for the upper and lower masses are shown in Equation 1 and Equation 2 where y_1 and y_2 are vertical displacements of the upper and lower masses, indicated as m_1 and m_2, respectively. The forces on the right-hand side of the equations of motion are F_s (the total strut force in its axis), F_{Na} (force normal to axis of shock strut at the tire axle), F_{vg} (vertical ground force applied to the tire), L (lift force) and Weights, shown as W_1 and W_2 for the upper and lower masses, respectively. The angle between the shock-strut axis and vertical, shown in Figure 2 [4], is also considered for the equations of motions. Using geometric relations and assuming the lower mass concentrated at the axle, F_{Na} can be expressed by Equation 3 where F_{Hg} is the horizontal ground force applied to the tire.

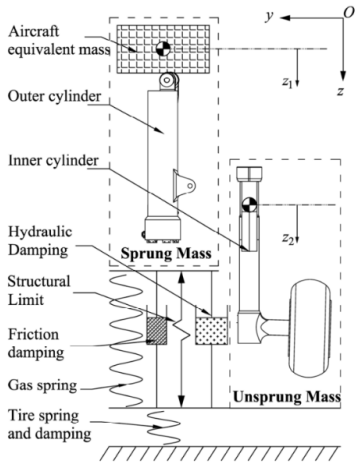

Figure 1. Schematic of the landing gear system as a mass-spring-damper system [2].

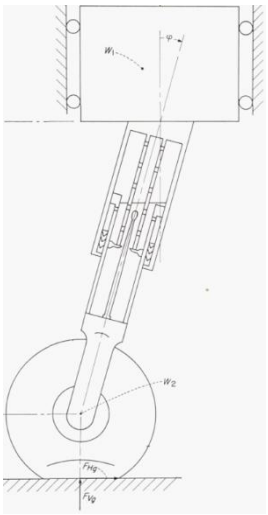

Figure 2. Demonstration of the rake angle (the angle between the oleo-strut axis and the vertical) [4].

An oleo-strut generally refers to a piston-cylinder assembly where the cylinder and piston are generally connected to the upper mass and lower mass respectively. During aircraft landing operation, the oleo strut compresses under load or extends as the load is relieved. A typical oleo-strut consists of two chambers separated by a plate with an orifice. The upper chamber is typically filled with gas like nitrogen or air and the lower chamber is filled with highly viscous fluids like oil, shown in Figure 3 [4]. As the oleo-strut compresses or extends, the damping force in the oleo strut is generated by the flow of viscous fluid into the orifice and the spring force is produced by the compressed air in the upper chamber. The vertical displacement difference between the upper mass and the lower mass is defined as the strut stroke. Similarly, the stroke velocity is the relative vertical velocity of the upper and lower masses. The stroke and stroke velocity can be obtained by utilizing Equation 4 and Equation 5 respectively [4]. The pneumatic spring force (F_p) and the hydraulic damping force (F_h) of the oleo strut total force (Equation 6), given in Equation 7 and Equation 8 respectively [5,6], nonlinearly depend on the strut's stroke and stroke velocity. Other than the stroke and stroke velocity, the spring and damping characteristics of the oleo-strut depend on the pneumatic and hydraulic chamber areas (A_a and A_h), orifice area (A_n), orifice discharge coefficient (C_d), initial gas pressure (P_0), polytropic exponent (n) and the density of the viscous fluid (d_{fluid}). The non-linearity in the strut's spring and damping behavior arises from the complex interactions between these parameters, with the force-displacement and force-

velocity relationships varying dynamically under different loading conditions. The non-linearity in the strut's spring and damping characteristics introduces additional complexities in the analysis and modeling of the landing gear system [3,4].

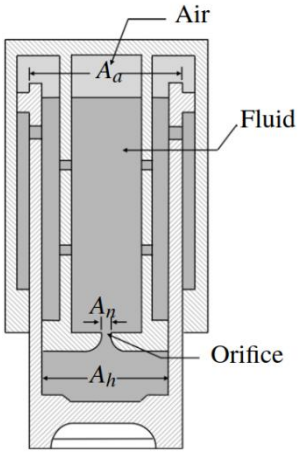

Figure 3. Schematic view of the oleo-pneumatic shock strut [8].

When the aircraft touches down, the tire compresses as it contacts the ground. The vertical force generated is the result of the aircraft's weight and vertical deceleration forces acting on the landing gear. The magnitude of this force mainly depends on the tire's mechanical properties and the vertical touchdown velocity of the aircraft. The higher the touchdown velocity, the greater the force exerted on the tire and, consequently, the landing gear system. Tire force-deflection curves, typically provided by tire manufacturers, offer a detailed relationship between the vertical deflection of the tire and the ground force. These curves generally exhibit exponential variation with vertical deflection, shown in Equation 9 where m' and rtire are tire constants and d_{tire} is tire overall diameter. This relationship is crucial for predicting the behavior of the landing gear during landing impacts, as the non-linearities in the force-deflection response significantly affect the overall shock-absorbing performance of the system [3,4].

In addition to the oleo-strut forces and tire vertical ground forces, the friction forces may play a non-negligible role during the vertical motion of a landing gear system. The friction forces within the oleo-strut itself arise from the bearing friction forces (F_{nf}) and seal friction force (F_{sf}) (Equation 10) [2,7]. These friction forces can be expressed by Equation 11 and Equation 12 where l1 and l2 are axial distance between upper and lower bearings and axial distance between tire axle and lower bearing for fully extended shock strut [2,4]. Other parameters reflect the friction coefficient for the bearing-chamber or seal-chamber contacts. Furthermore, the friction between the tire and the runway surface is another crucial factor that affects the behavior of the landing gear system. This friction is particularly relevant in the context of the horizontal tire-ground force. As a preliminary estimate, the instantaneous friction force can be considered equal to the vertical ground reaction force multiplied by an appropriate friction coefficient, as given in Equation 13, while the tire skids from the moment of touchdown until it stops skidding and spins up [4]. The instant at which the wheel stops skidding can be determined using a simple impulse-momentum relationship, given in Equation 14 where I_w, V_{H0}, r_d and t_{su} are polar momentum of inertia of the wheel, initial horizontal velocity, radius of the deflected tire and time of wheel spinning-up, respectively [4,7]. Especially for shock struts with a rake angle —defined as the angle between the oleo-strut axis and the vertical— the frictional forces between the tire and the runway surface can also affect the forces transmitted to the upper and lower masses of the landing gear system [3]. These frictional effects of internal strut contacts and the tire-ground contact introduce further non-linearities into the system's response, making the analysis of landing gear dynamics more complex [2,4].

Findings

Considering all the variants on the spring effects, damping characteristics and forces caused by the friction, the vertical motion of a landing gear system demonstrates a complex and non-linear behavior [2,3,4]. In this study, a Simulink-based model for the dynamics of an aircraft landing gear with an oleo-pneumatic strut is developed based on the non-linear mass-spring-damper system presented in [4]. The Simulink model includes the oleo strut non-linear responses as well as non-linear tire-ground interactions, summarized in Equations from 1 to 14. The model is validated with experimental data given in [4] and Figure 4 shows that the results from the model and the experimental data are aligned with each other.

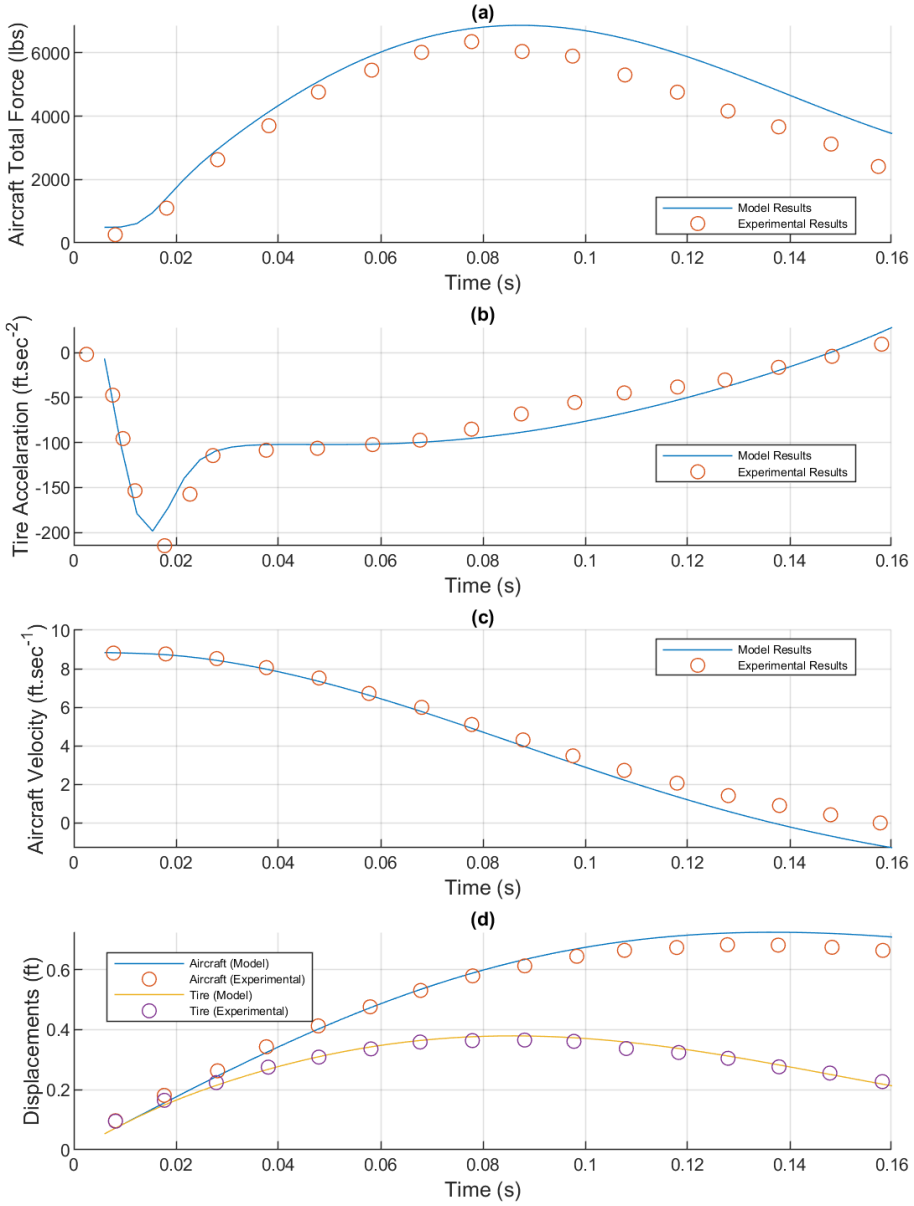

Figure 4. Comparison of model predictions and experimental data for aircraft landing gear dynamics: (a) Aircraft total force; (b) Tire acceleration; (c) Aircraft velocity; and (d) Displacements of the aircraft and tire.

Conclusion

In conclusion, this study provides a sensitivity analysis of the key design parameters of oleo-pneumatic strut landing gear systems, focusing on their impact on energy absorption capacity and maximum vertical acceleration during aircraft touchdown. The developed Simulink model successfully captures the non-linear dynamics of the system, including the complex and non-linear relationships for the oleo strut tire-ground forces. By validating the model with experimental data, it demonstrates the accuracy of the simulated responses in representing real-world behavior. The purpose of this study is to develop an approach to model the dynamics of aircraft landing gear and to provide in-depth discussion of the validation process, including comparisons between simulated and experimental results. Lastly, the study provides a comprehensive parametric study, analyzing the effects of key design parameters on the system's performance.

Summary of Equations used in the Model

$$m_1 * \ddot{y}_1 = -F_S * co(\varphi) - F_{Na} * si(\varphi) - L + W_1 \ \#(1)$$

$$m_2 * \ddot{y}_2 = F_S * co(\varphi) + F_{Na} * si(\varphi) - F_{vg} + W_2 \ \#(2)$$

$$F_{Na} = F_{Vg} * sin\ sin\ (\theta) - F_{Hg} * cos\ cos\ (\theta) + W_2 * \ddot{y}_1 * sin\ sin\ (\theta) - W_2 * sin\ sin\ (\theta) \ \#(3)$$

$$S = \frac{y_1 - y_2}{cos\ cos\ (\varphi)} \ \#(4)$$

$$\dot{S} = \frac{\dot{y}_1 - \dot{y}_2}{cos\ cos\ (\varphi)} \ \#(5)$$

$$F_S = F_p + F_h + F_f \ \#(6)$$

$$F_p = P_0 * A_a * \left[\frac{V_0}{V_0 - A_a * S}\right]^n \ \#(7)$$

$$F_h = d_{fluild} * \left[\frac{A_h^3}{2 * A_n^2 * C_d^2}\right] * |\dot{S}| * \dot{S} \ \#(8)$$

$$F_{vg} = m' * \left(\frac{y_2}{d_{tire}}\right)^{r_{tire}} \ \#(9)$$

$$F_f = F_{nf} + F_{sf} \ \#(10)$$

$$F_{nf} = \frac{\dot{S}}{|\dot{S}|} * |F_{Na}| * \left[(\mu_1 + \mu_2) * \frac{l_2 - s}{l_1 + s} + \mu_1\right] \#(11)$$

$$F_{sf} = -\mu_{sf} * F_a * sgn(\dot{S}) \ \#(12)$$

$$F_{Hg} = F_{vg} * \mu \ \#(13)$$

$$\int_0^{t_{su}} F_{Hg}\, dt = \mu \int_0^{t_{su}} F_{vg}\, dt = \frac{I_w * V_{H0}}{r_d^2} \#(14)$$

Aeroelastic Optimization with Genetic Algorithm

Ahmet Güver[a], Seher Eken[a]

[a] Istanbul Technical University, Aeronautics and Astronautics Engineering Program, Türkiye

guvera16@itu.edu.tr

Keywords: Aeroelasticity, Genetic Algorithm, Optimization.

Aim

After the Wright brothers' first successful flight attempt, the idea that humans could fly with machines was strengthened. Primitive aircraft were manufactured worldwide by entrepreneurs and companies for both military and civilian purposes. The early examples of these aircraft were made from wood and fabric. The wood was primarily used for structural purposes, while the fabric was used for the surface of the wings and stabilizers. Despite the successful attempts, there were also failures. Nine days before Orville and Wilbur Wright success Samuel P. Langley failed to fly his aerodrome with using a catapult mechanism due to wing torsional divergence. Some of these failures occurred because the aircraft structures lacked the static stiffness that necessary to resist wing bending. Additionally, as wing designs became more slender, dynamic instability issues arose, known as flutter. Flutter is an interdisciplinary subject that involves three disciplines: "Elasticity", "Aerodynamics", and "Dynamics (Inertia)". The Collar Triangle in Figure 1. expresses the relationship between these three scientific fields (Collar, 1946).

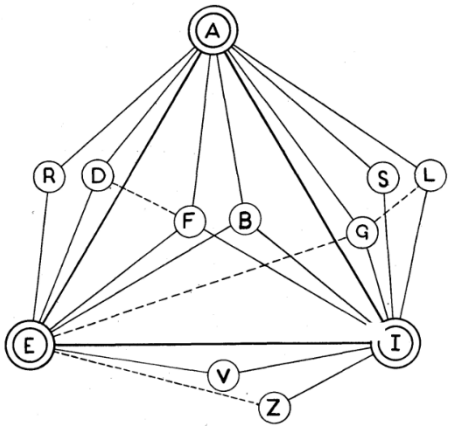

Figure 1. Collar Triangle (Collar, 1946).

The letters "E", "A" and "I" at the corners of triangle are represent the science fields respectively and the other letters at the middle and outside the edges are for inter disciplines. The meanings of these letter can be seen in Table 1.

Table 1. Collar Triangle Letters.

Letters	Interdisciplines
R	Reversal of Control
D	Divergence
V	Vibrations (Mechanical)
Z	Impact
G	Gust
S	Stability and Control
L	Loading
F	Flutter
B	Buffeting

The Collar Triangle also has simpler and more complicated versions that frequently quoted in academic publications. When "Control" added to the triangle servo-aeroelasticity and "Thermal Effects" added with "Control" thermo-servo-aeroelasticity can be defined as inter disciplines.

After World War I and II, there was a growing expectation for aircraft to fly faster and weight less. The need for structural strength to achieve higher flutter speeds required the use of more materials. However, the development of new high-strength materials can help reduce the structural weight, but a suitable design for high flutter speeds is still necessary. These design parameters are interdependent, and even a small change in one of them can cause significantly affect the dynamic stability of the aircraft. The complex nature of the flutter phenomenon can be overcome through design optimization methods. The primary aim of this project is optimize the aeroelastic flutter speed with GA optimization method.

Material and Method

Optimization is defined as "an act, process, or methodology of making something (such as a design, system, or decision) as fully perfect, functional, or effective as possible" (Optimization, 2025). There are two primary types of optimization methods mathematically. The first type of the methods is Gradient-based optimization methods. These methods rely on the derivatives of the system's governing equations. By using the gradient of the objective function, these methods adjust the decision variables in the direction of the steepest descent (or ascent) to reach an optimal solution. These methods require the objective function to be differentiable. Common examples include gradient descent and its variations. The second kind of methods is Gradient-free optimization methods. These methods do not require the calculation of derivatives. They are typically used when the objective function is non-differentiable, noisy, or difficult to compute. Examples of gradient-free methods include Particle Swarm Optimization (PSO) and Genetic Algorithms (GA), both of are metaheuristic, population-based techniques.

The genetic algorithm is founded by John H. Holland in his Adaptation in Natural and Artificial Systems book dated 1975 (Holland, 1992). Genetic algorithm optimizations are evolution based algorithms that structured on concepts like mutation, crossover and selection of elites in a population with respect to their fitness values. The inputs coded to binary strings and mutation and crossover done to this binary string. The mechanism of the genetic algorithm have been resembled to Darwin's Evolution by many researchers, also the binary string similar to the one string of a gene spiral with its mutation and

crossover capability. The crossover is the swap the binary code part between two parents after a particular point. That point can be called crossover point. The crossover can be seen in Figure 2.

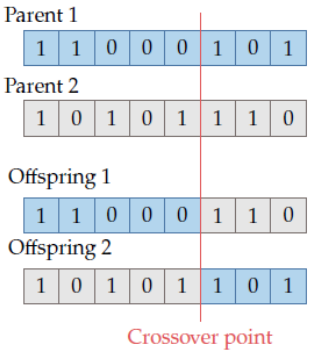

Figure 2. Crossover Procedure (Joaquim & Andrew, 2021).

The other method to create offspring in GA is mutation. The one or more binary code in string randomly changed to opposite and generate a new input. The change can be seen in Figure 3.

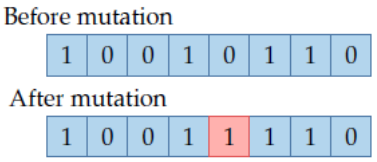

Figure 3. Crossover Procedure (Joaquim & Andrew, 2021).

In each iteration elites are chosen for mutation and crossover procedures with respect to their outputs (fitness value) in objective function. The inputs give the lower fitness value in a population are not used after. In other words become extinct. The elite ratio defines that how many design point remain after elimination. The higher elite ratio means less design point eliminated. The elites and their offspring are become new population and this procedure goes over and over until the goal have been reached.

For this project calculation of flutter speeds and genetic algorithm coded with python. The genetic algorithm optimization main function has three sub-functions for: one for crossover, one for mutation, and one for finding the best fitness value in a population of that generation, also a function is defined for flutter speed calculation for used for each design points in a generation. For calculation of fitness values for each design point parallel processing have endorsed for faster results. After initial population are randomly created the elites are chosen for next generation based on their fitness value. The crossover and mutations are done to elites and parents and children are become new population. The iterations continue to converge or reached to predetermined number of iteration limit. The inputs that give the optimum fitness value are the candidates for design points for wing design process.

Findings

There are flutter functions used in this project; K method, PK Method and Beam method. Although there are multiple modes for Galerkin method depends on mode number, for K method 2 and for PK 4 modes are present. For three methods flutter speed can be indicated with finding the lowest velocity that has zero damping. The negative damping ratio is where the

system is stable. When damping ratio is zero, the point is called stability border and for this specific problem "flutter". The velocity damping graph for Golan Wing can be seen in Figure 4.

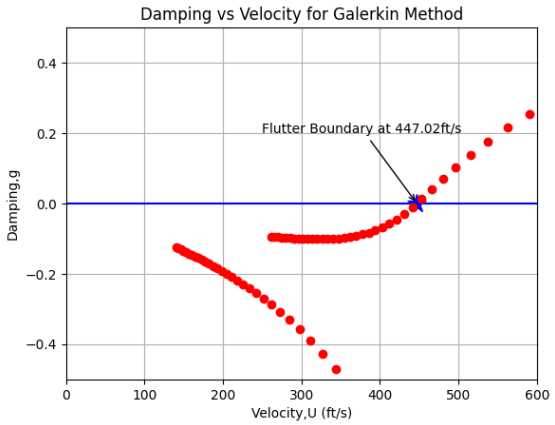

Figure 4. Velocity Damping Graph for Goland Wing.

The functions that used for this project find this velocity and return it when function called for population of each generation. For validate our function the results are compared with the (Lin & Iliff, 2000). The Goland Wing properties can be seen in Table 2.

Table 2. Goland Wing Properties.

Parameters	Definition	Values
m	Mass per unit span	0.746 *slug/ft*
Sy	Static mass moment per unit length about the elastic axis	0.447 *slug/ft/ft*
Iy	Mass moment of inertia about the elastic axis	1.943 *slug/ft2/ft*
EI	Elastic rigidity	23.6x10^6 *lb/ft*
GJ	Torsional rigidity	2.39x10^6 *lb/ft*
α	Location of the elastic axis	-1/3
l	Span of the wing	20 *ft*
b	Half chord	3 *ft*

The flutter speed for Golang Wing compared with Lin and Iliff's results (Lin & Iliff, 2000) in Table 3.

Table 3. Flutter Speed Comparison.

Functions and Reference	Flutter Speed	Difference
(Lin & Iliff, 2000)	447	-
Galerkin Method	447.02	≅0%

The improvement for generations are can be seen in Figure 5. This simplicity the population are 8 and generation is 25 for this graph. The two graphs show that the improvements can evolve different. While the increase in first graph in previous generation, in second graph the flutter speed increase after 10th iteration.

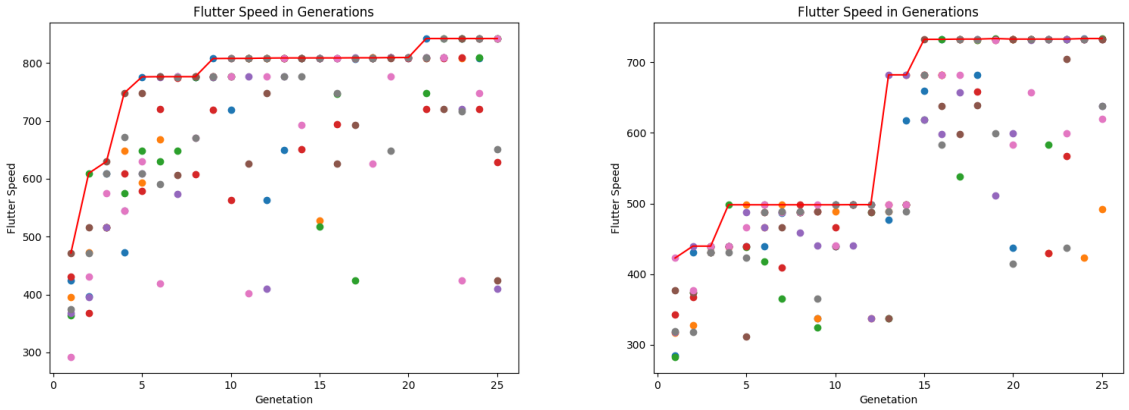

Figure 5. Flutter Speed in Generations.

The scatters on the graphs are represents the fitness values for population members. The fitness values in same generation share same x axis. The highest fitness value are connected with red line for showing the improvement on the flutter speed. Although the random crossover and mutation operations search for more optimum result, offspring can give lower fitness values than their parents. This is because the chaos nature of genetic algorithm. The random procedures can generate strong and weak offsprings but with the nature of genetic algorithm this lower fitness value design points are eliminated from the procedure. Eventually the final result is improved and lower fitness value design points are extinct in the system

Conclusion

Due to the complex nature of aeroelastic responses for design points its unpredictable to from just looking the design point values. Even a small change in values the response can change the dynamic stability characteristics severely, therefore an optimization procedure endorsed for finding the optimum design value. Genetic algorithm has been chosen for this optimization problem because the differentiability and continuity are not present for this problem which is essential for gradient based optimization methods. The results show that in each iterations the flutter speed improved or conserved. In some generation there are relatively high increase in response or small or not increase at all. This is because random operation in crossover and mutation procedures. After desired number of iterations the improvement of the objective results are achieved.

Feed-Forward Neural Network Based Prediction of Flutter Speed of 3 DOF 2D Wing Model

Osman Dağlı[a], Metin Orhan Kaya[a]

[a] Istanbul Technical University, Aeronautical and Astronautical Engineering Department, Aeronautical and Astronautical Engineering Program, Türkiye
dagli17@itu.edu.tr

Keywords: Aeroelasticity, Feed-Forward Neural Network, Flutter, Wing Model.

Aim

Aeroelastic flutter arises from the interaction of aerodynamic, elastic, and inertial forces, significantly impacting aircraft structures like wings and tails. It occurs when these forces combine to induce self-excited oscillations, which can compromise structural integrity. Given the complexity of flutter analysis, artificial intelligence (AI) has become an effective tool in predicting flutter speed and responses. This study explores artificial neural networks (ANNs) as a computationally efficient method for addressing aeroelastic flutter problems [1-3].
This paper describes a typical 2D airfoil model with a control flap. This model is developed in Theodorsen's unsteady aerodynamics theory and represents a typical section of a wing. The model can be seen in Fig. 1.

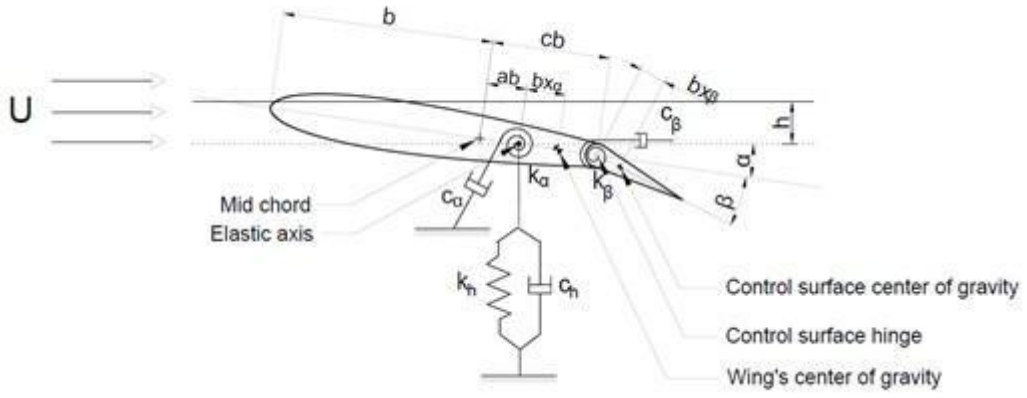

Figure 1. 2D 3 DOF Aeroelastic Typical Section.

Also, the aeroelastic equations of motion is in Eq. 1. To develop a robust dataset for ANN-based flutter prediction, this research integrates the state-space representation method with Theodorsen's unsteady aerodynamics theory.

$$m\ddot{h} + mx_\alpha b\ddot{\alpha} + mx_\beta b\ddot{\beta} + c_h\dot{h} + k_h h = L$$

$$I_\alpha\ddot{\alpha} + mx_\alpha b\ddot{h} + \left[mx_\beta b^2(c-a) + I_\beta\right]\ddot{\beta} + c_\alpha\dot{\alpha} + k_\alpha\alpha = M_\alpha \qquad \text{Eq. 1}$$

$$mx_\beta b\ddot{h} + \left[mx_\beta b^2(c-a) + I_\beta\right]\ddot{\alpha} + I_\beta\ddot{\beta} + c_\beta\dot{\beta} + k_\beta\beta = M_\beta$$

The nondimensionalized form of equations of motion obtained in Eq. 2. The state-space model represents physical systems through input, output, and state variables, while Theodorsen's theory provides insights into unsteady aerodynamic forces.

$$[\bar{M}_s - \bar{M}_a]\begin{bmatrix}\ddot{h}\\ \ddot{\alpha}\\ \ddot{\beta}\end{bmatrix} + [\bar{D}_s - \bar{D}_a]\begin{bmatrix}\dot{h}\\ \dot{\alpha}\\ \dot{\beta}\end{bmatrix} + [\bar{K}_s - \bar{K}_a]\begin{bmatrix}h\\ \alpha\\ \beta\end{bmatrix} = \bar{L}_\delta \begin{bmatrix}\ell_1\\ \ell_2\end{bmatrix} + \bar{L}_c[\beta_c] \quad \text{Eq. 2}$$

The state- space form is given in Eq. 3. Together, these methods create a dataset that captures flutter behavior under varying conditions. A multi-layer ANN architecture is employed, enhancing the predictive capability by processing different aspects of flutter data [4-9].

$$\dot{x} = Ax + Bu \quad \text{Eq. 3}$$

Recent studies demonstrate ANN's effectiveness in flutter analysis. Research leveraging Reduced Order Models (ROMs) and deep learning, including Long Short-Term Memory (LSTM) networks, has shown improved accuracy and reduced computational costs compared to traditional methods. Studies indicate that ANN can identify the most influential geometric parameters affecting flutter speed, with frequency ratio being the most critical factor [10-15]. Zhang et al. introduced Time Delay Recurrent Neural Networks (TDRNNs) for modeling nonlinear aeroelastic systems, further confirming ANN's reliability [16-18].

This study develops an ANN-based approach, specifically using Feedforward Neural Networks (FFNNs), to predict flutter speeds efficiently. The mathematical output of a node in an FFNN is determined based on the input it receives through these weighted connections as in Eq. 4. MATLAB is utilized for implementation, with results validated against theoretical predictions. The findings highlight ANN's potential in accurately modeling aeroelastic flutter, making it a valuable tool for aerospace engineering applications.

$$y_i = \varphi_i\left(\sum_{j=1}^{n^i} w_j^i z_j^i + b^i\right) \quad \text{Eq. 4}$$

The main aims of the study are:

- It provides a trustworthy dataset for flutter speed prediction based on state-space representation and Theodorsen's unsteady aerodynamic theory.
- Development and training of an FFNN model that can have good estimates in flutter speeds through key aeroelastic parameters are possible.
- To compare the ANN-based predictions with numerical results obtained by eigenvalue analysis and previous experimental studies.
- The use of machine learning in aeroelastic analysis for the purpose of establishing whether this can replace or supplement the conventional methods.
- It provides an example for a continuously developing field, namely AI-driven aerospace engineering, and points out the potentiality of using neural networks in modeling complicated aerodynamic behavior in order to reduce the reliance on costly experimental setups and high-fidelity numerical simulations.

Material and Method

In this work, an attempt has been made to predict the flutter speed by utilizing a data-driven approach using Feed-Forward Neural Network-FFNN, a kind of Artificial Neural Network-ANN. These procedures contain different steps such as dataset generation, the selection of neural network architecture, training, validation, and testing.

1. Dataset Generation

In this respect, the state-space representation and Theodorsen's unsteady aerodynamic theory will be implemented for the generation of the comprehensive data set of flutter. The aeroelastic parameters which are used in this work given in Table 1.

Table 1. System Parameters for Aeroelastic Analysis [11].

Geometric Parameters		**Stiffness Parameters**	
Chord	0.254 m	K_α, per span	14861 1/s^{-2}
Span	0.52 m	K_β, per span	155 1/s^{-2}
Semi-chord, b	0.127 m	K_h, per span	1809 1/s^{-2}
Elastic axis, a	-0.5		
Hinge line, c	0.5		
Mass Parameters		**Damping Parameters**	
Mass of the wing, m_α	0.62868 kg	ζ_α, log-dec	0.01626
Mass of the flap, m_β	0.18597 kg	ζ_β, log-dec	0.0115
Mass/length of the wing-flap	0.1558 kg/m	ζ_h, log-dec	0.0113
Mass of the support blocks	0.47485*2 kg		
Inertial Parameters		**Jones' Approximation Parameters**	
S_α, per span	0.08587 kg.m	λ_1	0.014
S_β, per span	0.00395 kg.m	δ_1	0.165
x_α	0.434	λ_2	0.32
x_β	0.01996	δ_2	0.335
I_α, per span	0.01347 kg.m^2		
I_β, per span	0.0003264 kg.m^2		
r_α	0.7321		
r_β	0.11397		

Both of those are mathematical methodologies which analyze the so-called aeroelastic system under various conditions. The dataset comprised flutter speed corresponding to the wide range of wing parameters; therefore, the generalization of the neural network could be pretty effective. The parameters used as dataset for flutter speed prediction are given in Table 2.

Table 2. Parameters Used as Dataset for Flutter Speed Prediction.

	C.G. Location	**E.A. Location**	**Mass of Wing Structure**	**Semi-chord Length**
Parameters	e	a	m	b
Range	-0.9, 0.4	-0.9, 0.4	0.4, 4	0.125, 0.25

The state-space form of representation casts the equations of motion that govern aeroelastic flutter in a matrix form that explicitly admits numerical eigenvalue analysis for determination of flutter speeds. Theodorsen's unsteady aerodynamic theory includes both circulatory and non-circulatory aerodynamic effects, hence it represents the most realistic model of aerodynamic forces acting on the wing.
The data comprises 625 samples of the parameters, which are location of CG, e; location of EA, a; wing structure mass, m; and semi-chord length, b.
These were selected to be influential in the dynamics of flutter and also for their easy applicability in FFNN models. The data were then split into training, validation, and testing subsets in the ratio 70:15:15, respectively, to give a robust model evaluation. The FFNN model used in this work is illustrated in Fig. 2.

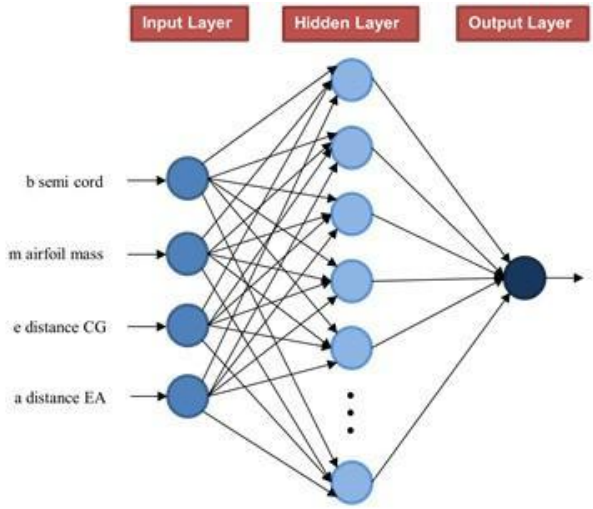

Figure 2. The Suggested Feed-Forward Neural Network Model.

2. Neural Network Architecture

The FFNN model comprises three layers which are:
Input Layer: Accepts four input parameters (e, a, m, b).
Hidden Layer: Utilizes sigmoid activation functions and contains 25 neurons, a value determined through experimental tuning.
Output Layer: Produces a single output, representing the predicted flutter speed.
The network is trained using a very powerful optimization technique for the training of neural networks: the Levenberg-Marquardt algorithm. The loss used was the Mean Squared Error (MSE) for ensuring that minimal prediction errors could be obtained from the model. It can be seen in Eq. 5 [19-21].

$$MSE = \frac{1}{n}\sum_{i=1}^{n}\left(Y_i - \hat{Y}_i\right)^2 \qquad \text{Eq. 5}$$

3. Training and Validation

In the training of the network, this iterative process was followed to continuously update the weights with the aim of minimizing the prediction error. This nonlinear relationship between aeroelastic parameters and flutter speed is learned during this training. The validation set can be used during training to monitor model performance in order to avoid

overfitting. Later, the generalization capability of the trained model was tested on unseen data. Regression coefficient R^2 was considered for measuring the correlation between predicted and actual flutter speed.

Findings

The aeroelastic analysis results and related flutter speed values are verified with the findings in the literature. The comparison between the results of this work and Conner et al.'s work is presented in the Table 3.

Table 3. Validation And Error Rates with Literature [11].

Results	Dağlı	Conner	Error Rate
Flutter Speed (m/s)	23.96	23.9	0.25%
Flutter Frequency (Hz)	6.12	6.112	0.13%
Pitching Nat. Freq. (Hz)	9.128	9.128	0%
Plunging Nat. Freq. (Hz)	19.44	19.44	0%
Flapping Nat. Freq. (Hz)	4.455	4.455	0%

The regression coefficient of the FFNN model thus trained was 0.92, which implied a very good correlation between the predicted and actual flutter speeds. The model predicted the flutter speed for different configurations of wings with very high accuracy.

FFNN predicted the flutter speed as 23.96 m/s at a frequency of 6.12 Hz. These values matched very well with numerical and experimental results, confirming the reliability of the model. This is visualized in Fig. 3 and Fig. 4.

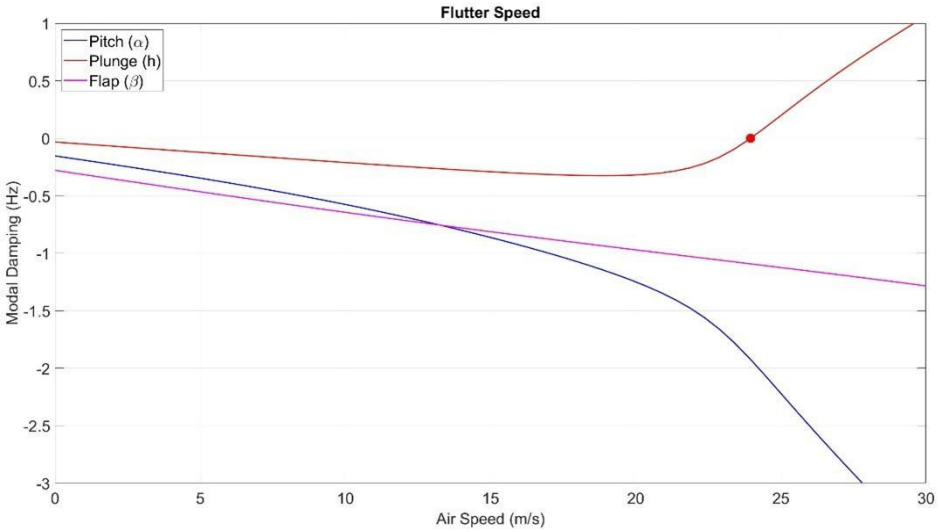

Figure 3. Flutter Speed Detection in U-G Plot.

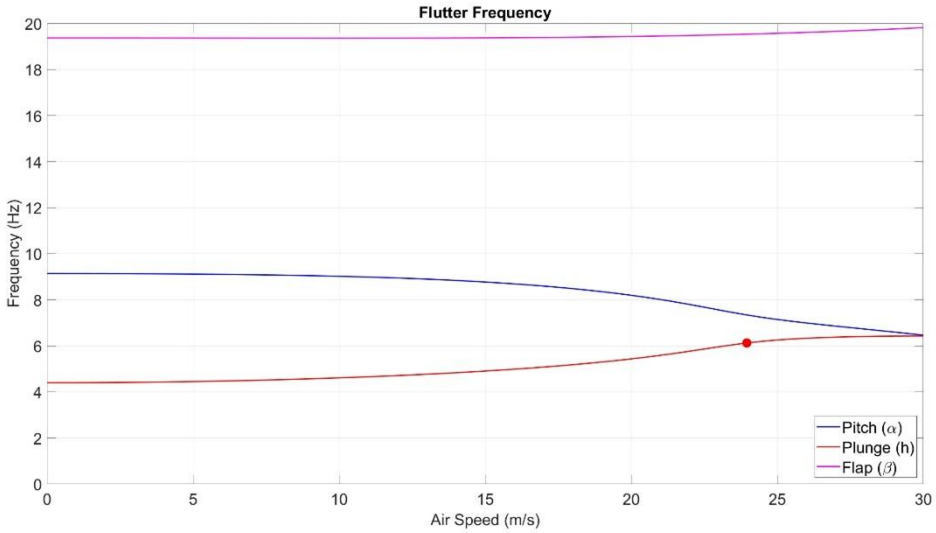

Figure 4. Flutter Frequency Detection in U-Frequency Plot.

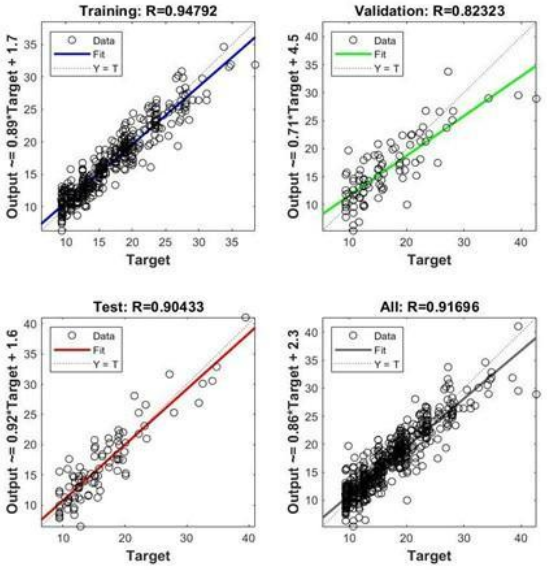
Performance Metrics are found as:
Training Regression Value (R^2): 0.9479
Validation Regression Value (R^2): 0.8232
Testing Regression Value (R^2): 0.9043
Overall Regression Value (R^2): 0.9169
The results from the FFNN model matched previous experimental and numerical studies, thus proving its accuracy. The result for the present study predicted the flutter speed, showing good agreement with the numerical result presented by Conner et al. at 23.9 m/s, corresponding to 6.112 Hz. It is this very good agreement which confirms that the FFNN-based flutter speed prediction is an effective alternative for the conventional computational procedure since it is considerably faster and efficient. The results are illustrated in Fig. 5 which are attached.



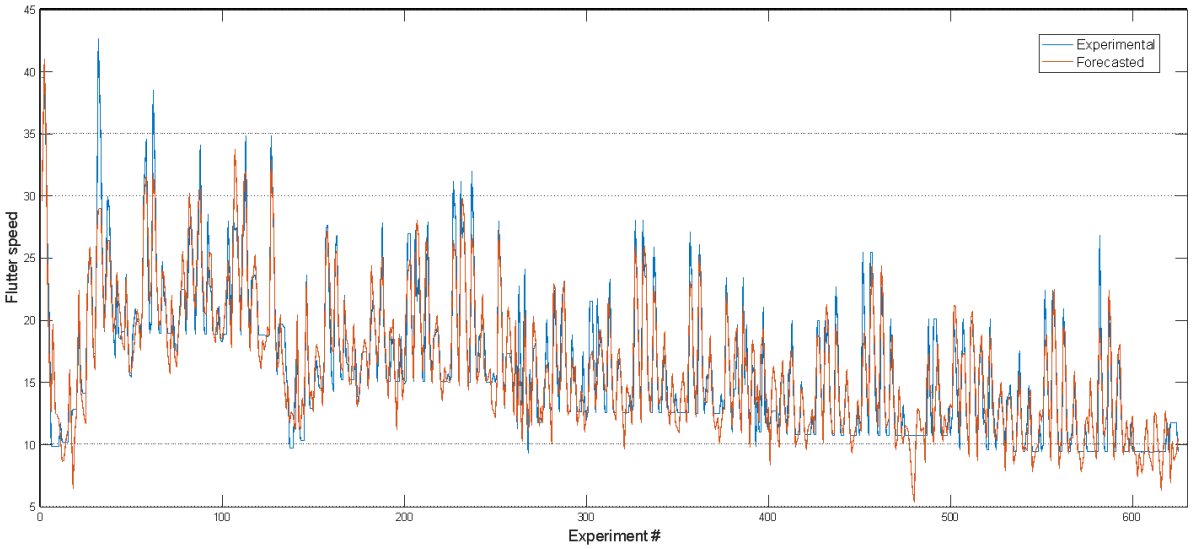


Figure 5. Comparison of Numerical and Forecasted Flutter Speed Values.

Conclusion

The research developed and validated an FFNN-based approach for the estimation of flutter speeds of aeroelastic systems. It shows the potential of machine learning in the advanced field of aerospace engineering, mainly due to reductions in computationally expensive CFD simulations and wind tunnel testing.

These results demonstrate that AI-driven approaches can significantly enhance aeroelastic analyses by giving fast and reasonably accurate predictions. This network gave a very high regression accuracy of 0.92 and thus proved to be pretty effective in estimating the flutter speed of an airfoil. The model predictions matched reasonably well with the experimental and numerical results, hence verifying their reliability. Besides, the proposed methodology here is economically viable and can be easily extended to other aeroelastic stability problems like flutter suppression and structural damping optimization.

This paper thus presents the viability of machine learning as an alternative to conventional aeroelastic analysis methods. The FFNN model was able to predict the flutter speeds successfully, hence reducing expensive and time-consuming simulations. As AI technology continues to advance, its application will become paramount in optimizing aircraft performance and safety.

Conceptual Modeling of a Multi-Axial Nonlinear Dynamic VibrationAbsorber for Helicopters

Özkan Karayiğit[a], Vedat Ziya Doğan[b], Halit Süleyman Türkmen[b], Ali Tatar[b]

[a] Istanbul Technical University, Aeronautics and Astronautics, M.Sc. Program, Türkiye
[b] Istanbul Technical University, Faculty of Aeronautics and Astronautics, Türkiye
karayigit23@itu.edu.tr

Keywords: Helicopter Fuselage Vibration Control, Multi-Axial Vibration Absorber, Nonlinear Dynamic Vibration Absorber, Optimization-Based Vibration Mitigation, Polynomial Nonlinear Stiffness Model.

Aim

Dynamic vibration absorbers (DVAs), which are an effective method for reducing vibrations caused by rotor, aerodynamic, and structural interactions in helicopters, are widely implemented in helicopter structures. DVAs are devices designed to minimize vibration amplitudes by adapting to the operating frequencies of a system. They were first introduced by Frahm [1] as a mass-spring system and later refined by Ormondroyd and Den Hartog [2], leading to their widespread use in different engineering applications. Over time, these absorbers have been further developed and integrated into various helicopter parts. In particular, bifilar and pendulum absorbers have been employed in rotor heads and blades, while fuselage-integrated vibration absorbers have demonstrated significant effectiveness. Today, DVAs continue to be widely used in many helicopter designs as highlighted in the reviews by Reichert [3] and Welsh [4]. As auxiliary mass is added to the main system, DVAs offer a practical and cost-effective solution without requiring major structural modifications.

Fuselage-integrated vibration absorbers are typically designed to operate in a single direction, predominantly targeting vertical (z-axis) vibrations. These absorbers are tuned to specific frequencies to effectively reduce structural vibrations in the fuselage. However, during dynamic flight conditions, such as maneuvers and varying aerodynamic loads, significant vibrations can also occur in the longitudinal (x-axis) direction. Additionally, conventional linear DVAs are only effective within a narrow frequency range, limiting their robustness against fluctuating excitation forces. These challenges necessitate the development of more adaptive and effective vibration control solutions.

To address these limitations, this study proposes a conceptual model for a multi-axial nonlinear DVA that can be integrated into the helicopter fuselage to mitigate vibrations in both the x and z directions. Unlike conventional linear absorbers, nonlinear DVAs can operate over a broader frequency range, enhancing vibration attenuation capabilities and adaptability to varying flight conditions. Most nonlinear vibration absorbers in the literature are modeled using various nonlinear stiffness formulations, such as polynomial, piecewise, hysteretic, and geometric nonlinearities. These different modeling approaches are discussed in detail in studies by Zheng Lu [5] and Balaji [6]. While many works, like Alsuwaiyan [7], have adopted cubic stiffness systems due to their simplicity and tunability, this study defines the absorber's stiffness characteristics as a polynomial function. This approach offers greater flexibility in shaping the force-displacement behavior, allowing for a more tailored response to varying excitation conditions. To achieve an optimal design, the polynomial coefficients of the stiffness function will be determined through an optimization process in MATLAB. This approach will enable the development of a nonlinear spring with customized stiffness properties, ensuring effective vibration mitigation across a wider frequency range.

Material and Method

In this study, a multi-axial nonlinear dynamic vibration absorber (DVA) is modeled as a two-degree-of-freedom mass-spring-damper system with nonlinear restoring forces in both the x and z directions. The nonlinear restoring forces are represented by third-degree polynomial functions, defined respectively for the x and z axes as follows:

$$f_{non,x} = a_1(x_2 - x_1)^3 + a_2(x_2 - x_1)^2 + a_3(x_2 - x_1) + a_4$$

$$f_{non,z} = b_1(z_2 - z_1)^3 + b_2(z_2 - z_1)^2 + b_3(z_2 - z_1) + b_4$$

The coefficients a_1, a_2, a_3, a_4 and b_1, b_2, b_3, $b_4$determine the force-displacement behavior of the absorber and will be optimized to maximize vibration attenuation. The excitation forces in both directions are modeled as harmonic sinusoidal loads and defined respectively for the x and z axes as follows:

$$F_x(t) = F_{0x} sin(\omega_x t - \varphi_x)$$

$$F_z(t) = F_{0z} sin(\omega_z t - \varphi_z)$$

Where F_{0x} and F_{0z} are the maximum force amplitudes, ω_x and ω_z are the excitation frequencies for x and z directions, and φ_x and φ_z represent the phase angles corresponding to these excitations, respectively. Same parameters are used for both axes to ensure the consistency of theoretical analyses and to validate the dynamic behavior of the system. The equations are numerically solved in MATLAB using the Runge-Kutta method. To compare the performance of the proposed nonlinear absorber, a conventional linear DVA model is also developed by replacing the nonlinear stiffness components with linear stiffness elements, k_{2x} and k_{2z}, in the x and z directions. The effectiveness of both models is evaluated by analyzing displacement-time responses under harmonic excitation.

Findings

The conceptual model of the multi-axial nonlinear DVA has been developed, and its analysis has been conducted using MATLAB. Additionally, results for the linear DVA have been obtained, providing a basis for comparison and further evaluation. In the preliminary analysis, the nonlinear model was constructed using unoptimized values for the coefficients, and the corresponding results were obtained. The values used for the analysis are shown in Table 1, with Figure 2 illustrating the displacement-time graph for the nonlinear model and Figure 3 comparing the initial results for both the linear and nonlinear models. Results are shown for the x direction only since the same values are used for both the x and z directions.

Conclusion

The conceptual model of the multi-axial nonlinear DVA shows promising results in mitigating helicopter vibrations in both x and z directions. The nonlinear stiffness function allows for better adaptability to varying operational conditions, enhancing the effectiveness of the absorber. Further studies will focus on optimizing the stiffness coefficients to maximize vibration suppression across a wider range of frequencies. Additionally, the proposed nonlinear DVA will be compared with existing fuselage-integrated absorbers to evaluate potential improvements in vibration mitigation. In addition, the enhanced adaptability demonstrated by the nonlinear system provides a solid foundation for future research on integrating smart control strategies. This advancement could lead to a new generation of vibration absorbers that dynamically adjust to real-time flight conditions, further improving helicopter safety and performance.

The authors would like to express their gratitude to Turkish Aerospace Industries (TUSAŞ) for providing the necessary resources and support throughout this study. Their financial and technical assistance have been instrumental in the successful completion of this study.

Aim

The aim of this study is:

- To obtain Sea Level and +15°C Cruise Chart of S70A-28D (UH-60L,Black Hawk) Helicopter by using Momentum and Blade Element Momentum Theory for hover and forward flight conditions for 23.500, 22.000, 20.000, 18.000, 16.000, 14.000 and 13.000 pound Take off Gross Weight [1] and
- To compare the manufacture's data with the obtained.

What is Cruise Chart

The chart gives:

- The fuel flow rate and fuel consumption rate per hour,
- True airspeed for various combinations of pressure altitude, temperature, and engine percent power,

Speed of;

- Maximum endurance and best rate of climb, where L/D is maximum.
- Maximum range speed, which provides the longest range during cruise, where fuel consumption is minimum, allowing an aircraft to travel the farthest possible distance on a given amount of fuel when the engine is operating at its most fuel-efficient point,
- Maximum level flight, which refers to the maximum airspeed while maintaining level flight at a specific altitude and configuration. It represents the highest speed at which the aircraft's thrust equals its drag in a steady, level flight condition [2].

Material and Method

In order to obtain the sea level +15°C cruise chart of the manufacturer's S70A-28D (UH-60L, Black Hawk) Helicopter, interpolations of;

- The temperature of the +10°C and +20°C cruise charts,
- Max level speed, max range speed,
- Max level speed, max endurance and rate of clımb, lift-to-drag ratio L/D maxımum (Figure 4),
- Torque need to be made interpolated (Figure 1) [2].

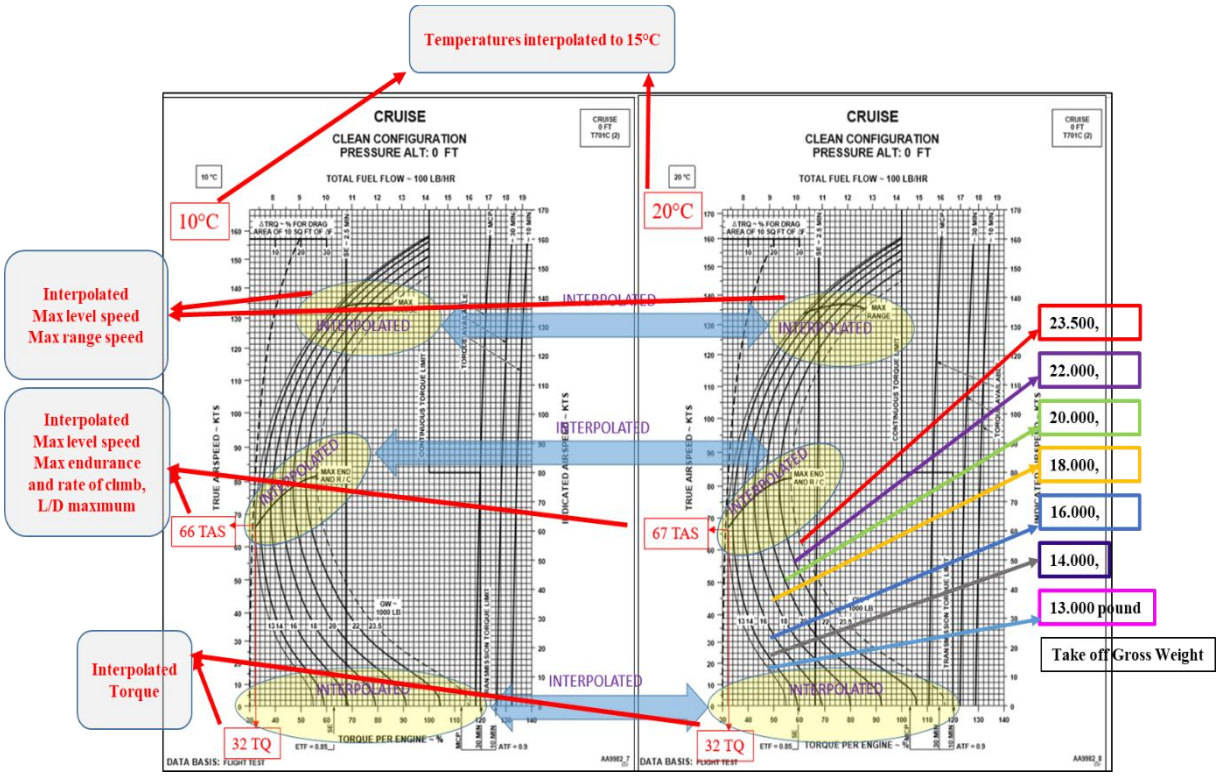

Figure 1. Cruise chart [1].

Interpolated data was prepared in advance and placed in the comparison table. At the end of the study, the obtained data will be placed in the comparison table and the differences between the two data will be evaluated. Accordingly, it will be determined how close we are to the manufacture's cruise chart (Table 1).

Momentum Theory in Hover

Momentum theory assumes;
- A smooth,
- Incompressible,
- With zero vorticity across the rotor disk.

It is based on three basic systems of fluid mechanics;
- Conservation of mass,
- Conservation of momentum,
- Conservation of energy.

Momentum theory accounts for;
- Thrust generation,
- Induced velocity,
- Mass flow rate,
- Power required,
- Energy conservation in actuator rotor disc.

The theory aims to **identify three unknowns**:
- Inflow velocity, λ,
- Wake,w, downstream velocity in the far field below the rotor disk,
- The fully contracted flow area, A4 [3][4][5].

To **summarize ;**
- The Momentum theory assists in the preliminary evaluation of a rotor and helps in the comparison of various rotors. However, the theory does not help directly with the design of a rotor.

The hovering efficiency of the rotor is defined as:

$$\text{Figure of Merit} = \frac{(\text{Minimum Power Required to Hover (ideal power)}(P_i = Tv_i)}{(\text{Actual Power in Hover } (P = \rho A\,(\Omega R)^3\ C_p)} \quad (2.1)$$

- The downwash in the far wake is twice the induced velocity at the rotor disk, $\mathbf{w}=\mathbf{2}v_i$,
- Momentum theory gives an expression for induced velocity at the rotor disk,
- It also gives an expression for consumed by a rotor of specified dimensions.

The flow characteristics around a rotor in hover are illustrated in Figure 1 and assumed pressure jump across rotor disk is uniform. Figure 1 summarizes momentum theory in hover. There are four stations, which are:
- Station 1: far feld upstream,
- Station 2: actuator rotor disc, rotor disc area (πR^2),where R radius of blade,
- Station 3: below the rotor disc,
- Station 4: far-field downstream.

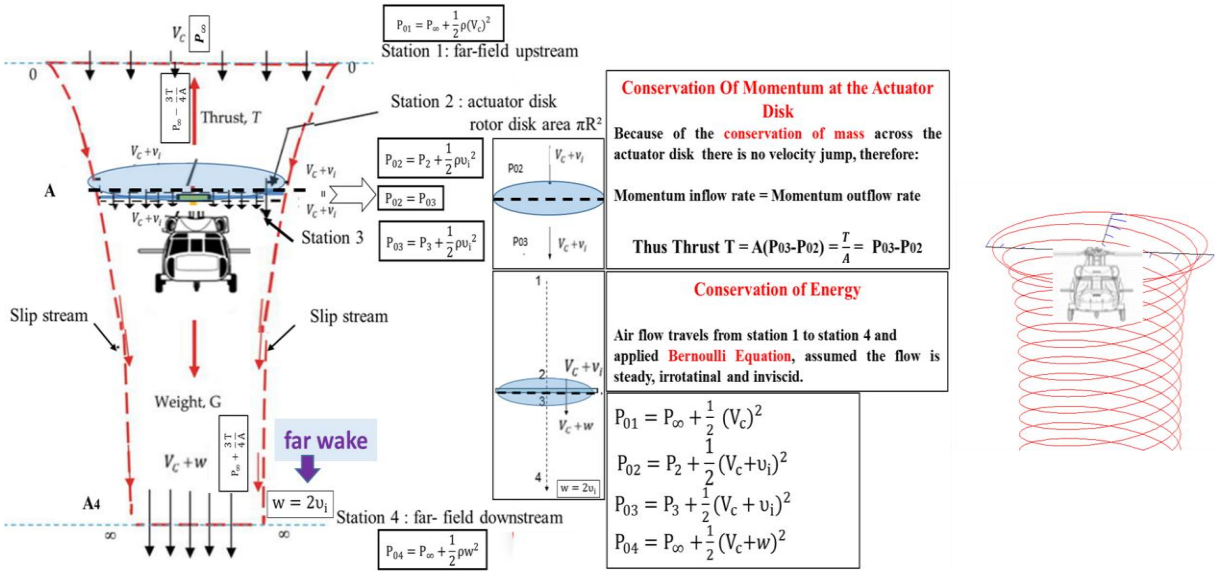

Figure 2. Air flow around rotor actuator in hover [3] [11].

Blade Element Momentum Theory in Hover

Blade element theory includes effects of rotor RPM and blade surface area. It examines the aerodynamic characteristics of an element of the rotor blade by utilizing methods that close mimic airfoil theory. In some cases, it is helpful to combine it with momentum theory in order to reach the necessary equations. Momentum theory and blade element theory are only adequate for conceptual and preliminary design and not for advanced blade design [3][4][5].

Momentum Theory limitations are;
- It provides no information on how rotor blades should be designed to produce a given thrust
- It does not account for
  - rotor rpm, number of blades, nor blade area,
  - airfoil characteristics (lift, drag, angle of zero lift),
  - blade planform (taper, sweep, root cut-out),
  - blade twist distribution,
  - compressibility effect.
- Profile – drag losses are ignored,
- Blade Element Theory provide ways to reduce these limitations.

Drawbacks of Blade Element Theory [5] [6]:
- It assumes that the induced velocity v_i is uniform,
- The predicted power is sometimes empirically corrected for these losses by using K_h=1.15,
- It does not handle tip losses,
- It does not account for swirl losses.

Momentum Theory in Forward Flight

The assumptions are:
- The rotor induced power in forward flight is obtained by a momentum theory,
- A uniformly loaded actuator disk is used to represent the rotor,
- In a forward flight such an actuator disk can be viewed as with a forward tilted, α, circular wing,

- Actuator disk operating at velocity resultant velocity,V_R with the angle of attack α between the free stream velocity and the rotor disk [1] (Figure 3).

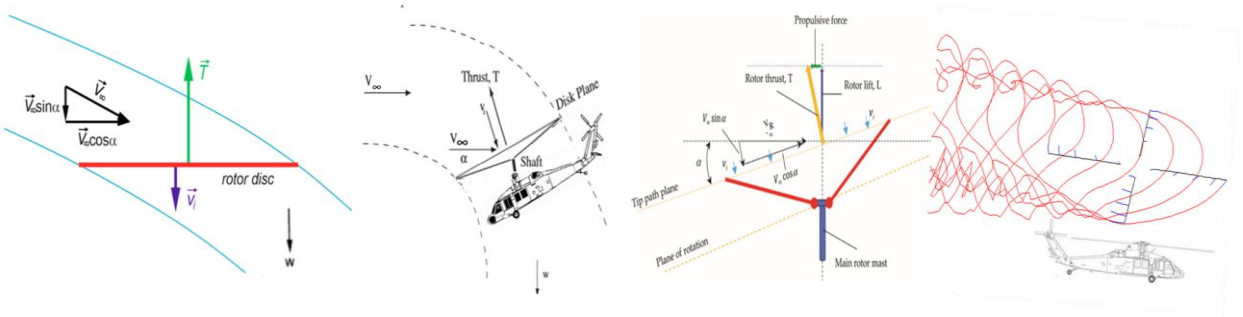

Figure 3. Forward flight [1]

Blade Element Momentum Theory in Forward Flight

Main Rotor Power Required:
The total power required at the rotor, P, can be expressed by the equation (Figure 4);

$$P = P_i + P_o + P_p + P_{tr} \quad (2.2)$$

Where

P_i = induced power,

P_o = profile power required to overcome viscous losses at the rotor,

P_p = parasitic power required to overcome the drag of the helicopter profile,

P_{tr} = tail rotor thrust [7].

$P_i = K_f T v_i$ Where $K_f = 1.2$,

$$P_o = \frac{\sigma C_{d_0}}{8} \rho A(\Omega R)^3 (1 + 4.65\,\mu^2)$$

$$P_p = \frac{1}{2}\rho f_v (V_V)^3 + \frac{1}{2}\rho f_f (V_f)^3 \quad (2.3)$$

$$T_{tr} = \frac{(P_i + P_0 + P_p)_{main\ rotor}}{\Omega_{mr}\, l_{tr}} \quad (2.4)$$

Where σ is the solidity, C_{d_0} is coefficient of zero-drag, μ is the advance ratio, f_v flat plate area in vertical is flight and f_f is flat area in forward flight [8], V_V is vertical velocity, V_f is vertical velocity, Ω is the angular velocity of the main rotor and l_{tr} is the tail rotor moment arm about the main rotor shaft.

$$P_{tr} = P_{i_{tr}} + P_{o_{tr}} + P_{p_{tr}} \quad (2.5)$$

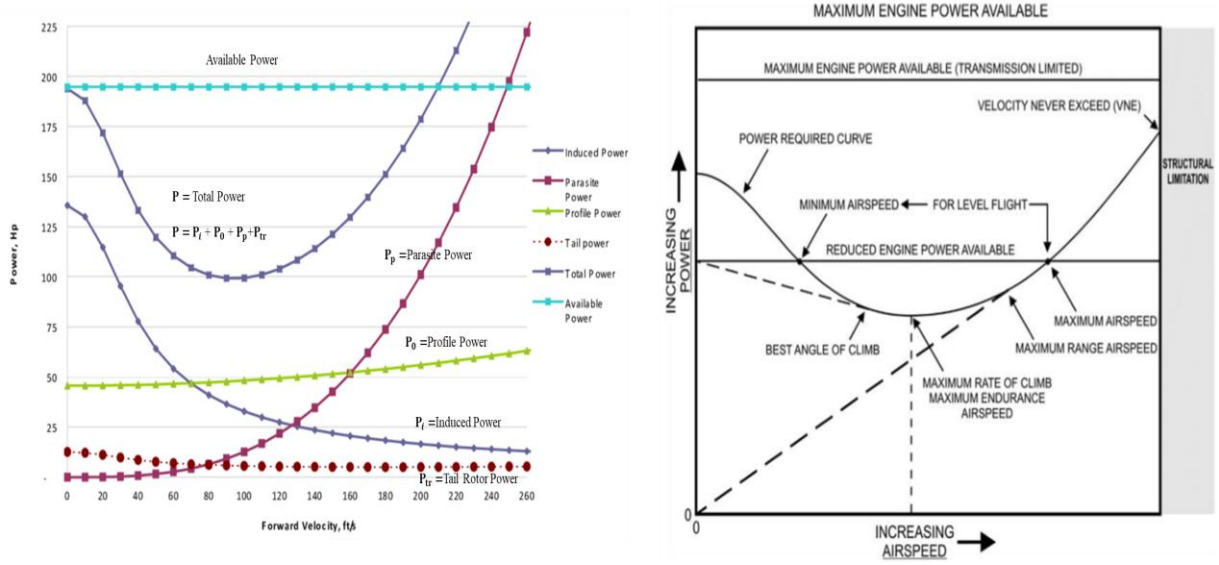

Figure 4. Main rotor power required in forward flight [9] [10]

Findings

The findings are divided into two sections, hover and forward flights.

Hover

Hover findings are shown in Table 2.

Forward Flight

The advance (μ) and inflow ratio (λ), calculated, are used for non-dimensionalized forward flight power coefficient calculation to obtain proper power curved diagram, otherwise it is impossible to achieve cruise chart. The curved diagram and iterations obtained are shown in Table 3.

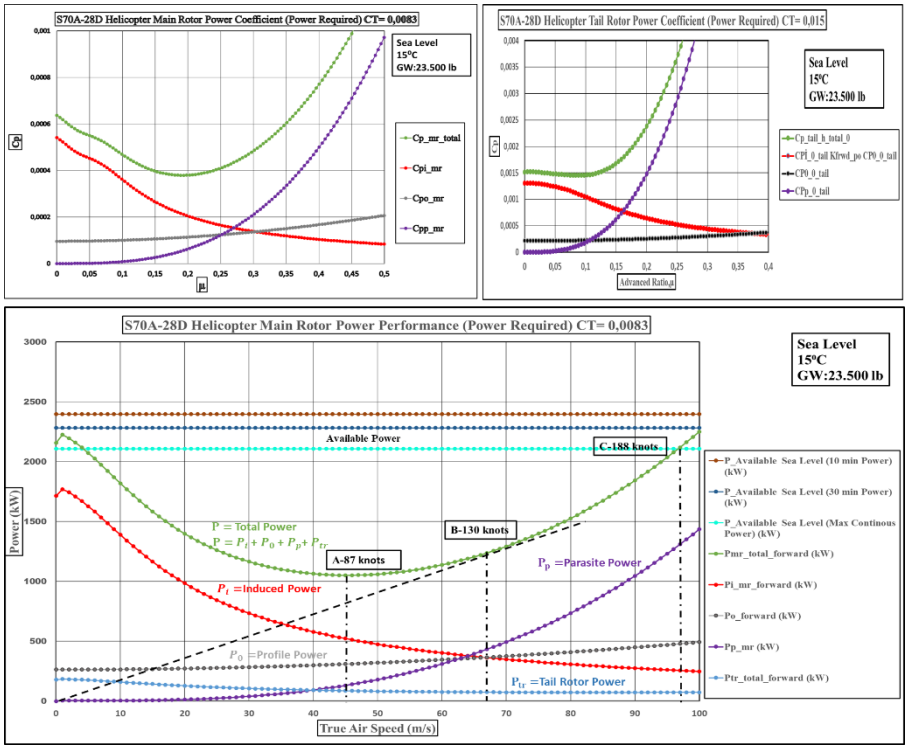
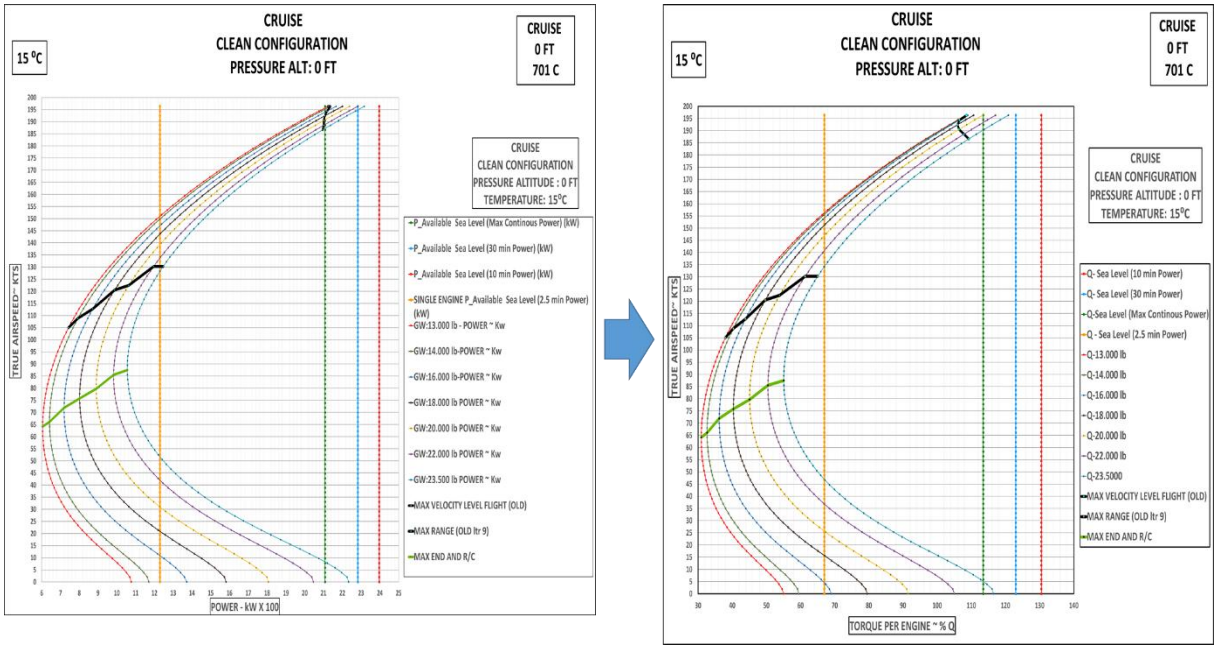
By using the total 360 of iteration, power required curves are obtained for the take-off gross weight of between 23.500 and 13.000 pounds (Table 4).

Table 4. Power required curves



The power required obtained for each the take-off gross weight of between 23.500 and 13.000 pounds are combined in one TRUE AIRSPEED versus POWER (kW) and then it is converted by interpolating into TRUE AIRSPEED versus TORQUE PER ENGINE (%Q), which is percent system in the cockpit (Table 5).

Table 5. Cruise chart obtained



The obtained,

- Max level speed, max range speed,
- Max level speed, max endurance and rate of climb, lift-to-drag ratio L/D maxımum,
- Torques are put into excel sheet (Table 1).

Conclusion

It can be seen as the forward speed increases from hover, the power initially decreases up to a forward speed of about μ = 0.14 - 0.2, which is between 64 and 88 knots (between 23.500 and 13.000 lb.) on the cruise chart referring mainly to the velocity of best endurance and rate of climb section, which represents the maximum L/D point and then the power increases drastically with forward speed.

The initial decrease in power requirement is mainly due to the reduction in induced flow through the main rotor as the helicopter increases its speed from hover.

As the speed increases for max range velocity and max velocity for level flight, the parasite drag power of the helicopter, $P_p = \frac{1}{2}\rho\, f_v(V_V)^3 + \frac{1}{2}\rho\, f_f(V_f)^3$ increases in cubic power of forward speed and the differences between findings and flight manual's gaps gets bigger.

The accuracy of this study is valid for lower speed and the data obtained can give an idea for conceptual and preliminary design process.

For more accurate output and solutions, there should be a thorough analysis of the underlying data, careful calibration of the models used, and the use of more sophisticated software tools to account for all relevant variables and complexities during test flight phase.

The C_{d0} value was used in calculating P_0, $P_o = \frac{\sigma C_{d_0}}{8}\rho\, A(\Omega R)^3\,(1 + 4.65\,\mu^2)$ for each TOGW. If the C_{d0} value, which should be calculated for the blade element segments according to blade element momentum theory, was used instead, the μ and V_∞ (knots) values would be lower than the delta value at forward speeds.

For speeds above 60 knots, a combination of momentum and blade element theory generally offers a sufficiently accurate foundation for routine engineering practice. This accuracy is enhanced when performance predictions made using this approach are validated with flight test results or compared with more precise theoretical methods, such as those based on vortex theories [12].

Therefore for the future study to obtain more precise data for max range and max velocity for level flight combined blade element momentum should be applied for each segment of the blades with accurate tip losses model.

Liquid Propellant Rocket Engine Performance Sensitivity Analysis

Turan Çopuroğlu[a], Fırat Oğuz Edis[a]

[a] Istanbul Technical University, Department of Aeronautical and Astronautical Engineering, Türkiye
copuroglut16@itu.edu.tr

Keywords: Engine Performance Fine-Tuning, Liquid Propellant Rocket Engine, Mixture Ratio Control.

Aim

Liquid propellant rocket engine is designed to ensure the stringent performance launch vehicle system requirement. In initial stages of project, there are a lot of uncertainties belongs to subsystem component designs. Variation in fluid thermophysical and thermodynamical properties and component manufacturing tolerances change engine performance outputs. Even small deviations in engine performance may cause significant deviation of launch vehicle operation. Engine performance map must be remained within the acceptable launch vehicle system requirement envelope. Otherwise, launch vehicle cannot perform success mission. For this reason, uncertainties regarding to engine sub-component performance must be considered at the engine initial design stage [1].

Analytical methods used in component design processes, computational fluid dynamic analysis results and manufacturing tolerances causes errors and differences in pre-determined performance. Therefore, each liquid propellant rocket engine subsystem has its performance margins individually.

In the early stages of liquid propellant rocket engine system design, all subsystem margins have to be considered to determine and optimize key parameters which have crucial impact on the engine performance. This enables to more manageable design process with controlled uncertainty as project progresses. Thus, the engine performance fine-tuning can be performed more robust and reliable to be met more precisely in the development stages.

In this study, Gas-generator cycle rocket engine is focused on. Gas-generator cycle is an open cycle rocket engine. The gas-generator cycle rocket engine consists of thrust chamber, feed system, turbopump, gas generator, valves and orifices [2].

For on-design conditions of engine, nominal inputs lead to the expected engine performance output. In order to examine key parameters changing effects on the engine performance, three parameters variations on performance dispersion were investigated. Pump efficiency, turbine efficiency, valve flow coefficient variations were examined. In these parameters, variation effects are investigated to analyze on chamber pressure, gas generator pressure, turbine inlet temperature, main chamber mixture ratio. It is aimed to examine not only the relationship between inputs and outputs but also the outputs effects interdependency. This study is also focused on determining pressure drop margins for orifices which are located in gas generator and thrust chamber feed lines [3]. Orifices, passive control components, are used to liquid propellant rocket engine fine-tuning [4].

Material and Method

The study involves performance calculations of the liquid rocket engine components, including the thrust chamber, turbopump, gas generator, oxidizer valves, fuel valves, feed lines, and orifices.

Engine performance map is derived after each component performance calculations performed. In order to obtain performance map, fluid dynamic and thermodynamic equations are solved. These equations provide the relation between pressure, mass flow rate, temperature, fluid thermophysical properties for all sub-components in the system. These parameters affect on the engine's overall performance are shown using developed zero-dimensional calculation program. This program provides a robust calculation for determining performance variations in the engine system. Thanks to this methodology, manageable design stages can be achieved during engine development process.

Findings

The mode analysis provides to obtain liquid propellant rocket engine performance for different conditions [5]. Variations in the three parameters lead to several important findings that impacted the overall engine performance. Changes in pump

efficiency were found to directly affect the pressure at the thrust chamber and gas generator combustion pressure and this affects overall engine performance. Similarly, since turbine efficiency governs the power transferred to the pumps, leading to scatterings in engine performance map. For higher the turbine efficiency, power generated turbine is increased and this leads the higher pump discharge pressures. Thus, better engine performance is provided. However, lower turbine efficiency causes to reduced pump discharge pressure and engine performance is reduced. The shifting pump curves causes to change engine operating condition because intersection with system curve is changed.

Changes in the valve flow coefficient also played a significant role in the system performance, as they directly influenced the pressure drop margins within the hydraulic system. These fluctuations resulted in adjustments to the flow rates within the engine, affecting the performance regime of the system. A higher valve flow coefficient lead to lower pressure drop across the valve, lower valve coefficient higher pressure drop across the valve. For this reason, system curve shift in response to changes in the valve flow coefficient. Furthermore, the relation between system curve and pump curve determines the engine operating point. Therefore, engine operating conditions may be changed with these small deviations on the valve coefficient.

Using randomness margins of three parameters, engine performance map was created. Visualization of overall impact of these parameter variations on the chamber pressure, gas generator pressure, turbine inlet temperature, main chamber mixture ratio was derived. In order to compensate engine performance deviations, orifice pressure drop margins were determined. It enables fine-tuning of the system to meet performance requirements more precisely. The introduction of controlled pressure losses using determined orifice margins allowed the system to compensate for performance variations and ensure engine performance requirements across different engine modes.

Conclusion

This study highlights the importance of considering performance dispersion factors during the design and development of gas-generator cycle liquid rocket engines. Investigating key parameters variations, the study provides a comprehensive understanding of how these factors influence engine performance. Through mode calculation program and detailed performance mapping, it was possible to visualize the impact of parameter variations and evaluate potential system uncertainties before they affect the final system performance. The orifice pressure drop margins derivation indicates the importance of fine-tuning sub-components to achieve precise performance requirements. In rocket engine development processes, the performance resolution of sub-components is increased through component tests and uncertainties in the system are reduced. Using the orifices pressure drop margins, system calibration can be achieved. This comprehensive approach ensures that the engine can perform reliably under a range of expected conditions.

In conclusion, the findings of this study contribute to the development of more robust and reliable liquid rocket engines. System engineers can enhance the engine's efficiency, stability and overall reliability with minimizing development risks using zero-dimensional calculation tool. This provides the opportunity to engine designer for suitable the demanding performance requirements of launch vehicle systems and ensures mission success.

Keywords: Axial Turbomachinery, CFD, Deep Learning.

Aim

Computational Fluid Dynamics (CFD) has been the standard for aerodynamic performance evaluation in turbomachinery design. However, traditional CFD simulations are computationally expensive and time-consuming, often requiring hours to analyze a single design iteration. This computational bottleneck significantly limits the number of design alternatives that can be explored within practical engineering timelines. As modern turbomachinery design increasingly demands high-fidelity simulations due to the nature of the complex physics, the need for a faster, data-driven alternative becomes crucial. Deep learning has emerged as a useful tool to overcome these computational limitations by providing rapid aerodynamic performance predictions based on previously simulated data. Deep learning models can learn the patterns behind turbomachinery flow physics and output the aerodynamic parameters within milliseconds once trained.This capability significantly increases the number of design iterations that can be evaluated in a given time, accelerating the overall design process while maintaining a high level of accuracy. As an example, pressure losses are predicted using generative adversarial networks architecture by taking the airfoil geometry as input [1].
This study aims to develop and evaluate a deep learning-based model capable of predicting CFD results for various turbomachinery geometries, significantly reducing computational costs while maintaining prediction reliability. The model takes as input geometric configurations of axial fan blades and predicts key aerodynamic. By integrating deep learning into the design workflow, this research demonstrates how artificial intelligence can revolutionize turbomachinery design by enabling faster, more data-driven engineering decisions.

Material and Method

In this study, the dataset is provided by TEI and consists of the blade and flowpath geometries as well as the CFD results. The dataset consist of 1800 separate CFD results including different rotational speeds, designs, number of rows and downstream static pressure (matching on speedline). NUMECA Software is used for pre-processing, solving and post-processing. Mesh resolution is determined such that y+ values remain under 5. Total pressure and temperature are set for the inlet boundary condition, while static pressure is set for the outlet boundary condition at different RPM values. The four parameters mentioned are used as input parameters for the deep learning model. As blade parameters should be investigated on each streamtube for the more precise investigations of turbomachinery flows, a post-processing algorithm to split rotor-stator interaction planes have been implemented. For each of the CFD results, all planes at the upstream and downstream of the rows are detected, and then divided into 15 parts in radial direction that contains the same amount of the mass flow rate. The physical quantities then exported for the divided streamtube planes.
Fan designs have been made using the AxStream software and the geometry information is exported as the "geomTurbo" format. The geometry dataset contains Cartesian Coordinates of the blades suction and pressure sides and axial-radial coordinates of the hub and shroud flowpath. Before preparation of the input tensor, blade geometries are converted to the Polar Coordinate system.
The input tensor for geometry is a 10-channel tensor consisting of:

- R theta Z coordinates for the suction side (3 channel)
- R theta Z coordinates for the pressure side (3 channel)
- R Z coordinates for Hub and shroud (2 channel)

- Number of blades (1 channel)
- Rotor or Stator information (1 if rotor, -1 if stator) (1 channel)

Height and width of the input tensor depends on the export parameters selection. Height represents the number of sections of the exported blade geometries. Width contains the number of rows and number of exported points for each airfoil section. To clarify, when the number of points exported for each of the suction and pressure sides is 200 and the number of rows is 4, the width of the tensor becomes 800. Typical setup for the datased used in this study is 15 sections and 225 points for the airfoil coordinates.

The Vision Transformer (ViT) is emerging architecture designed specifically for image processing tasks, employing attention mechanism for image input [2]. The model can outperform the other image recognition models based on convolutional neural networks and have many variants including different approaches.

Model used in this study is a combination of a Vision Transformer for geometrical input tensor and a standard transformer architecture for the boundary conditions input. Patch embedding and positional embedding blocks takes the geometry tensor as input and outputs the embedded vector with size defined by the patch size. In parallel, the simple transformer model processes the boundary condition information. After the boundary conditions and geometry is processed, resulting tensors are multiplied and becomes input for the attention blocks.

At the final stage, models forward head module results physical parameters for each streamtube and row. Resulting physical parameters areAbsolute Static Pressure and Temperature, Absolute and Relative Mach Numbers, three normalized velocity component in polar coordinates.

Absolute Total Pressure and Temperature are calculated using the isentropic relations inside the model to provide additional feedback from total quantities and reduce the model error and speed up the convergence. On the other hand, modelling the physical relations inside the model instead of adding as a penalty term during training, ensure the model gives phsically consistent results, specifically for the testing the unseen data, however, it is not possible to perform this strategy for each constraint.

As an additional constraint, the conservation of mass is imposed by calculating the mass flow rate at planes and standart deviation of the calculated mass flow rate values are added as the penalty term in training.

Findings

Model trained using 1800 CFD results and 80 percent of the datased used as a training and the remaining part is used for the test. The training phase converged to below 1% error for both the training and test datasets, as shown in Figure 1.

Figure 1. Train and test error.

Figure 2 shows the performance map results of an unseen axial fan geometry at design speed. Mass flow rate is calculated as the average of the rotor-stator stations. As seen in the figure, the model predicts the mass flow rate and pressure ratio with an error below 0.5%. However, most of the error comes from the mass flow rate deviation at choke and stall conditions.

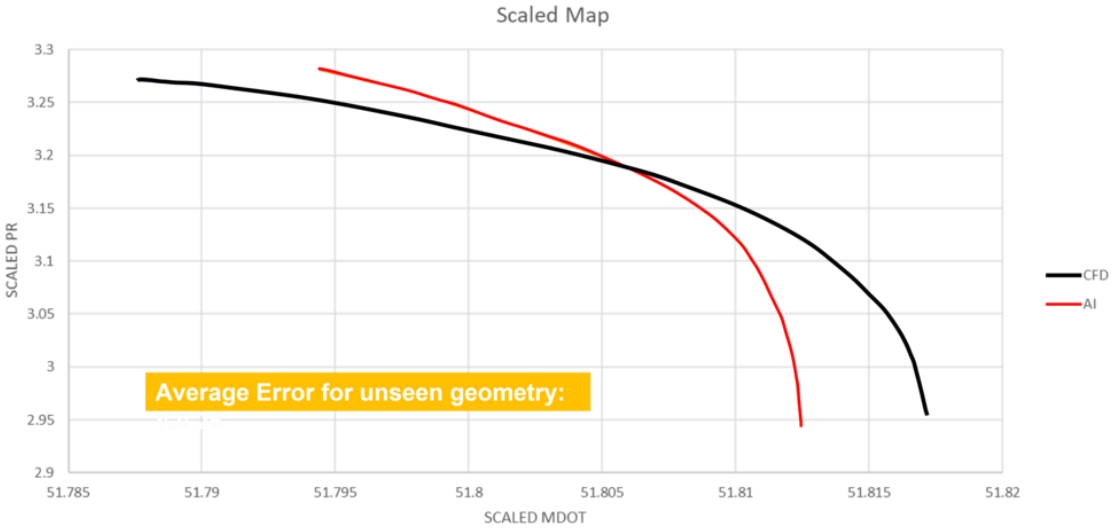

Figure 2. Performance map comparision.

In Figure 3, radial distribution of physical quantities for a single row is shown. Model successfully predicts the radial profile behaviour even at the endwalls, however there is a small deviation specifically on endwalls.

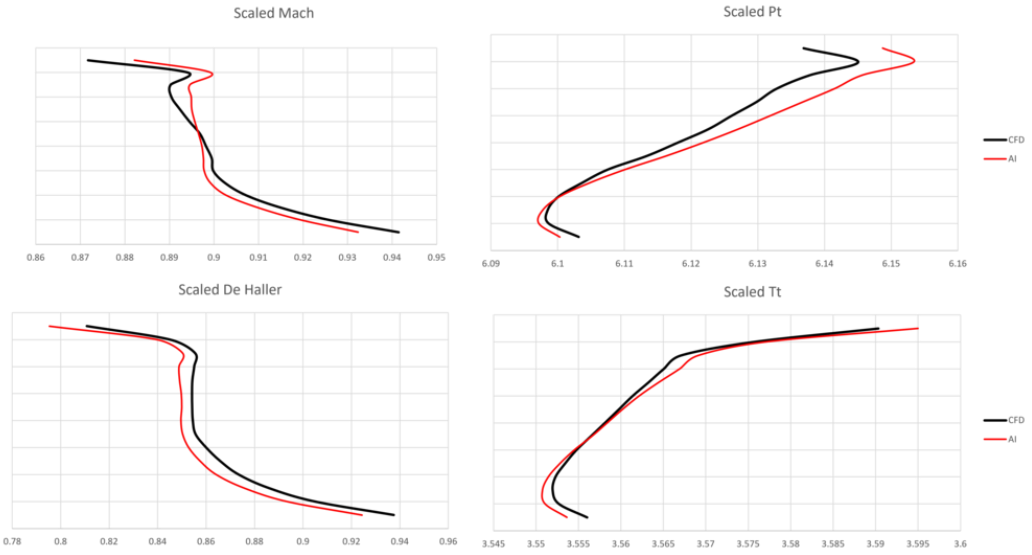

Figure 3. Radial profile for single row.

Conclusion

This study shows the potential of deep learning for predicting CFD results in turbomachinery applications. By leveraging a Vision Transformer-based approach, geometric features are mapped to aerodynamic performance parameters, significantly reducing computational costs and time compared to traditional CFD simulations. While the model performs well for general aerodynamic trends, its sensitivity to small-scale geometric variations remains a challenge for now. Future

work will focus on enhancing feature representation techniques and incorporating novel deep learning architectures to improve accuracy and generalization across turbomachinery geometries.

Keywords: Gust, Swept Wing, Vortex.

Aim

A considerable amount of research has been recently devoted to the study of massive separation and its control caused by large-scale discrete gusts [1]. Among the three major categories in discrete gust encounters [2], vortex gusts are probably the best representing the real-life scenario where only single direction velocity fluctuations are not possible to observe. Most of the investigations up to now, either experimental or numerical, are focused on quasi two-dimensional gust encounters. However, three-dimensionality is another important issue to be addressed to understand the flow physics for gust mitigation in civil and/or military applications considering that operations in extreme weather conditions become more important and necessary nowadays. As pointed out in recent studies [3, 4], knowledge on the physics of three-dimensional gust encounters is lacking and the aerodynamic response of finite-span wings with sweep angles encountering gust is of a great interest. Therefore, the main objective of this study is to investigate the three-dimensional flow structure interactions in a massively separated flow over a swept wing. The wing tip shape is also considered to include the misalignment of the tip with the flow.

Material and Method

This study is based on the previous experimental investigations where a vortex gust encounters a flat plate, aspect ratio of AR=4 wing [5, 6]. An upstream plate is used to generate a negative vortex gust with its half rotation around its center chord and different rotation rates (half rotation durations of 3s, 4s and 6s) are used to control the vortex gust and velocity profile gradient distance [7]. The positioning perpendicular to the freestream direction of the gust generator and the model is also considered as another parameter to control the encounter path of the vortex gust. T = 4s and $\Delta y = -36$mm constitutes the base case. For $\Delta y = -36$mm, the vortex gust moves aligned with the chord line of the model, therefore h/c = 0. Another trajectory where $\Delta y = -111$mm (h/c = −0.75) is also considered to study a weaker interaction. The flow speed is kept constant to have Re = 10 000 as in the previous experiments. The test model at 0° angle of attack throughout this investigation. In this study the flat plate is at a 45-degree sweep angle and with the same aspect ratio of 4 as before. 2D2C Digital Particle Image Velocimetry (DPIV) is used for the visualization of the flow structures, along with force measurements with an F/T sensor attached to the rod passing through the leading edge of the wing root.

Findings

Quantitative flow visualization results show that there is a non-linear shift in time for the occurrence of similar flow structures observed in the gust encounter. Figure 1 shows the vorticity plots of swept wing case in comparison with the previous study on 2D wing. Upstream camera results indicate that the generated vortex gust is not very affected by the wing being swept. However, the positive leading-edge vortex interacting with the positive vortex shed from the gust generator with comparable size and location obtained at t = 2s for the 2D case is now observed at 3s < t < 4s for the swept wing. It should be noted that the convective time, t*, is equal to t in these experiments $t^* = tU/c$ and the leading edge of the root section is at the same location as that of the 2D wing. Therefore, with the freestream speed, it would take a second for the negative vortex gust to encounter the leading edge of the illuminated plane. On the other hand, previous studies [8] showed that the negative vortex gust does not convect downstream at the freestream speed, rather its convection speed is approximately half of the freestream speed. As can be seen in Fig. 2, the lift transient for the base case (half rotation in 4s

and) occurs later in time in agreement with the quantitative flow visualizations and has considerably lesser effect for the swept wing. On the other hand, the flow structures are very similar at the minimum peak value of the lift coefficient. Although it is for transverse gusts, it has been shown that the occurrence of the peak transient shifts in time and the peak reduces down with increasing sweep angle [4]. In this study on the three-dimensionality and sideslip in strong transverse gust encounters, the rectangular wing is rotated to obtain a sweep angle and misalignment with the cross-flow jet [4]. As a consequence, a swept wing may have a sharp tip and a tip cross-section not aligned with the flow direction. For the current study on vortex gusts, Fig. 3 shows the results on the wing tip shape effect for the gust encounter in close interaction case ($\Delta y = -36$mm). Whether the tip of the swept wing is aligned with the flow or not, as long as the planform area is correctly considered, there are no major differences in the lift transient for all gust generator rotation speeds.

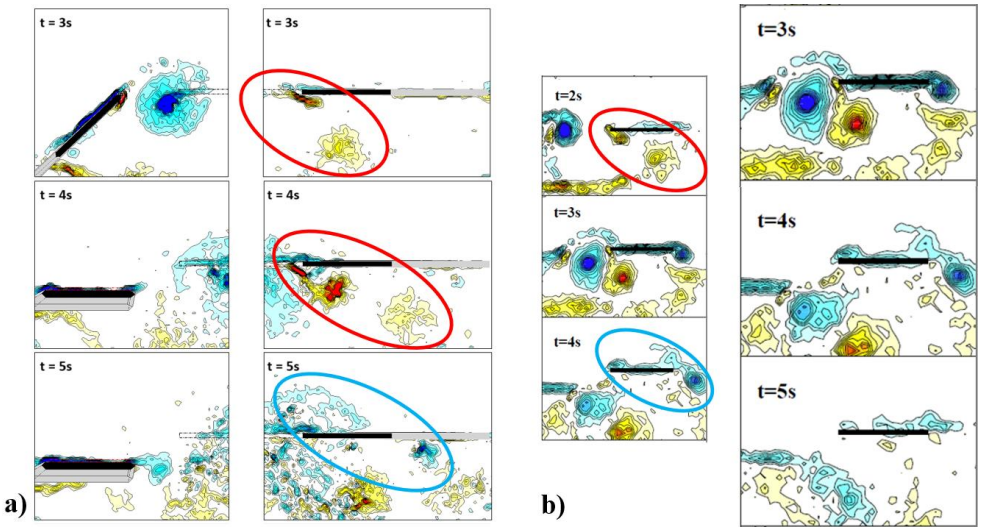

Figure 1. Vorticity plots for $\Delta y = -36$mm and T= 4s, a) swept wing, b) 2D wing.

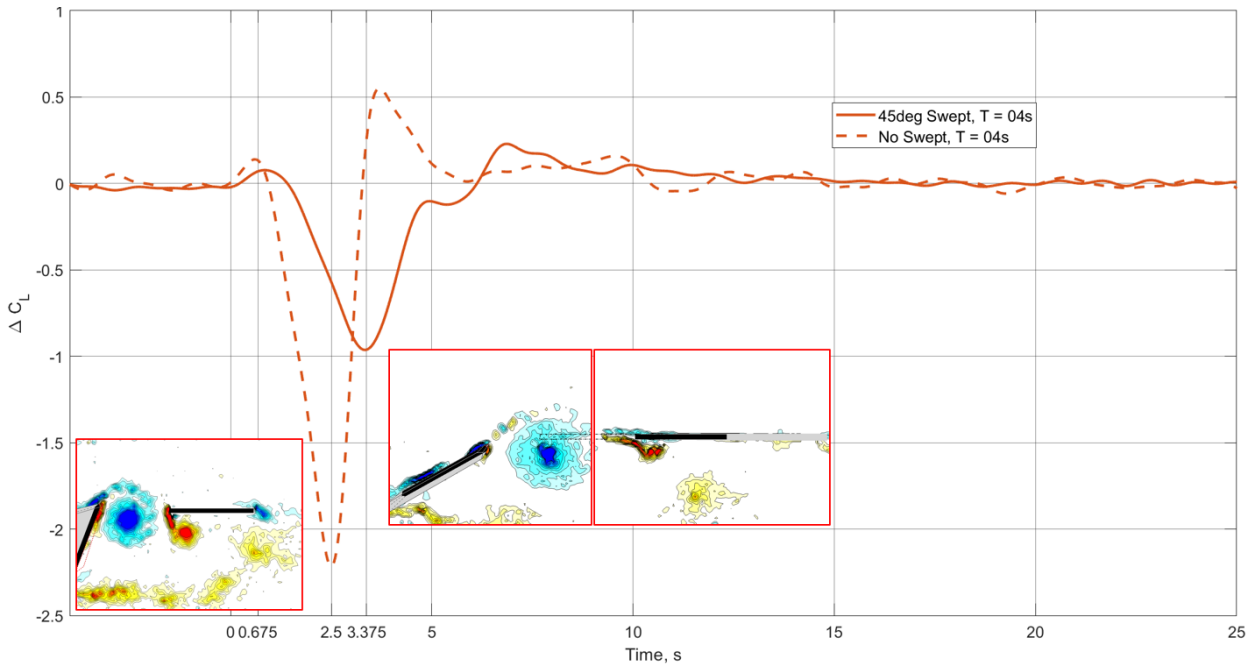

Figure 2. Lift variation for the base case (half rotation in 4s and h/c=0) for 45˚ swept and 2D wings.

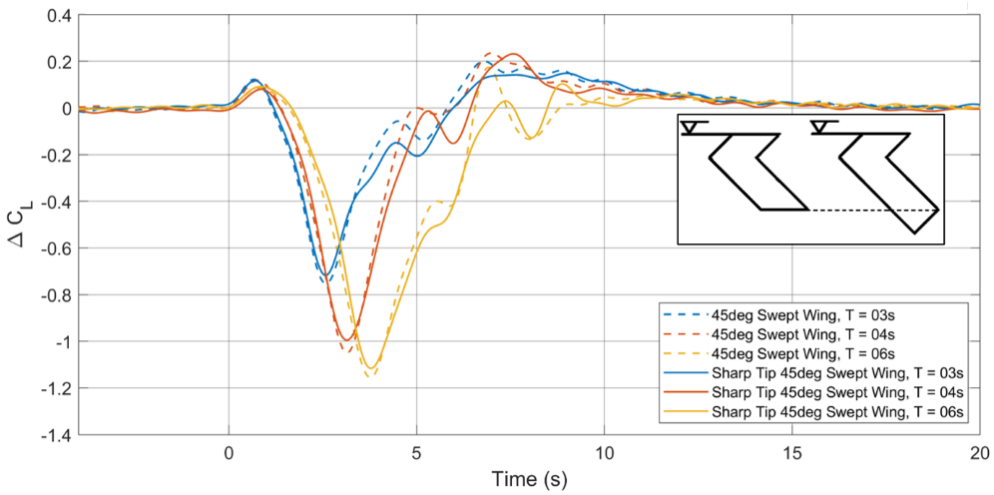

Figure 3. Lift variation for 45˚swept wings with different tip shape (Δy = −36mm).

Conclusion

As a conclusion, the force measurement results show that the lift transient observed in a vortex gust encounter is reduced and delayed for the swept wing at AoA=0° in all cases investigated. The occurrence of the peak value shifted in time can be also predicted from the flow visualization results. The tip shape of the swept wing does not make any difference in the force variations; however, it should be noted that although the flow is not aligned in the sharp tip cases, the cross section is not different for a thin flat plate (thickness of 5%). For future studies, the use of wings with airfoil cross section is recommended to investigate the tip shape effects or in other words, the flow misalignment at the wingtip.

It should be also noted that in the current experiments, the free-surface is either at the symmetry axis or at the 15% of the right wing from the symmetry axis (as seen in the inserts of Fig. 3), to study the effect of the three-dimensional structures emanating from the fuselage or the tip/nose in this case. However, as the wing is at 0° angle of attack for all cases investigated, the results are not much different, the effects are expected to become obvious in future studies when the wing is at an angle of attack or in pitching maneuver.

Fully-Coupled k–ω-SST Turbulence Model Implementation for Nonlinear Newton Method in Unstructured Vertex-Based Hemlab Algorithm

Atakan Okan[a], Mehmet Şahin[a]

[a] Istanbul Technical University, Faculty of Aeronautics and Astronautics, Astronautical Engineering, Turkey
okan15@itu.edu.tr

Keywords: Fully-coupled, non-linear Newton method, SST.

Aim

Industrial RANS simulations demand efficient solvers & mesh generation is still a major bottleneck. Although adaptive mesh refinement can resolve this, it requires stable solvers for complex geometries. Explicit solvers are easier to program; however they have slow convergence for stiff problems (Blazek, 2001), requiring implicit methods. SST model is often implemented loosely-coupled, preventing quadratic convergence for Newton method. If fully-coupling is enabled with exact Jacobians, solvers can achieve machine-precision level residuals (Sukaş & Şahin, 2025; Thompson & O'Connell, 2019).

Therefore, aim of present study is implementing Menter's k-omega Shear Stress Transport (kω-SST) turbulence model for Reynolds-Averaged Navier–Stokes (RANS) equations in a fully coupled (monolithic) and implicit manner to nonlinear Newton solver algorithm in density-based, unstructured, vertex-centered HEMLAB code for robust and efficient solution of external aerodynamics problems where achieving machine-precision residual tolerance is desired.

In order to achieve higher CFL values for rapid convergence of Newton method (as solution approaches steady state via pseudo-transient continuity (PTC)), rather than approximate methods for Jacobian contributions of turbulence-model source terms, it is intended to construct exact Jacobians using analytical derivatives of source terms in turbulence model equations. Another main goal is to investigate implementation accuracy on benchmark flat plate case and test convergence characteristics of fully coupled kω-SST implementation when combined with more challenging aerodynamic problems such as subsonic airfoil at 10 and 15 degrees of angle of attack.

Material and Method

To begin with, two-equation kω-SST Reynolds-Averaged Navier–Stokes (RANS) turbulence model (Menter, 1994) was non-dimensionalized using compressible, conservative form of equations with production limiter included for k-equation. According to NASA Langley Research Center (n.d.) format, model equations are written as follows:

$$\frac{\partial(\rho k)}{\partial t} + \nabla\cdot(\rho u k) = P_{lim} - \frac{Re_\infty}{Ma_\infty}\beta^*\rho\omega k + \frac{M_\infty}{Re_\infty}\nabla\cdot[(\mu+\sigma_k\mu_t)\nabla k] \#(1)\ \frac{\partial(\rho\omega)}{\partial t} + \nabla\cdot(\rho u\omega) = \frac{M_\infty}{Re_\infty}\gamma\rho S^2 - \frac{Re_\infty}{Ma_\infty}\beta\rho\omega^2 + \frac{M_\infty}{Re_\infty}\nabla\cdot[(\mu+\sigma_w\mu_t)\nabla\omega] + \frac{M_\infty}{Re_\infty}2(1-F_1)\frac{\rho\sigma_{w2}}{\omega}\nabla k\cdot\nabla\omega \#(2)\ P_{lim} = min\left(\frac{M_\infty}{Re_\infty}\mu_t S^2, \frac{Re_\infty}{Ma_\infty}20\beta^*\rho\omega k\right)\#(3)\ \mu_t = \frac{\rho a_1 k}{max\left(a_1\omega, \left(\frac{M_\infty}{Re_\infty}\right)\Omega F_2\right)}\#(4)\ S = \sqrt{2(S\cdot S)}\#(5)\ S = \frac{1}{2}(\nabla\cdot u + (\nabla\cdot u)^\top)\#(6)\ \Omega = \sqrt{2(W\cdot W)}\#(7)\ W = \frac{1}{2}(\nabla\cdot u - (\nabla\cdot u)^\top)\#(8)$$

$$F_2 = tanh\ tanh\ (arg_2^2)\ \#(9)\ arg_2 = max(2\Gamma_1, \Gamma_2)\#(10)\ \Gamma_1 = \frac{M_\infty}{Re_\infty}\frac{\sqrt{k}}{\beta^*\omega d}\#(11)\ \Gamma_2 = \left(\frac{M_\infty}{Re_\infty}\right)^2\frac{500\nu}{d^2\omega}\#(12)\ F_1 = tanh\ tanh\ (arg_1^4)\ \#(13)\ arg_1 = min(\Gamma_3, \Gamma_4)\#(14)\ \Gamma_3 = max(\Gamma_1, \Gamma_2)\#(15)\ \Gamma_4 = \frac{4\rho\sigma_{w2}k}{CD_{k\omega}d^2}\#(16)\ CD_{k\omega} = max\left(2\rho\sigma_{w2}\frac{1}{\omega}\nabla k\cdot\nabla\omega, 10^{-10}\right)\#(17)$$

where intermediate terms based on blending functions F_1 and F_2, and model calibration constants are shown below in Eq. 18 to 23:

$\sigma_k = F_1\sigma_{k1} + (1-F_1)\sigma_{k2}\#(18)\ \sigma_w = F_1\sigma_{w1} + (1-F_1)\sigma_{w2}\#(19)\ \beta = F_1\beta_1 + (1-F_1)\beta_2\#(20)\ \gamma = F_1\gamma_1 + (1-F_1)\gamma_2\#(21)\ a_1 = 0.31\ \beta^* = 0.09\ \kappa = 0.41\ \gamma_1 = \frac{5}{9}\ \gamma_2 = 0.44\#(22)\ \sigma_{k1} = 0.85\ \sigma_{k2} = 1.0\ \sigma_{w1} = 0.5\ \sigma_{w2} = 0.856\ \beta_1 = 0.075\ \beta_2 = 0.0828\#(23)$

For k and ω equations in Eq. 1 & 2, left-hand side of equalities denotes time derivative and convective terms while right-hand side shows production, destruction, and diffusion terms. Only extra term is cross-diffusion in ω equation which reduces freestream sensitivity of original k − ω model (Wilcox, 1988). Blending functions F_1 and F_2 in Eq. 9 & 13 help recover k − ω behavior towards no-slip wall and k − ϵ formulation near boundary layer edge towards freestream. Production limiter in Eq. 3 is recommended for cases involving stagnation points and to handle extreme turbulent kinetic energy production in adverse pressure gradient flows (Menter, 1994).

Due to stiffness of high-Re CFD simulations - requiring very small time steps to resolve boundary-layer gradients near walls —explicit methods are generally infeasible for industrial applications (Blazek, 2001). This necessitates matrix-based implicit methods where large-scale problems can be tackled more effectively thanks to fewer time step restrictions, therefore enabling faster convergence. Although they are more costly per timestep with increased memory requirements and more challenging to program, benefits owing to a proper linear matrix solver and effective preconditioner selection still outweigh the cons in the long run.

If residual vector of coupled equation system for node-based FVM approach using median-dual cells is given by R in Eq. 24, where F_i is inviscid fluxes and F_v is viscous fluxes and backward Euler implicit 1st-order time integration is used as pseudo-time continuation (PTC) strategy in steady-state, following consistent Newton method is obtained (Sukaş & Şahin, 2025) where pseudo-time is added to RHS residual as well in Eq. 25:

$$R(Q) = \frac{\partial}{\partial t}\iiint_{\Omega} Q dV + \iint_{\partial\Omega} n\cdot F_i dS - \iint_{\partial\Omega} n\cdot F_v dS = 0\#(24)\ \frac{\partial R}{\partial Q}\Delta Q^{m+1} = \left[\frac{M}{\Delta t} + J\right]\Delta Q^{m+1} = -R(Q^m) = -\left[\frac{Q^m - Q^n}{\Delta t}V + \sum \quad n\cdot F_i(Q^m)S - \sum \quad n\cdot F_v(Q^m)S\right]\#(25)$$

where Q is state-vector, n is outward face normals of dual volume faces around primal mesh vertices, J is flux Jacobian, ΔQ is solution update, M is mass matrix, V is dual-cell volume, S is dual-volume face area, m is mth Newton subiteration and Δt is pseudo-timestep in steady-state in Eq. 25.

Due to nonlinearity of RANS equations, having an implicit system does not immediately result in an unconditionally stable matrix where pseudo-timestep can be driven to infinity during steady-state problems if simulation undergoes unphysical transients (Blazek, 2001; Thompson & O'Connell). This is exacerbated by approximations in Jacobian construction or ineffective preconditioner selection (Sukaş & Şahin, 2025).

Therefore, a more consistent Newton's method was sought with a "line-search" technique to guarantee that nonlinear residual decreases at each pseudotime by adding time terms to both Jacobian and residual functions (Sukaş & Şahin, 2025; Thompson & O'Connell, 2019). In light of these, HEMLAB is a node-based FVM algorithm for hybrid-unstructured meshes with edge-based data structures for cache efficiency (Sukaş & Şahin, 2025). It is based on a consistent, nonlinear Newton method for robust and efficient solution of fully-coupled system of RANS equations where machine precision tolerance is sought. Nonlinear Newton method is implemented using PETSc Scalable Nonlinear Equations Solvers (SNES) with line-search (Balay et. al.,2018). This method allows both Jacobian-free finite-difference method as well as direct Jacobian construction for Jacobian-vector product.

In order to capture high-gradient regions more effectively, "pyAMG" anisotropic mesh refinement library by Inria (n.d) and "refine" library by NASA (n.d.) is integrated with HEMLAB for mesh adaptation. pyAMG works in metric space where generated mesh corresponds to a highly stretched anisotropic mesh in physical space (Loseille, 2016). In HEMLAB, target adaptation sizes, minimum edge lengths and L_2 and L_4-norms can be specified for Mach & distance-based refinement sensors (Sukaş & Şahin, 2025).

For inviscid flux reconstruction, blending of upwinding with central approach is utilized. At cell interfaces, flux-difference splitting of Roe (1982) is used. Other schemes such as HLLC, AUSM+up and AUSM+M are also available. Left/right state

vectors are obtained with unweighted least-squares approach. In addition, gradients of primitive variables in viscous fluxes are obtained at edge midpoints with Green-Gauss theorem. For convective terms of SST model, first order upwinding is used. Non-dimensional BCs in Eq. 26 to 29 are recommended for k and ω (Menter, 1994; NASA Langley Research Center (n.d.)):

$$k|_{wall} = 0 \#(26)\ k|_{farfield} = 9 \times 10^{-9} \#(27)\ \omega|_{wall} = \left(\frac{M_\infty}{Re_\infty}\right)^2 \frac{60\nu_{wall}}{0.075(\Delta y_1)^2} \#(28)\ \omega|_{farfield} = 1 \times 10^{-6} \#(29)$$

where ν_{wall} is wall kinematic viscosity, and Δy_1 is nearest wall normal distance away from wall in Eq. 33. Wall BC is only for the case with no wall functions where $y+ < 3$ (Menter, 1994). However, it was observed that BC in Eq. 33 is problematic due to quadratic nature of ω near wall and causes grid dependence due to Δy_1 term which is unacceptable for anisotropic refinement due to extremely stretched cells near wall. Since positivity of k and ω needs to be ensured for model stability in flux calculations at edge midpoints (Langer & Swanson, 2024), a transformed k-ω model which is called k-q SST is implemented in HEMLAB. A variable transformation from ω to q is used where Eq. 30 & 31 show transformation relation and wall BC for new q variable, respectively. Here, A is a positive constant for controlling residual equation for new q variable:

$$\omega = \frac{A}{q^2} \#(30)\ q|_{wall} = 0 \#(31)$$

High CFL numbers are critical in Newton methods for quadratic convergence, where accurate Jacobians are required. Automatic differentiation-based source code transformation library Tapenade by Inria (n.d.) is integrated with HEMLAB for exact Jacobians of inviscid fluxes. For turbulence equations' source term contributions to Jacobians, analytical derivatives of source terms in SST model is derived. Therefore, fully-coupling of Navier-Stokes system is achieved for higher CFL numbers. This is not preferred in most solvers due to implementation difficulty in implicit approach and computational cost associated with Jacobian matrix where usually approximate factorization methods are used. Finally, most SST model implementations use a loosely-coupled method of coupling Navier-Stokes equations while solving turbulence equations as segregated (Content, Outtier, & Cinnella, 2013; Langer & Swanson, 2024).

Findings

Validation on zero-pressure-gradient flat plate at Re = 5000000 and $Ma_\infty = 0.2$ was conducted using structured meshes (NASA Langley Research Center (n.d)). Focus was on behavior of k and ω in boundary layer to verify coupled SST implementation. Fig. 1 & 2 indicate that local k & ω behaviour in boundary layer is in good agreement with FUN3D solver. Only discrepancy is at outlet due to lack of "outflow" BC in HEMLAB solver. In addition, rapid residual convergence is observed in Fig. 3 with CFL reaching 10000. Finally, Table 1 shows both solvers are within 1 drag count difference.

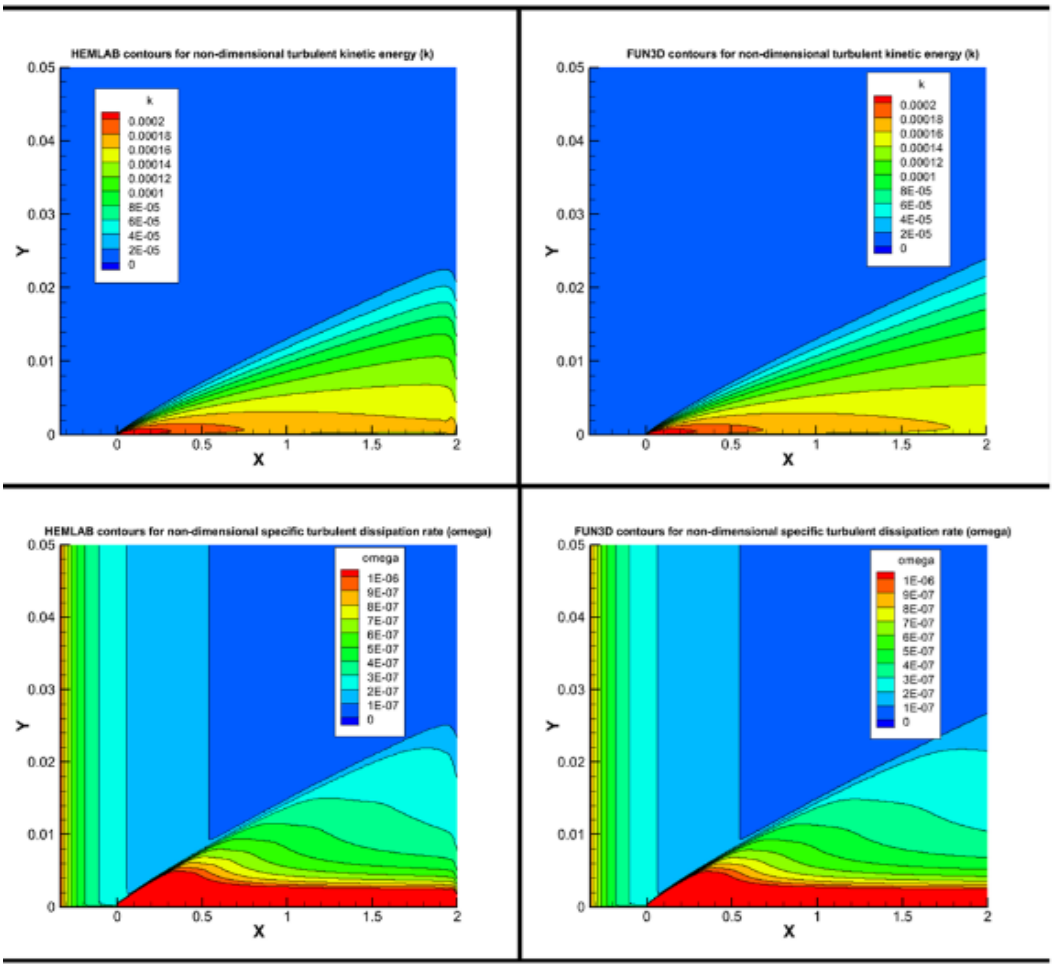

Figure 1. Comparison of HEMLAB and FUN3D (NASA Langley Research Center (n.d.)) contours of k and w in boundary layer for flat plate.

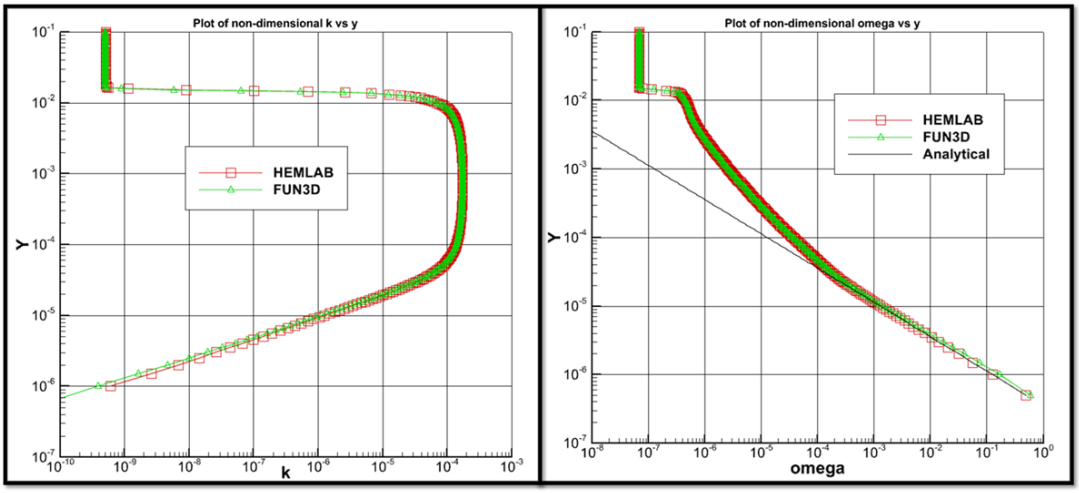

Figure 2. Comparison of HEMLAB and FUN3D (NASA Langley Research Center (n.d.)) profiles for k and w at x=0.97 section of flat plate.

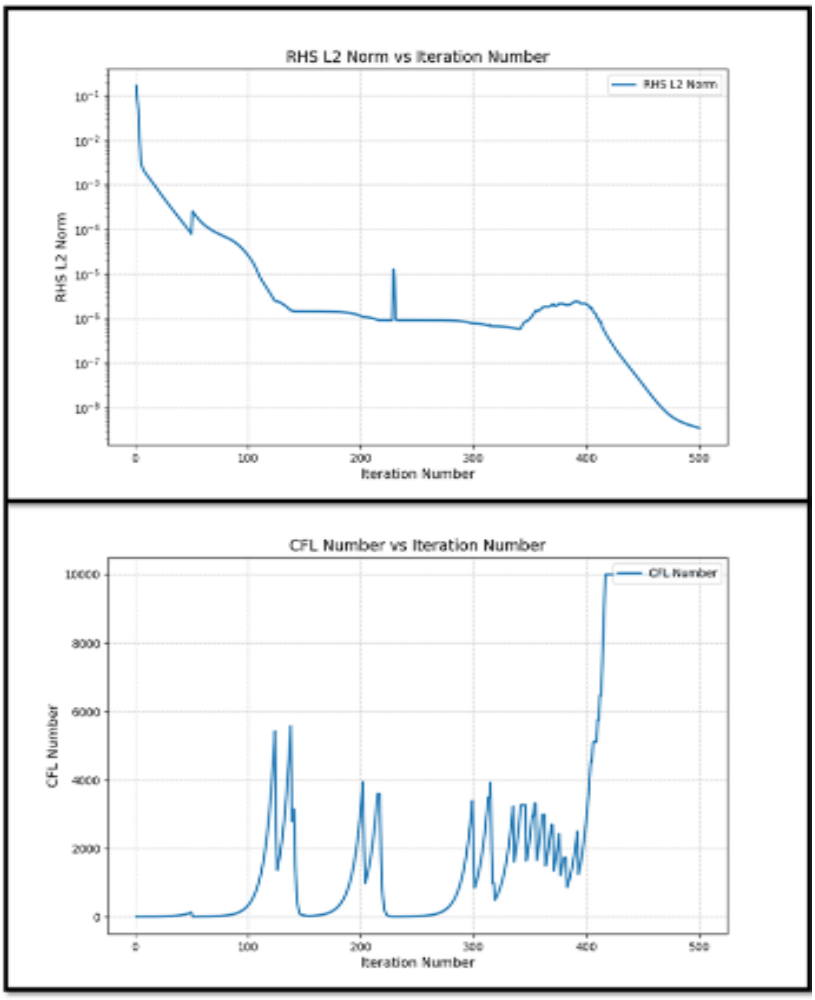

Figure 3. Convergence history of HEMLAB fully-coupled SST implementation for flat plate case.

Table 1. Comparison of HEMLAB and FUN3D (NASA Langley Research Center (n.d.)) turbulence model drag coefficient results for flat plate case.

Solver	Turbulence Model	Drag Coefficient
FUN3D	SA-neg	0.00285
FUN3D	SST-Vm	0.00283
HEMLAB	SA-neg-noft2	0.00296
HEMLAB	SST-m	0.00295

Furthermore, verification on NACA-0012 airfoil at Re = 6000000 and Ma_∞ = 0.15 at 0, 10 and 15 degrees of AoA was conducted. Focus was on robustness of coupled SST implementation in case of practical external-aerodynamics flows. In Fig. 4, mesh independency study comparing HEMLAB SA-neg and SST implementations is shown for structured o-grid, where number of airfoil surface nodes varies from 100 to 500, farfield extent is 500c and first layer height is 2e-6 m. Mesh level 4 was chosen for subsequent runs with 93000 grid nodes. Finally, as shown in Fig. 5, SST C_p plot at AoA=10 matches

well with the experiment and convergence is as robust as flat plate case with CFL reaching 10000 and residual dropping to 1e-10.

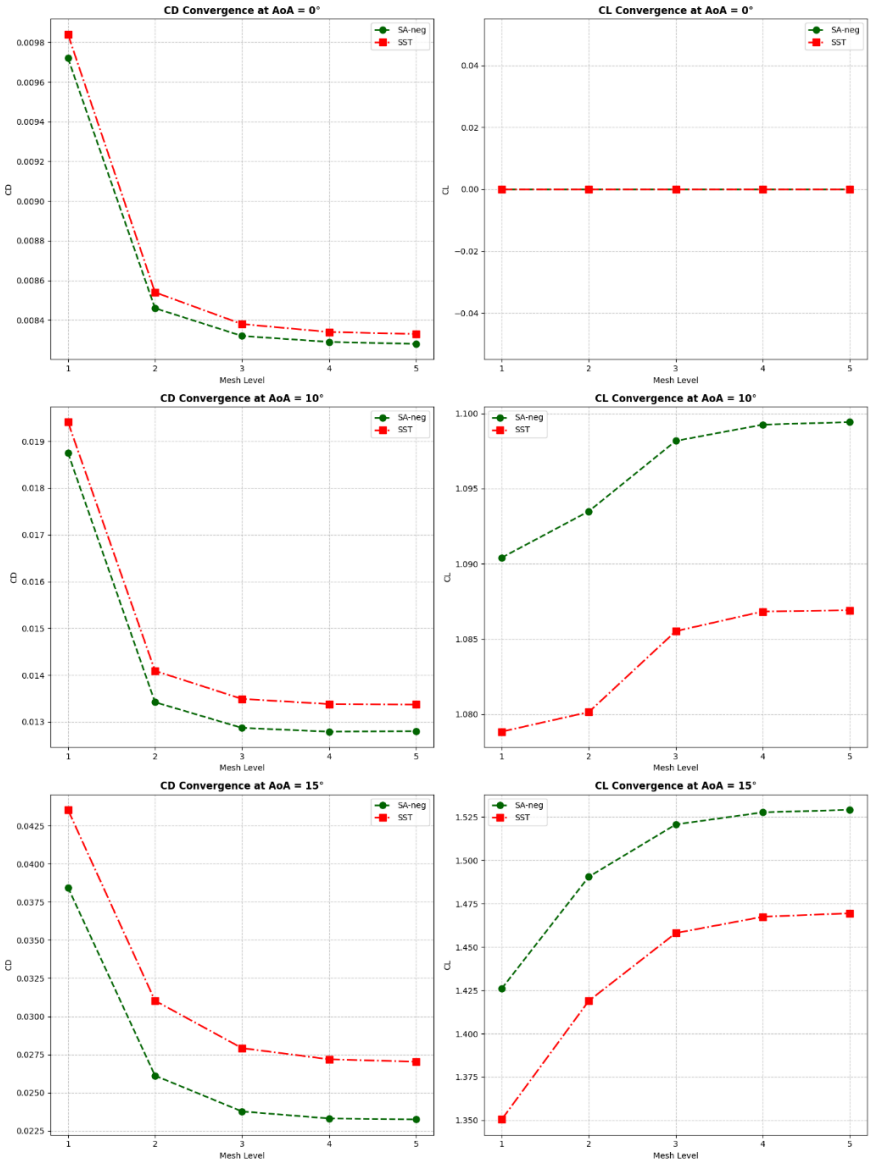

Figure 4. Mesh independency study for NACA-0012 case at all angles of attack.

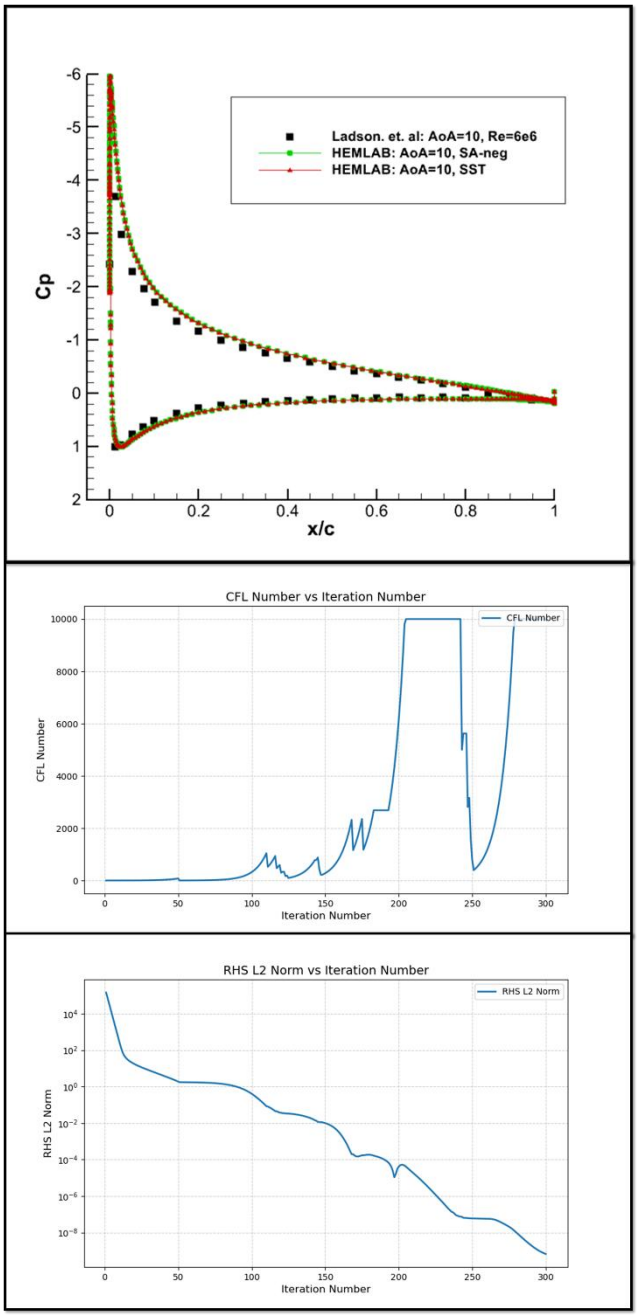

Figure 5. Pressure distribution for NACA-0012 case at AoA=10 and and convergence history of HEMLAB coupled SST implementation.

Conclusion

As a conclusion, k-ω SST model is implemented in HEMLAB in fully-coupled fashion with transformed form as k-q SST model. Exact Jacobians were used for turbulence model source terms. Implementation accuracy was verified based on boundary layer profiles for flat plate case. 2D subsonic cases achieved CFL around 10000 and residual norms of 1e-10. Airfoil flow physics at varying angles of attack did not negatively impact performance. As future work, 3D cases with mesh adaptation need to be assessed for robustness and accuracy as well as transonic & supersonic flows.

Digital Twin Approaches in System-Level Modeling for Aerospace and Propulsion Applications of Rocket Engines: A Review

Yasir Şimes[a], İbrahim Özkol[a]

[a] Istanbul Technical University, Faculty of Aeronautics and Astronautics, Department of Aerospace Engineering, Türkiye
shemis17@itu.edu.tr

Keywords: Digital Twin, System-level Modeling, Rocket Propulsion, Virtual Prototyping, Predictive Maintenance.

Aim

Digital Twin (DT) technology enables creation of high-fidelity, continuously updated virtual replicas of physical systems. In rocket propulsion, DTs offer a unified framework to simulate multi-domain interactions—including thermodynamics, fluid dynamics, structural mechanics, and control systems—under operational conditions. This review surveys the evolution of DTs, outlines system-level modeling methodologies, highlights key applications in design optimization and health management for rocket engines, and discusses challenges and future directions for advancing DTs in propulsion systems. The concept of a Digital Twin in aerospace traces back to mirrored simulators on Apollo 13 in 1970, formalized by Grieves in 2002 and Vickers in 2010, and has since matured through agency and industry efforts. Table 1 summarizes these key milestones.

Material and Method

A comprehensive literature survey identified rocket-engine digital-twin studies published from 2010 to 2025 that couple at least two physics domains (fluid, thermal, structural, control) and report validation errors ≤ 5 % against hot-fire or test-stand data (Grieves, 2002; Glaessgen & Stargel, 2012; Jiménez Mena et al., 2019; Satoh et al., 2020; Tao et al., 2018). Initial database queries returned 120 candidate papers; after title/abstract and full-text screening, 45 met our inclusion criteria.

From this corpus, we distilled a system-level co-simulation workflow: high-fidelity submodels of turbomachinery, feed lines, combustion chambers, actuated valves, and convergent–divergent nozzles are developed in Siemens Simcenter Amesim or Modelica (Mena et al., 2019; Orbi & Martin, 2020). Fluid–dynamics solvers capture transient mass-flow and pressure waves; thermal modules resolve heat-transfer and hot-wall soak effects; structural mechanics predict cyclic stresses; and control-logic blocks sequence valve and throttle commands (Lin et al., 2023; Zhang & Yue, 2021). To enable real-time execution, full-order physics components are replaced by reduced-order surrogates—via proper-orthogonal decomposition or neural-network approximations—that maintain overall simulation error within 1–5 % (Tao et al., 2018).

A continuous digital thread ingests live sensor streams (pressure transducers, thermocouples, accelerometers, rotor-speed encoders) through edge-computing gateways. Extended Kalman filters fuse these measurements with model states, and AI-based estimators iteratively calibrate uncertain parameters (combustion kinetics, heat-transfer coefficients) against historical test-stand and flight data until residual errors fall within prescribed tolerances (Satoh et al., 2020; National Academies of Sciences, Engineering, and Medicine, 2024).

Hardware-in-the-loop validation closes the loop by interfacing actual engine-control electronics—including fuel-valve drivers and ignitor circuits—with the virtual engine model. In benchmark studies on the RL10 expander-cycle engine, closed-loop tests of startup sequences, throttle ramps, and shutdown transients reproduced valve timing, chamber-pressure overshoots, and thermal spikes within a 1–5 % margin of empirical data (Mena et al., 2019; Satoh et al., 2020). Figure 1 shows the overall architecture of the rocket-engine digital twin, from physical test-stand through sensor fusion, multi-physics co-simulation, reduced-order surrogates, and hardware-in-the-loop validation.

Findings

Digital-twin methodologies have delivered up to 60 % reduction in hot-fire campaigns and ≈ 50 % shorter development schedules by enabling early virtual prototyping and in silico design iterations (National Academies of Sciences, Engineering, and Medicine, 2024; Tao et al., 2018). The RL10 expander-cycle twin in Simcenter Amesim reproduced startup valve sequences, chamber-pressure overshoot, and thermal spikes within 1–5 % of test-stand data, guiding injector and nozzle optimizations without additional hardware tests (Jiménez Mena et al., 2019).

Predictive-maintenance frameworks built on the "living twin" extend inspection intervals by 30–50 % through remaining-useful-life estimation, deferring borescope checks and cutting lifecycle costs (Lin et al., 2023; Zhang & Yue, 2021). Rolls-Royce's IntelligentEngine analogue reports similar gains—deferring routine inspections by one flight cycle in three—via real-time fusion of pressure, temperature, and vibration data with physics-based models and Kalman filters (cio.com, 2021; Satoh et al., 2020). When embedded in six-degree-of-freedom ascent simulations, propulsion twins sharpen gimbal-authority margins and payload-injection accuracy—for example, coupling the RL10 twin to a Delta IV model improved lateral-control margin by ~12 % and reduced injection error from 0.35 % to 0.08 % across Monte Carlo runs (Jiménez Mena et al., 2019; Liu et al., 2024).

Hybrid physics–AI surrogates—proper-orthogonal decomposition models and neural-network regressors—accelerate critical submodels (combustion chamber, turbopump) by two orders of magnitude while keeping global error below 5 %, enabling on-board twins running at 20 Hz for autonomous in-flight fault response (Tao et al., 2018; Orbi & Martin, 2020). Collectively, these results confirm that system-level digital twins—anchored in validated physics, continuously synchronized via digital threads, and reinforced with HIL validation—deliver quantifiable benefits in design efficiency, operational reliability, and lifecycle economy, charting a clear path toward fully integrated rocket-propulsion programs.

Table 1. Key milestones in the evolution of digital-twin technology.

Year	Development
1970	Apollo 13 "living model" ground simulators used for in-flight anomaly diagnosis
2002	Michael Grieves introduces the "Digital Twin" concept in product-lifecycle management
2010	John Vickers formally defines the Digital Twin for aerospace systems at NASA
2012	Glaessgen & Stargel publish the DT paradigm for future NASA and U.S. Air Force vehicles
2020s	Rapid explosion of digital-twin research and the emergence of nascent industry standards

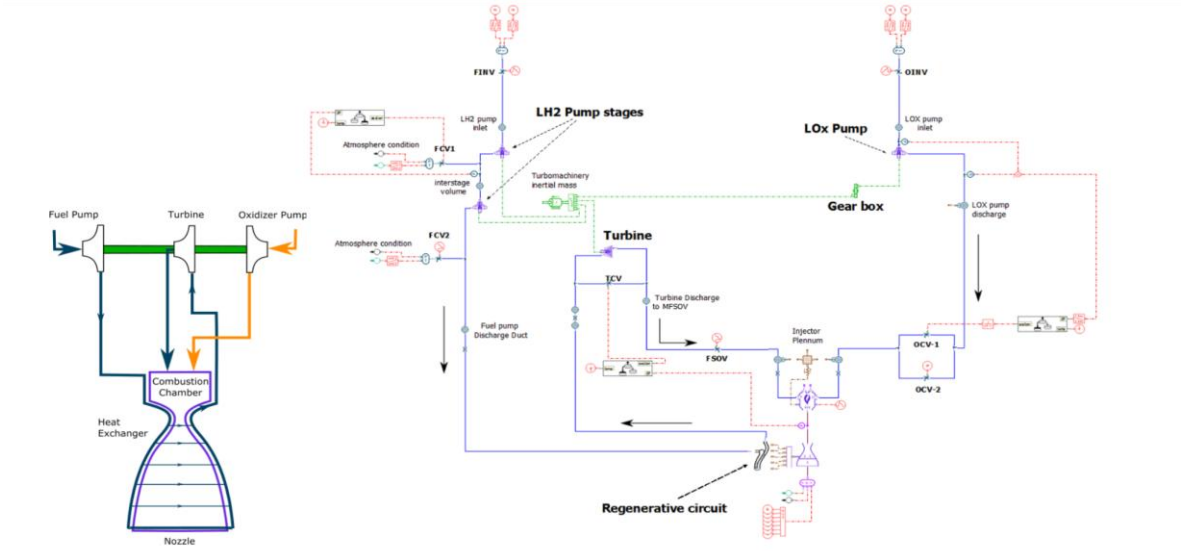

Figure 1. Architecture of the rocket-engine digital twin, showing sensor data ingestion, multi-physics co-simulation with reduced-order surrogates via the Functional Mock-up Interface (FMI), and hardware-in-the-loop validation (Jiménez Mena et al., 2019).

Conclusion

Digital Twin methodologies present a transformative approach for rocket engine development and operation by integrating multi-domain physics models with real-time data. They accelerate design cycles, enhance predictive maintenance, and enable comprehensive mission simulations. Future work should focus on AI-augmented models, lifecycle digital-thread integration, standardization, and onboard implementations to support autonomous operations and virtual certification, thereby reducing cost and risk in advanced propulsion systems.

Design and Analysis of Isogrid-Stiffened Cylindrical Structures for Launch Vehicles: Mathematical Modelling and Knockdown Factor Correlation with Finite Element Validation

Hakan Atkan[a], Atakan Altınkaynak[b]

[a] İstanbul Technical Universtiy /Graduate School, Defense Technologies, Turkey
[b] İstanbul Technical Universtiy /Faculty of Mechanical Engineering, Turkey
atkanh@itu.edu.tr

Keywords: Buckling, Cylindrical Structures, Isogrid, Knockdown Factor, Launch Vehicle.

Aim

Launch vehicle structures are subject to extreme mechanical environments, where mass efficiency must be balanced against safety and reliability. One structural configuration that has proven effective in this regard is the isogrid-stiffened cylindrical shell. These structures are widely used in aerospace engineering, particularly in interstages, skirts, and payload adapters. The key advantage of isogrid designs lies in their triangular rib pattern, which provides high stiffness-to-weight efficiency and near-isotropic structural properties. However, due to their thin-walled nature, such structures are also highly susceptible to buckling phenomena under axial, bending, and pressure loads.

Traditionally, engineers have used global knockdown factors (KDFs) to compensate for the discrepancy between idealized analytical predictions and the actual behavior of imperfect structures. These factors such as those presented in NASA SP-8007 [2] are widely accepted and applied in industry. However, they tend to be overly conservative and do not distinguish between the various buckling mechanisms present in stiffened shells. This over-conservatism often results in weight penalties and missed opportunities for optimization in structural design.

Recent advancements in research have introduced a more refined, mode-specific approach. Instead of applying a single global knockdown factor, different constants are proposed for distinct failure modes: c_0 for global shell buckling, c_1 for skin panel instability, and c_2 for stiffener (rib) crippling [4]. These updated knockdown factors offer a more accurate and physically meaningful framework for evaluating buckling resistance. However, applying these factors still requires caution, especially with skin buckling, where the interaction between panel aspect ratio, boundary conditions, and imperfections makes standardized correction factors less reliable.

This study aims to present a comprehensive analysis of isogrid-stiffened cylindrical structures by incorporating updated knockdown factors into classical shell theory and validating their performance using nonlinear numerical methods. Particular attention is given to the application and interpretation of skin-specific knockdown factors (c_1), which, unlike global knockdown values, cannot always be reduced to a fixed empirical constant and often require case-by-case analysis.

Material and Method

The methodology includes two main components: (1) analytical modelling based on thin-shell buckling theory, extended to include updated knockdown factors, and (2) finite element validation using nonlinear static analysis with geometric imperfections.

1. Analytical Formulation

The theoretical model is based on classical cylindrical shell buckling theory, extended to accommodate stiffening patterns and imperfection sensitivity. Three primary loading scenarios are considered:

- Axial compression, representing the majority of in-service launch vehicle load cases,
- Bending moment, simulating flight-induced bending loads and lateral thrust offsets,
- Internal pressure, relevant for structures integrated with pressurized tanks.

For each case, the ideal critical load is calculated using classical equations. Then, this value is modified using mode-specific knockdown factors:

$P_{actual} = c \cdot P_{ideal}$

where:

- P_{ideal} is the elastic critical load of a perfect geometry,
- c is the knockdown factor, selected from $\{c_0, c_1, c_2\}$ based on the dominant failure mode.

These constants originate from the Shell Buckling Knockdown Factor (SBKF) Project [4], which has provided a framework for applying them based on geometry, boundary conditions, and imperfection sensitivity. The global buckling factor (c_0) tends to be conservative and is often used for preliminary sizing. However, for skin buckling (c_1), no single value can be reliably applied across all geometries. Instead, skin buckling knockdowns depend on panel aspect ratio, loading configuration, edge support, and manufacturing imperfections.

As such, in this study, c_1 is not treated as a constant but rather as a design parameter to be evaluated through parametric and numerical methods. While empirical guidelines are available, especially for flat and rectangular panels, their application to cylindrical shell segments requires caution. This observation is crucial because underestimating c_1 may lead to non-conservative designs, while overestimating it results in unnecessary mass penalties.

2. Finite Element Modelling

Nonlinear simulations are performed to validate the analytical predictions. Finite element models are created to represent isogrid-stiffened cylindrical shells, including:

- Skin and ribs with representative aerospace materials (e.g., 2219-T87 aluminum),
- Boundary conditions approximating those found in real vehicle structures,
- Multiple geometric configurations with varying rib depths, panel lengths, and skin thicknesses.

To simulate realistic behavior, geometric imperfections are introduced into the models using the first buckling mode from linear analysis. The imperfection amplitude is typically scaled to 20% of the shell thickness, a standard practice in aerospace design.

Nonlinear static analysis using arc-length control methods is used to trace the load-displacement behavior until instability occurs. The simulations aim to identify:

- The critical buckling load,
- The location and nature of buckling (global, skin, or rib failure),
- Stress concentration areas and post-buckling stiffness.

Simulation outputs, including mode shapes and load-deflection curves, are then compared directly to the analytical predictions corrected with knockdown factors.

Findings

The updated knockdown-factor-based analytical model showed strong correlation with the results of nonlinear simulations across all loading cases.

1. Axial Compression:

Axial loading consistently produced buckling in either the shell (global) or skin (local panel) regions. When global buckling dominated, the c_0 factor predicted failure within 5–8% of the simulated critical load. When local panel instability governed, c_1 provided reasonable predictions, though slightly more variable, with discrepancies within 10–12%. These variations highlight the complexity of skin buckling and its dependence on panel geometry and boundary conditions.

It is important to emphasize that c_1 is not universally conservative. In some configurations, particularly those with long narrow panels or interrupted rib paths, the skin buckled earlier than predicted by generalized c_1 values from literature. This suggests that skin buckling must be evaluated case by case, using parametric analysis or detailed simulation rather than relying solely on catalogued constants.

Under pure bending, instability was more likely to initiate near structural transitions, such as weld lands or rib terminations. Here, combined effects of global and local deformation were observed. In these cases, both c_0 and c_1 needed to be considered. Predictions based on c_0 alone tended to underrepresent the contribution of localized buckling.

3. Internal Pressure*:*

In pressurized configurations, skin wrinkling under compressive hoop stress was the dominant mechanism. Although pressure generally stabilizes shell structures under axial load, it can exacerbate local instabilities when pressure loading is not symmetric or when pre-existing axial compression is present. The analytical model, adjusted with c_1, aligned well with simulation results, particularly when aspect ratio effects were included.

4. Rib Crippling:

For structures with high rib slenderness or under concentrated loads, rib crippling (c_2) was identified as the dominant failure mode. Predictions using c_2 matched simulation results within 6–9%. This agreement confirms the value of the rib-specific correction factor, especially in designs where rib height and thickness are optimized independently of skin stiffness.

Conclusion

This study demonstrates that mode-specific knockdown factors significantly improve the accuracy and reliability of structural buckling predictions for isogrid-stiffened cylindrical shells. While general knockdown values like c_0 are useful and generally conservative, skin-specific knockdown factors (c_1) require more nuanced application. The behavior of the skin under axial, bending, and pressure loading is influenced by several parameters, and generalized values may not always provide adequate safety margins.

Consequently, it is not appropriate to assign fixed values to skin knockdown factors. Instead, each cylindrical configuration should be evaluated individually, using empirical correlations, numerical simulations, or a combination of both. The findings suggest that incorporating updated knockdown factors into early-phase structural design enables mass savings without compromising safety.

The results validate the use of c_0, c_1, and c_2 as effective tools for refining theoretical models of stiffened shell behavior. Simulation outputs confirmed that these parameters not only yield improved accuracy but also help in identifying the dominant failure mechanism and its sensitivity to geometry and loading.

Future work may explore the integration of optimization routines for weld land transitions, the inclusion of thermal and dynamic effects, and the experimental validation of these findings using scaled structural test articles.

Numerical Modeling of Composite Laminates Under Out-of-Plane Impact

Vuslat Sena Avcı[a]

[a]Istanbul Technical University, Departmant of Aeronautical and Astronautical Engineering, Master of Science Program, Turkey
avciv18@itu.edu.tr

Keywords: Composite laminates, Out-of-plane Impact Behavior, Numerical Modeling Of Composite Damage, Cohesive Zone Method For Delamination.

Aim

The increasing use of composite materials in the aerospace industry is driven by their advantages in weight reduction, structural efficiency, and tailorability to specific load-bearing requirements. However, composite structures are highly sensitive to impact loading, which can induce complex failure mechanisms, including delamination, matrix cracking, and fiber breakage. These damage modes can significantly compromise structural integrity, leading to reduced mechanical performance and long-term durability.

Understanding the response of composite laminates to out-of-plane impact loading is crucial for ensuring their reliability in aerospace applications. The impact behavior of these structures is influenced by several factors, including impact velocity, energy, angle, and the stacking sequence of the composite layers. These parameters determine the nature of damage initiation and propagation, as well as the overall failure characteristics of the structure. Moreover, strain rate effects play a significant role in the dynamic response of composites, affecting their deformation and fracture mechanisms under out-of-plane impact conditions.

This study aims to numerically investigate the impact behavior of composite laminates subjected to out-of-plane loading using LS-DYNA. The analysis will focus on the influence of key parameters such as impact velocity, energy, angle, and stacking sequence on damage initiation and progression. Cohesive zone modeling (CZM) and appropriate composite damage criteria [1]will be employed to accurately capture the failure mechanisms. The findings of this study will provide valuable insights into the structural response of composite plates under out-of-plane impact loading, contributing to the optimization of composite material design for aerospace applications.

Material and Method

The impact model employed in this study is illustrated Figure 1. A cylindrical impactor with a hemispherical lower section, made of structural steel, is modeled as rigid to simulate realistic impact conditions. The impactor strikes the center of the composite laminate at two different velocities (10 m/s and 40 m/s) and two different impact angles (0° and 45°). The composite laminate measures 200 mm in length and 200 mm in width, with 2.944 mm and 4.416 mm thicknesses for the 16-layer and 24-layer configurations. The laminate is fully constrained along all four edges, restricting all six degrees of freedom (DOF) to prevent displacement and rotation. Constraints are marked in red in Figure 1.

[1] avciv18@itu.edu.tr

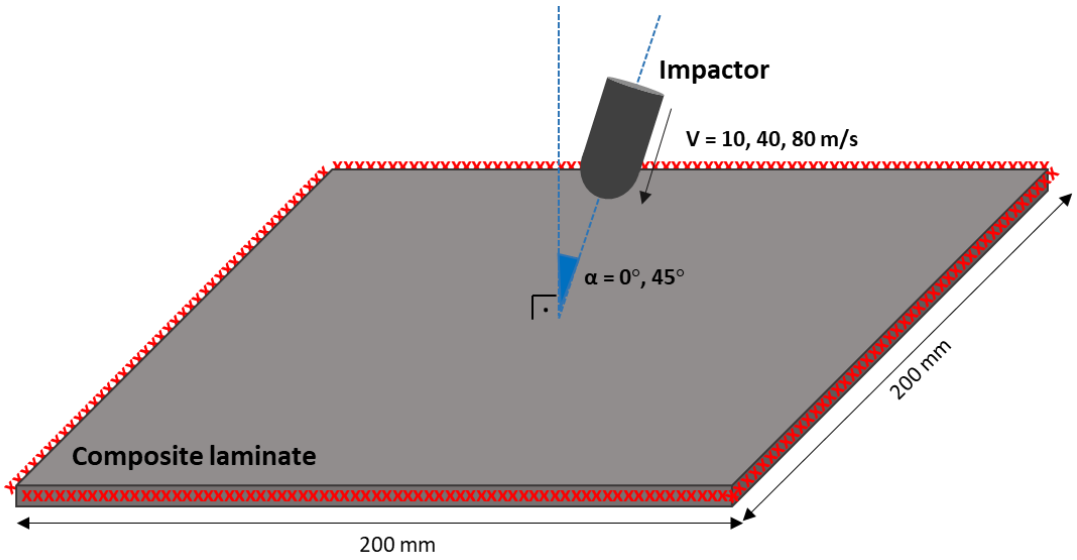

Figure 1. Geometry and boundary conditions for the simulation of out-of-plane impact on composite laminate.

An eroding contact is defined between the impactor and the composite laminate's top surface to accurately capture damage evolution, penetration, and material removal during impact. This setup allows for a detailed investigation of the influence of impact velocity and angle on failure mechanisms such as delamination, matrix cracking, and fiber breakage.

The composite material considered in this study is AS4/8552, a unidirectional carbon fiber/epoxy prepreg with a fiber area weight of 134 g/m². To assess the effect of fiber orientation on impact resistance, different stacking sequences are analyzed, including unidirectional (UD), quasi-isotropic (QI), and cross-ply (CP) configurations. All layups are designed symmetrically to ensure a balanced structural response. Two laminate thicknesses are examined: 16-ply and 24-ply. The 16-ply configurations, with a thickness of 2.944 mm, are defined as $[0°]_{8s}$ for UD, $[0°/45°/-45°/90°]_{2s}$ for QI, and $[0°/90°]_{4s}$ for CP. Similarly, the 24-ply laminates, with a thickness of 4.416 mm, follow $[0°]_{12s}$ for UD, $[0°/45°/-45°/90°]_{3s}$ for QI, and $[0°/90°]_{6s}$ for CP. These variations enable a comprehensive evaluation of stress distribution, damage initiation, and overall structural integrity under impact loading.

The material properties of the AS4/8552 composite, including elastic moduli, Poisson's ratios, shear moduli, strength values, and fracture energies, are presented in Table 1. These parameters are essential for accurately modeling the impact behavior of the composite laminates. The material coordinate system is defined such that the 1-direction corresponds to the fiber axis, the 2-direction represents the in-plane transverse direction, and the 3-direction denotes the through-thickness direction of the laminate.

Table 1. The material properties of AS4/8552 unidirectional composite prepreg.

The impact behavior of composite laminates subjected to out-of-plane loading is numerically investigated using LS-DYNA. To model the composite laminate, each layer is individually represented using solid elements to accurately capture the material's mechanical response. The interaction between layers is represented by cohesive zone elements, simulating the bonding interface where delamination may occur due to interlaminar shear or normal stress. These elements track damage initiation and progression based on stiffness and fracture toughness. Two different unidirectional configurations with 16 and 24 layers were developed, as has been done so far. The side views of both configurations are presented in Figure 2 and Figure 3, respectively. The 16-layer configuration is constructed as $[0°]_{8s}$, while the 24-layer configuration follows $[0°]_{12s}$.

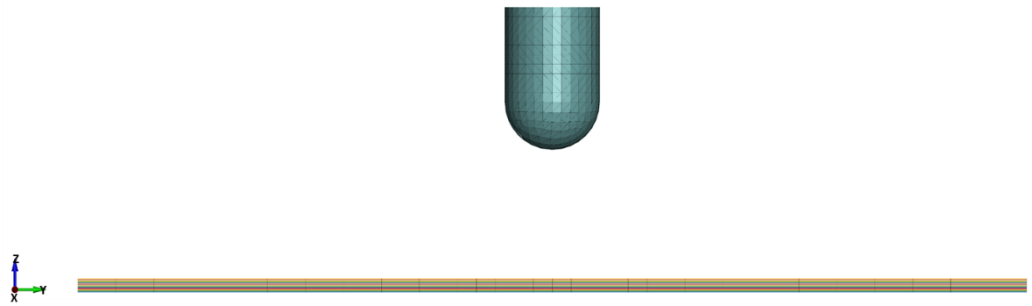

Figure 2. Side view of 16-layer UD composite laminate with $[0°]_{8s}$ stacking sequence.

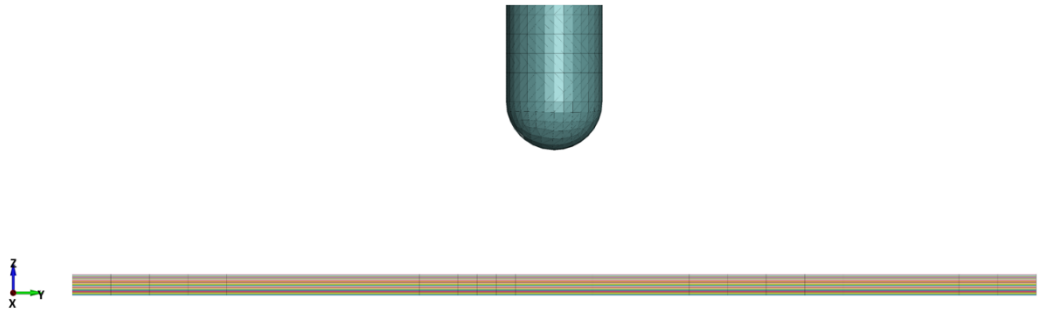

Figure 3. Side view of 16-layer UD composite laminate with $[0°]_{12s}$ stacking sequence.

The custom view of the model, as shown in Figure 4, illustrates the fiber orientations in the longitudinal (x-direction), transverse (y-direction), and through-thickness (z-direction) directions. A downward initial velocity is applied along the negative z-direction to simulate the impact, ensuring a realistic representation of the out-of-plane loading condition. The global mesh size is set to 8 mm with an aspect ratio of approximately 1:44, while a refined mesh of 4 mm with an aspect ratio of approximately 1:22, both determined based on the laminate thickness, is employed in the impact region to better capture localized deformation and stress concentrations, thereby enhancing the accuracy of the laminate's response under dynamic loading conditions.

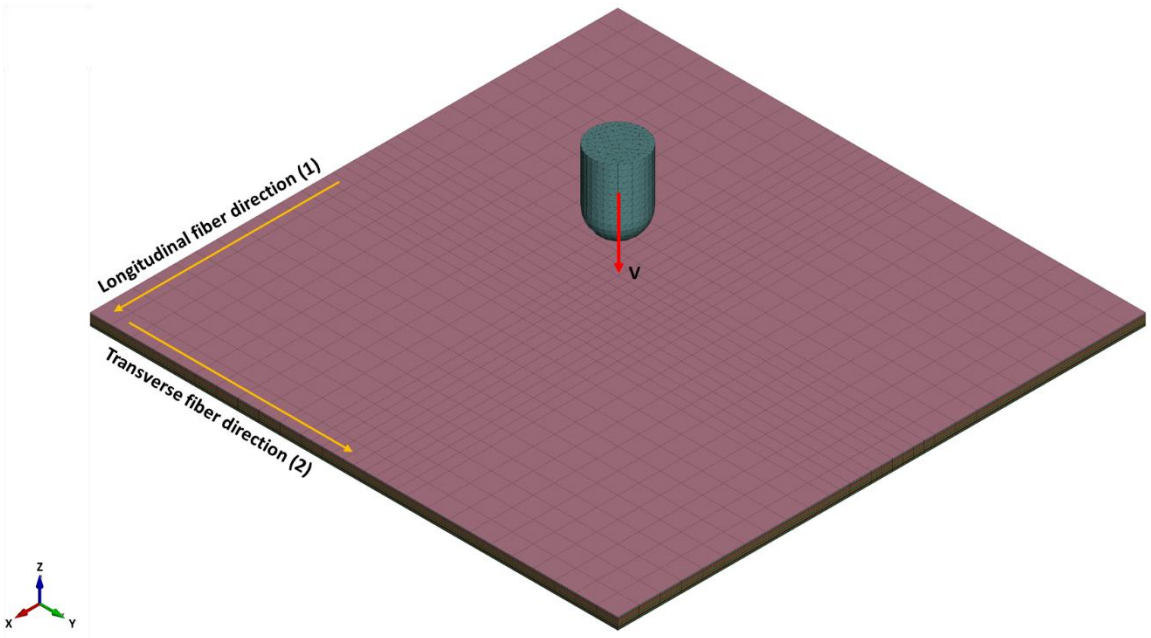

Figure 4. Custom view of 16-layer UD composite laminate with $[0°]_{12s}$ stacking sequence.

Findings

Although the study is still in progress, preliminary results obtained for the $[0°]_{8s}$ stacking sequence have already yielded valuable insights into the impact behavior of composite laminates. Experimental investigations from the literatüre suggest that impact velocity, energy, and angle will significantly influence damage initiation and progression, affecting failure mechanisms such as delamination, matrix cracking, and fiber breakage (Vaidya et al., 2006; Yang et al., 2024). Furthermore, the influence of different stacking sequences will be systematically analyzed, as variations in layer orientation are expected to significantly affect stress distribution, energy absorption, and overall damage tolerance.

Moreover, the stress profile obtained from the finite element model indicates that stress concentrations occur differently depending on the stress direction. For instance, in the x-direction (representing the longitudinal axis of the layered structure), compressive stresses develop along the upper surface of the laminate, while tensile stresses are observed along the lower surface.

Figure *5* illustrates the variation of the impactor's total energy throughout the impact event with the composite laminate. The initial high energy rapidly decreases as energy is transferred to the laminate through deformation and damage, followed by a slight recovery as the impactor rebounds. The stabilized energy level afterward reflects the residual energy remaining after the impact.

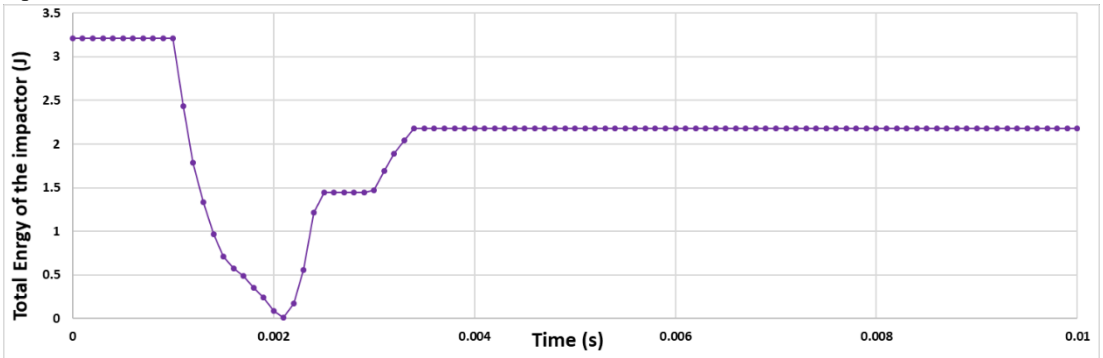

Figure 5. Total energy variation of the impactor during the impact with the composite laminate.

The graph presented in Figure 6 illustrates the stress distribution over 16 elements located in the upper lamina at the impact region throughout the impact event. The maximum stress occurs between 0.0021 and 0.0023 seconds, with the stress in the x-direction (representing the longitudinal axis of the layered structure) reaching up to 110 MPa. Figure 7 presents detailed stress contour plots for three representative time steps within this interval, providing a clear visualization of the stress evolution.

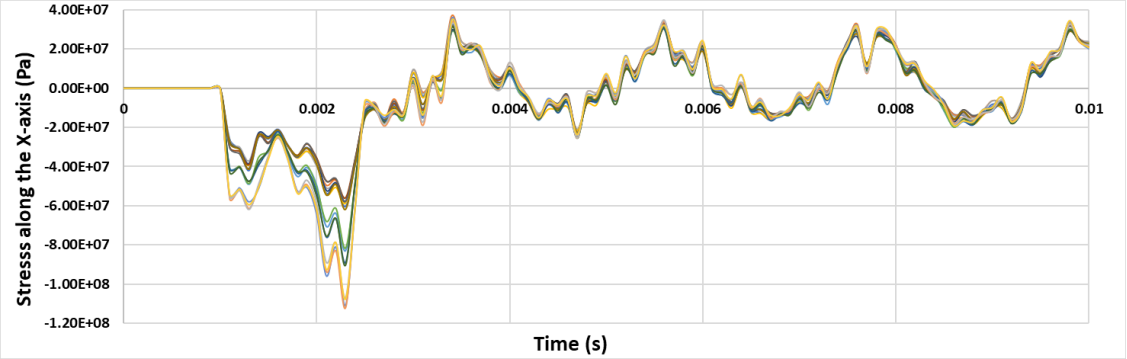

Figure 6. X-direction stress distribution in the upper lamina at the impact region.

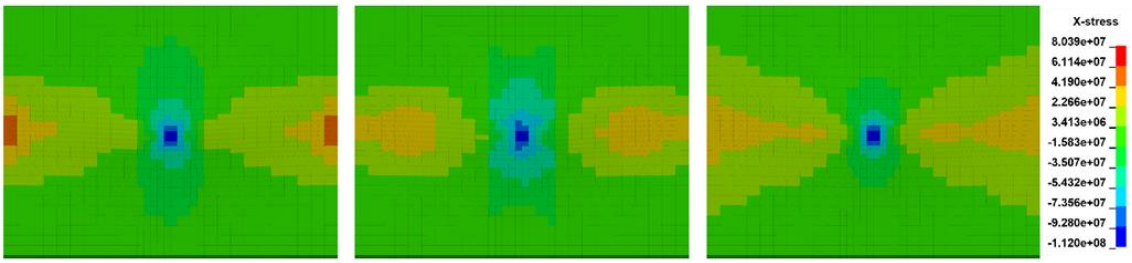

Figure 7. X-direction stress contour plots in the upper lamina at three time steps, from left to right: 0.0021 s, 0.0022 s, and 0.0023 s.

The graph presented in Figure 8 illustrates the stress distribution over 16 elements located in the upper lamina at the impact region throughout the impact event. The maximum stress occurs between 0.0021 and 0.0023 seconds, with the stress in the y-direction (representing the transverse axis of the layered structure) reaching up to 105 MPa. Figure 9 presents detailed stress contour plots for three representative time steps within this interval, providing a clear visualization of the stress evolution.

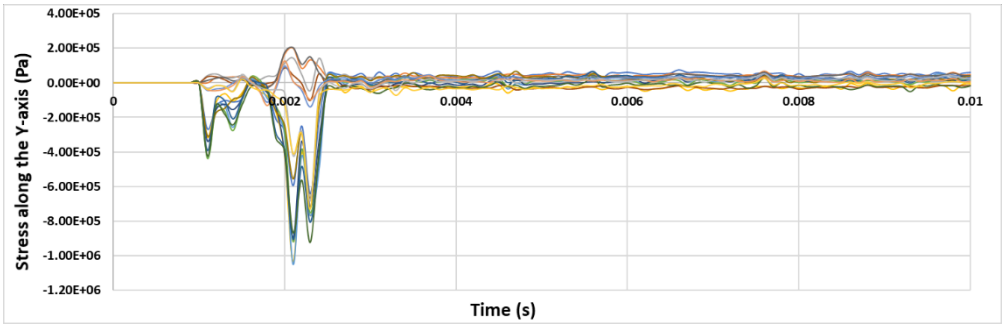

Figure 8. Y-direction stress distribution in the upper lamina at the impact region.

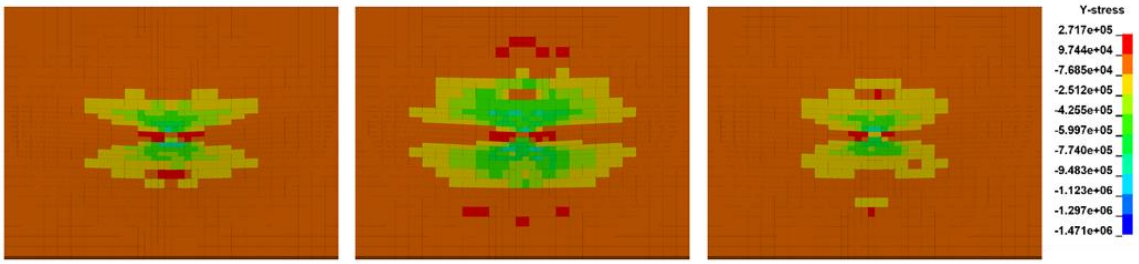

Figure 9. Y-direction stress contour plots in the upper lamina at three time steps, from left to right: 0.0021 s, 0.0022 s, and 0.0023 s.

Conclusion

Understanding the interplay between impact parameters and composite configurations is essential for predicting damage evolution and improving structural performance. This study establishes key correlations between stacking sequence, strain rate, and failure mechanisms, providing valuable insights into composite behavior under out-of-plane impact. The findings contribute to the optimization of composite materials, enhancing their durability and efficiency in aerospace applications.

Investigation Of The Interaction of Carbon Fiber Cylindrical Rocket Bodies With Radial Bolt Joints

Kubilay Sazan[a]

[a] Istanbul Technical University, Aeronautical and Astronautical Engineering, Turkiye
sazan19@itu.edu.tr

Keywords: CFRP, Finite Element Analysis, Mechanical Joint, Mechanical Strength.

Aim

Rockets are generally designed with cylindrical bodies to have more aerodynamically efficient performance. In this context, radial bolt connections are mostly preferred in the structural connections of rocket bodies. Bolt heads are hidden with special cut-outs to reduce aerodynamic drag in rocket bodies made of metals. However, this method causes deterioration of fiber integrity and reduction in structural stiffness in carbon fiber reinforced polymer (CFRP) material bodies.
In this study, the effects of radial bolt connections and bolt head clearance depth on structural stiffness of two-cylinder structures made of CFRP were investigated. Analyses were performed in Ansys ACP module using the finite element method. The effects of different connection configurations on stiffness were compared in terms of their stiffness. As a result of the study, it was determined that structural stiffness decreased with the deepening of bolt head cuts.
In the literature, CFRP and mechanical connection modeling have generally been examined with plates. In this study, it is aimed to provide a different perspective to the literature by through the analysis of cylindrical structures. In future studies, it is expected that the study will be detailed by adding flight conditions such as vibration and temperature to this connection area.

Material and Method

The usage of metal materials is a common practice due to high structural and thermal strength requirements in rocket designs (Khan et al., 2025). However, advances in material technology have made the usage of composite materials increasingly common, especially in applications which requires weight reduction. Although, composite materials are notable for their high specific strength, the use of these materials must design to meet high structural and thermal strength requirements. In this context, the usage of composite materials in rocket designs provides advantages over metal materials, but at the same time, the need to optimize the structural and thermal performance of these materials poses a challenge.
The designs of rockets are formed according to the main mission decided upon in the conceptual design phase in line with the user's demand. Example of this design mission is, to shoot down an aircraft, hit a ballistic target, or destroy a tank target. Rockets consist of various subsystems in line with their main mission (Hongxing et al., 2023). Each subsystem is a mechanical or avionic subunit that performs a specific function so that the rocket can fulfill its main mission. As can be seen form Figure 1. depending on their sizes and functional requirements, subsystems can be located separately on the rocket or as integrated units to cover a specific area. In this study, it is aimed to model the fracture and bending behavior of a 24 kg subsystem area under rocket maneuver.

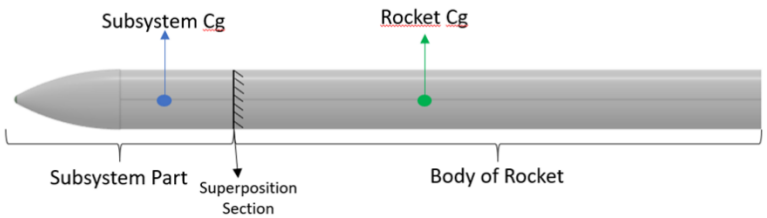

Figure 1. Rocket Body and Subsystem.

This study aims to investigate the effect of the shear and bending forces that a subsystem region will create under the maneuver to which the missile will be subjected, on the shear and bending forces that will occur in the connection area on the composite missile body. The maneuver to which the missile will be subjected is assumed to be 40 g. In the study, the type of coupling joint commonly used in rockets was preferred can be seen in Figure 2. Due to the shape connection they create, coupling joints are frequently preferred in order to provide a safe and rigid connection in applications requiring high stiffness.

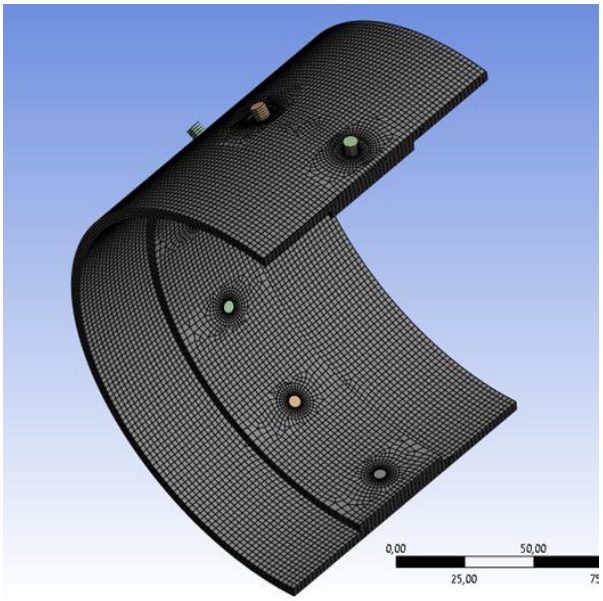

Figure 2. Ansys Workbench Mesh and Layer Solid Model.

In the coupling joint of rocket bodies, bolts or pins are used to limit the degree of freedom in the flight direction. In these types of connections, radial bolts drilled along the body section are mostly preferred to provide ease of assembly. In the scope of this study, it was preferred to fix the bodies with radial bolts. In the placement of radial bolts, the distance between the bolts and the distance of the bolts to the body edge are critical factors that directly affect structural stiffness. In this context, the W(distance)/D (bolt diameter) ratio plays a critical role in structural stiffness (Aktas et al., 2003). In this study, the use of 12 bolts with a diameter of 6 mm was preferred. It is anticipated that this choice provides a suitable solution in order to keep the structural strength high.

Different bolt types can be used in designs according to assembly requirements. Bolts are classified according to a series of features such as their heads, lengths, diameters, and thread types (Jack, 2013). In cylindrical rocket designs, it is preferred to embed the bolt heads in the body in order to prevent extra drag. In composite bodies, embedment of bolt heads reduces structural stiffness by disrupting fiber orientation locally. This study examines the strain, stress, and structural integrity of fibers in the connection areas of a composite body with a wall thickness of 4 mm with different embedment amounts (1 mm, 2 mm, and 3 mm) and no embedment.

Carbon fiber material is generally preferred in line with high structural and thermal requirements, in designs of rocket. Carbon fiber materials are quite suitable materials in terms of structural safety of rockets due to their high specific strength properties. However, due to the high production costs and certain performance deficiencies of other alternative materials, the usage of Kevlar and glass fiber materials is generally not preferred. In this study, MAT_162 UD fabric, which has been characterized as a material, was used (Lee et al., 2011).

First, the selected material information is defined in the material information section in the Ansys ACP (Advanced Composite Pre-Post) module. In the analyses performed, the basic mechanical properties of the material, young's modulus, Poisson ratio, shear modulus, tensile strength, compressive strength, shear strength, the modeling type will be layer-based

and the failure criterion information are defined. The specified material properties are defined according to the x, y and z axes (xy, yz, xz for shear modulus).

The design model to be loaded must be in shell format. The ANSYS application accepts each shell as a layer and layers these shells in the specified orientation when switching to the solid model. The geometry in shell form is meshed before being transferred to ACP. Since the analysis will focus on the hole perimeters, the mesh density around the holes must be fine. Within the scope of the analysis, the surroundings of the holes were divided into equal parts as ± 6°. Mesh was also assigned as course mesh to the non-hole areas in between and the parts of the bodies outside the connection area. As the Figure 2 shows, 2 mm mesh size was preferred for flat parts, the mesh size was reduced to 0.35 mm around the holes. Since fiber agents are seen more around the holes, these areas were left with a larger mesh size. As a mesh type, the analysis time was short and a more rectangular element was preferred.

Within the scope of this study, Figure 1 and Figure 2 shows the connection area to be analyzed was examined by making it independent from the center of gravity of the rocket with the superposition method. With this method, the body close to the center of gravity was locked by selecting a fixed support. On the other side, a 21 kg load was applied from the center of gravity of the subsystem which shown in Figure 3.

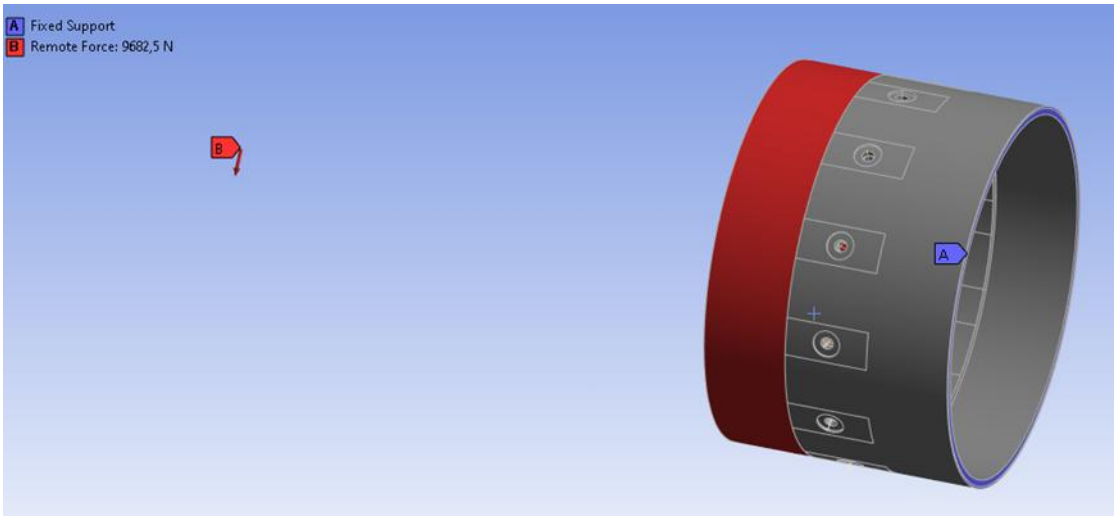

Figure 3. Support and Force Modelling in Ansys.

Finally, the obtained stress and strain values obtained and failure evaluation was made.

Findings

Within the scope of this study, analyses were performed on 4 different designs. The maximum stress, maximum deformation and the number of failing elements for the layer in contact with the bolt head are shared in Table 2.

The information in Table 3 shows the change in body stiffness depending on the increase in hole depth in percent in the column in Table 2.

Table 1. Material Features of MAT_162 UD (Lee et al., 2011).

Young's Modulus X direction (GPa)	122.51	**Tensile Strength X direction (MPa)**	1835.4	**Shear Modulus XY direction (GPa)**	4.76
Young's Modulus Y direction (GPa)	8.4	**Tensile Strength Y direction (MPa)**	40.5	**Shear Modulus YZ direction (GPa)**	1.5
Young's Modulus Z direction (GPa)	8.4	**Tensile Strength Z direction (MPa)**	40.5	**Shear Modulus XZ direction (GPa)**	1.5
Poisson's Ratio XY	0.1	**Compressive Strength X direction (MPa)**	700	**Shear Strength XY direction (MPa)**	41.5
Poisson's Ratio YZ	0.2	**Compressive Strength Y direction (MPa)**	184.2	**Shear Strength YZ direction (MPa)**	55
Poisson's Ratio XZ	0.2	**Compressive Strength Z direction (MPa)**	184.2	**Shear Strength XZ direction (MPa)**	55

Table 2. Analyze Results for maximum stress, maximum deformation and the number of failing elements for the layer in contact with the bolt head.

Hole Depth	Max Stress (MPa)	Total Displacement (mm)	Max. Num. Hole Element Fails
No Hole	903.79	0,6054	108
1mm	792.01	0,568	73
2mm	720.7	0,714	82
3mm	953.94	0,8758	159

Table 3. Comparisons of Deformation Change Percentage.

	No Hole to 1 mm	1mm to 2mm	2mm to 3mm
Deformation Change Percentage (%)	6,2	25,7	23,0

According to shared tables, it is possible to make the following outcomes,

- Figure 4. Shows the stress values observed for the design without embedment for the bolt head is higher than the configuration with 1mm embedment. The reason for this situation is that the bolt head, which has a flat surface, crushes the cylindrical body until it absorbs the load. Since it first provides point contact with the surface it crushes, it causes very high deformation and fiber failure for local elements.

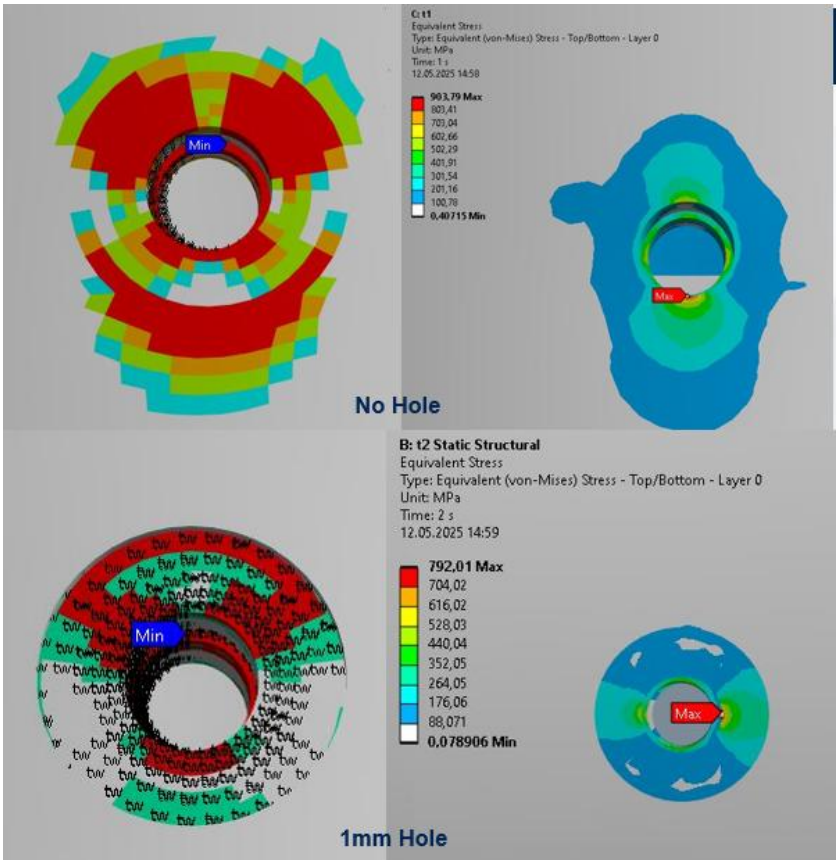

Figure 4. Stress and Failure Around Top Hole for No Hole and 1mm Hole Analyzes.

- As the bolt head embedment depth increases, although an aerodynamically efficient structure is formed, it has been observed that the stiffness decreases by approximately 18.3% for each mm of depth. When we plot the changing deformation due to the decrease, the graph shown in Table 3 can be obtained.
- As can be seen in Figure 5, the bolt tensions decrease as the approaches the neutral axis of the bending force. If the rocket's stiffness requirements were not directed towards maneuver in all directions, the amount of unloading in the bolts in the regions close to the neutral axis could be increased.

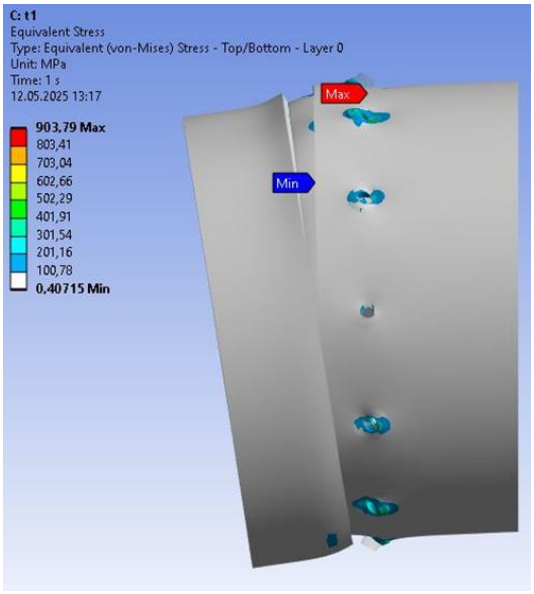

Figure 5. Stress Distribution for Each Hole from Top to Mid for no Hole Depth.

- Finally, if the desired maneuver in different direction is defined differently in the design requirements, there is not the same that the depths of the holes of embedment bolt head be the same as can be seen in Figure 5. In addition, incorrect assembly in the designs can be prevented in this way.

Conclusion

Composite materials are frequently used in applications such as aircraft which weight reduction is required. The sizes of composite structures used in aircraft are extremely high compared to their wall thickness. This situation causes, modeling and analysis are examined on flat plates for these structures. Within the scope of this study, the analysis of mechanical joint methods for a cylindrical body is a first in the literature.

Although radial bolted connection type provides ease of assembly for rocket designs, the drag caused by bolt heads is of critical importance. On the other hand, the use of radial bolts creates drag due to bolt heads and therefore they must be embedded in the body. In composite material bodies, embedding bolt heads creates an average of 18.3% stiffness loss for each mm of discharge.

In the analyses, it was assumed that the bolts did not fail under load, there was no stripping on the threaded surfaces, there was no assembly clearance for antennas, sensors or other structural parts in the bodies and the load was static. These assumptions cause the analyses to deviate from the real.

Rockets heat up excessively during the flight condition and enter low-pressure envelopes. In further studies, it is possible to study how high temperature affects this stiffness, the behavior of the body under low pressure, and the manufacturability, sustainability and pricing of this structure.

Nyström Integral Method for Mode Solving in Optical Waveguides with Arbitrary Geometries

Mücahit Hüseyin Özdilekler[a], Mehmet Çayören[a]

[a] Istanbul Technical University Faculty of Electrical and Electronics Engineering, Department of Electronic and Communication Engineering, Türkiye
ozdilekler18@itu.edu.tr

Keywords: Eigenmode Solution, Integral Equations, Nyström Method, Optical Waveguides.

Aim

The analysis of modes supported by optical waveguides is a crucial step in photonic system design. Optical waveguides serve as the backbone of photonic circuits and communication systems, making the accurate computation of supported modes essential. Various numerical methods, such as the Finite-Difference Time-Domain (FDTD) method, Finite Element Method (FEM), and Mode Matching techniques, are commonly employed to determine waveguide modes (Fallahkhair, Li, & Murphy, 2008). However, integral equation methods provide an alternative, often more efficient approach, particularly when dealing with complex geometries. In this study, we aim to solve the mode structure of arbitrarily shaped optical waveguides using the Nyström integral method. Unlike conventional discretization-based approaches, the Nyström method offers an efficient solution by discretizing integral equations rather than differential equations, providing improved accuracy and computational efficiency in certain cases (Wang, Cox, & Friedman, 1998).

Material and Method

To determine the mode profiles in optical waveguides with arbitrary geometries, we adopt an integral equation formulation of Maxwell's equations. The standard approach involves solving the Helmholtz equation, which describes the propagation of electromagnetic waves in waveguides. By converting the wave equation into an integral form, we can employ the Nyström method for discretization and numerical solution (Colton, Kress, & Kress, 1998).
The Nyström method is an efficient numerical approach for solving integral equations. It relies on quadrature rules to discretize the integral equation, leading to a system of linear equations that can be solved for the unknown field values. This method is particularly advantageous for problems involving complex geometries, as it avoids the need for mesh generation, which is a computational bottleneck in FEM and FDTD-based solvers.
In this study, we apply the Nyström method to optical waveguides with arbitrary shapes, including those with sharp corners and highly rounded geometries. We investigate the accuracy of the method by comparing solutions for different geometric representations, ensuring that mode solutions remain consistent across various approximations. For waveguides with sharp corners, we approximate the geometry using superelliptical shapes, allowing for smoother numerical treatment while preserving the essential mode characteristics.

Governing Equations and Boundary Integral Formulation

The foundation of our analysis begins with the two-dimensional Helmholtz equation, which governs the behavior of the modal field ψ in optical waveguides. The domain is partitioned into the core region Ω, characterized by a refractive index n_1, and the cladding region Ω^c, with refractive index n_2. Within each of these regions, the field satisfies a distinct Helmholtz equation, parameterized by the propagation constant β. These formulations (Equations 1 and 2) provide the starting point for mode analysis by describing the spatial variation of the guided fields.
To transform the problem into a more tractable numerical form, we invoke Green's third identity, which allows the Helmholtz equation to be reformulated as a boundary integral equation. This leads to two integral representations: one valid for points located within the core (Ω) and the other for points in the cladding (Ω^c). These expressions (Equations 3 and 4) recast the modal field in terms of boundary values alone, thereby eliminating the need to discretize the full domain. This

property is particularly advantageous for waveguides with complex boundaries, as it underpins the efficiency of boundary element methods such as the Nyström technique.

At the heart of this formulation lies the Green's function for the two-dimensional Helmholtz equation (Equation 5). This function is expressed via the Hankel function of the second kind, $H_0^{(2)}$, which captures the appropriate outgoing wave behavior in open domains. Serving as the kernel of the integral operators, the Green's function encapsulates the response of the system to point sources and allows for the coupling of boundary values across the domain.

Inserting the Green's function into the integral identities yields a Fredholm integral equation of the second kind (Equation 6), in which the field on the boundary is related to itself through two kernel functions, $L(t,\tau)$ and $M(t,\tau)$. This equation serves as the basis for applying the Nyström method, enabling the discretization of the boundary and the formation of a solvable linear system. This approach follows the classical methodology presented in Colton & Kress, adapted here for waveguide mode analysis.

A central challenge in solving the resulting boundary integral equation lies in the treatment of singularities in the kernel functions. The Green's function exhibits a logarithmic singularity as the source and field points coalesce, complicating numerical integration. To address this, the kernels are analytically decomposed (Equations 7 and 8) into singular and smooth parts. Specifically, the logarithmic singularity is isolated using the trigonometric identity, which naturally arises in periodic boundary parameterizations. The remaining components of the kernels, denoted L_1, L_2, M_1, M_2, are smooth and well-behaved, enabling the accurate application of quadrature rules. This singularity separation is critical for achieving high-order accuracy and numerical stability in the Nyström discretization.

Together, these equations establish a robust mathematical foundation for the boundary-integral-based mode solver. They enable the computation of guided modes with high precision, even in geometrically intricate waveguide configurations.

Equations

$$\nabla^2\psi + (n_1^2k^2 - \beta^2)\psi = 0 \quad \text{in } \Omega, \tag{1}$$

$$\nabla^2\psi + (n_2^2k^2 - \beta^2)\psi = 0 \quad \text{in } \Omega^c, \tag{2}$$

$$\psi(\mathbf{r}) = -\int_{\partial\Omega} \frac{\partial G_1(\mathbf{r},\mathbf{r}')}{\partial n'}\psi(\mathbf{r}')dl' + \int_{\partial\Omega} G_1(\mathbf{r},\mathbf{r}')\frac{\partial\psi(\mathbf{r}')}{\partial n'}dl' \quad \text{in } \Omega, \tag{3}$$

$$\psi(\mathbf{r}) = \int_{\partial\Omega} \frac{\partial G_2(\mathbf{r},\mathbf{r}')}{\partial n'}\psi(\mathbf{r}')dl' - \int_{\partial\Omega} G_2(\mathbf{r},\mathbf{r}')\frac{\partial\psi(\mathbf{r}')}{\partial n'}dl' \quad \text{in } \Omega^c, \tag{4}$$

$$G(\mathbf{r},\,\mathbf{r}') = H_0^{(2)}(k_0|\mathbf{r}-\mathbf{r}'|)/(4i) \tag{5}$$

$$\psi(t) - \int_0^{2\pi} \{L(t,\tau) + i\eta M(t,\tau)\}\,\psi(\tau)\,d\tau = g(t), \quad 0 \le t \le 2\pi, \tag{6}$$

$$L(t,\tau) = L_1(t,\tau)\ln\left(4\sin^2\frac{t-\tau}{2}\right) + L_2(t,\tau), \tag{7}$$

$$M(t,\tau) = M_1(t,\tau)\ln\left(4\sin^2\frac{t-\tau}{2}\right) + M_2(t,\tau), \tag{8}$$

Findings

Our results demonstrate that the Nyström method effectively computes the modes of optical waveguides with arbitrary geometries. By approximating waveguides with sharp corners using highly rounded superelliptical shapes, we achieve the same level of accuracy as models that explicitly include corners. This finding is significant, as it suggests that a smooth approximation can simplify numerical computations while preserving essential mode properties.

As seen in Table 1, the Nyström method finds 7 different β values for a multimode step-index fiber, compared with analytical solutions (Ghatak & Thyagarajan, 1998). Moreover, Table 2 shows the exact transcendental equation for scalar modes of rectangular dielectric waveguides compared with our presented well-rounded corner approach (Smartt, Benson, & Kendall, 1994). As seen in Table 2, our findings are highly consistent. Our well-rounded corner approximation is consistent and requires fewer computational steps compared to the graded mesh method (Colton, Kress, & Kress, 1998).

Table 1. Comparison of β values obtained using the Nyström method (N = 32) and analytical solutions for a multimode step-index fiber. Excellent agreement is observed across all guided modes.

Mode Name	Analytical Solution (β)	Nyström (N = 32)	Error

0.9	0.4507	0.4507618400	0.0000618400
1.0	0.5127	0.5125175506	0.0001824494

In Figure 1, the field intensity distributions of the same waveguide mode are presented using two different approaches. On the left, results from commercial software (Lumerical) are shown, while on the right, our implementation using Green's third identity is displayed. It can be observed that both distributions closely match, confirming the correctness of our numerical method.

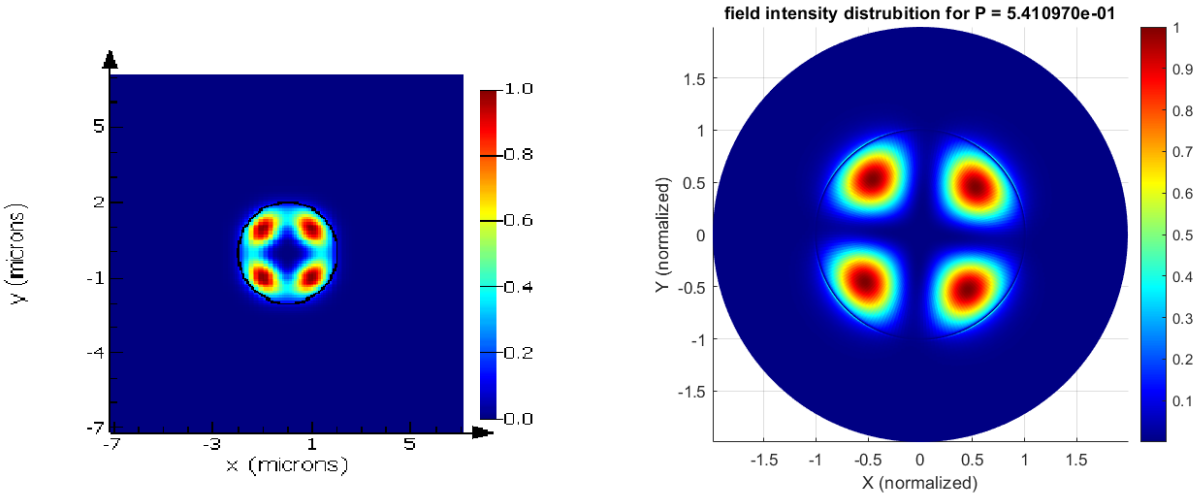

Figure 1. Field intensity from Lumerical (left) vs. Nyström method (right). The close match validates our numerical implementation.

In Figure 2, we present the computed E_{42} mode of a rectangular optical waveguide using the Nyström integral method. The rectangular geometry is defined with a normalized height h = 4 and an aspect ratio a/b = 2. The figure shows the transverse field intensity distribution corresponding to the propagation constant P = 0.602868. As expected, the pattern exhibits four maxima along the x - axis and two maxima along the y - axis, consistent with the modal index E42. The distribution closely matches reference results reported in Goell (1969), validating both the numerical accuracy and physical correctness of our implementation.

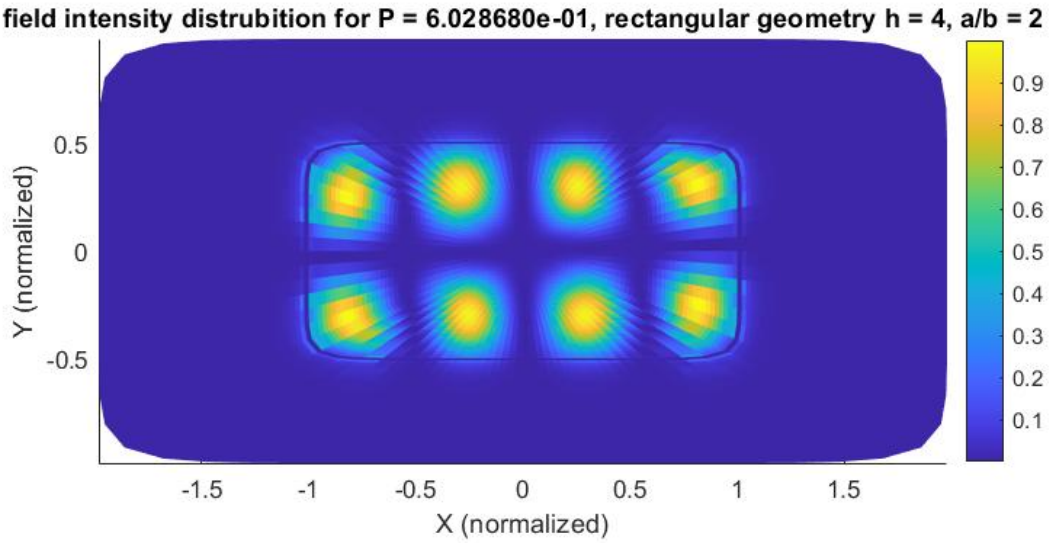

Figure 2. E_{42} mode field distribution in a rectangular waveguide ($h = 4$, $a / b = 2$). Results match the reference mode structure.

Moreover, the Nyström method exhibits improved convergence compared to traditional differential equation solvers. The integral formulation inherently captures the boundary conditions without requiring additional enforcement, leading to a

more stable numerical solution. The computational efficiency of the method is also evident, as it requires fewer discretization points to achieve high accuracy compared to mesh-based solvers.
Through extensive numerical simulations, we validate our approach by comparing computed mode profiles with reference solutions obtained from FEM-based solvers. The agreement between the results confirms the reliability of the Nyström method for solving waveguide mode problems.

Conclusion

This study presents the Nyström integral method as an effective approach for solving the mode structure of arbitrarily shaped optical waveguides. By leveraging the integral equation formulation, we achieve accurate and computationally efficient solutions without the need for extensive meshing. Our findings indicate that approximating sharp-cornered waveguides with highly rounded geometries, such as superelliptical shapes, does not compromise solution accuracy. This insight simplifies numerical computations and broadens the applicability of the method to various photonic waveguide designs.
Future work may focus on extending this approach to three-dimensional waveguides, exploring layered waveguide types, incorporating additional material properties, and investigating hybrid methods that combine the strengths of integral and differential equation solvers. The results of this study contribute to the development of more efficient computational tools for photonic system design, facilitating advancements in optical communication and integrated photonic circuits.

Keywords : Electromagnetic Scattering, Hadamard Finite Part, Nyström Method, Singular Integral.

Computational Electromagnetics (CEM) is a widely used approach for solving electromagnetic scattering problems, a phenomenon central technologies such as biomedical imaging and radar. CEM methods are generally classified as analytical or numerical. Analytical methods solve scattering for simple geometries, whereas numerical methods are preferred for complex ones. In this study, an integral equation-based model is used. The Method of Moments (MoM), a traditional technique, is commonly employed for solving such equations. However, Nyström Method (NM) is preferred for this study instead of MoM. The idea behind using NM is that it does not require basis functions unlike MoM. Nevertheless, the NM involves hypersingular integrals due to Dyadic Green's Function (DGF). This approach provides solutions to electromagnetic scattering problems involving conducting and arbitrary-shaped objects. The proposed strategy is based on numerical solution of surface integral equations using NM. The main contribution of this study is the development of a novel numerical approach for the accurate and stable evaluation of hypersingular integrals.

Aim

The aim of this study is to solve electromagnetic scattering problems using surface integral equations. This type of integral equation generally consists of two types of integrals: non-singular and singular integrals. Non-singular integrals can be solved using standard quadrature rules. Nevertheless, quadrature rules are not applicable to singular integrals. Singular integrals require new techniques due to their complex form. Singular integrals, which arise from the DGF, play a critical role in achieving stable and accurate solutions. However, there is limited research on the numerical treatment of singular integrals in the context of electromagnetic problems. Therefore, a new Nyström-based approach is proposed to solve singular integrals numerically and accurately.

Material and Method

As previously stated, the aim of this study is to solve the electromagnetic scattering problem for arbitrarily shaped perfectly electrically conducting (*PEC*) surfaces using *NM*. This section consists of four main parts: Electric Field Integral Equation (*EFIE*), Nyström Method (*NM*), the application of *NM* to *EFIE*, and the treatment of singular integrals.

1. Electric Field Integral Equation (EFIE)

EFIE is a widely used equation in electromagnetics. Derived from Maxwell's equations, it applies to both open and closed geometries. EFIE defines the relation between surface current density and scattered electric field. The integral kernel is the DGF, which includes second derivatives of the free-space Green's function. To apply EFIE, boundary conditions, the incident field, and the source and observation coordinates must be known. The EFIE for PEC surfaces is given as in Equation (1).

$$\vec{t}.j\,w\,\mu \int_s \left[1+\frac{1}{k^2}\nabla\nabla.\right] g(r,r').\vec{J}(r')dS = \vec{t}.\vec{E}^i(r) \quad \#(\,SEQ\ Denklem\ \backslash *\ ARABIC\ 1)$$

In Equation 1, $\vec{t}$ denotes the tangential unit vector, w is the angular frequency, μ is the permeability, k is the wave number, r and r' are the coordinates of the observation and source points, $\vec{J}(r')$ represents the surface current density at the source point, and $\vec{E}^i(r)$ is the incident electric field at the observation point. The scalar Green's function $g(r, r')$ describes wave propagation between source and observation points in free space. The DGF includes second derivatives of the free-space Green's function, making the integral more complex.

2. Nyström Method (NM)

NM is a numerical method for solving integral equations. Although it is a classical technique, its use in electromagnetics is relatively recent. It utilizes quadrature rules, which approximate integrals by summing weighted function values at specific points (Çalışkan, 2004). Various quadrature rules exist, such as Gauss-Legendre, Gauss-Lobatto, Tanh-Sinh, and Chebyshev. This study employs the Gauss-Legendre rule, which determines sampling points and weights using the roots of Legendre polynomials. In NM, the surface is divided into small elements (meshes), and integrals are evaluated over each mesh (Tong & Chew, 2020). The application of *NM* to a mesh element is given as in Equation (2).

$$\int_s f(x,y)dxdy = \sum_{i=1}^{N} w_i\, f(x_i,y_i)J(x_i,y_i) \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 2)$$

In Equation (2), f represents the kernel function, n is the total sampling points on a mesh element, w_i shows weight of the sampling point, J is the jacobian, x_i and y_i are the coordinates of the sampling points.

3. The application of NM to EFIE

In this section, the EFIE is applied using the NM. As discussed previously, the NM converts integrals into summations via quadrature rules, which evaluate integrals at sampling points. The surface is divided into small mesh elements, and sampling points are placed within each. Quadrilateral planar meshes are used in this study. In practice, the EFIE is applied twice: first to compute the surface currents, and second to obtain the scattered field. In NM, currents are defined only at the sampling points. The EFIE in Nyström form is given as in Equation (3).

$$\vec{E}_{inc}(r_i) = j\mu w \sum_{i=1}^{n} \sum_{j=1}^{n} \left[1 + \frac{1}{k^2}\nabla\nabla\right] g(r_i, r_j).\vec{J}(r_j) w_{ij} J_{ac,j} \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 3)$$

In the third equation, n is the total number of sampling points, $J_{ac,j}$ represents the jacobian value corresponding to the jth sampling point. w_j denotes the quadrature weight corresponding to the jth sampling point. The double summation covers for all combinations of observation index i and source index j. All combinations of the source and observation points are required to be considered in order to account for all electromagnetic interactions. The free-space Green's Function can be written as in Equation (4).

$$g(r_i, r_j) = \frac{e^{-jk|r_i - r_j|}}{4\pi|r_i, r_j|} \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 4)$$

In Equation 4, the free-space Green's function depends on the distance between the source and observation points. If the distance is zero, a singularity occurs (to be addressed in the next section). Otherwise, the Green's function and its derivatives have valid values usable in NM. When computing the scattered field from surface currents, all terms remain non-singular since the distance is non-zero (Tong & Chew, 2020).

Dyadic terms come from second derivatives of the Green's function. To reduce computational cost, local coordinates are used. The u and v components are unit tangential directions defined per mesh and may vary across elements. Equation (5) shows the dyadic matrix structure.

$$[g_{uu}\, g_{uv}\, g_{vu}\, g_{vv}][J_u\, J_v] = [E_u\, E_v] \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 5)$$

In the fifth equation, the dyadic matrix is a 2×2 matrix since it represents the *u* and *v* tangential components. The surface current and electric field vectors are 2×1 vectors containing the corresponding components. If the total number of sampling points is *n*, the global dyadic matrix becomes a $2n \times 2n$ matrix, while the surface current and electric field vectors become $2n \times 1$ vectors (Kılınç, 2010).

4. The Treatment of Singular Integrals

When the observation and source points coincide, DGF integrals become undefined. Standard quadrature rules fail in such cases, requiring alternative techniques like Duffy's or Radial transform (Hayami & Brebbia, 1987). This study uses the Hadamard Finite Part (HFP) method to evaluate singular integrals. Before addressing their treatment, the first DGF component expression is given in Equation (6).

$$g_{uu}(r) = g(r) + \frac{1}{k^2}\frac{\partial^2}{\partial u^2}\, g(r) \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 6)$$

In Equation (6), $r = \sqrt{u^2 + v^2}$ represents the local distance between the observation point and the source point, expressed in the local tangential coordinate system. To accurately calculate the singular integrals, the Taylor series expansion of the DGF is required. After expanding the DGF up to the first three terms, the first dyadic component can be written as follows in Equation (7).

$$g_{uu}(r) = \frac{1}{4\pi}\left[\frac{u^2 + 0.5v^2}{r^3} + \frac{2u^2 - v^2}{k^2 r^5} - \frac{2jk}{3} - \frac{k^2 r}{3} + \frac{jk^3 v^2}{6} + \sum_{n=4}^{\infty} \frac{(-jk)^n r^{n-1}}{n!} + \sum_{n=4}^{\infty} \frac{(-jr)^n k^{n-2}}{n!}\left(\frac{2u^2 - v^2}{r^5} + jk\frac{2u^2 - v^2}{r^4} - \frac{k^2 u^2}{r^3}\right)\right] \quad (SEQ\ Denklem\ \backslash *\ ARABIC\ 7)$$

The remaining components can be derived in a similar manner. These expressions will be used in the singular part of the integral computations, which will be handled by the HFP method.

4.1 Hadamard Finite Part Technique

HFP method is a variant of the Cauchy Principal Value (CPV) used to evaluate singular integrals. It follows a similar approach to CPV but retains only the finite part, discarding divergent terms. Unlike CPV, HFP provides physically meaningful, finite results (Chan, Fannjiang, Paulino, & Feng, 2007; Selçuk, 2014). The HFP part is denoted by H. An example is shown in Equation (8).

$$H\int_{-1}^{1} \frac{dt}{t^2} = \left(\int_{-1}^{-\varepsilon} \frac{dt}{t^2} + \int_{\epsilon}^{1} \frac{dt}{t^2}\right) = \left(\frac{1}{\varepsilon} - 1 - 1 + \frac{1}{\varepsilon}\right) = -2 \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 8)$$

The Equation (8) demonstrates the HFP concept. If a singular integral has an antiderivative, its analytic solution can be obtained using HFP. A numerical example over a square mesh is presented next.

4.2 Application of HFP to EFIE

In this study, the Gauss-Legendre quadrature rule is used, valid for integrals over the reference square $[-1,1]\times[-1,1]$. Sampling points are located within small mesh elements, and their coordinates are obtained by mapping the reference square. Therefore, singular integrals are evaluated using the HFP method on the reference square. The aim is to compute the singular terms in Equation (7) individually. The summation terms are non-singular and can be evaluated via standard quadrature (Selçuk, 2014). As an example, the second singular term in Equation (7) will be evaluated.

In Equation (9), u and v are the coordinates of the observation point, while u' and v' represent those of the source points. Thus, terms like $u-u'$ and $v-v'$ express the relative distance between these points. To simplify integration over the reference square, a coordinate transformation is applied: $A=u-u'$ and $B=v-v'$. This centers the singularity at the origin (0,0), making integral more manageable for numerical evaluation via the HFP method.

$$I = H\int_{-1}^{1}\int_{-1}^{1}\frac{2(u-u')^2-(v-v')^2}{((u-u')^2+(v-v')^2)^{\frac{5}{2}}}dudv \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 9)$$

$$I = H\int_{A=-1-u'}^{1-u'}\int_{B=-1-v'}^{1-v'}\frac{2A^2-B^2}{(A^2+B^2)^{\frac{5}{2}}}dAdB \qquad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 10)$$

The aim is to calculate the singular integral given in Equation (10). To achieve this, the integral is split into two parts as in Equation (11) and Equation (12): P and T. While evaluating P, an inner integral denoted as $I(A)$ arises, which is computed using the HFP method. During this process, the terms involving the $\frac{1}{\varepsilon}$ variable are disregarded. As a result, $I(A)$ can be expressed as shown in Equations (14), (15), and (16). The numeric values of P and T can be evaluated easily. Similarly, the remaining singular terms of the *DGF* can be evaluated using the same procedure. In Equation (15), C is $1-v'$ and D is $-1-v'$.

$$P = \int_{A=-1-u'}^{1-u'}\int_{B=-1-v'}^{1-v'}\frac{2A^2}{(A^2+B^2)^{\frac{5}{2}}}dAdB \qquad \#(11)$$

$$T = \int_{A=-1-u'}^{1-u'}\int_{B=-1-v'}^{1-v'}\frac{B^2}{(A^2+B^2)^{\frac{5}{2}}}dAdB \qquad \#(12)$$

$$I = 2P - T \qquad \#(13)$$

$$I(A) = \int_{B=-1-v'}^{1-v'}\frac{A^2}{(A^2+B^2)^{5/2}}dB \qquad \#(14)$$

$$I(A) = \frac{2C^3 + 3A^2C}{3A^2(C^2 + A^2)^{3/2}} - \frac{2D^3 + 3A^2D}{3A^2(D^2 + A^2)^{3/2}} \qquad \#(15)$$

Findings

In this study, singular integral arising in the EFIE formulation were evaluated using the HFP method over a reference square. All steps of the computation were carried out analytically by mapping each singular term to standard domain [-1,1]x[-1,1]. This approach allows for the accurate and stable evaluation of hypersingular terms, particularly those originating from the DGF. Table (1) presents the numeric evaluation of the singular integral like Equation (9). The source point is taken as $u' = 0.2$ and $v' = 0.4$ in the first case, and $u' = -0.6$ and $v' = -0.8$ in the second. The results are computed using the HFP and compared with those obtained via Mathematica.

Table 1: Numeric Evaluation of Singular Integrals using HFP and Mathematica.

Source Location	Method	$(2u^2\text{-}v^2)/r^5$
(u'=0.2, v'=0.4)	HFP	2.84069575921
(u'=0.2, v'=0.4)	Mathematica	2.840695759209953
(u'=-0.6, v'=-0.8)	HFP	4.103154172505319
(u'=-0.6, v'=-0.8)	Mathematica	4.103154172505318

Conclusion

In this study, HFP method was applied to evaluate singular integral arising in the EFIE formulation. By mapping the integration domain to a standard reference square and applying analytical techniques, hypersingular term originating from DGF were successfully computed. The numerical results obtained using the HFP method were compared with those computed by Mathematica, and an excellent agreement was observed. This confirms the validity and accuracy of the proposed approach. The findings confirm that HFP is a reliable and efficient method for the stable evaluation of singular integrals in computational electromagnetics. Future work will focus on applying the model to practical RCS computations.

[d]İstanbul Technical University, Faculty Of Electrical And Electronics Engineering, Control and Automation Engineering Department, Türkiye
korkmazs@itu.edu.tr

Keywords: Parenteral Nutrition, Infant, Machine Learning.

Aim

Total parenteral nutrition is a way of feeding patients who cannot use their digestive system properly. In this method, nutrients are given directly through a vein using a peripheral line or a central venous catheter. It was first used in the 1930s, but it became more common in the 1960s as scientists learned more about how the circulatory system works and how nutrients interact with metabolism and the immune system (Dudrick & Palesty, 2011).

In the late 1970s, parenteral nutrition started to be used for newborns. This made it possible to help premature babies survive, even when their chances were very low before. Total parenteral nutrition (TPN) has helped increase the survival rates of newborns by supporting their growth. It is especially useful for babies who are born too early, have an underdeveloped digestive system, or suffer from conditions like sepsis, malabsorption, short bowel syndrome, or breathing problems (Brine, 2004).

For infants with very low birth weight, the timing of initiating parenteral nutrition within the first hours after birth is crucial, as they exhibit lower weight gain due to hypermetabolism at the time of discharge from intensive care (Specht et al., 2020). In intensive care, the daily vital signs of newborns must be closely monitored to ensure proper nutrition and medication management. Patient information and the data on parenteral nutrition (PN) helps guide adjustments to the treatment plan (Brine, 2004).

It is still unclear whether the nutritional requirements of premature infants after birth depend on their gestational age or birth weight; moreover, there are different opinions regarding the concentrations of the required nutrients (Rizzo et al., 2022). Machine learning methods have been widely accepted and studied in fields requiring data-driven decision-making, such as dialysis (Burlacu et al., 2020). Research on data-driven decision support systems in neonatal intensive care has focused on sepsis, mortality, and discharge weight. However, more studies are needed to explore their use in determining the nutritional composition (Yalçın et al., 2023; Derakhshandara et al., 2024).

In this study, publications focusing on the adjustment of nutrient content in parenteral nutrition management through machine learning methods have been reviewed.

The aim of this study is to answer the question: "Is it possible to effectively use machine learning algorithms to optimize parenteral nutrition management in neonates?" It also aims to highlight the gap in TPN data management that needs to be addressed to enable more effective research in neonatal intensive care units (NICUs) in the future.

Material and Method

This was achieved with a systematic review of research on total parenteral nutrition (TPN) using machine learning. Using the keywords "parenteral nutrition," "infant," and "machine learning," searches were conducted in the PubMed and Scopus databases to identify the publications. Each search was carried out in English, and there were no time restrictions. Table 1 lists all of the inclusion and exclusion criteria.

Table 1. All of the inclusion and exclusion criteria.

Inclusion Criteria	Exclusion Criteria
Article on the analysis of the use of Machine learning with the Parenteral Nutriton	Studies in the form of cohort study, reviews, guidelines, book,congress proceedings
Open-access and fully available studies that have been published on the subject.	Studies that are not available in full text
Articles published in 1996 and up to and including Jan (5th) of 2025	Studies before 1995 and after Jan (5th) of 2025
Articles in English	Article in other languages

The study followed evidence-based review guidelines known as PRISMA. Two databases were searched and the details are shown in Figure 1.

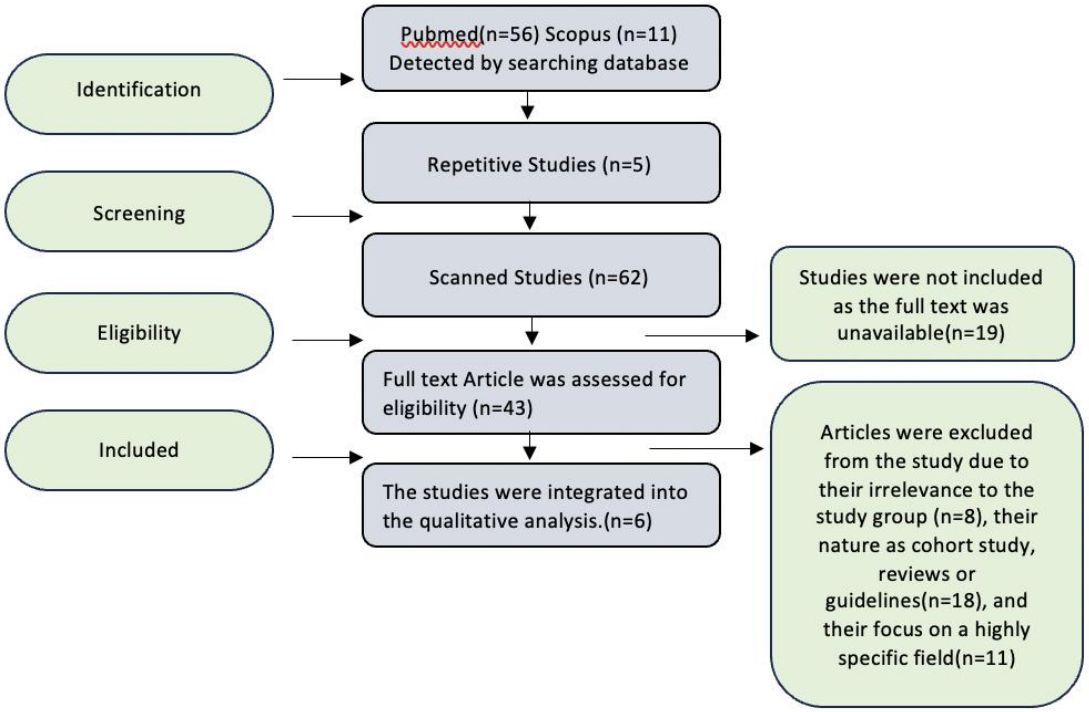

Figure 1. Databases that were searched at and details.

The PICO (Population, Intervention, Comparison, Outcome) technique was employed to determine the study's goal. Sackett and associates created the PICO method in the 1990s as an organized technique for creating research questions and carrying out methodical literature reviews. The following are the PICO criteria for this systematic review based on this methodology showed table 2.

Table 2. PICO criteria for this systematic review.

P(Population-based) :	Infants
I(Intervention) :	Parenteral nutrition control with machine learning support
C(Comparison) :	Manual parenteral nutrition control
O (The outcome) :	Weight gain, less nutritional errors, and a shorter hospital stay

A total of 67 articles were identified from the initial search, including 56 from PubMed and 11 from Scopus. After removing duplicate studies (n=5), articles without full-text access (n=19), cohort study, reviews, guidelines, and conference proceedings (n=18), irrevelant to the study group (n=8), and their focus on a highly specific field(n=11) a total of 43 full-text articles met the inclusion criteria. Following a thorough analysis of the full-text articles, the number of studies accepted into the systematic review (n = 6) was established, with preference given to those that were appropriate for the study's objectives (Table 3).

Findings

As a result of the systematic analysis, six articles were selected based on the inclusion criteria and their relevance to the research field. Of these six articles, five were based on neonatal data, whereas one study was conducted on an adult patient group. However it was included in the review since it focused on computer-assisted parenteral nutrition (PN) management. Since parenteral nutrition (PN) is delivered through an intravenous route, it is regarded as a high-risk procedure due to both the interaction between the patient and the nutritional components and the infection risk linked to the administration process. However, PN remains essential for neonates, particularly for those with an immature digestive system, where proper growth plays a crucial role in recovery. Some studies have indicated that physicians often lack confidence when prescribing PN (Van den Broucke & Deleenheer, 2022; Lenders et al., 2014; Adams et al., 2010). In a pre-post randomized study conducted in Belgium, the impact of decision support systems on physicians' prescribing behavior and their ability to guide physicians was examined. As a result, it was stated that decision support systems could alter the physician's initial PN planning, but no direct impact was observed (Van den Broucke & Deleenheer, 2022).

Physicians' clinical experience, their familiarity with parenteral nutrition (PN) guidelines, and differences in assessing the clinical conditions of infants can lead to variations in PN prescriptions. A study comparing standardized, computer-assisted ready TPN orders (based on ASPEN and with physician-modifiable options) and manually prepared PN orders found that while there was no difference in the length of hospital stay among infants, there was a difference in calorie intake and weight gain. Infants who received computer-assisted PN were found to have gained more weight (Skouroliakou & Koutri, 2009).

When assessed in terms of error rates and time efficiency, parenteral nutrition (PN) is a time-intensive process and is susceptible to errors at every stage, including prescription, order review, preparation, labeling, distribution, and administration (MacKay & Anderson et al., 2016). A survey conducted between 2003 and 2013 on the use of parenteral nutrition (PN) identified that the main factor contributing to error rates was the lack of implementation of computerized prescriber order entry (CPOE) (MacKay & Anderson et al., 2016). In a study conducted in Greece, a TPN Formulation Automated Assistant was developed, which calculated recommended nutrient values based on the entered parameters of the infant. These values were then compared with manually prepared ones. The error rates were found to be very low, and the system required significantly less time, with the results being statistically significant (Skouroliakou & Koutri, 2005).

Newborns typically lose some weight after birth, and how much time it takes to go back to their birth weight can be a sign of adequate nutrition. This process may take longer in preterm infants, indicating possible nutritional challenges. In a study conducted by Kyle A. Franco and Keliana O'Mara at a neonatal center in Florida, the time to regain birth weight, hyperglycemia episodes, and electrolyte imbalances were compared between pre-CPOE and post-CPOE groups in infants born weighing less than 1750 grams. The study revealed that in the CPOE-assisted TPN order group, the achievement rate

of target macronutrient levels improved, the requirement for order corrections declined, and the occurrence of electrolyte imbalances was positively impacted (Franco & O'Mara, 2016). CPOE practices were designed based on protocols for baseline, minimal, and gradually increasing amounts of nutritional components or by using predefined minimum and maximum values set according to newborn weight range thresholds (Franco & O'Mara, 2016; MacKay & Anderson et al., 2016).

In a study where machine learning techniques were applied, machine learning methods trained on a 17-year dataset were compared in predicting macronutrient amounts. The random forest (RF), gradient boosting machine (GBM), support vector machine (SVM), and multilayer perceptron (MLP) techniques were compared in terms of rmse and r^2 values to predict pn volume, protein, lipid, and carbohydrate amounts. The results showed that RF and GBM were the most interpretable and explainable models (Derakhshandara et al., 2024).

Table 3. Studies accepted into the systematic review.

	Title	Year	Article Accsess	Subject	Purpose Of Study	Conclusion
1	Comparison of two types of TPN prescription methods in preterm neonates (Skouroliakou & Koutri, 2009)	2009	PubMed	60	Standardized, computer-assisted ready TPN orders (based on ASPEN and with physician-modifiable options) were compared with manually prepared PN orders.	There was no difference in the length of hospital stay among infants, there was a difference in calorie intake and weight gain.
2	Computer assisted total parenteral nutrition for pre-term and sick term neonates(Skouroliakou & Koutri, 2005)	2005	PubMed	96	A study developed a TPN Formulation Automated Assistant that generated recommended nutrient values based on infant parameters and compared them with manually prepared values.	The study compared error rates between the manual and computerized methods, finding a statistically significant difference.
3	Offering Guidance and Learning to Prescribers to Initiate Parenteral Nutrition using a Validated Electronic Decision TREE (OLIVE TREE)(Van den Broucke & Deleenheer, 2022)	2022	PubMed	73	The impact of decision support systems on physicians' prescribing behavior and their ability to guide physicians was examined.	In this study, it was found that 53% of PN initiation could be prevented. The preliminary results of the conceptual evidence analysis conducted in this study indicated a potential impact (16.4%) on preventing PN use, but no directly effective outcome was observed.
4	Impact of Computerized Provider Order Entry on Total Parenteral Nutrition in the Neonatal Intensive Care Unit(Franco & O'Mara, 2016)	2016	PubMed	91	The study aimed to compare between pre-CPOE and post-CPOE groups in infants born weighing less than 1750 grams.	The study found that CPOE-assisted TPN orders improved macronutrient target achievement, reduced order corrections, and positively impacted electrolyte balance.
5	Machine Learning Decision Support for Macronutrients in Neonatal Parenteral Nutrition(Derakhshandara et al., 2024)	2024	Scopus	17 years data	The study aims to investigate the potential of evidence-based decision support systems implemented with machine learning as a valuable tool for predicting nutritional outcomes in neonatal clinical practice.	The results showed strong estimation capabilities, with R-squared values consistently above 0.7, confirming machine learning's potential as a valuable tool for predicting nutritional outcomes in neonatal care.

6	Frequency and Severity of Parenteral NutritionMedication Errors at a Large Children's Hospital AfterImplementation of Electronic Ordering and Compounding(MacKay & Anderson et al., 2016)	2016	PubMed	PN orders within a specific time period	According to the ASPEN guidelines, nutrition recommendation data generated using an integrated CPOE system was compared with errors reported in the existing literature.	This resulted in a significant cost reduction and a lower error rate compared to those reported in the literature.

Conclusion

Few studies have been conducted on decision support systems in the context of managing newborn parenteral feeding. Only one research which conducted to estimate 4 values of TPN employing machine learning methods has been carried out in this field so far.

In order to increase the diversity of the TPN data pool and enhance algorithm models that make use of this field, more research is also required.

The nutritional care of newborns with a variety of real-life medical disorders is not well supported by current decision support systems, despite the fact that they offer clinical recommendations based on values provided in medical guidelines. Given the significant degree of heterogeneity in the newborn population, the number of subjects that have been investigated in decision support system research is still insufficient, as seen in Table 3. Physician knowledge, previous nutrition prescriptions, and their results must be documented and organized as a usable data source for these systems to improve newborn nutrition management. Machine learning-based decision support systems, which can integrate historical data and medical expertise, are the most practical way to close this knowledge gap.

Keywords:Biomedical Imaging, Breast Tumor Detection, Deep Learning, Faster R-CNN, Magnetic Resonance Imaging.

Aim

Breast cancer is one of the most prevalent malignancies among women worldwide and continues to be a leading cause of cancer-related mortality (Siegel, Miller, Wagle, & Jemal, 2023). If breast cancer is diagnosed at an early stage, the five-year survival rate exceeds 90% (American Cancer Society, 2016). Traditional imaging methods such as mammography and ultrasound, though widely used, may have limitations in detecting tumors, particularly in dense breast tissue. In contrast, Magnetic Resonance Imaging (MRI) has emerged as a powerful and widely utilized imaging modality for breast cancer screening and diagnosis, owing to its superior sensitivity in detecting malignant lesions, especially in high-risk patients (Mann, Kuhl, Moy, Baron, Borelli, Goerres, & Weinstein, 2019). Therefore, this emphasizes the importance of MR imaging in breast cancer screening.

Recent advances in artificial intelligence (AI) have significantly impacted the field of medical imaging and cancer detection. Detecting lesions or regions of interest in medical images is a crucial and labor-intensive task for clinicians, often requiring the positioning and identification of small lesions across the entire image. Convolutional neural networks (CNNs), a common deep learning-based model, are widely used in computer-aided detection systems and help to automate lesion detection and improve diagnostic accuracy or shorten the time needed by experts (Litjens, Kooi, Bejnordi, Setio, Ciompi, Ghafoorian & van der Laak, 2017). AI-assisted detection systems can assist radiologists by identifying subtle patterns in imaging data, reducing interpretation time and minimizing human error. These models have shown great potential in detecting breast cancer in early stages, enabling timely interventions and improving patient outcomes. A study by McKinney et al. (2020) showed that AI systems can detect cancers earlier than conventional methods. Furthermore, analysis of the localization performance of the AI system reveals its potential to flag suspicious sites for examination by specialists. As AI continues to evolve, its integration into clinical workflows is expected to enhance diagnostic efficiency, optimize resource utilization, and ultimately contribute to improved patient care. For this study, one of the widely preferred detection algorithm Faster R-CNN, was used. Faster R-CNN improves upon previous region-based models by introducing a Region Proposal Network (RPN) that shares convolutional features with the detection network, enabling nearly cost-free region proposals. As explained by Ren, He, Girshick, and Sun (2015), the region proposal network (RPN) is a fully convolutional architecture designed to generate object bounding boxes and estimate the likelihood of objects being present at each location. This design allows Faster R-CNN to efficiently generate high-quality region proposals and refine them for precise object detection, making it a widely adopted model in various detection applications.

The aim of this study is to develop an advanced deep learning model for breast cancer detection using MRI scans. The proposed model is developed by obtaining the parameters of the Faster R-CNN model through a hyperparameter tuning process with Optuna. In addition, the model is designed to track tumor locations along slices. This provides a comprehensive detection framework that can be applied to real-world clinical settings. The developed model was also used and tested to track the tumor location in other slices when it is marked in one slice.

Material and Method

1. Dataset:

In this study, a comprehensive breast MRI dataset was used to train and evaluate the proposed model. The dataset consists of 6,670 tumor-containing breast MRI scans obtained from the Duke Breast Cancer MRI dataset, which is available through The Cancer Imaging Archive (TCIA). Additionally, an independent dataset comprising 3,146 healthy breast MRI scans was retrospectively collected from a private medical center, under appropriate ethical approval, to ensure a balanced representation of non-cancerous cases. For model evaluation, a separate test set was curated, including 208 tumor-containing MRI scans and 177 healthy MRI scans.

2. FasterRCNN:

In this study, Faster R-CNN was utilized as the object detection model for identifying tumor regions in breast MRI scans. The model employs a ResNet-50 backbone combined with a Feature Pyramid Network (FPN) to enhance multi-scale feature representation, improving its ability to detect tumors of varying sizes. The Faster R-CNN architecture was trained from scratch, rather than using pre-trained weights, to ensure that the model learns directly from the medical imaging data without biases introduced from non-medical datasets. This approach allows for better adaptation to the unique characteristics of breast MRI scans, potentially improving detection performance.

A crucial aspect of developing a deep learning model is addressing the optimization problem defined by the loss function. Stochastic Gradient Descent (SGD) is one of the most widely used algorithms for tackling these optimization challenges (Ketkar, 2017). In this study, SGD was used for model optimization. The learning rate, weight decay, and momentum values were fine-tuned through Optuna-based hyperparameter optimization, ensuring optimal convergence.

3. Hyperparameter Tuning:

Hyperparameter optimization plays a crucial role in enhancing the performance and generalization capability of deep learning models. For this study, Optuna, was employed to systematically tune key parameters of the Faster R-CNN model. The selected hyperparameters learning rate, weight decay, and momentum were optimized.

The learning rate is one of the most critical hyperparameters influencing model convergence and performance (Smith, 2017). The search space for the learning rate was chosen as the range that gave the highest accuracy after testing with 10 epochs.

The weight decay parameter helps prevent overfitting by penalizing large weight values during training (Krog & Hertz, 1992). Prior research has shown that selecting an appropriate weight decay value can significantly improve generalization (Zhang et al., 2017).

Momentum is used in SGD to reduce oscillations and accelerate convergence by taking into account previous gradients. This helps the model to reach the optimum point more smoothly and quickly (Seyyarer, Ayata, Uçkan, & Karci, 2020). As in this study, values of 0.9 or higher are generally preferred for momentum (Shi, 2024).

By leveraging Optuna's Bayesian optimization approach, the best-performing hyperparameter combination was identified, leading to improved model accuracy and robustness. The tuning process enabled a more efficient exploration of hyperparameter space while reducing computational cost compared to exhaustive grid search methods (Akiba, et al., 2019).

4. Testing:

The proposed Faster R-CNN model was evaluated on a test set consisting of 208 tumor-containing MRI scans and 177 healthy MRI scans. Model performance was assessed using a confusion matrix, and key evaluation metrics were computed to measure detection accuracy.

To quantify the model's effectiveness, sensitivity, specificity, and Intersection Over Union (IoU) were calculated. Sensitivity reflects the model's ability to correctly detect tumor-containing slices, while specificity indicates how well the model distinguishes healthy slices from tumor-containing ones. IoU measures the overlap between the predicted bounding box and the ground truth, with a higher IoU value indicating better localization of the tumor.

These evaluation metrics together provide a comprehensive assessment of the model's performance in detecting and distinguishing tumor-containing and healthy slices, as well as its ability to localize tumors accurately.

Findings

The performance of the proposed Faster R-CNN model was evaluated using 208 tumor-containing MRI scans and 177 healthy MRI scans. Detailed evaluation results, including sensitivity, specificity, and IoU, are presented in Table 1.

Table 1. Accuracy results of the model according to different metrics.

Metrics	Results (%)
Specifity	88
Sensitivity	93
IOU	68

While the model demonstrated relatively high sensitivity, indicating its effectiveness in detecting tumor-containing slices, there remains a small chance of missing tumors. The specificity score of 88% suggests that the model is reasonably good at distinguishing healthy slices from tumor-containing ones, though there could still be instances of false positives. The IoU score of 68% reflects the overlap between predicted and ground truth bounding boxes, suggesting that while the model performs well, further refinement is needed to improve localization accuracy. These results indicate that, although the model is effective overall, there is room for improvement, particularly in reducing false positives and increasing detection accuracy across all cases.

Conclusion

In this study, we developed a Faster R-CNN-based deep learning model for breast tumor detection using MRI scans. The model demonstrated promising performance, achieving a sensitivity of 93%, a specificity of 88%, and an IoU score of 68% on the test dataset. These results suggest that the model is effective at identifying tumor-containing slices and distinguishing healthy tissues. However, there is still potential for improvement in minimizing false positives and enhancing accuracy, particularly in complex or ambiguous cases.

Future work could focus on refining the model's ability to generalize across a broader set of data, potentially by incorporating larger and more diverse datasets or exploring different network architectures. Additionally, using carefully annotated training and test datasets, where tumor regions are precisely marked by experts, can enhance the model's performance and contribute to a more reliable evaluation. Overall, the results of this study highlight the potential of deep learning models like Faster R-CNN in assisting radiologists with breast cancer detection, but further development is needed to make these models more robust and reliable for clinical use.

Prediction of Microsatellite Status Using Deep Neural Network

Fatma Vildan Engin[a], Ender Mete Ekşioğlu[a]

[a] Istanbul Technical University, Electronics and Communication Engineering Department, Türkiye
enginfvildan@gmail.com

Keywords : Colorectal Cancer, Deep Learning, Digital Pathology, Microsatellite Instability, Whole Slide Image.

Aim

Microsatellite instability (MSI) is an important biomarker for colorectal cancer (CRC). Due to cost and time issues, many patients remain untested for MSI. However, recent studies illustrated that patients with MSI respond better to immunotherapy (Kather et al., 2019a). Hence, segmentation for MSI in CRC patient images stands out as an important problem. In this study, hematoxylin and eosin (H&E) whole slide image samples from The Cancer Genome Atlas (TCGA) are used to develop a model for MSI segmentation. Additionally, data augmentation is applied to the used dataset. Two distinct models have been trained in a sequential setting. The first model realizes the segmentation of tumor and non-tumor tissues, whereas the second model is applied for the classification of MSI status. aim section should be written in Times New Roman font, justified-alignment and in 10-point size.

Material and Method

Tissue segmentation and classification are two separate problems. Therefore, two different datasets were used in the study. For segmentation, public tissue images are used, and these are labeled into three classes. The first class is ADIMUC, which consists of adipose tissue and mucus, and it is known as loose non-tumor tissue. The second class is STRMUS, which consists of stroma and muscle, and it is also called dense non-tumor tissue. The third and final class is TUMSTU, which consists of colorectal cancer epithelial tissue and stomach cancer epithelial tissue (Su et al., 2022). Microsatellite instability occurs in tumor tissues. Hence, tissues classified as TUMSTU are significant for microsatellite status detection, while the other classes are not important for further steps. The dataset for segmentation includes approximately 12,000 tissue images, which were split to train and test subsets with a ratio of 0.8 and 0.2. material and method section should be written in Times New Roman font, justified-alignment and in 10-point size.

The second dataset used for microsatellite status classification consists of whole slide tissue images from The Cancer Genome Atlas (TCGA). The samples from whole slide images belonging to TCGA-READ and TCGA-COAD were used because TCGA-CRC specifically focused on colon adenocarcinoma and rectum adenocarcinoma. A whole slide image involves both tumor and non-tumor tissue. For microsatellite status detection, only tumor tissues are essential. Each whole slide image is divided into image tiles. These patches are then classified as adipose tissue, stroma tissue, or tumor tissue. Tumor tissues were considered meaningful for microsatellite status detection. The classifier for the segmentation task was created by using the ResNet-18 architecture. ResNet-18 utilized in this study has 71 layers in total. ResNet-18 model was trained using transfer learning by building upon a model pre-trained on the ImageNet dataset. The end layers of the model need to be re-arranged for our particular application, hence, these layers were fine-tuned using the dataset. The initial learning rate was chosen as 0.00001 . Such a small learning rate necessitates a rather large number of epochs (Jepkoech et al., 2021). Hence, 100 epochs were applied.

After the classification, tumor tissues for colorectal cancer were obtained. To obtain image patches, n = 1922 whole slide images belonging to 1687 patients were acquired. After division and elimination, considering the tumor or non-tumor tissue, patches were acquired. These patches are considered significant for MSI status because the classification of MSI status can be determined for tumor tissues. Therefore, non-tumor tissues such as adipose or stroma were eliminated.

Then, color normalization was applied to these image patches to normalize the pixel values. For color normalization, the Macenko method was used (Macenko et al., 2009). This method is utilized to overcome the color variation problem in histopathology. The method uses a reference image to normalize the pixel values (Macenko et al., 2009). A vital information

for microsatellite status detection is the location of the pixel. This can be determined by the colors of pixels. Because H&E staining was used in pathology images, in this staining technique,blue staining represents the nucleus while red parts are used for coloring the rest of the cell. Thus, the locations of pixels are determined. Color normalization kept important pixels while removing or blurring the insignificant pixels of the image.

After the color normalization, images are augmented to improve the model's performance. Every tissue image has similar textures. There is a homogeneous distribution within the image. For the augmentation purpose, cut-out and cut-mix methodologies have been used. These techniques both determine a certain part of the image. This part was chosen as a square area for both models. The cut-out technique suggests filling this area with zero padding, while the cut-mix suggests filling it with a patch from another image (Rao et al., 2023). A sample of the application of the cut-mix technique for an image from the dataset is shown in Figure 1.

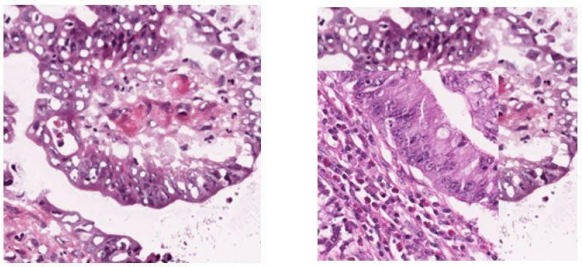

Figure 1. A sample of Cut-mix Application.

Finally, the obtained dataset was divided into train, test, and validation sets with a ratio of 0.7, 0.2, and 0.1. Also, patient labels are considered for splitting into the test and train subsets. All patients have more than one patch because of the whole slide image division (Kather et al., 2019b). Also, for some cases, the same patient might have more than one whole slide image, which leads to more image patches. These image patches should be considered in the same class to determine if the patient has MSI. Thus, the labels for each case were kept. Then, a pre-trained ResNet-18 model was used for microsatellite status prediction. The last layers of the architecture were fine tuned, while the other layers were fixed

Findings

This study aimed to detect microsatellite status on colorectal cancer images using the Resnet-18 model. The utilized performance evaluation criterion was based on the Reciever Operating Characteristic curve. The area under the curve (AUC) was calculated as 0.88, as seen in Figure 2. This result suggests that our model performed rather well for the whole slide tissue image classification problem under consideration.

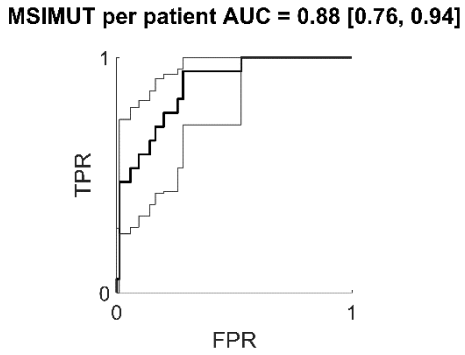

Figure 2. ROC Curve for Microsatallite Status Prediction Model.

Additionally, accuracy, sensitivity, precision, and f1 score were also calculated, which can be seen in Table 1. These additional results confirm the performance of our developed model.

Table 1. Evaluation Metrics of the Model.

Evaluation Metric	Results
Accuracy	0.95484
Sensitivity	0.95484
Precision	0.82738
F1 Score	0.88655

Conclusion

The purpose of this study was to predict microsatellite status models in colorectal cancer (CRC) tissue slides by using deep learning. The AUC result and additional evaluation metrics demonstrated the performance of the utilized ResNet-18 model and also the importance of data augmentation. The proposed model would be a beneficial asset for pathologists. The model also provides a fast and accurate approach to cancer tissue segmentation. The model can be extended in a rather straightforward manner to the images for other types of cancer patients.

Keywords: Biomedical Imaging , Breast Tumor Segmentation , Deep Learning , Magnetic Resonance Imaging, U-Net.

Aim

Breast cancer is one of the most common invasive cancer types worldwide and is a leading cause of cancer-related deaths among women (Bray et al., 2018; Siegel et al., 2019). Early diagnosis in breast cancer is critically important for the success of the treatment process, and for this purpose, medical imaging techniques are extensively utilized. Magnetic Resonance Imaging (MRI) is a widely preferred imaging method in the diagnosis of breast cancer and the detailed morphological analysis of tumors (Yousaf, Dervenoulas, & Politis, 2018). Manual annotation of tumor regions in MRI images, which is essential for training artificial intelligence (AI) based diagnostic models, is a time-consuming process that requires significant effort and radiological expertise (Jiang, Diao, & Yao, 2022). This step, typically carried out by expert radiologists, is crucial for preparing high-quality labeled datasets needed for developing automated diagnostic systems. This manual process can affect the accuracy of segmentation among different observers, potentially leading to incomplete evaluations. In this context, the development of automatic or semi-automatic segmentation methods to reduce radiologists' workload, ensure segmentation consistency, and improve the accuracy of diagnostic processes has emerged as an important research topic in the field of medical imaging.
The main objective of this study is to enhance the accuracy and efficiency of tumor segmentation in breast MRI images by utilizing a U-Net-based approach. The proposed method aims to improve segmentation performance by addressing the limitations of existing fully automatic models.

Material and Method

1. Dataset

In this study, two different datasets were used for the segmentation of breast cancer lesions: the Mama Mia Breast MRI Dataset (Garrucho et al., 2024) and the Zenodo Breast MRI Dataset (Zhang, 2023). Both datasets include segmentation masks that indicate the tumor regions.
The Mama Mia dataset is a research-oriented dataset containing breast MRI data from a total of 1506 patients. This dataset includes dynamic contrast-enhanced MRI (DCE-MRI) images captured at different time points for breast cancer diagnosis. In the study, only the last post contrast images from the Mama-Mia dataset were used in the dataset.
The breast MRI dataset obtained from the Zenodo platform contains breast MRI data from a total of 100 patients. For each patient, the dataset includes six types of images in total, consisting of pre-contrast and post-contrast scans. Both image types were used in the study. Subtracted images, which are obtained by subtracting pre-contrast and last post-contrast images from each other, are used to analyze which image format the model performs better in segmentation. Accordingly, the model was trained with both post-contrast and subtracted images separately and performance comparisons were made. Based on the findings, the image type with higher performance was identified and this dataset was combined with post-contrast images from the Mama-Mia dataset to create a hybrid training set.
To enable data analysis and enhance the effectiveness of the segmentation models, a comprehensive data preprocessing step was carried out. In the initial stage, the minimum rectangular area (bounding box) that best encloses the tumor regions was calculated, and each image was cropped based on this bounding box. This approach allowed the models to focus only on

the tumor-containing regions, preventing background information from negatively affecting model performance. However, to better model the boundary areas between tumorous and healthy tissues and to gain a deeper understanding of the transitions between tissues, the bounding box areas were expanded by 10% and 20%, respectively, and the resulting images containing surrounding healthy tissue were also included in the training process.
Subsequently, the datasets were individually optimized according to the input size requirements of the segmentation models to be used. The images prepared for the U-Net model were resized to 256x256 pixels.

2. Methodology

In this study, a segmentation pipeline is proposed to accurately delineate tumor regions in breast MRI images. Initially, the dataset was prepared for the training and testing processes through the application of various data augmentation techniques. Subsequently, the model's performance was evaluated using two different image types—post-contrast and subtracted images—exclusively on the Zenodo dataset. Based on the comparative results, the image format that yielded a higher Dice score was selected. In the final step, the U-Net model was trained using a combination of the Mama Mia and Zenodo datasets, utilizing the selected image type to enhance segmentation accuracy.
The U-Net model is a type of fully convolutional network (FCN) that is widely used for medical image segmentation and follows an encoder-decoder architecture (Azad et al., 2024). In the encoder phase, the model processes the input image at multiple resolution levels to learn deep and semantic features. In the decoder phase, it reconstructs the original resolution by enriching the high-level features obtained from the encoder with detailed information. This process provides the ability to capture global contextual information while preserving fine details, which is particularly important for segmenting small and irregularly shaped structures such as tumors (Du et al., 2020).
In this study, the U-Net model was trained using the Dice Loss function. Dice Loss is a loss function commonly used in segmentation models and is particularly effective in cases of imbalanced class distributions; it aims to improve segmentation accuracy by maximizing regional overlap (Zhao et al., 2020). The AdamW optimization algorithm was employed to ensure stable progression during the learning process.
In addition, to increase the diversity of tumor shapes and enhance the model's generalization ability to different tumor morphologies, an affine transformation—a two-dimensional geometric transformation method—was applied in this study. This method involves a combination of operations such as translation, rotation, scaling, and shearing applied to the images (Stearns & Kannappan, 1995). Through this data augmentation technique, the model gains the ability to better recognize tumors with varying shapes and locations that may not be present in the training dataset, thereby enabling stronger generalization to diverse tumor morphologies in real clinical settings.

Findings

To assess the impact of image selection on segmentation performance, two different input strategies were compared: subtracted images (obtained by subtracting pre-contrast from last post-contrast images) and last post-contrast images alone. The evaluation was conducted using the Zenodo dataset, and the results are presented in Table-1 and Table-2:

Table 1. Dice Score (%) for the Subtracted Images Dataset.

Dataset	Dice Scores (%)
Validation	77
Test	76

Table 2. Dice Score (%) for the Last Post-Contrast Images Dataset.

Dataset	Dice Scores (%)
Validation	90
Test	83

The comparison reveals a clear performance advantage when using last post-contrast images. Specifically, a 13% increase in Dice score was observed on the validation set and a 7% increase on the test set, demonstrating that last post-contrast images offer better lesion visibility and enable more accurate segmentation.
Based on these observations, last post-contrast images were selected for the construction of the hybrid dataset used in the proposed approach. The U-Net model was trained on tumor positive images with the application of various data augmentation techniques. The performance on this hybrid dataset is reported in Table-3:

Table 3. Dice Score (%) for the Hybrid Dataset.

Dataset	Dice Scores (%)
Validation	83
Test	84

These results indicate that the U-Net model, when trained under the specified conditions, achieves high segmentation accuracy and generalizes well across different patient data. The combination of contrast-enhanced image selection, targeted training, and data augmentation played a crucial role in obtaining these performance levels.

Conclusion

This study aimed to improve tumor segmentation performance in breast MRI images by leveraging a U-Net-based approach trained under a carefully designed pipeline. The results demonstrate that the proposed method achieved high segmentation accuracy and efficiency, particularly when trained on tumor-positive images augmented with appropriate data augmentation techniques. The U-Net model exhibited a strong learning capacity, effectively capturing and delineating tumor regions with precision.
An important finding emerged from the comparative analysis of subtracted images (pre-contrast subtracted from last post-contrast) and last post-contrast images. The model performed considerably better on last post-contrast images, achieving higher Dice scores and more accurate segmentations. This insight guided the selection of last post-contrast images for the composed dataset used in this study, contributing significantly to the model's improved performance.
Moreover, integrating multiple datasets to form a composite training set enhanced the model's generalization capability. This hybrid dataset enabled the U-Net model to adapt effectively to a variety of imaging characteristics, leading to robust and consistent results across different data distributions.
These findings indicate that both selective training on tumor-present images and the incorporation of diverse, contrast-enhanced datasets are key to improving segmentation accuracy. Overall, the proposed training strategy has proven effective and highlights the potential of the U-Net architecture as a reliable and generalizable tool for breast tumor segmentation in both clinical and research contexts.

Spatial Representation In French New Wave Cinema: An Analysis Through Agnès Varda's Cléo De 5 À 7 (1962) Film

Miraç Kaykulu [a], Demet Arslan Dinçay[b]

kaykulu22@itu.edu.tr

Keywords: Cinematic Space, France New Wave Cinema, Post War II, Contextual Analysis, Semantic Analysis.

Aim

Space, the primary subject of architecture, is also a fundamental component of cinema. According to Pallasmaa, architecture, much like cinema, exists in the dimensions of time and movement. Designing and interpreting a building takes place through sequential spatial experiences. Constructing a building involves anticipating and composing the effects of contrasts and connections experienced within the spatial flow. When considering a building as a continuous plan/sequence, the architect essentially works with cuts, montages, framing, and openings. (2012) In this regard, architectural and cinematic space intersect in their exploration of time and human experience.

The New Wave was a cultural movement that emerged in the 1950s as a result of the economic, political, aesthetic, and social developments in post-war France. (Neupert, 2007) This movement developed a complex relationship with architecture, as filmmakers created a new cinematic language that reflected the cultural context of post-war France. By focusing on Paris's built environment, they revealed its cultural, social, and aesthetic dimensions, presenting a panoramic urban view.

This study investigates the use of space in French New Wave Cinema, with a specific focus on Agnès Varda's Cléo de 5 à 7 (1962). Varda's innovative use of space in the film will be analyzed, showing how its settings document Paris's urban fabric and how cinematic space conveys the narrative and the characters' experiences.

Material and Method

This study employs a qualitative analysis to explore the use of space in Cléo de 5 à 7, focusing on both semantic and contextual aspects. The theoretical framework is grounded in a review of the socio-political, cultural, artistic, and architectural conditions in post-World War II France, which influenced the rise of French New Wave Cinema. The analysis progresses from broad urban landscapes—reflecting socio-cultural dynamics in public spaces—to more intimate, personal interiors that align with the character's internal journeys within the film's narrative.

Findings

1. Post-World War II France

According to Hoffmann, post-world War II France experienced not only a crisis but also a political and social reconstruction process (1961). The colonial wars in Algeria and Indochina deeply affected France's national identity, setting the stage for May 1968 protests, which led to significant cultural changes (Wolin, 2010).

The cultural and artistic environment following World War II saw a dynamic shift where traditional structures were dismantled, and experimental approaches emerged. Hopkins notes that this period marked the rise of modern art movements in France (2000). Similar innovation was observed in architecture. The devastating effects of the war led to a severe housing crisis, bringing issues of reconstruction and repurposing to the forefront. At the same time, debates about balancing the preservation of historical heritage with modernization took place. While the historic fabric of Paris was prioritized for preservation, modern development was concentrated in the city's suburbs. Modernism, led by figures such as Le Corbusier and Auguste Perret, influenced urban planning projects. However, these experimental projects remained largely conceptual

and were only implemented on a limited scale (Ragon, 2010). Notable examples of modernist planning include the La Défense project and Le Corbusier's Cité Radieuse and Unité d'Habitation projects (Cohen, 2013).
Similarly, cinema also saw new developments, with the French New Wave emerging in this context. André Bazin's Cahiers du Cinéma (1951) played a key role in spreading the French New Wave. Alexandre Astruc developed the ‘‘auteur’’concept, viewing cinema as a language and form of expression in the ‘‘camera-stylo’’ era (Makal, 1996). According to Kovacs, French New Wave auteurs positioned themselves as representatives of modern cinema in France and Europe. In their films, they used sound, music, and dialogue in ways that contrasted with visual storytelling, thus developing a new aesthetic approach where meaning was conveyed predominantly through visuals (2010).

2. Cléo de 5 à 7 (1962)

In Cléo de 5 à 7, the film depicts the two-hour internal journey of the singer Cléo as she awaits her hospital test results, unfolding almost in real-time (Mennel, 2019). The narrative centers on the character's emotional state, exploring themes such as the fear of death, mental distractions, and the rapid process of reinterpreting life from a new perspective. Space plays a crucial role in enhancing the narrative. The film's settings will be analyzed in three sections: urban spaces, public interiors, and personal interiors, with semantic and contextual analyses.

2.1. Urban Spaces

The urban landscapes reflect real life. The character is static in one sense, awaiting test results for a possible cancer diagnosis, while in another, she is dynamic, walking through Paris, navigating taxis, cars, and buses (Stark, 2012). This contrast emphasizes the tension between her internal stillness and the city's external movement, enriching her emotional journey.

2.1.1. Semantic Analysis

In the 1962 Paris city panorama, the architecture of the city center reflects historical influences rather than modernist ones (Figure 1) (Url-1). This period coincides with the acceleration of modern construction and mass housing on the city’s outskirts. In the film’s public spaces, locations such as Parc de Montsouris and Hôpital de la Salpétrière are featured (Figure 2). Varda uses the city's streets, avenues, parks, and dynamic spaces as stages in the film. Long takes, wide-angle shots, and over-the-shoulder tracking shots highlight the character’s continuous interaction with the city, emphasizing movement and change.

Figure 1. The urban spaces of the film, the panorama of the city of Paris.

Figure 2. Hôpital de la Salpétrière ve Parc de Montsouris.

2.1.2. Contextual Analysis

According to Mennel, commercial areas like Rue de Rivoli and Boulevard Montparnasse symbolize Cléo's initial consumption-driven world. In contrast, Parc de Montsouris represents natural, open public spaces where Cléo begins to experience freedom and connect with others (2019). Varda presents Paris not only as an aesthetic backdrop but as a dynamic space where socio-political events unfold. The details Cléo encounters while walking, taking a taxi, riding a bus, or traveling in her friend's car reflect the political climate of the time.

2.2. Public Interior Spaces

2.2.1. Semantic Analysis

In examining the public interior spaces in the film, while modernism had not yet influenced mass architecture in 1960s Paris, it began to emerge in interior design through rational furnishings, functional solutions, and the use of mirrors. In the opening tarot scene, Cléo encounters her reflection in a mirror as she exits the fortune teller's room; in another mirror in the lobby, she questions her youth and beauty. After leaving the fortune teller, Cléo sits with Angèle at a café in front of a mirror; as she gazes into it, she begins to cry. This mirror reflects not only Cleo and Angèle but also the café interior and the street outside. In a hat store, mirrors fragment the space and multiply Cléo's image, emphasizing her dominance in the space while the city fades into the background . Later, at Le Dôme café, reflections in glass mirrors and modern paintings stand out. When Cléo visits her friend's sculpture studio, both the interior and exterior are shown from different angles. Finally, at the cinema, a falling mirror shatters, with Cléo's reflection symbolizing her confrontation with herself (Figure 3).

Figure 3. Public Interior Spaces.

2.2.2. Contextual Analysis

The public interior spaces in the film offer a glimpse into Cléo's daily life. Amid the vibrant surroundings, the fear and anxiety brought on by shifting circumstances are reflected through mirrors placed in these spaces. Mennel notes that mirrors in public spaces extend the perceived boundaries of the environment and enable the multiplication of characters. The split-screen effect created by mirrors emphasizes a space where private life is revealed in the public domain (2019). The mirrors symbolize Cléo's confrontation with herself.

2.3. Cléo's Flat

2.3.1. Semantic Analysis

In areas like Montmartre and Montparnasse, artist studios rapidly multiplied, and building complexes such as La Ruche and Le Bateau Lavoir were constructed. In these areas, it is common to find artist studios with glass roofs opening onto courtyards of buildings with classical façades (Delanoe, 2001). Cléo's apartment is located on Rue Huyghens, near the

Montmartre district (Url-2). Upon examining the features of Cléo's home, it could be considered one of the artist studios mentioned above.

The interior of the apartment is a single space with high ceilings and white walls. In the interior, a Jacobin-style wooden bed and table stand out. The style includes vertically oriented chain-effect load-bearing elements. Additionally, there is a Neo-Baroque pair of armchairs next to the bed. The apartment also features Michael Thonet's rocking chair model no.1 (1862) and chair model no.14 (1859) (Url-3). The furnishings do not form a cohesive composition within the interior but are displayed individually. Within the spatial furnishings, attention is drawn to the mirrors (a freestanding singular mirror, a vanity mirror, and several mirrors hanging on the wall) as well as the collection of numerous clocks arranged side by side on the shelf (Figure 4).

Figure 4. Cleo's Flat.

2.3.2. Contextual Analysis

Cléo's apartment interior reflects her fantasy world, with furnishings arranged without cohesion, mirroring the fragmented state of her mind as she faces death. The Jacobin-style furniture, representing the past, contrasts with rational pieces symbolizing the future. Items like wigs, wings, mirrors, and clocks further embody her complex mental state.

The fluted carriers on the furniture resemble chains, symbolizing her captivity to illness. The duality of the Neo-Baroque armchairs and two Thonet chairs highlights the life-death dichotomy. Mirrors on the walls symbolize her confrontation with reality, while the clocks emphasize the passage of time and the life-death process.

Kitsch accessories such as feathered wings and costumes suggest her immersion in fantasy. She does not use the rational furniture, which is instead used by others (e.g., her assistant or friends), while she sits in the rocking chair. This may symbolize her subconscious desire to escape into her fantasy world.

Conclusion

Cléo de 5 à 7 is a key example in French New Wave Cinema, where emotion-driven storytelling is placed in a spatial context. The narrative centers on the chaos in the protagonist's mind. The film uses spaces, from urban public areas to personal interiors, as a tool that enhances the narrative.

The public spaces reflect Cléo's connection to life, while her home symbolizes detachment from reality. Through urban landscapes, public interiors, and Cléo's apartment, the film captures 1960s Paris's architectural structure and explores the emotional transformation of the character. The spaces are not just a backdrop but an active part of the narrative, with Paris's urban fabric carrying the story. Through cinema, architectural space becomes a reinterpretable text. In this sense, Cléo de 5

à 7 is more than a film; it exemplifies how cinematic space integrates with the narrative, shedding light on the socio-cultural and architectural context of the time.

Legitimisation through Elevation: Romanos' Myrelaion

Ömer Faruk Ulusoy[a], Bilge Ar[a]

[a] Istanbul Technical University, Department of Architecture, Architectural History Program, Turkey
ulusoyo17@itu.edu.tr

Keywords: Legitimisation, Myrelaion, Patronage, Romanos I Lekapenos, Visibility.

Aim

This study constitutes the transformation of a conceptual practice concerning the external perception of the Myrelaion structure into a scholarly research project. It represents a line of thought that proceeds from the externally observable architectural features of the structure toward the possible intentions of the patron who financed its construction. Although not all externally perceived characteristics of the building may have been consciously designed, it is certain that some were intentionally crafted to evoke specific impressions in viewers. In this respect, buildings serve as intermediaries between patrons and the perceptions they aim to instill in people.

The Myrelaion Church was constructed on a platform that radically increased the building's height. This deliberate manipulation of the topography evidently contributed significantly to enhancing the visibility of the structure. However, the external perception of Myrelaion has been profoundly altered due to the radical transformation of its surrounding physical environment in recent centuries. Today, the tall apartment buildings surrounding the site have erased its once-dominant position within the urban fabric and greatly diminished its visibility. Nevertheless, due to its dominant position in the topography of Constantinople and the substantial substructure elevating it, Myrelaion must have been a much more visible and prominent structure at the time of its construction.

Some complexes built on the sloped topography of Constantinople were erected on substructures designed to create flat surfaces for construction (Janin, 1964). These substructures typically generated level platforms accessible from higher ground. In the case of Myrelaion, however, the substructure rises from all directions, preventing pedestrian access to the church's platform. Therefore, unlike other examples, the sole purpose of Myrelaion's substructure cannot have been merely to produce an accessible flat surface on sloping terrain. In the literature, it is commonly stated that the reason for Myrelaion's elevation was to align the church with the elevation of the adjacent palace (Striker, 1968). However, like the church, the palace also rises on a substructure and is similarly inaccessible from street level. Considering that the adjacent palace was also commissioned by Romanos Lekapenos, the patron of Myrelaion, it is likely that the patron played a role in this unconventional architectural approach.

Based on existing studies in the literature, it can be suggested that Romanos was an emperor who sought to establish legitimacy through various means (Runciman, 1969). In this study, Romanos' patronage and his quest for legitimacy will be examined specifically through the example of Myrelaion—his only surviving architectural work today. While the structural features of this building have previously been analyzed in detail, this study adopts a different approach, treating the church's architectural and locational characteristics as the result of intentional decisions. By investigating the underlying motivations that led the builders to such outcomes, a conceptual framework is constructed, moving from the structure's physical features toward the patron's potential intentions.

Material and Method

The unique substructure of Myrelaion, uncommon in its period, suggests a deliberate and exceptional architectural choice likely tied to the patron's personal intentions. Its execution by builders unfamiliar with such forms reinforces this view. To explore this relationship, the study compares Myrelaion to other elevated religious buildings from the same period—namely the Monastery of St. Mary Peribleptos, Hagia Georgios in Mangana, and the Gül Mosque.

Another approach to understanding Myrelaion's distinct architectural form involves examining other structures commissioned by Romanos. While many are now lost, the Chalke Chapel—described in reliable sources—shares similar elevated and inaccessible features. This suggests a consistent architectural strategy across Romanos's projects.
Understanding the motivations behind these design choices also requires insight into Romanos's political career and personal ambitions. Primary sources, particularly Theophanes Continuatus, offer valuable context.
This study follows a conceptual framework moving from Myrelaion's external perception to its design rationale and patronal intention. The investigation began by asking why the church was elevated without any evident topographical necessity. Since the surrounding environment has changed considerably, historical maps and travel accounts—especially those of 16th-century visitor Pierre Gilles—were used to reconstruct the structure's original visual prominence.

Findings

Although it is currently impossible to comprehend due to the high-rise buildings surrounding Myrelaion, the study has demonstrated—based on visual and textual sources—that Myrelaion was, at the time of its initial construction, a highly visible structure occupying a dominant position within its surroundings. This pronounced visibility was partly the result of the strategically chosen dominant location and, undoubtedly, also a consequence of the unconventional form of the substructure upon which the building was erected. Through a comparative analysis of the substructure employed in Myrelaion with those of other contemporaneous constructions, the unique nature of its architectural solution has been identified. Moreover, by including other buildings commissioned by the same patron in the scope of the study, it has been established that this distinctive architectural approach was a recurring practice in the constructions associated with Romanos.
Comparable examples of churches built on substructures include the Monastery of St. Mary Peribleptos, Hagios Georgios in Mangana, and the Gül Mosque, likely built slightly later. All were elevated on substantial platforms that enhanced their visibility.
Of Peribleptos, only the substructure survives, with a later church built above. Set on a slope, it was accessible from the higher side, while its lower façade rose impressively on a massive base. The 17th-century traveler Simeon described it as "on a high place overlooking the sea," likely referring to this effect.
Hagios Georgios, now lost, was rebuilt multiple times. Its final form rested on deepened foundations with added columns (Psellos, 1953), also rising on a slope with support from below.
The Gül Mosque, of uncertain original identity, was built atop a leveled hilltop. Its platform meets the ground at only one point, making it accessible only there, while its retaining walls become increasingly prominent from a distance.

Conclusion

In the sloped topography of Constantinople, it was common to build substructures to create level construction platforms. In the examples above, these substructures primarily served to counteract the slope and provide accessible flat surfaces. Myrelaion, too, stands on a massive substructure. Pierre Gilles, who visited Istanbul in the 16th century, wrote: "Above the Blancha to the North, there stands a temple upon an eminence, called Myreleos; in the inside of which was a cistern, the roof of which is supported with about sixty marble pillars" (Gilles, 1555). This substructure significantly shaped the external appearance of the building. Unlike the other examples, the Myrelaion is raised on all sides and its upper platform is inaccessible on foot, suggesting that the purpose of its elevation was not only to create a flat surface accessible on foot.
Myrelaion was constructed simultaneously with Romanos' adjacent palace, which itself was built atop the ruins of an ancient rotunda—the largest in Constantinople at the time. Romanos converted this rotunda into a cistern by filling it with columns and building his palace on top (Striker, 1968). Like the church, the palace platform is elevated and inaccessible by foot from any direction. This inaccessibility distinguishes Romanos' architectural approach from that of his contemporaries. It suggests that his intent was not only to create flat ground but also to elevate the structures symbolically and visually.
The same principle appears in Romanos' Chalke Chapel. Though the structure no longer survives, it is described in primary sources. Cedrenus (1839) notes that the chapel was built atop the Chalke Arch. Deacon Leon described it as "a narrow chapel that could accommodate at most fifteen people, reached by spiral staircases, difficult to access, almost like a labyrinth

or a hiding place" (Talbot & Sullivan, 2005). These descriptions confirm that the chapel was elevated above ground level and accessible only by a long, winding staircase.

The unique architecture of the Chalke Chapel represents an exceptionally singular implementation. The peculiarity of its location choice for a chapel was even criticized in contemporary sources. However, we are fortunate that one event, recorded in a primary source from the period, helps illuminate why such a location may have been chosen. In the Chronicle of Theophanes Continuatus, there is an account of Romanos delivering a speech to the people in front of the Chalke Chapel, publicly announcing one of his charitable acts.

"On the other hand, Emperor Romanos was striving to repay his obligations to the city and to win the favor of the people. To this end, he annulled all public debts and ordered the official debt registers to be torn up. These documents were publicly burned at the Chalke Gate, and the people applauded the gesture with great enthusiasm." (Theophanes Continuatus, 1838, p. 429).

This account describes Romanos standing on the terrace and publicly declaring his philanthropic act in a highly political display. Despite the small size of the chapel, its elevated position made it easily visible from a distance. Romanos, speaking from the terrace, could also be clearly seen by the gathered crowd. Behind him stood a physical embodiment of his piety and generosity — the chapel he had built.

The repetition of this unusual architectural choice in both Myrelaion and the Chalke Chapel—structures commissioned by the same patron— strongly suggests that elevation was a personal preference of Romanos.

What might have motivated Romanos to favor this solution? Understanding this requires consideration of his career and political ambitions. Romanos came from a peasant background and rose through the ranks of the Byzantine navy, eventually usurping the throne from the young Emperor Constantine VII Porphyrogenitus. He later declared his own sons as heirs. Romanos was attempting to build a dynasty while facing serious legitimacy issues. Constantine described Romanos as "a common illiterate fellow... not of imperial and noble stock" (Constantine VII Porphyrogenitus, 1967). Another source that reflects Romanos' efforts to legitimize his rule is the correspondence of Patriarch Nicholas Mystikos, which includes personal anecdotes about him (Marić, 2013).

The elevation technique used in Romanos' buildings undoubtedly enhanced their visibility from afar and ensured they appeared more monumental when seen up close. Although it seems to be an exceptional feature in Myrelaion, the fact that we see the same approach in the lost Chalke Chapel strengthens the argument that this was a deliberate strategy. By elevating his buildings, Romanos may have aimed to draw daily attention to these impressive structures, prompting discussions about their patron.

Romanos' speech in front of the Chalke Chapel may serve as a key to understanding these elevated structures, which are otherwise difficult to interpret—particularly due to their deliberate inaccessibility. In this instance of overt political propaganda, a chapel built under his patronage formed the backdrop. This architectural form can be seen as part of Romanos' broader campaign to reinforce his legitimacy and authority. The buildings he commissioned were not merely structures, but instruments of political messaging and visual expressions of imperial power.

Rural Houses in Renaissance Architecture: Proposals of Sebastiano Serlio According to the Social Hierarchies in his Sixth Book

E. Merve Aksoy Oral[a], Aygül Ağır[b]

[a] Istanbul Technical University, Graduate School, Architectural History Program, Turkey

Keywords: Renaissance Architectural Treatises, Sebastiano Serlio, Domestic Architecture, Rural Houses, Social Classes.

Renaissance architectural treatises are invaluable documents that provide deep insights into the architectural culture and social classes of the period. Among Renaissance theorists, Leon Battista Alberti (1404-1472) defined cities in relation to their houses, describing the house as a "miniature city," thus indicating that houses are concrete examples reflecting the dynamics of cities (Alberti, 1:9, 1988). This perspective highlights that domestic spaces do not merely serve residential purposes but also reflect the social and spatial dynamics of the city on a smaller scale.

Architecture, in this context, does not merely accommodate social stratification—it plays an active role in visualizing and legitimizing it. Vitruvius's architectural principles, particularly the concept of *decorum*, served as a primary reference for Renaissance architects and patrons in domestic architecture (Pellecchia, 1992). Accordingly, the application of *decorum* ensured that domestic spaces were aligned with the owner's social status.

The architectural treatises written during the Renaissance period reflect the existing social stratification in a strict hierarchical order. However, housing for low-income groups has often been overlooked in architectural treatises, despite their significance in reflecting social hierarchy. In this context, Sebastiano Serlio's (1475–1554) Sixth Book is remarkable for its systematic approach to housing across different social strata, establishing a valuable resource for understanding the architectural expression of class distinctions (Fiore, 1994; Rosenfeld, 1996). Serlio proposed a wide range of housing designs, from humble thatched cottages for the poorest to grand palaces for the nobility, aiming for designs that were comprehensible not only to the educated but also to the "average person" (Fiore, 1994; Rosenfeld, 1996).

The necessity of designing country houses according to social status and specific needs is a recurring theme in rural architecture and agricultural treatises of the period. This notion can be found in works such as Crescenzi's *De Agricultura* (1495), Alberti's *De re Aedificatoria* (1485), and Anton Francesco Doni's *Le Ville del Doni* (1566) (Lazzaro, 1985, p. 346). Doni, for instance, categorizes country houses based on five social classes, referring to "functional huts" (*capanna dell'utile*) for peasants, in contrast to villas for the nobility, which are described primarily as spaces for retreat and leisure (*podere di spasso*). Correspondingly, Serlio designs a modest hut for the poorest peasant, which aligns with Doni's description of a simple shelter for the lower classes. However, Serlio takes this concept further by introducing different layers within the peasant class, categorizing them into economic strata.

Aim

The study examines Serlio's rural house designs for the peasants, focusing on the social hierarchy he established in housing for the lower classes. Through a critical reading of Renaissance literary sources regarding farmhouses and villas, the study aims to explore how the agricultural economy influenced rural architecture and Serlio's interpretations of ancient and local traditions.

Material and Method

This study employs a comparative analysis of theoretical texts and illustrations presented in Serlio's Sixth Book. The research also contextualizes Serlio's designs within the broader framework of rural architecture, considering the socio-economic and agricultural factors that shaped his approach. Additionally, the study investigates the influence of ancient and local traditions on Serlio's interpretations by comparing textual descriptions with visual depictions in contemporary sources.

Findings

In the 16th century, class distinctions became increasingly pronounced even within the peasant class. Wealthier peasants—typically landowners or long-term tenants—came to form a "peasant aristocracy," whereas short-term tenants and wage laborers constituted a poorer group with limited economic power (Brocchieri, 2020, p. 245). Some of the affluent peasants portrayed by Serlio likely belonged to the urban aristocracy, as indicated by the social profiles depicted in Andrea Palladio's *I Quattro Libri dell'Architettura* (The Four Books of Architecture), one of the most influential works of the period (Palladio, 1997). The size of landowning peasant groups varied depending on land rental agreements (Waley & Dean, 2021). Within this system, short-term tenants were employed either permanently or seasonally by wealthier peasant families. Social stratification in rural areas was also reflected in living spaces. In the Veneto region, impoverished peasants resided in modest rural houses called *casóne*, which typically consisted of a simple living space and a stable under a thatched roof. In contrast, wealthier peasants lived on farms that featured a two-story main house with an attic used as a granary, a stable, and a porticoed barn (Cosgrove, 2000).

During the Renaissance, rural houses were also influenced by traditional vernacular architecture as well as ancient Roman architecture (Forster, 1974). In the Venetian countryside, simple rural houses typically consisted of the landowner's residence, *barchesse* (utility buildings for agricultural use), and dovecote towers. While these structures were generally dispersed within the landscape in the 15th century, by the 16th century, rural settlements had evolved into more cohesive complexes organized around a quadrangular courtyard (Suitner Nicolini, 1973) (Figure 1).

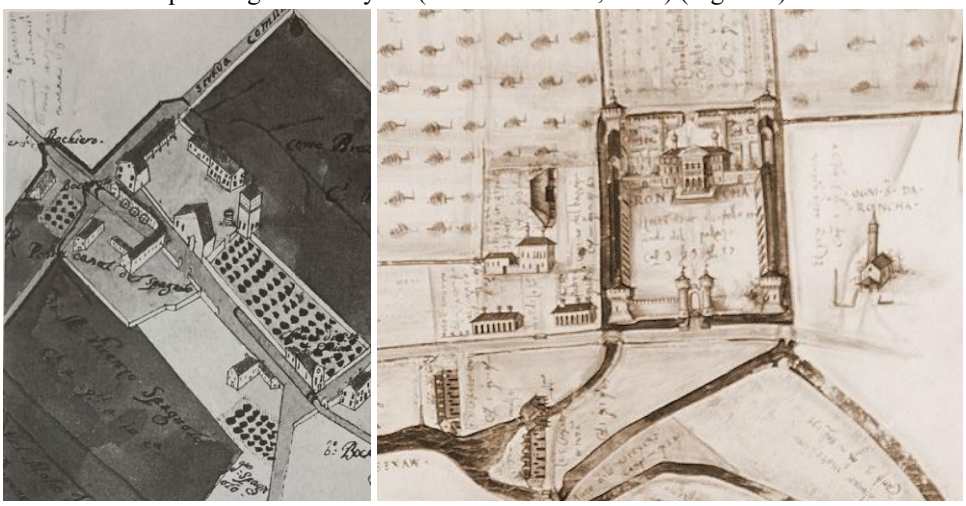

Figure 1: 15th century Farmhouse, Marano, Vicenza (from a 18th century drawing, Ackerman, 1990); Villa Giustiniani, Roncade (1511-1522) (Burns, 2012).

Accordingly, Serlio designed rural houses with careful consideration of living conditions, the economic status of their inhabitants, and their social standing. Having categorized peasants into three economic categories—poor, middle-class, and wealthy—and Serlio designed three different rural houses to match these distinctions. Interestingly, his designs also exhibited variations within these categories based on degrees of wealth (*gradi di ricchezza*). These rural houses generally featured a main residential unit—occupied by either the peasant or the landowner—organized around a courtyard, accompanied by service structures related to agricultural activities and additional wings integrated into the main building.

Serlio defined the poorest peasant as "a person who owns a small piece of land, can manage their own work, and is self-sufficient," and accordingly, he developed a design consisting of a minimal living space and a hearth (Serlio, fol. 1v) (Figure 2). This design is reminiscent of the thatched-roofed houses that preceded the porticoed and towered villa typology in Venice and the Veneto region (Forster, 1974) (Figure 3).

The rural house of the mid-level peasant was designed according to three different wealth levels. The core unit opens from its porticoed front façade into a small hall (*saletta*), which provides access to the surrounding spaces. Interestingly, Serlio suggested that if the mid-level peasant required additional rooms for a more comfortable life (*per esser più agiato*), two

rooms could be added to the sides of the core unit, depending on the width of the farm. This flexibility illustrates Serlio's sensitivity to varying farmhouse needs and spatial comfort. His rural house for the "mid-level" peasant reflects the influence of Late Roman architecture, particularly the U-shaped villa with projecting blocks and a central loggia (Ackerman, 1990). As Forster (1974) pointed out, Serlio's plan bears a resemblance to the Late Roman Villa of Theodoric in Galeata, which was discovered through archaeological excavations in 1541–42, as well as the rural traditions of the Veneto region (Figure 4).

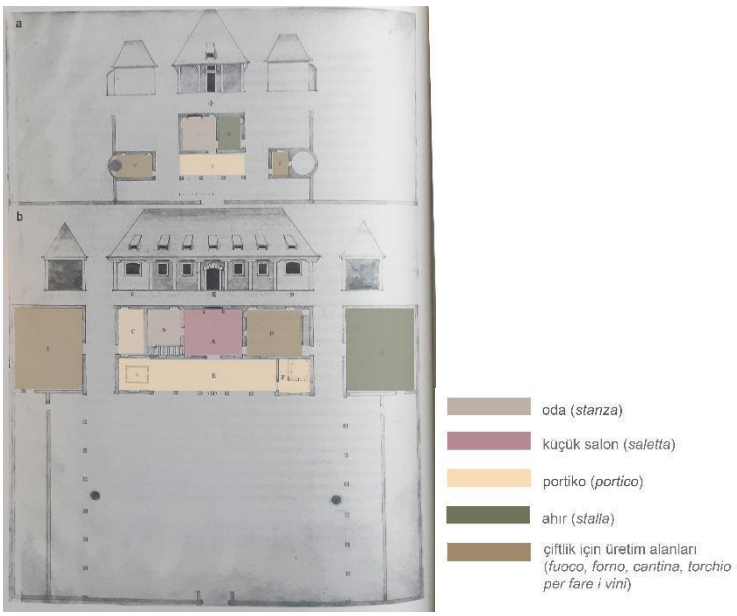

Figure 2: Serlio, (top) Rural house for the poorest peasant (*casa del povero contadino*) (bottom) Rural house for the middle-class peasant (*casa del mediocre contadino*) (Munich manuscript, Fiore, 1994, adapted from plate 1).

Figure 3: Thatched cottage, unknown date, Rosara di Codevigo, Padova (Kubelik, 1986).

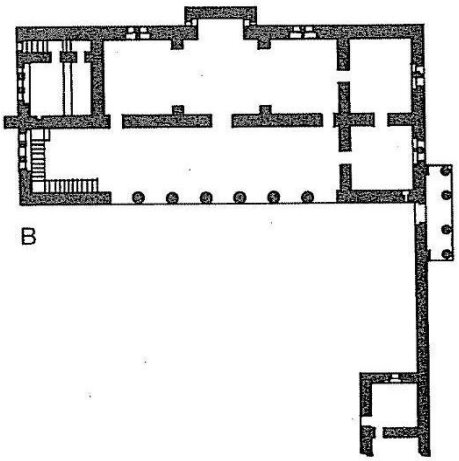

Figure 4: Villa of Theodoric in Galeata, c. 500 (Ackerman, 1990).

At the upper end of the hierarchy, Serlio depicts the wealthy peasant as a "village prince" (*rustico principe*), a figure he observed in many Italian cities (Serlio, fol. 2v, 1994). This depiction aligns with the concept of a "peasant aristocracy" within the peasant classes. The representation of the wealthy peasant as a "village prince" can be interpreted as a continuation of the feudal system organization, which was beginning to dissolve in Italy. This interpretation also finds its expression in architecture: the wealthy peasant's rural house is carefully structured to accommodate both residential and agricultural functions. Distinct side wings are dedicated to wine and olive oil production, incorporating additional spaces for agricultural activities (Figure 5). The inclusion of production tools in Serlio's plan is a significant detail, reflecting a holistic approach to farm organization. Behind the house, stables for cattle and poultry are located, with cultivated land (*il bruolo e i campi*) extending further beyond. The core unit, which functions as the owner's living quarters, is two stories high and features a central common room (*sala comune*), echoing earlier designs.This space serves as a gathering place for the farm's inhabitants around the hearth, where the family head keeps the farm's key. Through its integrated layout, Serlio's design creates a more harmonious connection between the dwelling and the agricultural wings—a notable contrast to the spatial configuration observed in Villa Giustiniani.

Figure 5: Serlio, Rural house for wealthy peasants (*abitazione del ricco contadino per tre gradi di ricchezza*) (Munich manuscript, Fiore, 1994, adapted from plate 2).

Conclusion

Serlio's rural house designs span a wide spectrum, ranging from the most basic structures that provided minimal shelter for the poorest peasants to the more elaborate dwellings of wealthy landowners, often referred to as "village princes". These proposals reveal a gradual increase in spatial complexity, carefully aligned with the economic status and specific needs of their inhabitants. While Serlio's designs may not fully reflect the realities of land ownership of the period, they nonetheless represent a significant effort to give architectural form to the social and cultural dynamics of 16th-century Italy. By incorporating hierarchical distinctions within the peasant class and highlighting them through design, Serlio developed a spatial vocabulary that both expressed and reinforced social stratification. Through this approach, his work provides valuable insight into the multi-layered nature of Renaissance rural society.

Semi-Open Spaces as a Result of Climate and Culture in Mediterranean Architecture

Furkan Sağdıç[a]

[a] Istanbul Technical University, Graduate School, Architectural History Program, Turkey
sagdicf@itu.edu.tr

Keywords: Mediterranean, Palace Building, Semi-Open Space.

Aim

This research aims to investigate whether the common living practices that emerged as a result of the interaction of different ethnic, religious and cultural structures throughout history in the Mediterranean geography can be traced through architectural elements. In particular, the reflections of the commercial and cultural relations that accelerated in the Mediterranean between the 14th and 17th centuries on the 'loggia/exterior sofa', one of the semi-open space types, are analysed. While the natural and human geography of the Mediterranean region necessitates semi-open spaces that provide shade and air circulation due to the hot and dry summers, different communities' understanding of privacy and use of space has created diversity in the design and functions of these spaces. The main purpose of the research is to reveal whether the 'loggia/exterior sofa' as a semi-open space is one of the indicators of a common architectural culture in the Mediterranean. In this direction, the relationship between more introverted spaces such as courtyards and the extroverted natural and human environment is also questioned, and how the lifestyles of Mediterranean societies shape architecture is analysed.

Material and Method

In this research, the approaches of different disciplines (history, geography, sociology, architecture, etc.) examining the Mediterranean are analysed and the common features and/or differences in the Mediterranean are determined within the scope of the subject. From this point of view, the interaction between architecture and the natural and human environment is discussed. Academic sources on the place of the concept of semi-open space in Mediterranean architecture, its definitions, purposes of use and historical development are analysed. The existing literature on how similar semi-open spaces are named in different geographies, what kind of functions they undertake and what formal characteristics they have is reviewed. The use of semi-open spaces in both Mediterranean vernacular architecture and Modern architecture has been analysed in the existing literature. With a special focus on the period between the 14th and 17th centuries, the buildings built during this period were identified and the buildings to be analysed were selected based on their state of preservation and representativeness. Based on different studies, the Mediterranean is culturally divided into seven regions. Although these seven regions are located on different continents, they have been in intense interaction in the historical process since they are located on the Mediterranean coast. The examples selected from each region constitute examples of palaces or residences that have been preserved to a certain extent to the present day and have the potential to represent the local residential culture in the most qualified way. The buildings are analysed in terms of plan types, relationship with the building, formal features, usage functions and courtyard relationship. The similarities and differences between the sample buildings are revealed.

Findings

The research has revealed that climatic conditions in the Mediterranean basin support the prevalence of semi-open spaces, but the design and use of these spaces may vary from region to region. In particular, the loggia/exterior sofa element has been found to assume both an 'introverted' identity associated with the courtyard that fulfils the need for privacy and an 'extroverted' identity that facilitates interaction with the natural and human environment by opening outwards.
Although the names and design details of the loggia/exterior sofa spaces may vary in the seven regions analysed in this study, the common point is the functions of providing shade and increasing air circulation. These spaces have become an

important part of daily life in the Mediterranean climate, where summers are hot, and provide semi-public or semi-private gathering spaces that increase social interaction. On the other hand, the positioning and shaping of these spaces have varied in line with the privacy perceptions of different cultures. For example, in some regions, the loggia/exterior sofa was designed as an inward-oriented element as a continuation of the courtyard, while in other regions it was transformed into a living space that opens to the outside and establishes a relationship with the landscape or street.

Between the 14th and 17th centuries, political, commercial and technological developments in the Mediterranean accelerated architectural interaction. As a result of this interaction, while regional differences were preserved, spaces sharing similar functional and formal characteristics also emerged. It has been determined that the loggia/exterior sofa element exists under different names, but basically responds to similar needs. This situation provides important clues that a common architectural culture can be traced in the Mediterranean.

Conclusion

The findings of the research show that despite the existence of different political, religious and cultural structures in the Mediterranean basin, common architectural elements have developed with the influence of historical interactions as well as the requirements of climate and geography. Semi-open spaces, defined as loggia/exterior sofas, stand out with their features that support both privacy and social interaction by acting as a threshold between interior and exterior spaces. Despite their different names and design variations, these spaces, which are shaped around functions such as providing shade, coolness and social communication, can be considered as one of the clear indicators of the shared living culture in the Mediterranean.

Through analyses of buildings constructed between the 14th and 17th centuries, this study reveals that the concept of a 'shared architectural culture' in the Mediterranean can be discussed. The findings show that beyond climatic and geographical conditions, centuries of interaction between different societies played an important role in the shaping of architectural elements. Thus, it is concluded that the living practices and spatial understanding specific to the Mediterranean are part of a multi-layered cultural heritage with the balance it establishes between inward and outward use.

The Historical Layers of Selimpaşa in Constantinople Hinterland Context

Nil Ceren Karagülle[a], Bilge Ar[b]

[a]Istanbul Technical University, Graduate School, Architectural History Program
[b]Istanbul Technical University, Faculty of Architecture, Department of Architecture
karagulle15@itu.edu.tr, bar@itu.edu.tr

Keywords: Constantinople Hinterland, Thrace, Road Networks, Land Use Continuity.

Aim

The aim of this study is to examine the town of Selimpaşa, located in Silivri region in Istanbul, through historical research with architectural and regional analysis. This study will explore the role of Selimpaşa in Constantinople's hinterland in Thrace, focusing on it as one of the satellite settlements and trade networks that sustained the imperial capital. The definition of the hinterland will be explored in detailed historical context, with its structural and economic functions in relation to Constantinople. Several settlements in Thrace, positioned along key commercial routes, served as supply areas, providing agricultural goods and other essential resources. Among these, some locations, due to their size and historical documentation, allow for a more comprehensive analysis of their economic and logistical contributions to the capital.
The chosen case study will represent a typical example of such settlements rather than an exceptional or unique site. By studying Selimpaşa, the aim is to reconstruct the broader dynamics of regional trade and resource distribution in Thrace. Unlike Selymbria (modern Silivri), which was a highly trafficked and well-documented urban center directly on the main trade route, the selected Selimpaşa offers insight into a more localized and decentralized network of provisioning systems. While Selymbria played a direct role in supplying Constantinople, its surrounding settlements were further divided into smaller subunits, each operating within a specific economic and ecological framework.

Material and Method

This study will be examined by using a comparative approach, analysing the selected settlement of Selimpaşa alongside neighbouring sites and its connections with Selymbria and Constantinople. Through this, the aim is to reconstruct and understand the economic and logistical framework of medieval Thrace, particularly along its trade routes. The study will also assess continuity and transformation in settlement patterns, tracing their evolution from antiquity to the Middle Ages. While some settlements experienced disruptions during the transition from the ancient to medieval periods, many have shown continuity since the 9th century CE, therefore this will be a major analysis point for the study.
The continuity analysis will incorporate factors such as land use, climatic conditions, and geographical features, including river systems and fertile plains of Thrace, demonstrating how these elements shaped settlement sustainability from the Byzantine to the Ottoman period and beyond.

Findings

Throughout history the Byzantine capital had been supported by its hinterland, the surrounding rural areas, economically, militarily, and logistically. The hinterland borders varied over time, consisting from parts of Thrace in the west and Bithynia and Anatolia in the east. These regions have been vital for food supplies, materials, trade networks and manpower, ensuring the city's sustainability and strategic importance (Mango & Dagron, 1995).
Western hinterland of Constantinople is the region of Thrace, which today is split between Türkiye, Greece, and Bulgaria. The historical region of Thrace, located in the southeast Balkans, is defined as the area bordered between the Balkan Mountains to the north, the Aegean Sea to the south, the Black Sea, and the Sea of Marmara to the east and is named after Thracians tribes that inhabited the area. During the Middle Ages the region was interchangeably ruled by the Byzantine Empire, Bulgarian and Serbian medieval states until it became part of the Ottoman Empire in the 14th and 15th centuries.

Thrace was the immediate hinterland for fifteen centuries and one of the prime sources for the grain supply for the capital (Magdalino, 2006).

One of the most important settlements of the immediate Thracian hinterland was Selymbria, todays Silivri. Throughout time Selymbria, located by the coast Marmara, and about 60 km west of Constantinople, played a significant role in trade, defence and regional administrations. For trade context, Via Egnatia one of the major routes, passed through Selymbria and made the town became important hub for trade (Külzer, 2019). For defence, Selymbria had a major role for having fortification that is today known as the Silivri Castle (Çiçek, 2019) and being close to Anatasian Walls. Anastasian Walls or Long Wall, was a significant late Roman and Byzantine fortification stretched from the Black Sea near Karacaköy to the Sea of Marmara near Selymbria. The wall originally extended for 45 km, though much of it has deteriorated over time. It was constructed with a curtain wall, outer works, and a system of forts and towers, a major defensive barrier against outsider attacks (Crow & Ricci, 1997).

The focus of this paper will be about Selimpaşa (formerly known as Bigados and Epivates/Epibatai) one of the smaller settlements located in this region. Laying 13 km to the east of Selymbria (47 km east of Constantinople), Epivates was a town with agricultural life and trade and where several historical events took place. Such as the meeting of Emperor Andronikos II and his grandson Andronikos III in 1322 to end their disputes over control of the empire, during the civil war, with a peace treaty that lasted for five years (Külzer, 2008). Epivates also was one of the last centers of Byzantium power in Eastern Thrace; with the final conquest by the Turks only taking place after February or March of 1453 (Külzer, 2008).

The first survey and excavations on Selimpaşa were done by D. H. French in 1960s (Eyice, 1969). The tell (höyük) of Selimpaşa is identified as the last remaining tell on the western side of Istanbul (Aydıngün, Ş., Heyd, V., Güldoğan, E., & Öniz, H., 2014). Most recent excavations showed remains from various historical periods, notably from: Chalcolithic Age, Bronze Age Iron Age, Classical Antiquity, Byzantine Period. Surveys and excavations have identified ceramic fragments and tone tools. The site is registered as a cultural heritage site.

Between 1453 -1923 Ottoman rule of the town, the name of Epivates slowly came to known as Bigados and have been referred to as such in official documents and maps. According to two mukataa (parcels of land owned by the Ottomans) tax records dated 1476 and 1479, the Istanbul and Galata customs office covered the area from opposite Yoros to Bigados on the Rumelian side and from Yoros to Aydıncık (Edincik) on the Anatolian side (Anhegger & Inalcık, 1956). In other words, the document showed that the Bosphorus and a part of the Marmara coast were within the area of this customs office (Bulunur, 2013).

British clergyman and traveller John Covel visited Istanbul in 1675 and later wrote about his travels in his books. Covel stopped by the town of Pebatos (Πεβάτος), and he described it as a pleasant market town with a harbor for small boats, called Epivates in Greek (Külzer, 2008). He stated that although most of the people living there were Greek, he saw many Turks on the streets and adds that there was a small fortress with thick walls here and that it was used as a granary (Covel, 1998). But claimed it was not possible to see the walls that once surrounded this town as they have completely disappeared.

In Verdic Registers (Ahkam Defterleri) about Bigados in 18th century shows the continuing agricultural activities (Tabakoğlu, 1994). In majority of the registration documents, Bigados is referred as a village under Çekmece-i Kebir (Büyükçekmece) or Silivri.

One of the ways to track land use continuity can be done by looking at the history of the Church of St. Paraskeva. The earliest written source about the building is from Anthony the archbishop of Novgorod, who visited Constantinople in 1200 and wrote about what he saw in his pilgrimage book named "Kniga Palomnik" (Majeska, 2002). He mentioned about a church dedicated to St. Paraskeva in his writings as "a day's journey from Constantinople", therefore it can be identified with the one in Epivates (Külzer, 2008). Until its destruction in 1980, it was a three-naved church built in the same location as the original in 1884 (Han, 2000). The following verdict that was found in Directorate of State Archives with following title translation "July 7, 1884, construction of a church for the Greek community in the village of Bigados in Silivri.". This document serves as evidence to how residents continued the land usage for the church (BOA.İ.DH.923/73182).

After the foundation of Turkish Republic, in accordance with the Ankara Treaty signed in 1924, population exchange between Greeks and Turks made the Greek inhabitants of Bigados migrate to Greece in 1926. Following years the name of

the town was changed to Selimpaşa. This name came from the former Ottoman Grand Vizier Mehmet Selim Sırrı Paşa, who had visited and stayed in the town and had the İkizli Fountain built to his name 1828 (Taşkın, 2002).

Conclusion

This research will demonstrate that Constantinople's hinterland was not merely a passive supplier but an active and organized economic system with hierarchical settlement structures, efficient trade networks, and sustainable agricultural practices. Hinterland settlements functioned as interconnected units, supporting both local economies and the larger provisioning needs of Constantinople.

The presence of major trade routes, particularly the Via Egnatia, facilitated economic integration and ensured the movement of goods across Thrace. Settlement continuity from the 9th century onward indicates a stable economic framework, with medieval land-use patterns persisting into the Ottoman period. Thrace's temperate climate and favourable agricultural conditions ensured long-term settlement continuity, supporting the study's hypothesis regarding sustained land-use patterns. By integrating environmental and historical perspectives, this research contributes to a deeper understanding of Constantinople's hinterland and its enduring functionality over centuries.

And among these satellite settlements in hinterland of Thrace, Selimpaşa (Epivates/Bigados) was not a unique region but showcased a typical example with its existence and therefore will be able enhance understandings and to open space for further studies about the areas involved and historical periods.

Furniture Consumption in Istanbul at the Beginning of the 20th Century: The Role of Periodicals

Sezin Dirihan[a], V. Gül Cephanecigil[a]

[a] Istanbul Technical University, Graduate School, Architectural History, Turkey

Keywords: Furniture, Consumption, Periodicals, İstanbul, Ottoman Empire.

Aim

This study examines how furniture was represented in everyday life in early twentieth-century Istanbul, and how these representations were connected to changing patterns of consumption. Drawing on advertisements and content from contemporary periodicals, it aims to understand how furniture—beyond its functional role—became associated with concepts such as social identity, belonging, and status. The period under examination was marked by significant social and cultural transformations, including industrialisation, increased access to imported goods, and the growing influence of Western-oriented ideas of modernity. Within this context, furniture emerged not only as a reflection of these shifts but also as a medium through which new forms of taste and identity were constructed and communicated.

Material and Method

The conceptual framework of the study is informed by theoretical approaches that understand consumption not only as an economic act but also as a culturally and symbolically meaningful practice. Various theories have discussed how consumption reflects not just material need but also social positioning, aesthetic preferences, and distinctions of taste. For instance, Thorstein Veblen's notion of conspicuous consumption highlights how the display of goods—such as furniture—functions as a marker of refinement and status.[2] Pierre Bourdieu has emphasized how taste operates as a form of social differentiation shaped by class habitus, while Jean Baudrillard draws attention to the symbolic function of objects in constructing identity through systems of signs.[3] These perspectives together provide a conceptual lens through which the study interprets how furniture was represented in periodicals as both a reflection of social aspiration and a means of cultural expression.

The main sources of this study are periodicals published in early twentieth-century Istanbul. These publications include content related to consumption culture, domestic life, and practices of social representation, offering valuable insight into the cultural and economic changes of the period. The main periodicals examined in the study are Servet-i Fünun, Hanımlara Mahsus Gazete, Şehbal, Mahasin, and Süs. In addition to these, other periodicals that contained relevant content about domestic life and social imagery were also used. These publications were selected because of their regular circulation, the variety of their content, and their extensive use of commercial advertising.

This study uses a qualitative approach to explore how furniture was represented in early twentieth-century periodicals. Advertisements, visual content, and selected articles were examined through close attention to language and imagery, with a focus on how meanings related to taste, identity, and social roles were constructed. The aim is to understand how furniture functioned not only as a material object, but also as a cultural expression that reflected and shaped emerging forms of consumption and modern identity.

Findings

In the periodicals examined, references to the West often appear as a clear marker of distinction in the representation of furniture. Expressions like "American style," "London-made," or "English marocain" frequently appear in advertisements. These phrases do more than indicate the origin of the products—they also suggest associations with quality, taste, and a certain lifestyle.

Such language was also deliberately used by furniture producers of the time. In the advertisements of firms like Narlıyan, Baker, and Psalty, the European or American origin of the products is often emphasized (Figure 1, 2). Items such as bedroom sets, armchairs, or sofas—especially those placed in the more visible parts of the home—are given particular attention. At the same time, women's magazines from the period often featured decoration advice and illustrations for spaces like living rooms and bedrooms. These examples suggest that furniture for these areas was not only seen as functional, but also carried strong symbolic value. References to Western origins served as signs of good taste and modern identity, but also reflected a broader belief that Europe and America represented a more advanced and respectable way of life. In the context of early twentieth-century Istanbul, aligning with Western styles implied access to a more advanced, rational, and prestigious way of living. For this reason, Western labels became signs of social status and helped people show where they belonged—or wanted to belong—in the social hierarchy.

Although some advertisements and articles mentioned specific origins—such as American, British, or Austrian—these references rarely served to differentiate between distinct stylistic traditions. Instead, they contributed to a broader, idealised image of "the West" as a unified cultural construct associated with refinement, modernity, and prestige. In this context, Western styles functioned less as nationally distinct aesthetics and more as a symbolic language of civilisation, shaped by the discourse of taste and aspiration.

Expressions such as European elegance[4], civilised ornamentation[5] and Western civilisation[6] used in various publications made a clear link between aesthetic taste and the ideal of civilisation. In an article published in Servet-i Fünun, the yacht of the Egyptian Khedive Sefai-Bahir was described as an example of refined British design, its ornate furniture and sophisticated interior praised and presented as a perfect example of cultural refinement.[7] Similarly, an article on wicker chairs in Austria and Germany emphasised Europe's sense of continuous improvement, arguing that it manifested itself even in everyday objects and contributed to a more relaxed and enjoyable lifestyle.[8] These descriptions reveal that design and taste were seen not only as aesthetic concerns but as reflections of a broader ideal of civilisation. In this context, Western elegance was framed as a sign of moral and intellectual superiority - qualities believed to be readable in even the most ordinary furniture.

Many of the periodicals examined suggest that furniture carried cultural meanings and became part of how people positioned themselves socially. Advertisements presented these products not just as functional or decorative objects, but as reflections of personal taste and lifestyle. The language of "elegance," "refinement," and "refined and cultivated taste" described not only the furniture, but also the type of person who would choose it. In this context, furniture was imagined not only as a possession, but as an object of cultural appreciation. Through these preferences, one's social and aesthetic position was subtly communicated.

This kind of narrative was especially visible in advertisements published in popular women's magazines and commercial periodicals of the time. For example, in an advertisement for the Psalty store, elegant and durable furniture was described as suitable for every taste and budget, but it also stated that such items would be chosen with satisfaction and approval refined taste and elegance. Similarly, in an advertisement for the Selanik Bonmarşesi, it was implied that the target

[8] "Yeni Hasır İskemleler," *Mahasin*, no. 10.

customers were not only those seeking quality products, but also those who had the aesthetic capacity to appreciate them.[9] The combination of refinement and affordability made it possible to present a privileged lifestyle as both desirable and accessible. These examples show how taste, access, and identity were closely linked in the language of furniture consumption.

In some publications, the arrangement of the home and the choice of objects were directly linked to personal identity, emotional state, and social belonging. This connection was especially visible in content associated with women. In Süs magazine, for example, home decoration was described not only as a visual or practical act, but as a space where a woman's personality was realized. The shape, placement, and style of furnishings were presented as tools through which personal ideals and emerging notions of taste could be expressed. This kind of discourse shows how interior design and furniture became ways to shape and communicate one's identity, especially within the broader desire to be modern.

Conclusion

The findings of this study suggest that furniture in early twentieth-century Istanbul was more than a set of domestic objects; it was deeply intertwined with contemporary discourses on taste, identity, and modernity. Advertisements and articles in periodicals did not merely promote products but participated in shaping a symbolic language through which social roles, aspirations, and cultural values were expressed. The frequent references to European and American origins, the emphasis on refinement and affordability, and the association of furniture with personal character and modern lifestyle all indicate that furniture became a medium through which both aesthetic ideals and social distinctions were negotiated.

Rather than highlighting clear stylistic differences between national traditions, the materials examined tended to present a composite image of "the West" as a unified symbol of civilisation, elegance, and progress. This symbolic construction of Westernness served to legitimise certain tastes and ways of living as modern and desirable. Overall, the study shows that periodicals were not only platforms for promoting consumer goods but also active agents in the cultural redefinition of domestic life, where material choices became intertwined with broader social transformations.

The Impact Of Governmental Power On Urban Morphology: A Case Study Of London

Hande Nur Çalışkan Yüksel[1] , Tan Kamil Gürer[1]

Istanbul Technical University

caliskan18@itu.edu.tr

Keywords: Change, London, Power, Typomorphology, Urban Morphology

Introduction and Aim

Urban form is inherently dynamic and can only be comprehended by examining it within its historical context; it is not feasible to define it as a finished object (Moudon, 1997). According to Lefebvre, space is a social construct, continuously reproduced through social relations (Lefebvre, 2014). Throughout history, changes in a country's ruling powers are reflected in the structure of its cities. Therefore, analyzing a city's layout is essential for understanding the spatial influence of administrative power. As argued by David Harvey (1997), cities are shaped in accordance with the interests of capital and power, which in turn defines the class structures and economic networks of space. Public spaces, monumental structures, and symbolic projects materialize the power of ruling authorities in the urban fabric. City plans are shaped by ideological and economic strategies. Shifts in power manifest in urban plans through the construction of monumental buildings, the emergence of new building types, the formation of axes, squares, statues, and street names (Colombijn, 2006). While administrative power is predominantly held by the state, it can sometimes be in the hands of religious or aristocratic classes. Individuals seeking to benefit from this power tend to physically position themselves near these groups. This proximity reinforces social status and provides economic advantages.

In line with the sociological and ideological transformations of the city, structures representing central authority and power significantly influence the shaping of urban form and contribute to its evolving character over time. The most tangible examples of this governmental power and urban space relationship are capital cities. Capitals of countries with a long-standing historical presence offer a robust framework for observing this temporal transformation. With a two-thousand-year history, London, the capital of the United Kingdom, has been chosen as the study area for this research.

The aim of this study is to examine the influence of administrative power on the urban morphology of London throughout its historical evolution. In this context, the study analyzes the physical transformation of the Strand axis—which links the city's dual-centered urban structure—along with its associated spatial components, using the typomorphology method. The research seeks to reveal how changes in power are reflected in urban plans by evaluating building typologies, parcellation systems, and road networks, thereby demonstrating how urban form has evolved in its historical context.

Material and Method

The morphological examination of the Strand axis, which connects the London and Westminster districts, and the identification of its morphological character will be conducted using the typomorphology method in architecture. Typomorphology is a fundamental analytical method used to reveal the principles and rules of urban design when studying the city as a human living environment. This method enables the conceptualization of the complexity of physical form and allows for a deeper understanding of how cities grow and develop (Oliveira, 2022). The study will analyze the morphological structure of London and Westminster by utilizing the taxonomy developed by M.R.G. Conzen, a historical geographer and one of the key figures in typomorphology. His methodology examines urban morphology through town-plan analysis. In this approach, the basic spatial components of the city—street networks, building blocks, and parcellation systems—are classified and analyzed.

By applying this methodology, the study aims to systematically interpret the morphological characteristics of the urban space at different scales. This will facilitate a deeper understanding of how the social needs of communities along the Strand have changed over time in relation to administrative structures and how they have reshaped the physical environment around them. To achieve this, the research will quantitatively examine the building routes (streets) connected to the Strand matrix route, the parcellation system along this route, and the building texture and density within the parcellation system. It will also statistically demonstrate the mathematical relationships between these systems, analyzing the functions, land use, and building types along the Strand.

The study will present the historical dimension of the area's urban development from its foundation to the present by consulting various sources. The morphological transformations of the study area and the social content driving these changes will be documented using these sources. Simultaneously, the physical changes will be demonstrated through the analysis of historical maps. The current morphological condition will be identified using zoning maps, aerial photographs, street photographs, personal archives, and on-site observations. Thus, the historical morphological analyses will be compared with current data to reveal the physical transformations caused by administrative power over time.

Historical Background and Findings

As a continuous settlement and center of power from the Roman era to the modern period, London offers an ideal research area for understanding the spatial impacts of ruling powers throughout history. The city was founded by the Roman Empire in 48 AD under the name Londinium. Initially, access to the city was provided by the London Bridge, followed by the construction of a basilica and a forum, establishing the administrative center. The city was planned as a typical Roman town, featuring marketplaces, religious, and cultural structures. It was connected to other major cities through the Roman road network, quickly becoming the capital of Britannia province (Morris, 1982).

After the Romans abandoned Britain in the 4th century, Celtic uprisings and Viking raids inflicted significant damage on London. Although it was not used as a settlement for a long period by the Anglo-Saxons, its location on the Roman road network allowed it to retain its commercial importance. During the late medieval period, increasing attacks led to the city's restructuring into a fortified settlement. Numerous ports were built, strengthening trade with Europe. Following a brief Viking occupation in the 9th century, the city was fortified with castles and walls as part of a general planning strategy to protect it from future attacks.

After the Normans conquered England in the mid-11th century, they constructed the Tower of London (White Tower) as a symbol of military power, reinforcing the city's defense system. However, as the Tower's administrators gained influence, London moved toward becoming an autonomous entity, culminating in the signing of the Magna Carta, which marked the beginning of parliamentary monarchy in England. This event represents a significant example of the relationship between power and urban morphology.

One of the most influential factors in the city's morphological transformation was the Norman kings' decision to abandon their itinerant government system and establish a monastery and palace in Westminster, where they chose to reside. This decision transformed the area into the administrative and religious heart of the United Kingdom. Consequently, Westminster (The City of Westminster) became the administrative center, while intra-muros London (The City of London) remained the capital of commerce and economy (Inwood, 1998). These two centers were connected by the Strand axis, forming Greater London (Figure 1).

Figure 1

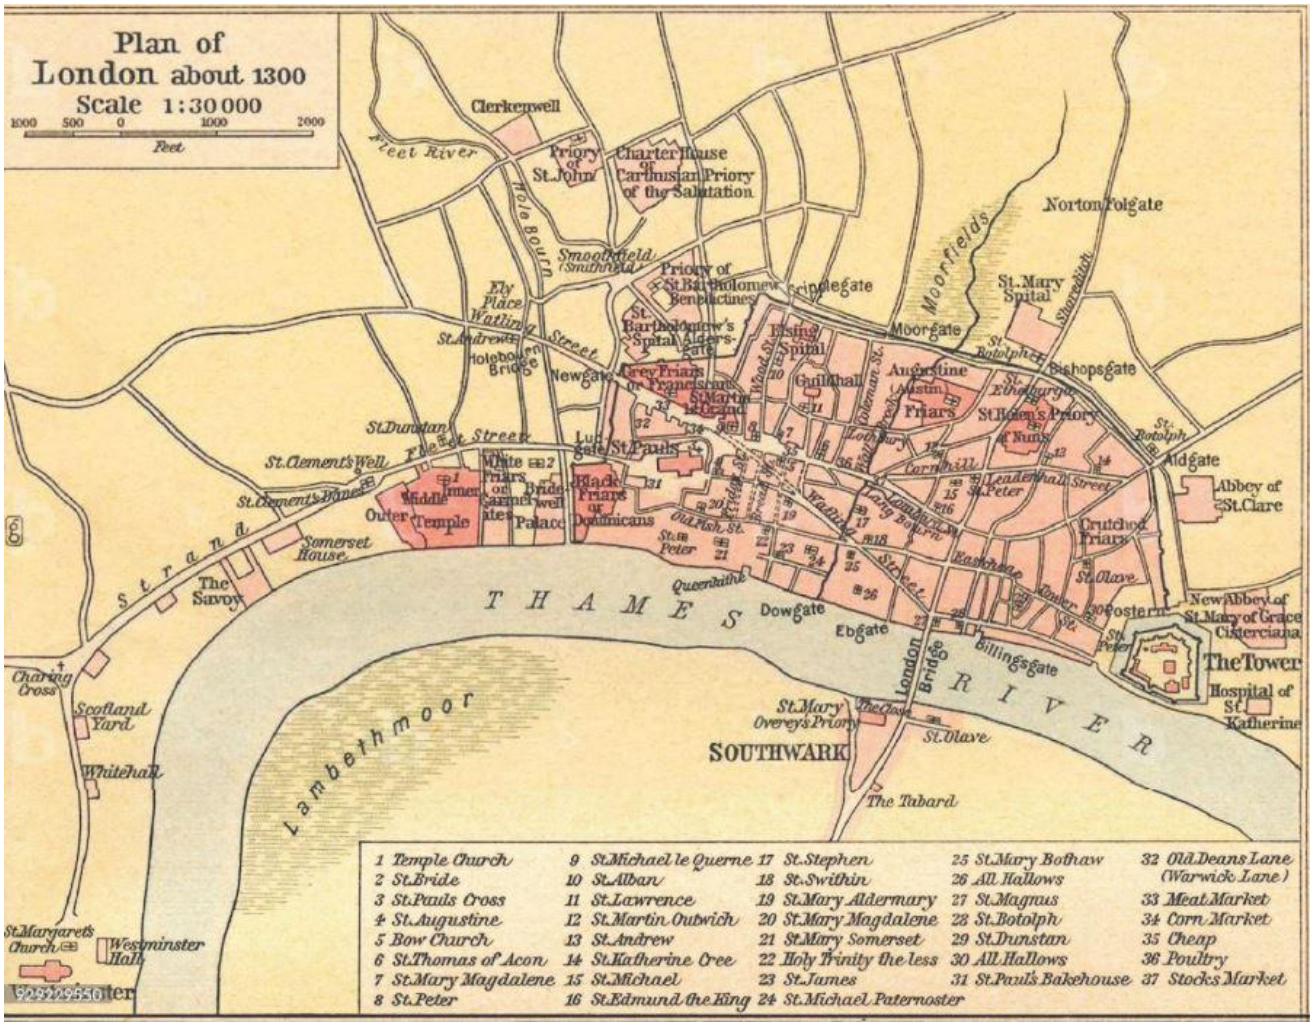

Figure 1. The Strand axis developing between London and Westminster (Historical Atlas, 1923).

Over time, new palaces and administrative buildings were rapidly constructed along the Strand axis. These included Somerset House, Savoy Palace, and Whitehall Palace, alongside bishop's residences for clergy members seeking proximity to the royal court—Durham, Bath, Chester, Carlisle, Exeter, Norwich, Worcester, and York Bishop's Palaces. In addition, noble estates such as Albemarle, Bedford, Berkeley, Burghley, Clare, Drury, Hungerford, and Northumberland Mansions were established along the axis (Figure 2) (Croot, 2014).

Figure 2

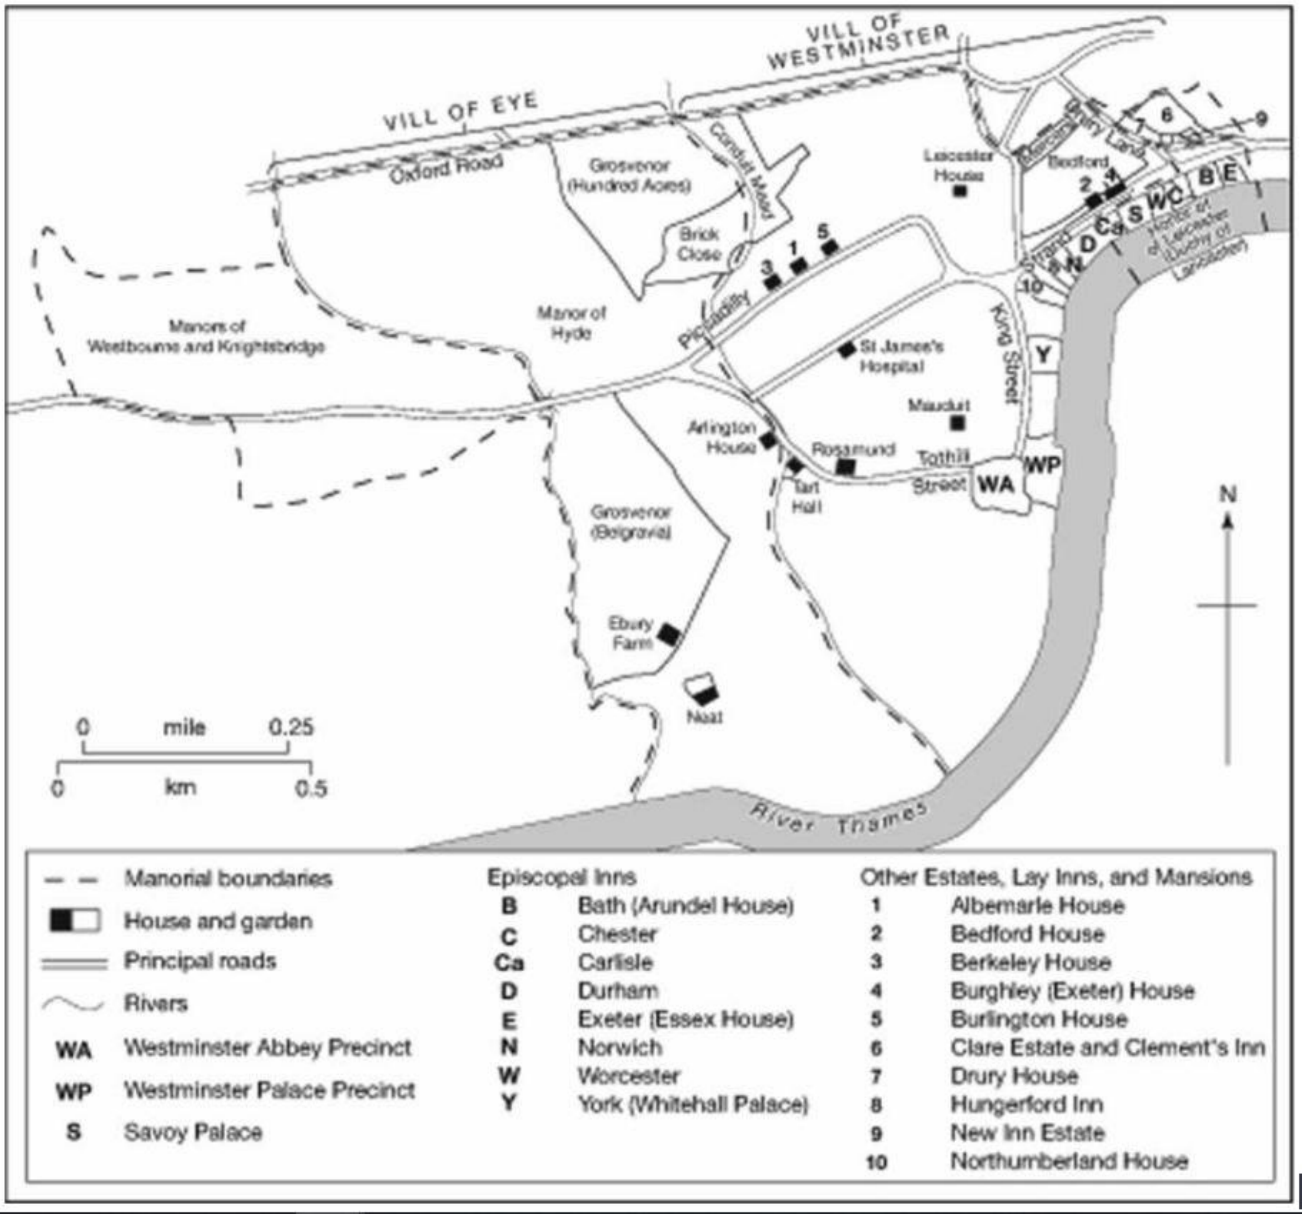

Figure 2. London and Westminster in the Early Modern Period (Croot, 2014, s. 87).

By the 12th century, historical records indicate that 75 buildings belonging to leading nobles and bishops were located in this area (Inwood, 1998). These manors and palaces created a significant marketplace for London merchants, boosting the trade of luxury goods with Europe. Consequently, the development of Westminster also enhanced London's international commercial influence. In the modern period, with the transition to parliamentary monarchy and the royal court's relocation to Buckingham Palace, Westminster was repurposed as the House of Government (Parliament Building) and has maintained its position as the administrative center ever since. According to Hanson (1989), new commercial spaces emerged around Westminster to meet the needs of the royal court. The study also focuses on the typologies of buildings that emerged while examining the urban plan of the region, including palaces, mansions, churches, hotels, offices, and public buildings (Figure 3).

Figure 3

Figure 3. Whitehall Palace (Danckerts, 2016)

Notably, during the periods of Roman, Anglo-Saxon, and Norman rule, and the subsequent transfers of power between various noble families, the formation of road networks and the differentiation of the building block system in the city were observed. It is understood that the city responded to historical events and interventions of power. At the end of this historical process, the Strand axis has become one of the most important regions of London, today lined with ministries, administrative and military offices, luxury hotels, and commercial buildings (Figure 4).

Figure 4

Figure 4. Westminster, Whitehall, Savoy Palaces on the Strand axis (mapping.cityoflondon.gov.uk, 2025).

Conclusion

It is understood that urban form is continuously evolving and that this evolution is directly connected to the power relations in its historical context. This study demonstrates how spatial interventions and strategic decisions of power have shaped the city form through the example of London. The strategies of power throughout history have directly affected the organizational structure of the city, and spatial decisions have determined the morphological characteristics of the urban form. In this process, the existence of a dual-center city structure and the main axis connecting these centers has emerged as one of the most significant urban characteristics of London today. The study offers an analytical framework for understanding the historical evolution of cities by examining the relationship between power and the city from a typomorphological perspective. Studying the spatial organization of cities in relation to administrative powers, evaluating the city as a reflection of the socio-cultural structure of these powers, brings a historical perspective to urban architecture. As in the case of London, considering the historical and social context is of great importance in understanding the identity of modern cities. This study also highlights the necessity of planning processes that will contribute to the evolution of cities while preserving their identity, demonstrating how modern powers' decisions can influence urban development. The analysis of the morphological transformation of the Strand axis concretely reveals the impact of spatial interventions of power on urban form and emphasizes that such axes can be used as an analytical model for investigating how administrative power leaves its mark in the physical space of modern city planning strategies.

The Performance of the Archive or Archive as Event: Exhibiting Architecture

Derya Yıldız[a], Funda Uz[b]

[a] Istanbul Technical University, ITU Graduate School, Architectural Design Doctor of Philosophy Program, Turkey
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Turkey
yildizd18@itu.edu.tr

Keywords: Architectural Archives, Exhibition as Performance, Collective Memory, Institutional Mediation.

Aim

This study treats the concept of the archive in architecture not merely as a repository for historical documents but rather as a dynamic event or "performance." Building on Derrida's (1996) emphasis on the self-preserving nature of archives and Foucault's (1972) view of archives as frameworks that shape knowledge, the paper discusses how exhibitions function as primary sites where archival materials are activated and reinterpreted. Focusing on architectural exhibitions, it argues that archival practices in architecture are not confined to storage and retrieval but instead manifest as performances that are socially and spatially enacted. Consequently, the archive informs not only our perception of architectural history but also how collective memory is continually constructed, revised, and transformed.

Reflecting on the relationality between "archive" and "event" in the title, this discussion centers on exhibitions and the venues that host them. Exhibitions are highlighted because they render archives tangible for diverse audiences and bring together different actors through curatorial strategies and visitor experiences within institutional contexts such as museums, architecture centers, and schools. This multiplicity in performance largely depends on the mediation of cultural and research institutions. The overarching aim of the study is to demonstrate how architectural exhibitions, by underscoring the ever-changing and context-dependent nature of archival materials, become catalysts for new modes of knowledge production and secure a place in collective memory through spatial practices.

Material and Method

This research adopts an interdisciplinary approach, integrating perspectives from archival studies, architectural history, and memory theory. Derrida's (1996) views on archives highlight how meaning is generated through both preservation and selective omission, while Foucault's (1972) "archaeology of knowledge" provides a historical foundation for understanding the archive as a basis for discursive structures. Deleuze's concept of the "event" resonates with the "multiplicity" that shapes both archives and exhibitions. Maurice Halbwachs's (1992) notion of "collective memory" and Pierre Nora's (1989) concept of "sites of memory" (lieux de mémoire) further clarify the role of space in generating memory and in shaping how archives are preserved and transmitted. Additionally, key texts on architectural exhibitions (Forty, 2008; Cohen, 1999; Colomina, 2013) are examined to trace how the definition and content of exhibitions have evolved. Museum studies literature is also incorporated to analyze the function of exhibitions as a form of research (Herle, 2013).

The study uses a comparative analysis method. First, the classifications proposed by Adrian Forty (2008) and Jean Louis Cohen (1999) are employed to explain the diversity of architectural exhibitions in terms of form (full-scale vs. representational) and content (e.g., forgotten works, thematic displays, paradigm-shifting shows). Then, it evaluates selected institutions that organize, archive, and exhibit architectural documents. By referencing both international and local cases, the study explores how architectural exhibitions interact with archival processes and, in contexts with limited archival infrastructure, how they can function as de facto repositories.

This methodological framework reveals how exhibitions, understood as "archival performances," continually rewrite and reinterpret architectural discourse within specific contexts. The dimension of institutional mediation is also integrated into this approach, clarifying how the archive is performed through multiplicity.

Findings

The first key finding is that exhibitions are more than mere displays of objects; they serve as unique platforms for architectural research. Forty (2008) points out that architecture is not confined to "building" alone but appears in multiple media. Exhibitions integrate different types of materials — models, drawings, photographs, digital projections — within a spatial narrative, offering a highly immersive experience. Consequently, the production and circulation of architectural knowledge is enriched through exhibitions.

From a performance theory perspective (Schechner, 2013), exhibitions reorganize archived materials to generate new narratives. Decisions about selection, sequencing, and thematic emphasis can reinforce or challenge canonical discourse. This process echoes Derrida's (1996) notion of "archive fever," highlighting the intertwining urges to preserve and rewrite.

A third finding is that the multiplicity that characterizes the performance of the archive largely relies on the mediating role of institutions. Museums, research centers, and architecture schools — such as the Canadian Centre for Architecture (CCA), Het Nieuwe Instituut (HNI), SALT, and VEKAM — preserve and digitize archives, curate exhibitions, and organize public events that open up new interpretive possibilities. For instance, SALT activates diverse archives of Istanbul and its surroundings, while HNI hosts research on how the digital era influences both architectural practice and archiving. The CCA focuses on global architectural heritage, using archival exhibitions and publications to evolve into an international research hub. VEKAM, meanwhile, expands and sustains Ankara-centered archives through public programs, thus contributing to spatial memory research. In academic settings (e.g., ITU and METU), exhibitions compensate for limited archival infrastructures by enriching institutional memory.

Exhibitions are frequently supplemented by symposia, panels, workshops, and publications that regenerate archives. The photographs, documents, and critical essays arising from these events re-enter the archive, expanding it and providing additional resources for further investigation. Each exhibition thus leaves a lasting "trace" on institutional and societal memory.

Lastly, following the democratization of architectural culture in the 1960s (Okumuş Solmaz & Doğrusöz, 2022), exhibitions play a decisive role in making architectural discourse more accessible. Forgotten or fragmented works (Cohen, 1999) become visible once again through exhibition formats, thus enlarging the architectural canon by foregrounding alternative design histories. This inclusivity expands the audience and fosters engagement with a collective architectural heritage.

Conclusion

The perspective of "the performance of the archive" and institutional mediation underscores how pivotal architectural exhibitions are in archival processes. Far from being passive repositories, archives become dynamic processes that are ceaselessly reinterpreted and reactivated in space. Consequently, our understanding of architectural history undergoes continual renewal, while collective memory is enriched through novel forms of engagement and encounter.

In particular, architecture faculties and research centers introduce exhibitions into their educational and public programs, bringing previously undocumented materials to light and stimulating new discussions. Institutional efforts toward digitization, participatory practices, and open access transform archives from static collections into sustainable "archival landscapes." This approach underscores not merely the "construction" of the archive but its "performance." As a result, the roles of exhibitions and institutions broaden our view of how architecture is recorded, recalled, and reshaped, prompting critical reflection on the policies and curatorial strategies that inform these collective endeavors.

Typological Transformations and Urban Isolation: Rethinking Architectural Production along Eskişehir Road

Ahmet Günel[a], Celal Abdi Güzer[a]

[a] Middle East Technical University, Department of Architecture, Architecture Design Theory, Türkiye
ahmet.gunel@metu.edu.tr

Keywords: Urbanisation in Turkey, Urban-scale Building, Urban and Architecture Relationship, Urban Transformation, Eskişehir Road in Ankara.

This study is based on the author's master's thesis conducted at the Department of Architecture at Middle East Technical University (METU)under the supervision of Prof. Dr. Celal Abdi Güzer. The presented research is derived and adapted from the thesis titled "Re-Mapping Contemporary Architecture in Turkey Based on the Relationship Between Urbanisation and Architecture: Eskişehir Road Development in Ankara". The key arguments and findings of the thesis have been restructured for this paper, with some sections directly reproduced. In line with academic integrity principles, proper attribution to the original work is provided throughout. All intellectual rights, data, methodological framework, and analyses belong to the author. Unauthorized use without citation whether partial or full reproduction is prohibited and constitutes a violation of academic ethics. All academic rights are reserved.

Aim

This study aims to investigate the relationship between architecture and urbanisation through some examples with a focus on the transformative impacts on each other and the problems of contemporary situation. By examining this relationship, it is intended to evaluate and demonstrate the transformation of architectural typologies and productions. In this sense, the significant aims in this study are exemplifying and mapping the emerging typologies, the changes in the use of existing typologies, the reflections of typological multiplicity on urban scale, and the determinative relationship between architecture and city.

The study also seeks to re-map the existing theoretical discussion from a different perspective, offering an interpretive framework for analysing, understanding and evaluating contemporary architecture within urban context. A wider meaning of context will be carried out through the study extending beyond the physical environment to include political, social, ideological, economic, physical, urban development and planning dimensions. The gap between urban and architectural scales is examined to propose an alternative ground to new models through theoretical background, concepts, architectural productions and the case study representing the contemporary situation of Turkey.

Material and Method

The method of this research is based on the examination of an area as the case study which has great representative potential. In other words, the contemporary architecture in Turkey is examined through the situation of this specific example representing Turkey. The case study as the main research material consists of new building typologies which come together and form an urban fabric through their coexistence. It will be analysed through the observed problems which continuously occur in architectural and urban scales. Therefore, the repetitive patterns and determinative situation of architecture in Turkey will be discussed.

It is aimed to examine and evaluate a specific area of Eskişehir Road in Ankara as an urban part of the city, while architectural concepts and building typologies are used as important discussion topics in the methodology to investigate and test the urban scale of contemporary Turkish architecture and to understand the relationship of architecture with urbanisation, context, and city. In addition, the coexistence of the buildings on this corridor leads to form integrity in terms of urban fabric. Thereupon, the methodology incorporates to examine whether these typologically large-scale urban buildings really contribute to the city or not. Accordingly, the main concern is to evaluate the new understanding of

urbanization in Turkey through this case study as a representative example of the contemporary situation. For this reason, changes and transformations of the contemporary architecture in Turkey will be discussed through the analysis of Eskişehir Road.

This area will be analysed through its impacts on urbanisation, urban scale, architecture and Ankara, focusing on:

- Building typologies,
- Relationship of buildings with each other,
- Site plan characteristics and complex-wise architectural organization,
- Their contributions to city,
- Integration with infrastructure, traffic, pedestrian, public transportation, car parking,
- Forms of representation of some architectural concepts.

The methodology of this research is based on the examination of a certain area with concepts and typologies. This area representing almost completed new development zone, accommodating large-scale public buildings and different typologies, serves as the main axis of this research.

Figure 1.a. The case study area along Eskişehir Road, Ankara [Source: Google Maps, https://www.google.com/maps (accessed on 26.12.2018) The image is edited and drawn by the author].

Figure 1.b. Developments and impacts on the case study area [Source: Google Maps, https://www.google.com/maps (accessed on 26.12.2018) The image is edited and drawn by the author].

Selected area (Figure 1.a) can be considered as an appropriate corridor where lots of new buildings come together rapidly in Ankara. The public buildings along this area are selected and evaluated. Selected contemporary buildings were built after 2000, representing the transformation and new developments in Turkey. They will be scrutinized and discussed to support and embody the main discussion framework. It is not intended and aimed to criticise the buildings on single scale but rather to discuss with concepts through urban and architecture relationship. In addition, there are three important focal points having significant impacts on the case study area with regards to developments and densities coming from these points (Figure 1.b).

Findings

Contemporary architecture in Turkey demonstrates a limited interaction in terms of feeding and feeding from urban scale, despite a significant increase in new architectural productions and process in building scale. Therefore, architecture does not contribute enough to city and is not sufficiently fed from urban data, urban dynamics, and context. This aligns with Aldo van Eyck's call for a reciprocal understanding: "the time has come to conceive of architecture urbanistically and urbanism architecturally." (as cited in Ellin, 2006, p.17).

Considering many factors and changes, contemporary architecture has undergone some certain transformations all around the world; and a new state has inevitably emerged which is effective on all scales. The fundamental problems observed among these emerged situations are:

- understanding of planning approach in urban scale,
- understanding of design with values in architectural scale,
- continuity between values is no longer a necessity,
- introversion of architectural productions,
- many of the projects try to maintain their own existence as an "entity" in urban scale.

These affect not only the urban state, but also typology, scale, identity and language of architectural productions, their relationship with each other, city, silhouette, and density. Within this perspective, many of the urban problems stem from this transformation.

As Rossi (1984, p.22) states "destruction and demolition, expropriation and rapid changes in use as a result of speculation and obsolescence, are the most recognizable signs of urban dynamics." The rapid change of production, urban fabric and urbanisation in Turkey has become inevitable with the increase of these large-scale introverted buildings as new urban dynamics. Since urban dynamics "refers to any process capable of transforming the urban or social morphology of a certain space" (Mahmoud, 2017, p.434), fifteen-year evolution of Eskişehir Road is analysed, indicating how urban fabric changes with the emergence of new building typologies (Figure 2).

Large-scale buildings emerge in such an eclectic way and are independent of each other, forming an urban fabric through their coexistence. This causes an increase of density and traffic since these typologies host and undertake city-center functions. 1990 Master Plan's decentralization of public institutions further contributes to this density.

This main artery hosts ministries, public institutions, shopping malls, many residential projects and office buildings forming a radial development along this corridor. From another perspective, a corridor can spontaneously form in time by itself and can be a focal development as it develops as a metamorphosis. This can be observed on different scales and in different cities. For this reason, it has become a representative example for Turkey.

Within this area, seven different types of building typologies are examined as case studies. Figure 3 indicates their location, density, scale, and their coexistence in the area. This map is significant in terms of how such a coexistence of multi-functionality regenerates each other as a repetitive pattern in case study area.

It is observed that the case study area represents the features including restricted urban accessibility, creating urbanism within itself, introversion, scale, the discontinuity between local zoning plan and main plan, eclectic and partial planning, and functional multiplicity. (Figures 4-5).

Conclusion

Introverted large-scale urban buildings exclude relationship with context and isolate themselves. For this reason, these can be located anywhere and become a prototype without giving contextual, historical and cultural references. This points out the creation of cities where car transportation forms the boundaries, social relations become spatially impossible, and public spaces are commercialized and privatised. In this way, cities start to consist of such clusters which have become isolated and create their own world within themselves through introversion and their bigness. This is because urban-scale buildings change and transform cities. Without the need for a city, these gated entities create their own urbanity and fulfil all functions inside in a self-sufficient way which refers directly to being competitive of city, simulating the urban life by accommodating all urban facilities inside, and replacing the public nature of city. As a result, architecture becomes an object as a commodification of consumer society to be consumed and reused again. Some of the increasing results of such urban-scale buildings are as follows:

- They are introverted, enclosed, and tautological. They neither contribute to city, nor take advantage from the city. This weakens their relationship with context pointing out placelessness.

- When these buildings do not have a relationship with concepts of memory, belonging, and identity, their presence does not contribute to the city in terms of urban identity.
- Their planning approach is not based on local and contextual problems, but rather on the priorities of the marketing strategies.
- Instead of integrating with urban life, they form gated entities that simulate urbanity.
- They are independent from their contexts that make architecture be reproduced in anywhere regardless of surrounding, built environment and city.

As an urban impact, the concept of city-center has been transformed along Eskişehir Road. It took on a central function suddenly and in an unplanned way. Although it is not appropriate to be a city-center; lots of state buildings, shopping malls, business centers have been built which create huge density. There is a common tendency towards creating isolated and gated entities rather than urban space, which represents disconnection of architecture from city because each entity creates its own urbanity within itself whereas "architecture takes its function and program from the city" (Mutlu, 2006). Many of the buildings as 'closed-boxes' simulate the city with functional multiplicity, which causes the relationship between city and architecture to diminish and isolation from urban life. These make architectural productions be forced to a typology which is isolated. Introversion of privileged architectural productions demonstrates their lack of reference to the built environment. This problem is directly related to the understanding of eclectic and partial planning since the formation of urban fabric is based on parcels rather than a main plan, which leads to the following observations in the case study area:

- Multiple shopping malls next to each other,
- Large-scale city hospital without planning,
- Understanding of city-center is changed,
- Buildings are surrounded by vehicle traffic around parcels and have weak relationships with each other,
- Transportation-oriented, car-dependent, introverted urban habitat developments.
- Exclusion of greenery and open-public spaces.

In conclusion, there is a transformative relationship between urban and architectural scales as a new understanding of urban dynamics in Turkey. Eskişehir Road reveals not only a physical transformation of the cityscape, but also a deeper shift in the way architectural productions interact or fail to interact with their built environments. The case study exemplifies a broader situation that large-scale building typologies are increasingly detached from urban context and collective spatial experience. The emergence of typologically repetitive, introverted, isolated, self-sufficient urban entities reflects a transformation from contextual responsiveness to self-referentiality, where architecture operates in isolation from the socio-urban fabric. This tendency results in placelessness and weakening of the role of architecture in shaping urban life. Thus, rethinking performative role of architecture within the urban realm becomes imperative for envisioning more inclusive and integrated built environments.

Keywords: Architectural Representation, Critical Representation, Conditions of Representation.

Aim

The aim of the study is to seek and understand the conditions of criticality in order to reveal the possibilities and challenges of architectural representation. The study provides an understanding of the history of architectural representation in order to discover the context of current discussions and different positions related to this area of research. Through the literature review, it has been seen that the 15th century, 18th century, and the second half of the 20th century act as three primary thresholds in the history of architectural representation. The parallels between scientific representation, representation of thought, and architectural representation are discussed at these thresholds. However, it has been argued that the current break is characterized by the transition from the representational to the performative. Through this break, critical approaches to architectural representation mediated a field of discussion within their current context. The aim of transformation, the relationship between knowledge production, power dynamics and ethics, and the disconnection between thought and action have been observed as common themes of criticality. Particularly in the field of architecture, the social and cultural structure of criticality, the differences between criticality and criticism, the possibilities of other ways of making, and the creative potential of criticality have become significant.

Material and Method

This study approaches "representation" as an active, co-constructive process, rather than a passive depiction, and considers "criticality" as inherently contextual, situated, and relational, rather than fixed by a singular definition. A broad historical framework is employed deliberately, as much of the current discourse on architectural representation tends to concentrate on specific time periods, historical or contemporary, often overlooking the longer evolution of representational practices. By tracing this historical trajectory, the study aims to foreground the ways in which "ways of making" have shaped the relationship between representation and the represented. Recent examples from critical cartography are examined not only to illustrate contemporary practices but also to highlight the need for a deeper discussion of critical approaches. This perspective invites renewed attention to the conditions under which architectural representation operates and suggests that a more expansive temporal and conceptual framework is essential for understanding its evolving role within spatial practices.

Findings

In discussions of criticality in architectural representation; established ideas of architectural representation, thresholds that mediate the questioning and challenging of established ideas, predictions of other ways of making, and qualities of a critical representation were encountered. In order to question the scope of representation, attention has been drawn to the distinction between representation and the reality it represents. This approach problematized the premise of drawing as a neutral tool that conveys absolute information and highlighted the role of drawings in producing and maintaining power dynamics. The position of representation in perceiving and making sense of the world has been considered for its power to change, hide, reveal, and reproduce the things it represents. These dynamics have exposed the creative potential of representation as well

as the visibility of its restrictive structure. The transformation of drawing into a field of discovery has mediated the search for other ways of representation and enabled the evaluation of issues such as authority, precision, and fragmentation. These discussions on representation made it possible to move from the question of representation to the conditions of representation. The parallels between media theory and critical architectural representation have been observed and evaluated within this scope. Such studies did not remain only in the conceptual field but also problematized the techniques, technologies, tools, and mediums, as well as the power dynamics they involve and their relations with ethics and discipline of architecture.

Along with the thresholds determined through studies examining the history of architectural representation, it is thought that the most recent break, as stated by Vidler (2002), is the adoption of a performative approach in productions instead of a representational one. Through this break, a paradigm shift occurred in architectural representation, and the association or relationship between representation and non-representation began to be questioned. Additionally, this break emphasized the idea that works in the category of representation are viewed as entities in themselves, rather than merely representations of something else, which was pivotal for the productions of this period. Regarding the relationship of architectural drawings with architecture, Van Gerrewey (2021) suggests that architectural drawings always point to what the architect can do in the future, refer to something other than themselves, and are related to something beyond their own scope. Discussions on criticality in architectural representation problematize these established ideas about production processes by questioning such assumptions. Although criticality debates frequently emerge in the field of architecture, it appears that the accepted notions of architectural drawing and representation can still be reproduced in current studies. This indicates that criticality may not begin to infiltrate production processes and transform them if it remains limited to the content of the productions.

Critical approaches to architectural representation have revealed the determining factors of representation and, therefore, the problem of the conditions of representation. This transition becomes visible in studies that bring the space of representation into focus. Especially in the last twenty years, studies in the field of cartography that discuss the space of representation have increased and supported this transition. By looking at what maps do instead of what they represent, the emphasis on action in the field of cartography has become significant. The transition from map to mapping was not only a conceptual leap, rather made the actions involved in mapping visible. Especially in studies referred to as counter or critical mapping, many qualities such as bringing the neutrality of representation into question, mediating transformation, revealing hierarchies, and the relationship between academic and non-academic form similarities with critical approaches to architectural representation. In studies where the conditions of representation are questioned, the methods, techniques, mediums, tools of representation, as well as the scope and content, and the relations between these elements have been opened to discussion, where the search for new forms of production and the interactions in these processes become visible.

Conclusion

Among the concepts included in the study, thresholds express certain periods that are encountered. There have been common perspective changes at these thresholds, and these changes have occurred simultaneously in multiple areas of study. Breaks, such as the transition from the representational to the performative, are accepted as intervals that are present and opened to discussion. Unlike thresholds, breaks have not been observed in more than one area simultaneously. Breaks include fractures, disintegrations, proliferations, and differentiations, making it impossible to express them in a linear narrative. Conditions, another concept included in the study, involve the ongoing search to understand the domain of the concept discussed, such as representation or criticality. The conditions were chosen to identify the common approaches to the concept evaluated in different fields of study and research. In studies where the conditions of representation are questioned, the methods, techniques, mediums, tools of representation, as well as the scope and content, and the relations between these elements have been opened to discussion, where the search for new forms of production and the interactions in these searches become visible. Through this study, it has been argued that the conditions of criticality in representation hold a creative and transformative potential, which does not reside in the disciplinary boundaries but in the shared space of representation.

Exploring Experiential Learning Design Practices Grounded in Social Responsibility in Mardin

Betül Toy[a], Yüksel Demir[a]

[a] Istanbul Technical University, Architectural Design PhD Programme, Türkiye
toyb20@itu.edu.tr

Keywords: Experiential Learning, Social Responsibility-Based Learning, Community-Engaged Learning, Social Benefit.

Aim

The study aims to explore strategies to strengthen students' understandings of social responsibility through the outcomes of ITU Mardin design studies, which extends beyond the design studio space in schools and tackles non-hypothetical, real issues through processes conducted directly in the field. This aspect of ITU Mardin design studies (onwards, ITU Mardint) also has the potential to bridge the gap between society and architecture schools. Accordingly, the research mainly focuses on ITU Mardint design studies conducted in Mardin, Türkiye, between 2005 and 2012, which comprise a series of interdisciplinary and integrated design studios, including the application project studio supervised by Cem Altun, the survey and restoration studio supervised by Yegan Kahya et al., as well as landscape studios, all developed in coordination with the architectural design studio.

The concept of social responsibility can be briefly defined as the obligation to take into account the interests of society rather than individual interests. Architecture, as a social action field with a direct impact on society, holds a significant place in this regard. Berman (1990) states that social responsibility for the well-being of society will not develop spontaneously; it requires intention, interest and time. Therefore, architectural education should intentionally and continuously engage students with issues of social responsibility, providing both the time and context necessary for this awareness to emerge and deepen.

The study has been conducted to structure the research in a way that ensures the transfer of a process previously carried out at ITU to future generations in alignment with these objectives, questioning its sustainability, exploring its positive and negative feedback through actors' individual experiences, investigating its socio-spatial contributions to the society, and helping to develop social responsibility-based approaches in architectural education through the expansion of such initiatives as practice research centers, associations, studios, etc. The primary research question of the study is: "What are the socio-spatial impacts of ITU Mardint studios in terms of social responsibility, considering experience, communication and collaboration, reflection, and social benefit?" The study has been structured based on Kolb's (2015) experiential learning paradigm, which has been restructured and expanded in light of the field data from ITU Mardint. Thus, the learning cycle has been redefined around four key components-experience, communication & collaboration, reflection, and social benefit-within the context of social responsibility.

Material and Method

The method of this research can be described as "experience-based action research" methodology, within the theoretical framework of Kolb's (2015) learning paradigm and the methodological framework of action research design. It can be considered, in a sense, as the overlap of methodology and theoretical background that intersect ontologically.

Prepared in alignment with the research question, the semi-structured interview questions constitute the primary method of data collection in this study. Accordingly, data were primarily gathered through reflective interviews conducted with groups composed of (former) students, academic staff, the people of Mardin, and representatives of stakeholder institutions (or institution representatives, onwards), alongside various documents such as researcher and practitioner notes, student projects, posters, booklets, etc. The data obtained from these interviews are analyzed using qualitative analysis methods to explore the complex and context-specific nature of social responsibility. The interview data were examined through content analysis. The analysis of interviews was conducted using MAXQDA to deeply examine participants' reflective thoughts

through code-subcode models and facilitate the identification of patterns, themes, and relationships within the data. Among the ITU Mardint participants reached through the snowball sampling method, 42 out of a total of 132 individuals voluntarily participated in the research, including 21 out of approximately 36 students, 10 out of 26 academic staff, 5 out of 30 individuals from Mardin, and 6 out of 40 institution representatives.

Findings

The findings are analyzed to reveal the students' thoughts on social responsibility in architecture and its role in enhancing their skills such as encountering real problems, collaborating, using regional data, integrating it into their designs, etc. At the same time, these analyses provide an opportunity for the evaluation of the perspectives of academic staff on the studies, the experiences of institution representatives, and the socio-spatial contributions of these studies to the people of Mardin. Participant responses were examined through multiple perspectives of actors using code-subcode models, and the findings contributed significantly to the conclusions of the study. The analysis revealed that people of Mardin primarily addressed issues related to socio-spatial contributions; institutional representatives focused on communication and collaboration; whereas faculty members and students emphasized ITU Mardint's non-hypothetical, proactive, and reactive approaches.
Overall, 88% (n=42) of participants found the experience satisfactory, 5% reported dissatisfaction, and 7% stated they were moderately satisfied. It has been determined that dissatisfaction arises from factors such as lack of communication, insufficient information and publicity, as well as disruptions in project implementation. Participants also stated that they had the chance to explore the region and experience various aspects of Mardin such as its unique geography, daily lifestyle, and climate. Additionally, it has been determined in the study that when the student responses were analyzed, the incorporation of daily life and local data was evident in addressing design problems, with an emphasis on user-centered solutions and communication reflected with the people of Mardin and other stakeholders. When examined in terms of social benefit, it was observed that all participants from Mardin stated that the studies contributed to the preservation of the historical fabric and fostered a change in the perception of the city as a socio-spatial contribution.

Conclusion

In the study, various strategies have been proposed based on the areas where ITU Mardint is lacking. It was revealed that issues such as communication breakdowns, discontinuation of collaborations, and a lack of information sharing must be addressed. It has been revealed that, although challenges such as the discontinuation of the studies, communication gaps, insufficient information, and the non-application of projects were encountered, the majority of participants held positive views regarding the process, contributing to the development of social awareness and facilitating the establishment of university-community collaboration. The feedback received has shown a significant need for university-community collaborative studies, particularly the need for an agile, circular, and sustainable model that integrates academy with the society. The findings of the study indicate that more permanent and systematic strategies need to be developed to sustain community–university collaborations. The development and sustainability of such studies will be crucial for the advancement of experiential learning based on social responsibility & community-engaged learning, which is the primary focus of the research.

Urban Destruction in Malatya's Green Belt Project: A Struggle for Public Space or Capitalist Gain?

Furkan Evliyaoğlu[a], Nurbin Paker Kahvecioğlu[b]

[a] Istanbul Technical University, Graduate School, Architectural Design, Türkiye
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Türkiye
evliyaoglu16@itu.edu.tr

Keywords: Green Belt Project, Malatya, Public Space, Urban Demolition, Urban Memory.

Aim

This study examines the partially implemented "Green Belt Project" in the Battalgazi district of Malatya. Initiated by then-mayor Selahattin Gürkan, who described it as his "greatest dream," the project aims to expand the existing Hürriyet Park northward, creating a continuous green zone within the dense urban fabric. Marketed as an unprecedented initiative in Turkey, this park aspires to be Malatya's "Hyde Park" or "Central Park" (Url-1).

However, to expand Hürriyet Park and implement the "Green Belt Project," the demolition of several public and semi-public buildings was necessary, including the State Hydraulic Works (DSI) Service Building and Residences, Malatya İnönü Stadium, Atatürk Indoor Sports Hall, an indoor swimming pool, Şehit Kemal Özalper Vocational and Technical Anatolian High School, and Atatürk Girls' High School. As part of this process, a new municipal building was constructed on the former DSI Service Building and Residences' site, while the DSI facilities were relocated to another part of the city. After the relocation, the old structures were demolished. Similarly, a new stadium was built on the city's outskirts, and upon its completion, the old İnönü Stadium and Atatürk Indoor Sports Hall were demolished. The former stadium site was transformed into the "Nation's Garden." Finally, Atatürk Girls' High School was relocated due to seismic concerns, and its original structure was replaced with the "Nation's Library." The Şehit Kemal Özalper Vocational and Technical Anatolian High School remains standing, as it is a registered historical building (Figure 1).

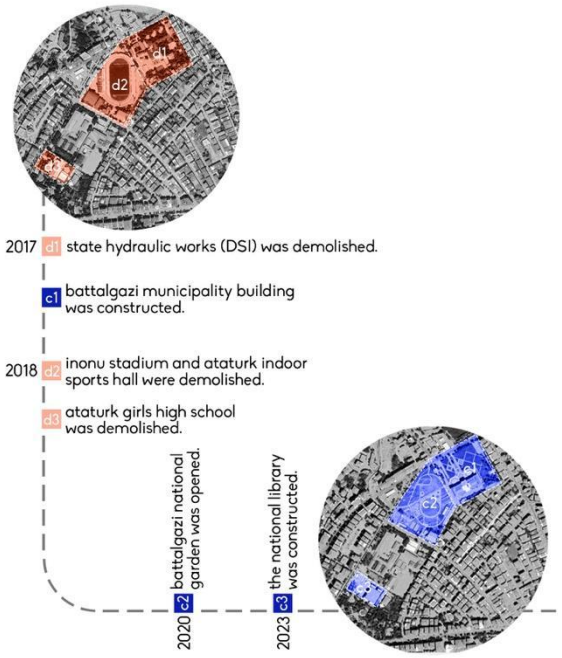

Figure 1. A diagram describing the destruction process (Evliyaoğlu, 2025).

Although the "Green Belt Project" ostensibly aims to create a public recreational space, it has led to the demolition of several significant structures, including the stadium, which held a strong place in urban memory. This study hypothesizes that the project, framed as a struggle to create public space, embodies diverse ideological motivations. Instead of prioritizing public access, the transformations align with broader aspirations such as positioning Malatya as a global city or a branded city. Consequently, these urban spaces have been commodified and instrumentalized for consumption, essentially serving as tools for economic gain (Harvey, 2013). Moreover, projects such as the "Nation's Garden" and "Nation's Library" have been utilized as election campaign promises. The demolition of structures embedded in the city's memory can also be interpreted as a deliberate attempt to erase urban history.

The primary motivation of this study is to decipher the ideological underpinnings of these transformations carried out by state actors. In other words, the research aims to expose the panorama of urban demolitions as a tool of political struggle and to test the hypotheses regarding their underlying motivations.

Theoretical Framework

Public space is generally defined as parks, streets, squares, and recreational coastal areas under public ownership and administration, which urban residents use to meet various needs such as relaxation and socialization (Aksoy & Firidin Özgür, 2020). Beyond these functions, public space is also a site of interaction and encounter, bringing society together and granting visibility to urban dwellers (Akkar Ercan, 2016; Lefebvre, 2014). As such, the public spaces of a city are essential components of the public sphere, serving as arenas for political action and engagement among different social groups and individuals (Bilsel, 2006).

With the rise of neoliberal capitalism, high-value public spaces in city centers have increasingly been transformed into pseudo-public spaces—such as shopping malls and theme parks—designed for consumption and serving only specific segments of society (Smith, 2005). As a consequence of privatization, these spaces no longer function as shared public areas accessible to all but have instead become exclusive domains claimed by particular social groups (Bilsel, 2006).

Material and Method

The demolitions in question involve various actors, including state mechanisms, capital-related stakeholders, and social actors. However, rather than focusing on the perpetrators of these demolitions, this study centers on the urban residents who were affected by them. Therefore, this study is based on qualitative content and discourse analysis of a variety of user comments gathered from Malatya-based local news platforms, media outlets (e.g., Malatya Haber), social media, and from users associated with the physical spaces under study—such as the demolished stadium, schools, and public facilities affected by the "Green Belt Project." The data were gathered through a purposive sampling strategy, focusing specifically on comments related to the demolition of key structures. The analysis followed a thematic framework, aiming to identify recurring discursive patterns—particularly those reflecting nostalgia, ideological critique, and urban memory shaped by environmental transformation. This analysis provides insight into both the political authorities' perspectives and the responses of Malatya's residents.

Findings

Public reactions to the project varied across different segments of society. For instance, some citizens criticized the decision to construct the Battalgazi Municipality Building on the former site of the DSI Service Building and Residences rather than on vacant land, labeling it an example of profiteering. They argued that the reported project cost was misleading, as it failed to include the expenses for constructing the new DSI facilities elsewhere. Others, however, defended the project, asserting that the expenditure was justified.

Beyond the demolition of existing buildings, the project also faced criticism for cutting down numerous monumental trees within the so-called "Green Belt" area. Additionally, incorporating the municipal building into the space, rather than solely preserving it as a green zone, sparked further disapproval.

Similar criticisms were directed at the "Nation's Garden," which replaced the demolished stadium. Initially, many citizens welcomed the project, emphasizing the need for green spaces in an increasingly concrete-filled city. However, one resident

argued that the stadium should have been preserved, as it could have been used for morning exercises, rallies, and concerts. Others suggested that the indoor sports hall and swimming pool should not have been demolished and should have been integrated into the "Nation's Garden." Many users also expressed concerns that the new park would become unsafe at night. Some residents opposed relocating the stadium to the city's periphery, arguing that this decision undermined the city's football culture. Others lamented the loss of personal memories associated with the stadium. One resident, for instance, recalled participating on April 23rd performances as a child and attending football matches with their father, expressing sadness over the demolition.

A significant portion of the comments were ideological. Many believed that the demolitions were politically motivated, pointing out that the stadium bore the name "İnönü" and the sports hall was named "Atatürk." The removal of these names from the new structures intensified public backlash. Critics argued that the demolitions targeted Malatya's historical and cultural values.

Even after the project was completed, criticism persisted, particularly regarding the insufficient number of trees and green areas in the park. Many users claimed that the park was overly dominated by concrete structures and lacked essential recreational elements. Additionally, the park's children's play areas were deemed inadequate, and the presence of surrounding walls was another major point of contention.

The last demolished structure in the project area was Atatürk Girls' High School, which had been deemed structurally unsound before the 2023 Kahramanmaraş earthquakes. The school was relocated, and the "Nation's Library" was built on its former site. However, unlike other transformations, the architecture of the new library drew significant criticism. Many compared it to a prison or a military barracks, arguing that its design bore no resemblance to traditional library typologies. Additionally, residents questioned the rationale behind demolishing the school only to construct a much larger building in its place. Some sarcastically asked, "If you were going to build a library, why demolish the school?" or "Wasn't this supposed to be a green park?"

Conclusion

The "Green Belt Project" was presented by political actors as a series of ambitious initiatives. The Battalgazi Municipality Building was promoted as a "green and smart" structure, the "Nation's Library" was introduced as "Turkey's largest indoor library," and the "Nation's Garden" was marketed as a major public space initiative. However, despite its overarching goal of creating a green belt within the city, the project ultimately fell short. The newly created green spaces remained limited, and multiple concrete structures were added within the area. Moreover, the envisioned seamless integration of green zones with Hürriyet Park was not achieved, resulting in a fragmented and restricted green corridor.

In summary, the project received widespread public criticism. The first major concern was its excessive cost, with many citizens believing that the outcome did not justify the expense. The second major criticism was that the project failed to fulfill its mission of providing a public breathing space, as the park's landscaping elements, such as tree cover, walking paths, and recreational facilities, were deemed inadequate. Lastly, the project was seen as an attack on urban memory, with critics arguing that demolishing structures such as the stadium and schools erased Malatya's historical identity. Additional concerns included the deliberate erasure of names associated with "Atatürk" and "İnönü," reinforcing the perception that these demolitions were ideologically motivated and systematically targeted at Republican-era structures.

Reading Architectural Memory Through Cinematic Image: Atatürk Cultural Center

İsmail Gökkaya[a], Funda Uz[b]

[a] Istanbul Technical University, Graduate School, Architectural Design Program, Turkey

[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Turkey

gokkaya17@itu.edu.tr

Keywords: Architectural Memory, Cinematic Montage, Architectural Representation, AKM.

Aim

The Atatürk Cultural Center (AKM) has maintained its place in urban and collective memory despite its tumultuous history, including a 23-year-long design and construction process, destruction in a 45-minute fire, reopening in 1978, and closure in 2008 for renovations. As Boysan (2005) aptly stated, AKM is a building that has been influenced by "countless people." This study does not seek to document the present state of AKM but rather to explore how its multilayered memory can be traced through cinematic images. Contrary to the traditional understanding of architectural history, the study searches for a memory by following the traces of numerous ignored time-space experiences, not only through conventional representation tools (plans, sections, facades, etc.). The aim is to reconstruct the memory of Atatürk Cultural Center through photographs, narratives, texts, and archives with cinematographic images and to present a narrative far from linear historiography.

Material and Method

The representation of AKM through cinematic montage involves assembling different fragments, images captured at various points in time, and even speculative visualizations of the building before its construction. This research methodologically examines the architectural memory of AKM under three main themes: Memory, Memory of Representation, and Representation of Memory. These categories are designed to explore how the building's memory can be reconstructed and understood through a cinematic perspective. The study employs a range of montage strategies to investigate the intersection of memory, space, and representation. The Atatürk Cultural Center is reimagined as a living archive, where images, written narratives, and layered temporal fragments interact continuously through the lens of the present. Examining AKM in this manner helps reveal the intricate and evolving memory embedded in the building. The different design processes that AKM has gone through—construction, idle waiting, and redevelopment—not only make it a physical structure that exemplifies the architecture of the 20th-century Republic but also a constantly transforming image in Istanbul's collective memory. Its direct relationship with the city and its monumental facade's connection to Taksim Square reinforce its layered historical significance. This layered structure between the past and the present can be revealed with cinematographic montage techniques.

Findings

The idea of constructing an opera house in Taksim first emerged in 1939, within the urban plan developed by French architect and urban planner Henri Prost. As a spatial embodiment of the newly established republic's national identity, the project carried significant symbolic value. While Auguste Perret initially proposed a design in 1939, the foundation was laid in 1946 based on plans by Günay and Kip. The foundation of the building, laid in 1939 based on Prost's proposal and Günay and Kip's plans in 1946, initially reflected the "neoclassical architectural language". The neoclassical architectural language of the period is generally characterized by monumentality, symmetry, classical proportions, and prominent façade features such as columned entrances or arched windows. These early designs aimed for a more traditional, grandiose, and

representative structure, seeking to spatially embody the national identity of the newly established Republic. Although these earlier designs reflected a neoclassical architectural language, economic constraints delayed construction progress.

When Hayati Tabanlıoğlu was commissioned in 1956, the project was redesigned with the modernist approach of the period. The 'Istanbul Cultural Palace' (as it was known at the time), which was the 2nd largest opera house in Europe and the 4th largest in the world when it was opened in 1969, was rendered unusable by a fire that broke out in November 1970 during a performance of The Crucible. After repair and renovation works in 1973-78, it was reopened as the Atatürk Cultural Center. Due to the constraints imposed by the previously constructed concrete frame, Tabanlıoğlu had to adhere to this existing structure (Ganiç, 2016). However, in contrast to earlier monumental design proposals, he envisioned a transparent facade facing Taksim Square, which became a defining feature of the building. As Tabanlıoğlu stated, "This facade was designed to be unlike any other existing building facade in the world, yet it possesses an artistic identity" (Ganiç, 2016, p. 68). Tabanlıoğlu's modernist approach, in contrast to the previous neoclassical grandeur, was distinguished by functionality, transparency and the use of industrial materials. The existing reinforced concrete frame influenced Tabanlıoğlu's design decisions and imposed certain restrictions on him. This led to the adoption of modernist and fluid solutions in the general form and interior arrangement of the building, in line with what the existing structure allowed.

The Atatürk Cultural Center has a very rich archive in terms of historical and spatial memory. The Tabanlıoğlu Archive, especially located in Salt Galata, is valuable in that it contains documents from different periods of the structure. This archive includes not only architectural plans and drawings but also detailed process photographs related to the structure. When such archive materials are brought together using the cinematographic montage method, the memory and transformation processes of the Atatürk Cultural Center can be examined in their entirety. Cinematic montage, as an analytical tool, employs various techniques derived from Eisenstein's montage theory, including intellectual montage, rhythmic montage, tonal montage, and speculative montage. Intellectual montage traces the building's urban footprint and its evolving relationship with the city through aerial imagery from different periods, categorizing it into three layers: pre-construction, original structure, and reconstructed building. Rhythmic montage visually documents the architectural and experiential differences among the various design phases. Overtonal montage explores the spatial atmosphere of AKM, particularly its monumental facade facing Taksim Square. Finally, speculative montage generates digitally manipulated and collaged images of AKM, enabling alternative temporal and spatial readings (Eisenstein, 2014).

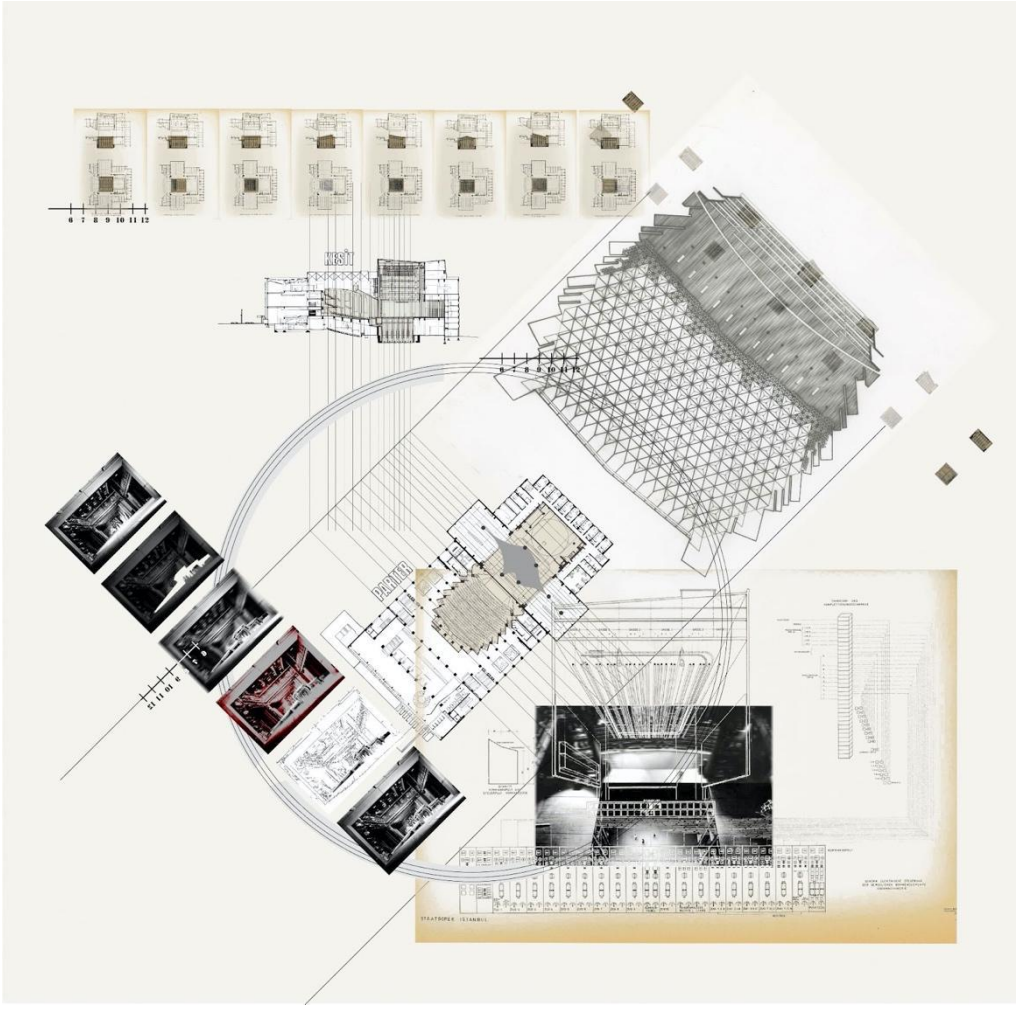

Figure 1. Rhythmic Montage (İsmail Gökkaya, 2025).

One example of a cinematic image study (Figure 1) focuses on the main hall of AKM, particularly the stage-audience relationship. The study visualizes the movement and temporal sequences of the mechanical and electrical stage systems, creating a dynamic representation of spatial memory. The interior configuration of AKM, especially the stage-audience relationship in the main hall, is the architectural expression of the functional heart of the building. The gradual rise of the audience area, the central location of the stage and the acoustically optimised ceiling and wall details are designed to ensure that the performance is perceived as an interactive experience. The complex mechanical and electrical structure of the stage systems demonstrates not only a technical functionality but also that the stage is a living space that transforms within itself. Visualising the temporal sequences of these systems allows the space to be perceived not only as a static volume but also as a dynamic 'performance machine'.

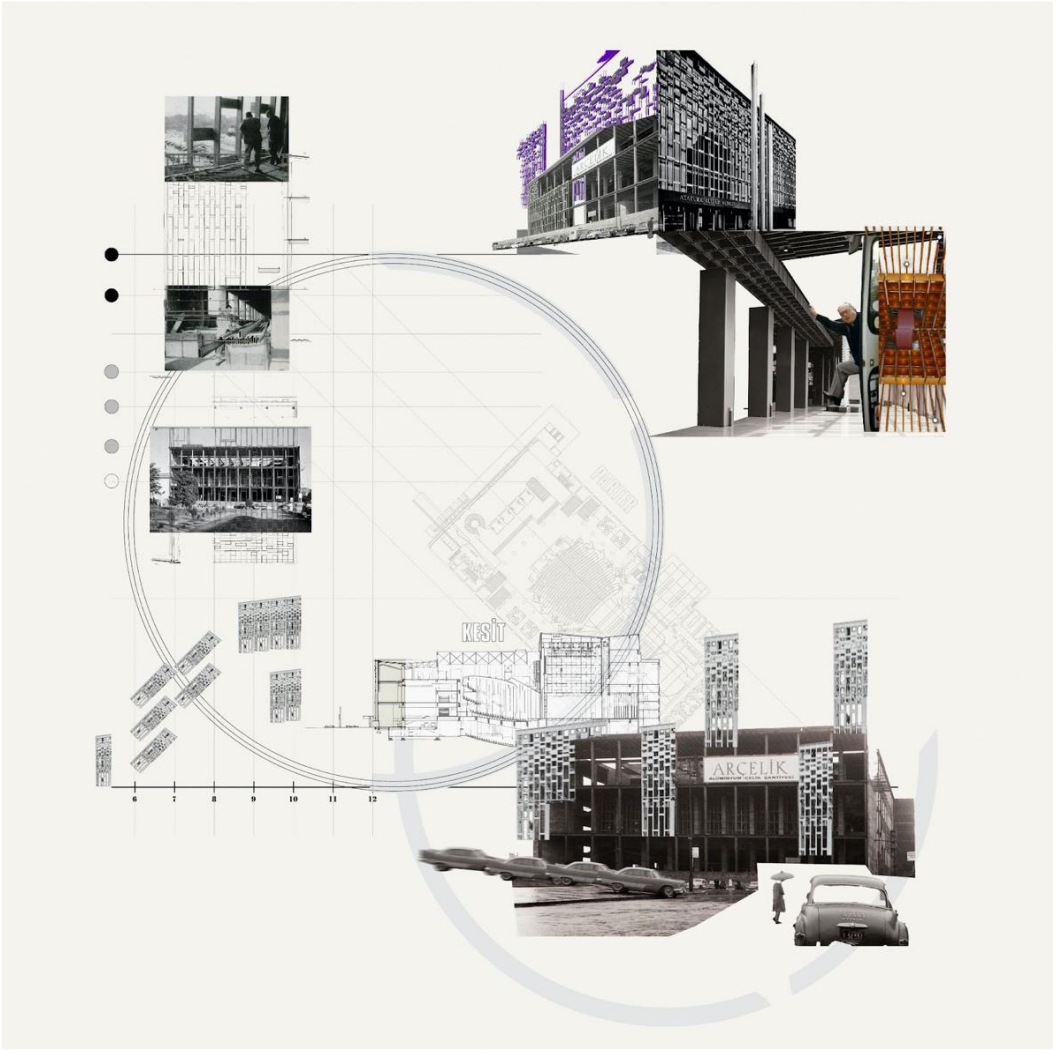

Figure 2. Overtonal Montage (İsmail Gökkaya, 2025).

Another experiment (Figure 2) examines the iconic steel-aluminum facade, which serves as both a backdrop and an active participant in the city's theatrical life. The monumental façade of the AKM overlooking Taksim Square is the most striking expression of Hayati Tabanlıoğlu's modernist vision. Steel and aluminum materials were preferred in its design with the intention of creating a constantly changing surface with light and reflections. This transparency opened the interior of the building to the outside, creating not only a performance space, but also a dynamic urban interface that participated in the city's own 'real life drama' as a stage and audience. The fact that the initial concept of the façade was created by Tayman, implemented in collaboration with Boysan and Arçelik Construction Department, and produced in Arçelik workshops with technical support from Germany (Aluminium-Walzwerke Singen) shows that this architectural element is not only aesthetic, but also the product of a complex production and industrial cooperation process. The fact that it was completely rebuilt in Türkiye by the Türkeli company after the 1971 fire emphasizes that the façade is not only a design but also an indicator of national construction capacity (Uz, 2017). As Akcan (2013) asserts, "AKM is as much a stage for the performances inside as it is a backdrop and spectator for the real-life drama unfolding in Taksim. The spatial atmosphere and architectural expression of this monumental façade are deeply investigated through the overtonal montage technique. Overtonal montage questions how the façade has produced an image in different periods. By examining both the façade's installation and its

relationship with the square, it is clarified how the façade is perceived not only as a physical boundary but also as a dynamic part of the city and a focal point of emotional connection.

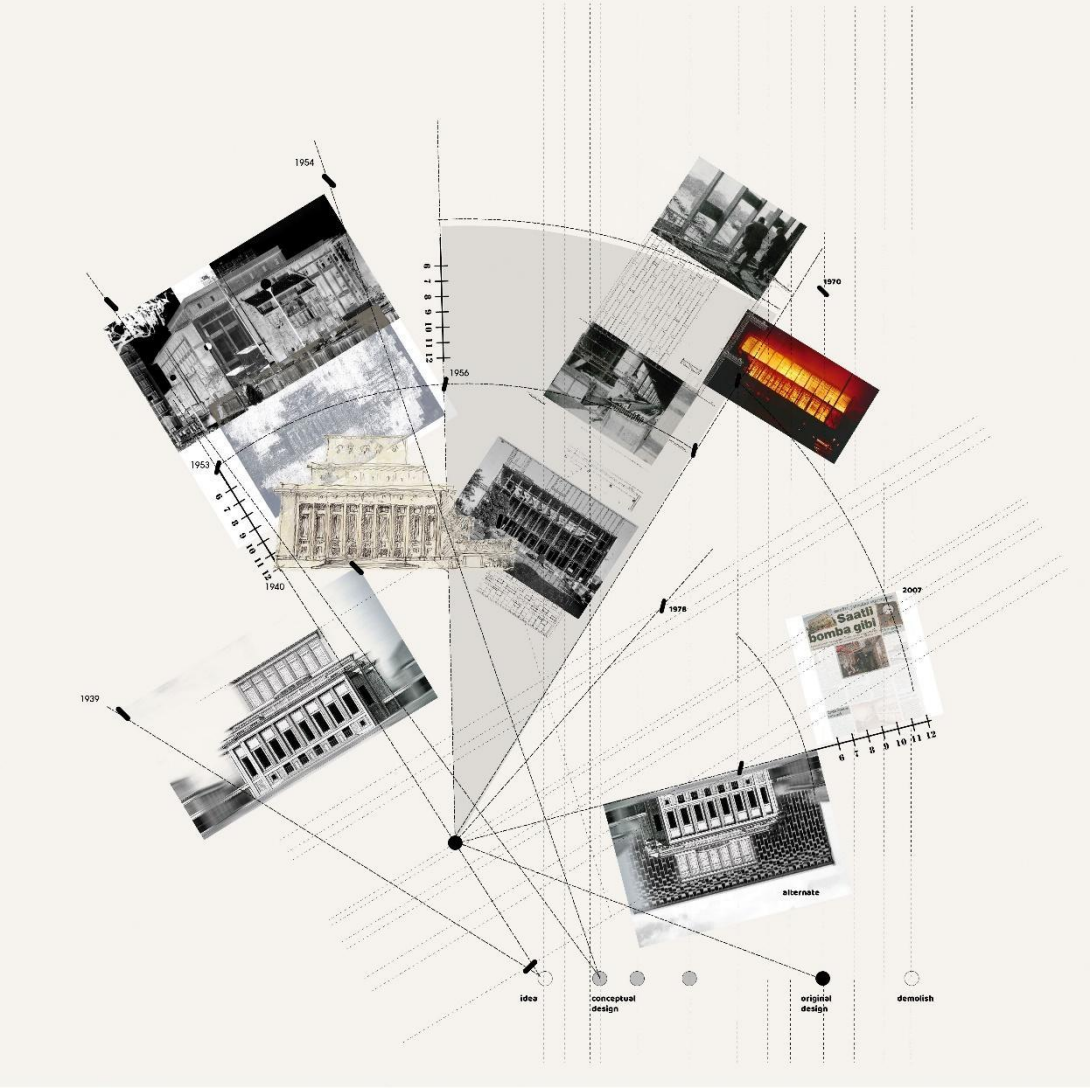

Figure 3. Speculative Montage (İsmail Gökkaya, 2025).

Speculative montage (Figure 3) allows for different thought experiments on the architectural composition and spatial potentials of the AKM. This technique combines existing archival materials (plans, photographs) with digital manipulations to visualize unbuilt versions of the building, alternative uses or hypothetical states in different time periods. For example, it explores architectural scenarios such as how spatial arrangements in early plans could be integrated into the present-day structure or how a different design approach in post-fire restoration could change the spatial flow of the building. This shows that the AKM is not only a completed building, but also a spatial archive that can be continuously re-imagined.

Conclusion

In the previous sections, the place of the Atatürk Cultural Center (AKM) in collective memory, its historical processes and spatial transformation were discussed. The study examined not only the transformation of the Atatürk Cultural Center as a physical structure but also how it exists as a constantly evolving image in the cultural memory of Istanbul. Many layered

elements, from the design and construction process of the building to its history interrupted by fire, reconstruction processes and the strong relationship it establishes with Taksim Square with its transparent façade, were analyzed with cinematographic montage techniques. An image inventory of the AKM was made using archive photographs, plans, written narratives and digital collages, and its memory was reconstructed through elements such as the stage-space relationship and façade design. In this context, the research conducted with Eisenstein's montage techniques revealed the AKM as a memory space that is constantly reshaped in terms of time and space, rather than a static structure. In conclusion, the findigs demonstrates how cinematic montage serves as a powerful analytical tool for reconstructing architectural memory. By moving beyond linear historiography and integrating archival imagery, textual narratives, and speculative visualizations, AKM's evolving identity is revealed as a continuous dialogue between past and present. This method not only offers an alternative way of perceiving AKM but also provides a broader framework for understanding architecture as a dynamic and temporal entity within urban memory.

Fluid Bodies of Space: Rethinking Architectural Relationality Through The Medusa Head

Esra Yüksek[a], Sıdıka Aslıhan Şenel[a]

Keywords: Spatial Ecology, Fluid Bodies, Relationality, Vulnerability.

Aim

It always begins with the Medusa Head, catching me in the garden of the Istanbul Archaeological Museums. She's not tucked away in some sterile gallery but sits out there, majestic yet fragile, her stone face shifting under rain, plants, fungi, and time. Each visit shows a new face of her. Myths, the space it occupies, the keystone of an old structure—all of its relationships intertwine, and new states of being, fluid bodies, emerge. She's my way into this research, a quiet call to rethink architectural space not as the fixed, invulnerable volumes we're taught to design, but as fluid bodies, open to wounds and transformation. This study aims to explore how spaces, especially this museum, live through their entanglements, challenging the static ideals of architectural design with a feminist lens that's personal and porous. As a young woman, architect, researcher, and student, I ask: what if we design for relationality, for vulnerability, instead of control? Rooted in feminist research methods and pedagogy, this isn't abstract theory. It's a dialogue with the museum, a 250-year-old complex that's more than a repository or static archive, but a spatial ecology of social, material, fictional, and trans-temporal dynamics (Figure 1.).

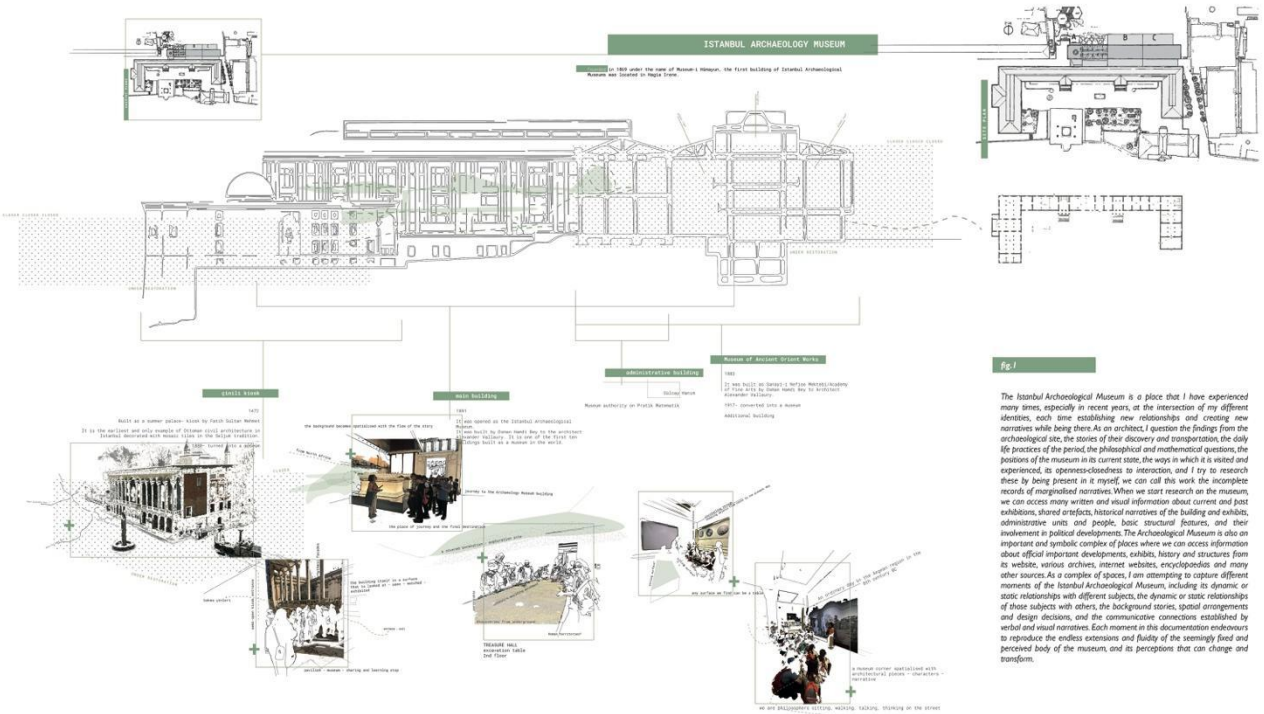

Figure 1. Multi-layered and multi-relational mapping trials about the Istanbul Archaeology Museum.

Material and Method

The Medusa Head stands in contrast to the museum's imagined autonomy: a sterile, regulated space that architectural norms might demand. My methodology, like the spaces that are the subjects of the research, defines a multi-layered, variable, and fluid production process. It's not a precise blueprint or a key solution to an architectural problem; it's about wandering the museum space, sketching at the corners, and looking for alternative methods. Later, I dig into archives and research, weaving with on-site mappings, architectural drawings, narratives, and performances to construct altering stories of the space. With students, I've led "Mathematics in the Museum" events, pausing at corners like the sarcophagus hall, where Osman Hamdi Bey's excavated finds from the Sidon site. How these massive pieces moved from Lebanon to Istanbul, and how the hall's layout and visual narratives shape their story. It's a method of co-creation, not observation. I'm not outside this but part of it, my identities are intersecting with the museum's actors, from artifacts to visitors (Figure 2.).

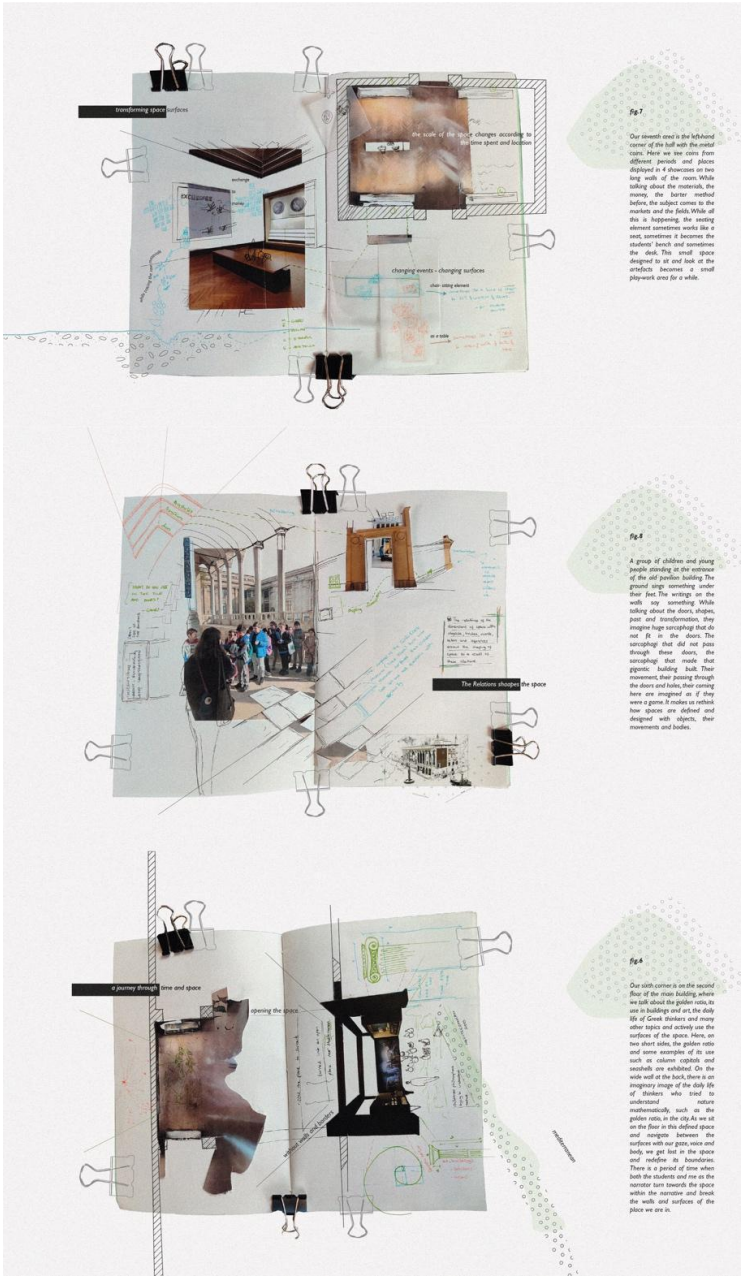

Figure 2. Istanbul Archaeology Museum's reproduced multi-layered fluid bodies I.

Neimanis (2019) guides my research practice here, rejecting "we" for "I'm a body of water," urging us to ask not just what a space is, but where, how, when, and with what it flows. Trying to think and make sense of architecture and space with such a fluid concept of the body makes it possible to critically reconsider our view of them and to be aware of the potential of a more relational, dynamic, nomadic, fluid space and spatial installation as opposed to static-autonomous perceptions of architecture. Rich (1984) adds that there's no single state of being. The Museum's halls and corners change dynamically, shifting their bodies like a body of water. Along with feminist literature, research about agency plays a critical role in this research-design study. In his text Reassembling the Social, Bruno Latour uses the Actor-Network Theory (ANT) to show that the social world consists of dynamic relations rather than a static structure. With this approach, Latour (2013) argues that the subject-object distinction in social studies should be overcome and that each actor should be given real importance. When talking about space, it may be a critical nodal point to think about the whole network of relations established with human and non-human, 'other' actors, and to see the care relations established by the actors in this network of relations with each other in a non-hierarchical manner as valuable. Thanks to the care-oriented collaborations established by the actors with each other, the space tries to live a hybrid life together with them, not despite them. Without seeking stability, it continues its existence in an unpretentious manner and by transforming between different body states.

Findings

These fluid bodies take shape through mappings that are transformed across scales and senses. In the sarcophagus hall, students and I construct narratives of objects and spaces that brought those heavy relics here, their display blurring boundaries between continents and times. The excavation site corner recreates digging gestures indoors, its surfaces and tools forming a small ecology of fluid narratives of excavating actions. In the Troy room, a 3D animation plane and a cross-section of a mound allow us to imagine between scales and temporal plans that overlap with the physicality of the museum, revealing how perception changes with the relationships between actors. These multi-layered mappings are not just recordings; they construct the body of the museum, making its intersectionality and fluidity visible.

Neimanis' figurations (2019) fuel this, opening up planes where space is fragmented and reshaped, while Stengers' ecology of practices (2011) frames it as a living network of actions and subjects. I'm not pinning the space down; I'm producing with its ecology, seeing its wounds as strengths, building situated knowledge that's feminist, embodied, and never universal. This subject I am discussing is trying to turn conventional, rigid, static architectural design on its head and make the possibility of other potentials possible. We're taught to design spaces that are resistant, durable, controlled, and human-centric. But the Istanbul Archaeological Museum's fluid bodies, also Medusa's, describe other kinds of spaces. Its physical structure may not shift daily, yet its interior is constantly becoming through artifacts' narratives, visitors' steps, and restoration's touch. The sarcophagus hall's design doesn't just hold relics; it leaps across geographies, its fluid body mixing past and present. The olive tree corner redesigns a corridor into a multi-temporal commons, its spatiality alive with imagined uses. The excavation site's ecology redraws boundaries, letting us inhabit archaeological time through design gestures. The Troy room's layered scales show how design can multiply a space's states, not fix them.

Conclusion

These findings reveal the museum as a vibrant, reshaping entity, its boundaries transgressible, its control an illusion. Tsing's Matsutake (2015) finds a resonance here; survival is not about stability but adaptation, a lesson for architectural design practices where fluidity is more potential than permanence. The museum's fluid bodies, documented through these corners, challenge static norms, offering a design practice that bends with its ecology, not against it (Figure 3.).

This research reimagines architectural design through relationality and vulnerability, with the Istanbul Archaeological Museums as a spatial ecology. It's not a monolith but a series of spaces, alive with me, Medusa, movement, time, and countless actors. My conclusion isn't a rulebook; it's a call to design spaces that reflect this interplay, that embody historical and contemporary dynamics through openness. Feminist objectivity anchors this, valuing the situated over the universal, my voice as architect and educator threading through (Haraway, 1988). For the conference, I bring a museum that's more than its walls, a fluid, evolving design where every crack, every relation, tells a story. It's a bit wild, a bit poetic, but that's an architectural narrative in between theory and practice.

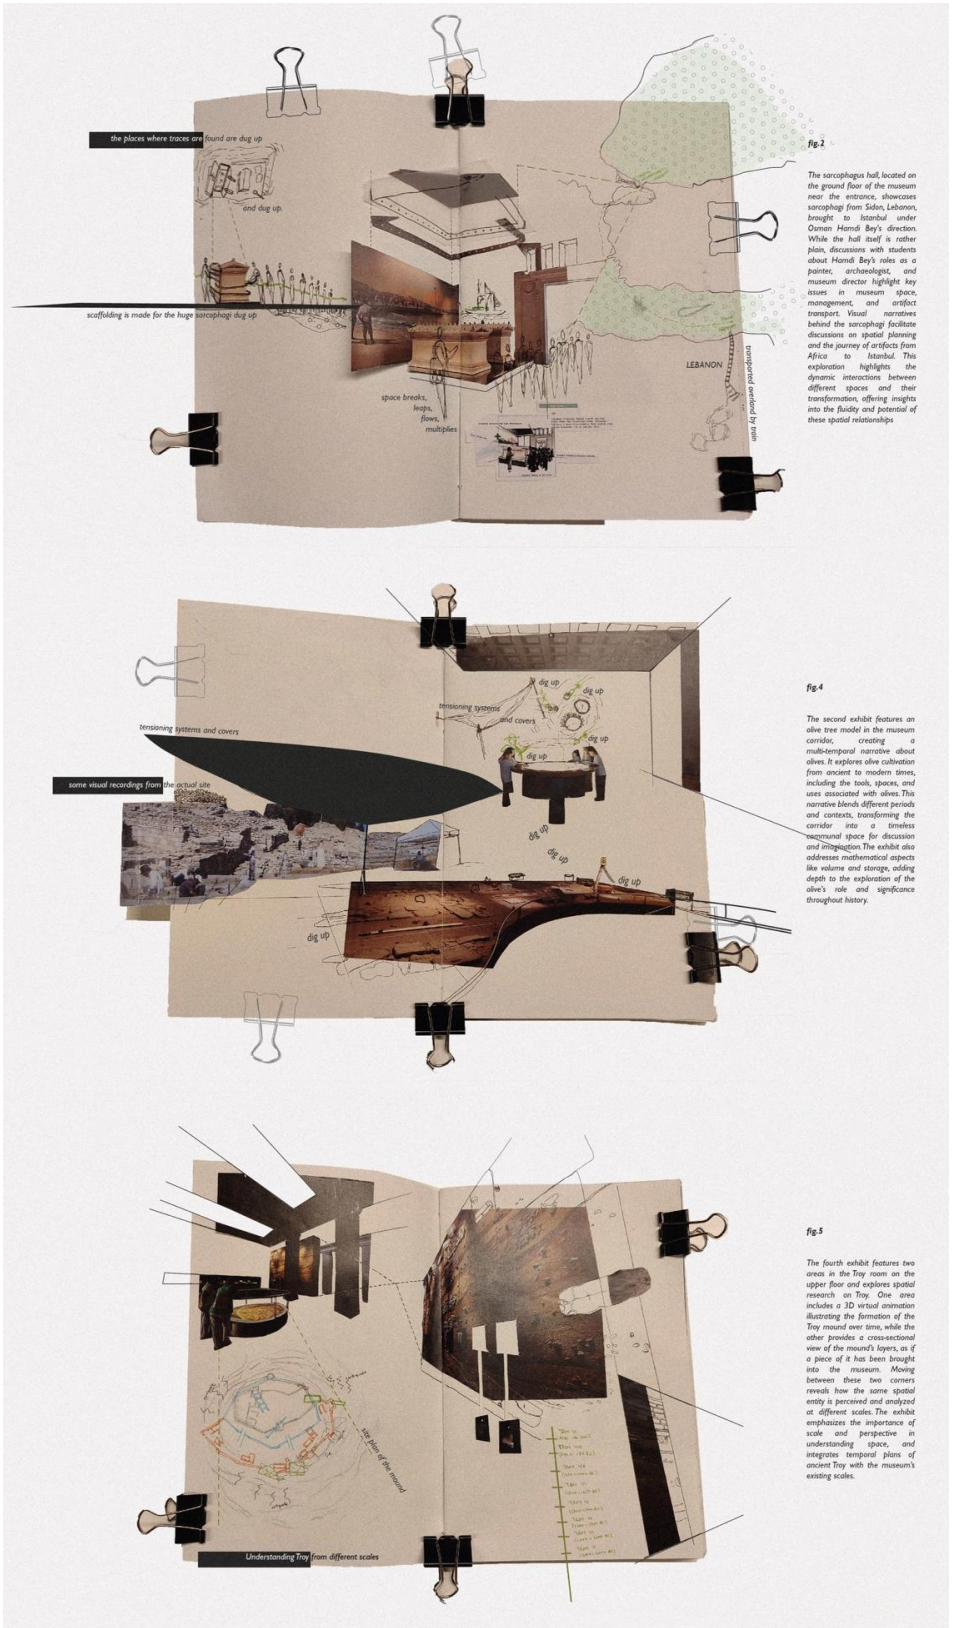

Figure 3. Istanbul Archaeology Museum's reproduced multi-layered fluid bodies II.

Archival Encounters: Rewriting Istanbul Women's Works Library and its Memory Through Bodily Practices

Seray Rusçuklu[a], Sıdıka Aslıhan Şenel[b]

[a] Istanbul Technical University, Graduate School, Architectural Design Program, Türkiye
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Türkiye

Keywords: Feminist-Objective Knowledge, Library, Archive, Spatial Dialogue.

Aim

In architecture, research space is often seen as a controlled, rational structure that produces objective knowledge through predetermined inputs and singular outcomes. This reinforces a hierarchical dynamic, positioning the researcher as the active subject and the research object as passive, leading to a singular, absolute conception of knowledge. The knowledge produced is definitive and singular, establishing a one-sided, hierarchical relationship between the researcher and the research object, placing the object in a passive position within the research space. The precise production process of objective knowledge eliminates room for error and does not allow for any deviation. This normative approach thus reduces the research space to a linear framework aimed at ensuring predictable outcomes in the research process. This paper's aim is to examine the potential of a non-human-centered gaze in the research space and its multi-layered architectural representation. The study challenges the linear and predictable nature of research space by examining how rethinking the relationship between the controlled research interior and the exterior realm of shared knowledge can embrace uncertainty, fostering more dynamic and exploratory environments through the research by design.

Material and Method

As a critical dimension of the discussion, feminist theory and research by design emerge as potential methods for questioning the nature of knowledge process and its architectural representation. Donna Haraway's "situated knowledge" critiques claim of objectivity, arguing that knowledge is always produced from specific positions. She challenges traditional views of science as neutral, emphasizing that diverse backgrounds shape knowledge itself (Haraway, 1988). In such a framework, the research space that perpetually evolves, the researcher and the research object are no longer distinct; they transform into, learn from, and influence one another.

Fiction, as research by design method, serves as a critical tool for rethinking the interior of the research space, where feminist-objective knowledge is produced and continuously multiplied through overlooked narratives. Le Guin's fiction weaves layered temporalities, using narrative as a political tool to critique contemporary worlds rather than imagining unreal spaces (Naimon&Le Guin, 2018). Rather than only constructing imaginary worlds, it serves as a tool for critical engagement with contemporary realities. In literature, fiction functions as a feminist-political instrument, creating alternative modes of writing. Similarly, incorporating fiction into architectural practice and representation becomes essential for amplifying marginalized voices and generating alternative forms of architectural knowledge.

Using fiction as a creative method in architectural representation is essential for amplifying the voices of marginalized agents and generating alternative forms of architectural representation. Stead and Frichot also introduce fiction in architecture as another creative thinking method. Ficto-criticism is a writing practice that combines essay, criticism, and storytelling (Stead&Frichot, 2020, pp.15-16). As actions shift between reality and fiction within spaces, unexpected spatial and temporal intersections arise, exposing the diverse agents engaged in feminist-objective knowledge production. These dynamics manifest through the body's engagement with space. These relationships will unfold through the body's movements in, around, and beyond space within the specific context of the work with the help of creative spatial dialogues.

Findings

The laboratory, frequently depicted in fiction literature, serves both as a physical space and a metaphor, offering a critical framework for analyzing the interaction between research subjects and objects. This study explores the laboratory in two dimensions: first, as a physical space that facilitates experimentation, and second, as a conceptual catalyst that, through its fictional nature, inspires new spatial possibilities for feminist knowledge production. In the novel Frankenstein, Mary Shelley envisioned a researcher creating "a hideous creature". The ethical tensions between researcher (Mr. Frankenstein) and subject (the monster), both sharing the same name, exemplify the complex dynamics between agents within the research space (Shelley, 2017). Shelley defines the space where Frankenstein was created as a laboratory rather than a room, emphasizing the experimental nature of the process and its unpredictable results (Shelley, 2017, p.143).

On the other hand, Latour and Woolgar consider laboratory practice as a literary writing and translation system (Latour&Woolgar, 2013, p.246). Translation typically understood as the researcher's application of symbolic representation onto the research object implies a hierarchical relationship, thereby neglecting the significance of bodily movements and actions within the laboratory. The study questions the potential of translation as an architectural act that takes place within the research space through bodily practices. Writing and recording thus becomes a way of communicating with the research object through research space. Information does not transfer directly from the laboratory bench to the world; it carries its own temporality and spatiality. The involvement of human and non-human agents in the research process, as well as their interactions within the research space, is frequently overlooked. In contrast, feminist knowledge resists de-historicization by recognizing research outcomes as one of many possible truths. Informal communications and the documentation of bodily practices further politicize and feminize the research process and its architectural representation.

The research extends to the Women's Works Library and Information Center in Istanbul, the first and only women's library and information center in Türkiye. Situated within an 18th-century Fener House, the library serves as an evolving research laboratory, shaped by the embodied and archival practices of its users. Housing a diverse collection of letters, photographs, and documents from women artists, writers, researchers, and activists, the archive-library actively integrates women into history by preserving their narratives. This process extends visibility to non-human agents involved in archival practices, emphasizing the dynamic and embodied nature of research within the archive. The main research question arises from the library space: "How can alternative narratives of agents and their relations, obscured in normative history, reframe the archive-library's temporal spatiality through female bodily archival practices?"

Karen Barad's concept of intra-action challenges conventional notions of interaction, asserting that objects, people, and forces emerge through entanglements (Barad, 2007, p.33). Grounded in Piaget's notion of spatial engagement, this study reframes act-ings on space through Barad's lens as creative spatial dialogues, constructing the research space's temporality through fiction. Spatial knowledge is acquired through movement in space (Piaget, 1964, p.179). This study proposes that research, as demonstrated in spatial sequences drawn from within the library (Figure 1.), creates tangible connections with architectural elements such as stone arches, reinforced wooden staircases, niches, and windows. These features shape the physical movement of bodies and objects, influencing the research process and imbuing it with spatial actuality. Building on this idea, research space is continuously reconstructed through the actions of human and non-human agents.

Figure 1. Spatial Dialogue Frames and Creative Spatial Dialogues Between Library and Bodies As An Alternative Method for Architectural Representation (Rusçuklu, 2023).

To illustrate this, the study employs a fiction-construction method, layering archival research with speculative narratives to generate alternative architectural representations of the research space and its often-overlooked characteristics. Sculptor Zerrin Bölükbaşı, whose works are found within the Library's archive, is examined to explore how the subject within the research space is constructed through bodily practices. The Women's Library is read in conjunction with Bölükbaşı's archival materials, revealing how sculpture, research, and archival practices intertwine across different temporal layers. The creative spatial dialogues established between the researcher and the research object (Figure 2. and Figure 3.) dissolve traditional hierarchies, proposing an alternative approach to architectural representation and construction. In this way, it is found that constructing creative spatial dialogues enables a multi-temporal and layered architectural representation of the research space, transcending normative archiving practices (Figure 4. and Figure 5.).

Figure 2. Non-Human Agencies in the Library (Rusçuklu, 2024).

Figure 3. Bodily Practices in the Library (Rusçuklu, 2024).

Figure 4. Transcending the Normative Archiving Practices (Rusçuklu, 2025).

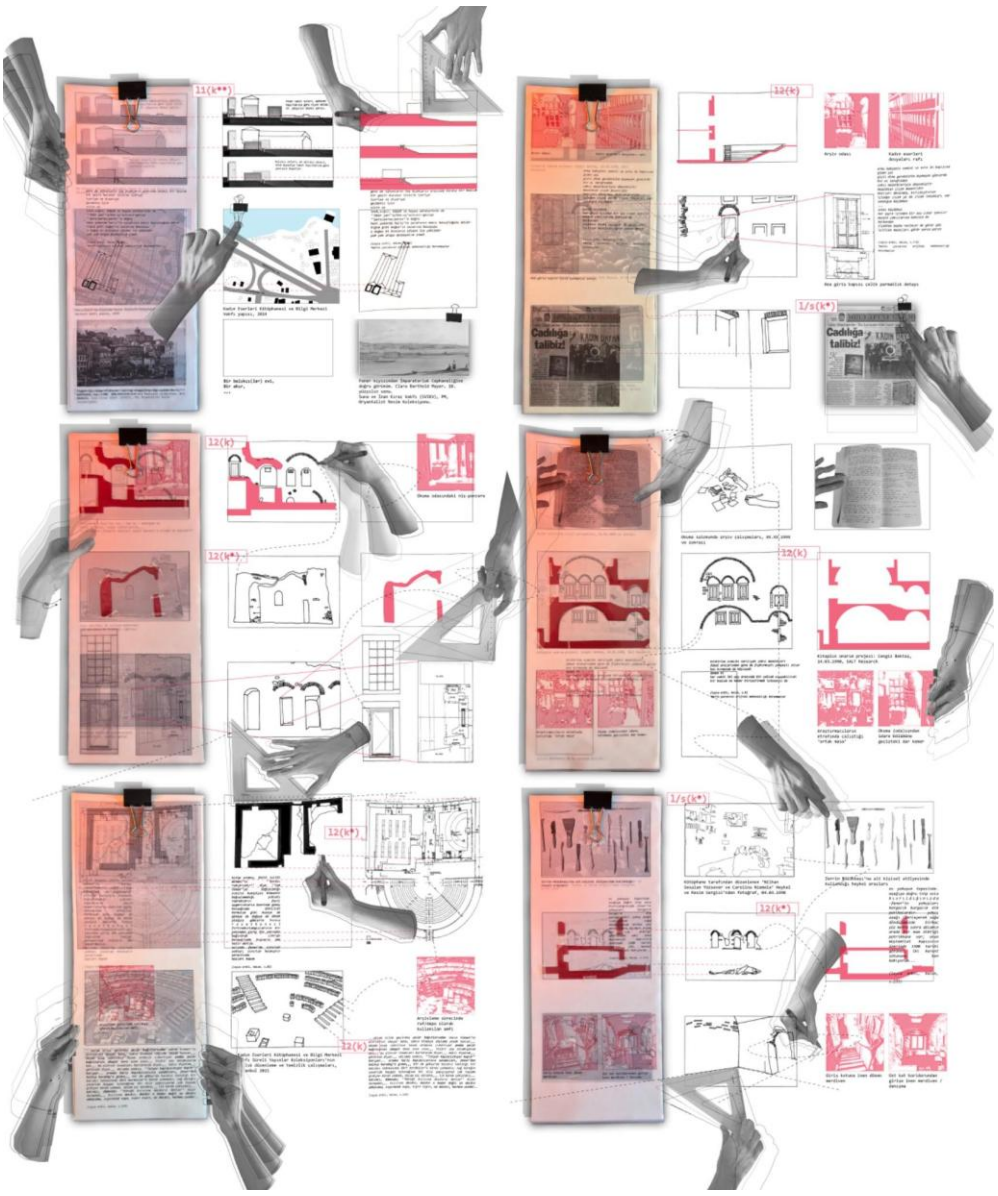

Figure 5. Transcending the Normative Archiving Practices-2 (Rusçuklu, 2025).

Conclusion

Consequently, the paper challenges the hierarchical and static nature of research spaces by proposing a non-human-centered gaze and exploring the entanglement of human and non-human agents in knowledge production. Through feminist-objective knowledge, fiction, and bodily archival practices, the research repositions the archive-library as an evolving laboratory, where spatial and temporal dynamics unfold beyond normative frameworks. By employing a fiction-construction method and mapping bodily interactions, the study demonstrates how alternative representations can reveal the temporality of research space. Ultimately, this approach offers a multi-layered architectural representation that disrupts conventional research methodologies, fostering a more dynamic and inclusive framework.

The Potentialities, Displacements, and Spatial Projections of Concepts

Ümran Aydın[a]

[a] Beykoz University, Department of Architecture, Turkey
umranaydin@beykoz.edu.tr

Keywords: Aesthetics, Conceptualization, Spatial Layer, Spatial Transformation, Tectonics.

Aim

The space, which is both the primary tool and object of architectural production, describes a multi-layered dimension through the elements it contains and the possibilities it provides. In other words, space points to a realm beyond its mathematical boundaries: how do we perceive through the mediation of space? What is the social, communal, and intrinsic knowledge produced by this perception? What potentials and healing aspects does this knowledge bring to the surface? In short, what does space mediate in its purest form, and how, why, and to what end? In order to bring the complexity generated by this question to a reasonable level, space is subjected to a deconstruction within the context of work. This deconstruction is necessitated by the fact that the more we touch space, the more it dares to approach us in the same way; as we alter the space, the space changes us. The first layer of space is unfolded through the existing: it is analyzed through its material and immaterial, real and virtual, physical and atmospheric components. How space provides a foundation and time and the components through which it achieves this are examined. The relationships within the tectonic structure of space manifest themselves in this layer, appearing as a structure, a stage, or a foundation. In the second layer, the perceptual and sensory dimensions of space on the individual are unraveled: perception enables space to produce meaning, here, space is taken beyond mere existence and acquires an aesthetic dimension that can be both learned and felt. The third layer is the meaning-driven knowledge that is unfolded: in this realm, the inputs and outputs of space in the social dimension through power relations, decision processes, agents, and authors are explored. The political potentials of space not only generate knowledge in this layer but also transform and redistribute it. With this tripartite deconstruction, answers are sought to the question of what the possibilities of space are in terms of affect, by weighing the distribution of being, meaning, and knowledge within space. On the other hand, this deconstruction reveals that when space reaches a certain fullness in its tectonic, aesthetic, and political layers, it gains the ability to offer perception, produce emotion, and distribute knowledge. Thus, space assumes an authoritative position.

These deconstructions can be elaborated as follows:

- Ontological-Layer, Tectonic — What exists in space?
- Phenomenological-Layer, Aesthetic — What is the meaning produced by what exists?
- Epistemological-Layer, Political — What knowledge does the produced meaning offer?

Material and Method

The tripartite conceptual deconstruction begins with the meaning code attributed to the material in the tectonic aspect. This corresponds to Semper's (1989) description of the four elements and the harmony it creates with perception. This initiative incorporates an anthropological perspective on the origins of architecture. These four elements, which also allow similar readings in the traces of traditional arts, carry a presentation beyond the pure form of being. In other words, the aforementioned origins, which are not treated materially, trigger certain behaviors and shape communications; on the other hand, they have already emerged from here. For example, the hearth, being central, statically describes the beginning, where people gather, meet, form alliances, and organize; enclosure, by marking a boundary, completes the instinct for protection that inherently thrives within its material presence. For instance, a stone on the sidewalk, beyond its materiality, invites people to stop, wait, and can even become the focus and trigger of a potential conversation. As a cast, space leans on the aesthetic concept with its movements and perceptible states. In this case, aesthetics does not present itself as a form of beauty; it integrates as an experience and a mode of perception into space (Rancière & Gage, 2019). In this way, space

becomes an area where affect and sensation spread. The aesthetic perspective emphasizes the meanings added to an object rather than its materiality (Perniola, 2013). This perspective makes the world perceptible and facilitates the organization of social structures, the shaping of behavioral patterns, and the direction of communication preferences. A simple illustration of this is the paving stone; its materiality invites bodily actions and suggests possibilities.

Rancière's (2019) ideas about the interaction between perception and sensation offer another dimension of the potential enabled by space. Here, the capacity of politics rises, incorporating the interaction between space and body. The micro-decisions space makes about where we will see, hear, or walk evolve into macro-level practical ideas and creative emotions after perception. Aesthetics, by dispersing the senses, can transform social order; its autonomy surpasses issues of representation or expressing knowledge systems. In this way, space becomes a place of organization, presenting a political narrative. Aesthetics is the configuration of experience, and thus, it shakes, wraps, and redistributes knowledge. Decisions made regarding the relationships to be established, the places to be seen, are political, and the state of being observed is hidden within the perceptible stimuli emitted by space (Rancière, 2020). The relationship between aesthetics and epistemology, when considered in the context of space, is fundamental in a philosophical sense, as aesthetics invokes curiosity about knowledge, making it a primary authority. Aesthetics serves as a tool, desire, or curiosity for accessing knowledge of a situation triggered by a spatial condition. This inquisitive nature and questioning of truth position aesthetics at the forefront and allow us to read it through its relationalities (Young, 2019).

Findings

The lexicon, which serves as a tool for expanding the distribution of emotions, focuses on the reflections and potentials of the concept within space. The goal is to gain access to the meaningful role of the concept in the spatial distribution of emotion and its potential within the toolset created by the concept and its selected pool. The main structure of the lexicon is formed by thresholds; the primary support lies on the vertical axis. Thresholds encompass the time, narrative, or event during which concepts undergo transformation. The transformation of concepts here is unveiled through the sub-concepts that describe them. The attempt to bring these hidden transformations of the threshold to the surface is conceptually framed within the sub-concepts of the concept. This section is situated on the secondary supports in the horizontal axis, where the possibilities of the concept intersect with those of space.

Exploratory Framework:

- Main-Concepts: What is the concept that reveals the presentation/possibility of space in the ontological/tectonic, aesthetic/phenomenological, and political/epistemological context?
- Sub-concepts: What sub-concepts open up in the narrative of the main concept?
- Thresholds: How do these sub-concepts evolve in the context of architectural tools and transformations?

The Seyrantepe Auto Industry Complex, designed by Architect Seyfi Arkan in 1957 and completed in 1959, emerges as a significant example reflecting both spatial and economic transformation in Turkey's modernization process. The complex, consisting of 350 workshops and garages, encapsulates modern architecture's clean geometry, modular units, strip windows, and a sense of linear continuity through its original system solutions and typological design approach. Initially conceived as an isolated production area on the northern periphery of Istanbul, the complex has, over time, become a socio-cultural hub as surrounding residential developments and social amenities have expanded. The site has led to the formation of a neighborhood transforming it into a communal space beyond just an industrial site. Today, the Seyrantepe Auto Industry Complex, situated in Istanbul's urban center, holds a significant position due to its architectural elements of group value, social amenities, and contribution to the cultural urban landscape, although its continued existence is threatened by rapid urban transformation in the surrounding area. This situation enables a multi-layered reading of the spatial history of the building and its environment (Bereket & Aydoğan, 2020).

The lexicon that aims to reveal how space mediates the spread of emotional resonance opens the discussion through the Seyrantepe Auto Industry Area. As a collective production space, the industrial site was initially experienced as a place with clearly defined boundaries and a self-contained spatial cycle due to the low density of settlement in Istanbul's northern outskirts when it was established. However, as construction increased in the surrounding areas, various intersections emerged within its boundaries. These transformations in boundaries have, over time, been interwoven with the social and

cultural structures of the era, architectural principles, and environmental mentality, adding new layers to the modern architectural lines. We are presented with various sections and breaking points regarding the transformation of space (Figure 1):

Figure 1. Threshold 1: Environmental Constriction, Main Concepts: Boundary, Encounter, Society.

The initially defined and expansive boundaries of the structure have narrowed, become more permeable, and more complex with the addition of residential areas. This situation has created a new network of interactions, where encounters have increased instead of individual isolation, transforming the social information produced by the structure from a singular and autonomous form into a relational dynamic resembling a neighborhood (Figure 2).

Figure 2. Threshold 2: Integrated Surfaces, Main Concepts: Tectonics, Continuity, Intervention.

The tectonic purity of the structure has fragmented over time with the integration of additional floors, projections, and interventions, adopting a plural and heterogeneous language. These integrations have disrupted the visual and experiential continuity of the space, causing interruptions in perception, and generating a new form of knowledge production that reveals the political and social responses of the structure to interventions.

Figure 3. One of the lexicon page and its description.

The production rituals inherent in traditional craftsmanship have been transformed by modern technological interventions, leading to ruptures in the continuity created by the union of hand, mind, and space. This rupture has altered the trace of spatial production, changing the content of the craftsman's knowledge and evolving into anonymous new production practices. In traditional craftsmanship, the relationship between manual labor and space is strong; every movement and decision holds meaning, and the process operates like a ritual. However, with the influence of technology, these rituals are disrupted, and the direct interaction between manual labor and space diminishes. Instead, production processes become more anonymous, mechanized, and standardized. Technological interventions create a mechanical production process, and the knowledge and experience offered by space also undergo a transformation. This shift allows traditional forms of knowledge to give way to a more industrial and systematic form of knowledge. As a result, the craftsman's personal skill and deep connection to space evolve into a more generalized, colder, and more anonymous form of production (Figure 3).

Conclusion

These thresholds deeply transform the ways in which space mediates the dissemination of emotional experience. Environmental constriction allows for a shift from individual isolation to collective encounters and interactions, breaking down previously distinct boundaries. This reshapes the social context of space, providing emotional transitions and a sense of closeness between layers. Integrated surfaces, through interventions that disrupt the functional and visual continuity of space, blur the boundaries between perception and emotions. These interruptions make the spatial experience more complex, allowing space to begin to be 'written', with emotions shaped according to this writing. Production rhetoric, through the ruptures between technological and traditional practices, transforms the emotional traces and atmosphere created by space. This rupture presents emotional separations and reconnections at each step of the production process, enhancing the depth of the connection space establishes with its users. These thresholds reshape the emotional aspects of the spatial experience, shaking and redistributing previously unobservable, layered, and multidimensional emotional activities within space.

Soft Matters: (Re)drawing Architecture Through Feminist Material Practices

Beyza Nergis Özbek[a], Sıdıka Aslıhan Şenel[a]

[a] Istanbul Technical University, Graduate School, Architectural Design Program, Türkiye

ozbekbe@itu.edu.tr

Keywords: Architectural Drawing, Ecological Creative Practices, Intra-Action, Soft Materiality.

Aim

The paper begins with a desire to investigate the material-semiotic, discursive and corporeal entanglements between tools, bodies and materials in the practice of architectural drawing, entities that are simultaneously assigned to represent, while also being entangled in representation and the matter/environment they inhabit. These interactions are explored through the framework of an ontology of relationality, which posits that selves do not pre-exist drawing but rather emerge within the "intra-actions" they enact (Barad, 2007). Rather than treating drawing as a fixed representational tool, the study approaches architecture as a practice operating within "ecologies of creative practices" (Frichot, 2019) embracing embodiment, material agency and relationality. In this context, it questions the habitual structures of architectural representation and suggests alternative ways of thinking through drawing.

The research unfolds through an inquiry into the limits of architectural drawing encountered while attempting to trace the material, corporeal, and discursive imprints of soft components such as curtains, cushions and fabrics within the Giritli Mustafa Pasha Han, a 19th-century trade inn in Istanbul. The observations made in this inn emphasize the importance of craft practices that resist mass production and the necessity of documenting them with their spatial counterparts. Incoming orders, bodies folding fabrics, the accelerating rhythms of sewing machines, and the transformation of materials into inhabitable forms render space as constantly in mobility. Attempts to document these processes reveal the limitations of conventional drawing tools, leading to the central question: "how can mobility, interiority, soft materiality be represented?". Building on this, the study aims to examine soft components through materials, bodies, and forms of relationality that remain excluded from architectural representations and spatial imaginaries.

Throughout the study, objects such as curtains, cushions, and fabrics are referred to as soft components, a term adopted to foreground their material characteristics, such as lightness and flexibility, and to approach them with what Lloyd Thomas (2007) defines as "material attention". This concept, as defined by Llyod Thomas (2007, p. 5), is a reminder of the need to question "the material as part of a network of forces and actions and a collective rejection of a purely visual (static) contextualization of the material".

Material and Method

A theoretical framework for this study is provided by philosophy of science studies (Stengers, 2010), material-semiotic approaches (Haraway, 1988; Barad, 2007), which emphasize that knowledge objects are generative and their boundaries are illusory and fluid, and agential realism (Barad, 2007), which provides a causal account of how discursive practices relate to material phenomena. This theoretical framework enables a critical examination of architectural production processes by challenging traditional notions of representation and materiality. In order to argue that the object of architecture is only a small part of what constitutes the highly differentiated discipline, architecture is reconceptualized as operating within "ecologies of creative practices" (Frichot, 2019).

The boundaries encountered in the drawing essays open up a relational discussion on how the hard, structural, and measurable historically marking the normative permanence of architecture are intertwined with the soft, ephemeral, and interior. This entanglement raises questions about how they co-constitute one another and how exclusion is maintained. Grounding the argument in the binary oppositions of the hard, structural and measurable, which signify permanence in architecture, versus the soft, ephemeral and domestic, as Haraway puts it, "misrepresents in a critical way the positions of embodied objectivity" (1988, p. 588). With this approach, instead of creating oppositional positions such as soft-hard, permanent-impermanent, inside-outside, the study advocates for a careful reading of the traces of difference created by materials, bodies, tools, and discourses, in order to explore how knowledge is produced, interpreted, and made meaningful. In this context, the study proposes to reflect on the meanings created based on Emmons's (2019, p. 13) claims that "architectural drawings are indexes of construction" for limitations of architectural drawing to incorporate soft components into its representational systems.

As Emmons (2019, p. 13) critiques, the rationalized theory of architectural drawing derived from Cartesianism rejected the implicit embodied approach that was once defined drawing practices. While architectural drawings initially functioned as "iconic indexes" of construction in direct parallel to the building, they have been reduced to abstracted symbols under the dominance of linguistic models (Emmons, 2019, p. 13). In my thesis, I extend the discussion to the corporeal, material and instrumental indexes in drawing, including their soft components, mobility, materiality, and interiority, although this paper focuses specifically on instrumental indexes. Emmons (2019, p. 33) further argues that architectural drawing tools originate in construction tools. However, it is important to recognize that drawing tools are not merely technical instruments to which specific actions are attributed, they also possess "agency". Barad's (2007) proposition of "intra-action" refers to the mutual constitution of entangled agents and challenges the assumption that agents exist as separate individual agents prior to their intra-action. In this understanding, drawing tools are not just extensions of the designer's intention, but as co-constitutive agents that emerge through entanglement with materials, environments and users actively engaged in ecologies of creative practices.

An ecology of practices utilizes tools to think through and with a situation, making sense of what is happening. As Stengers (2005, p. 185) argues,"where we take up our tools for thinking, habit must be resisted" highlighting that the act of passing or receiving a tool creates a meaningful relation between the tool, its user, and the context in which it is applied. Considering drawing as a representational tool that generates architecture through its material-semiotic relationships, and examining the habits embedded in architectural drawing, provides critical insights into how we think and produce with this tool. Emmons (2019, p. 166) explores the relationship between architectural drawing tools and drawing practice beyond a simple matter of instrumentality, embedded in a reflexive relationship that transcends simple subject–object dualism. This approach emphasizes that drawing tools should not be considered passive instruments, but rather as active components within the interplay of relational engagement.

Findings

Drawing tools are also active components in the creative process. In the work titled "Lost in Translation" (Figure 1.), representational experiments were conducted through the remains of an abandoned wooden structure, using the analogy between drawing and sewing. These experiments explored the material interactions into which the tools used during the act of drawing enter, beyond their attributed instrumentality. Drawing attempts that began with an ink pen on the fabric in a fixed position produced various deviations on a smooth surface, while narratives concerning both the fabric and the structure were developed through drawing–sewing methods. The layers of the wooden remnant began to be processed by sewing on the two-dimensional surface, engaging movements of the drawing body, different visual angles toward the wooden forms, and material interactions formed by folding the fabric and stretching the threads.

Figure 1. Lost in Translation, Material encounters beyond instrumentality (Özbek, 2023).

The documentation of the soft components of the inn draws on Evans's (1997) analysis of 18th-century furniture maker's drawings, in which architectural elements are represented orthographically, while furniture and decorative objects, often classified as interior materials, are represented in perspective. These examples highlight opposing positions within representational systems of dichotomies such as interior/exterior, structure/fill, solid/soft. In the representational work conducted at the inn, these dichotomies are challenged through representational deviations that explore the ambiguity of such boundaries (Figure 2.). While the workshops that produce soft components are spatially organized around a courtyard, material movements such as the flow of fabrics, the entry and exit of materials, and the hanging of cloth on the surrounding railings blur spatial boundaries. In this system of representation, collage techniques have been adopted to express the complex spatial entanglements, rather than to depict such binary conditions.

Figure 2. (Re)drawing Soft Components: Plan unfolding as a method for unsettling spatial hierarchies (Özbek, 2024).

While drawing the plan, measurements were made using leftover fabric pieces from the inn's production process and transferred to paper by approximating the proportions of elements captured in photographs. At the same time, the fabric surface itself functioned both as a measurement tool and a tactile documentation medium, recording the textures of surrounding materials. In the documentation drawings of the inn, the bodily actions of a curtain seamstress such as standing on a chair to measure curtain lengths with reference to her own body, hanging a piece of leftover fabric from a railing to

deliver completed orders to the ground floor, placing another piece at the threshold to cover, separate, and soften the passage, or using her favorite golden scissors beside the sewing machine are recorded as part of the spatial interactions of soft components (Figure 3. and Figure 4.). These experiments attempt to trace the complex intra-actions between tools, materials and spatial gestures through the traces of soft components, relationships that are largely unrecognized in architectural drawing practices.

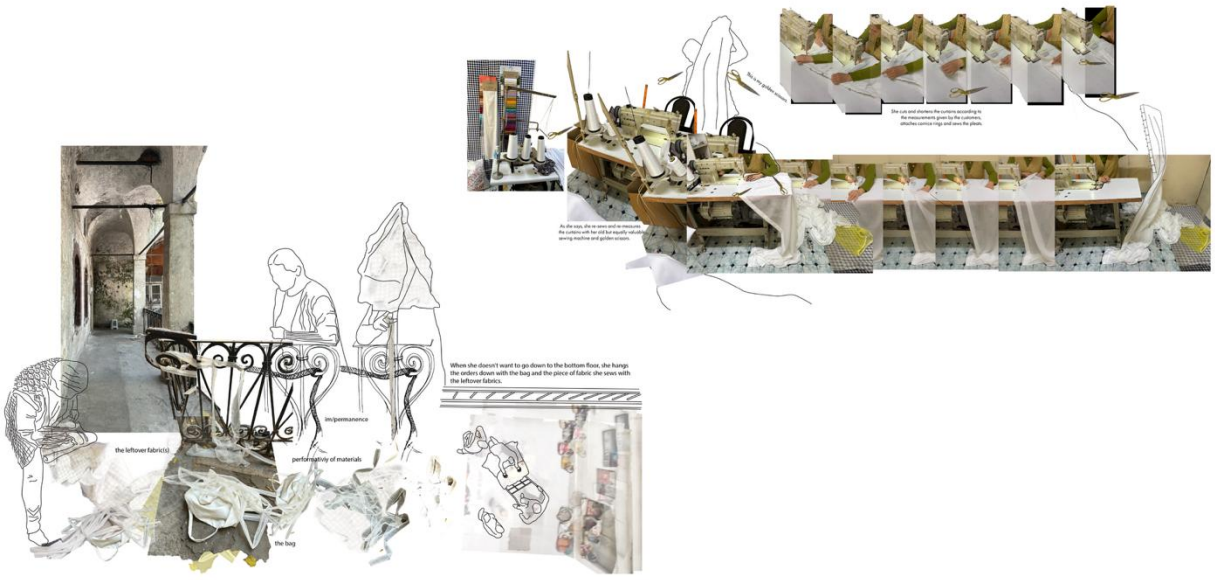

Figure 3. (Re)drawing Soft Components: Tracing mobility and repetition in sewing-based spatial production (Özbek, 2024).

Figure 4. (Re)drawing Soft Components: Everyday soft materialities and improvised spatial arrangements (Özbek, 2024).

Conclusion

While the practice of architecture is constituted in interaction with bodies, materials and tools, addressing the affinities of these components with representation draws attention to the network of material-representational, discursive and corporeal relations that interact with drawing. The possibility of witnessing what systems of representation relate to, their tools and how they function is one of the methods of embodied feminist objectivity (Haraway, 1988).

These habits of representation are deeply embedded within normative structures that sustain specific power relations and ideological assumptions. As Haraway (2016, p. 12) says, "it matters what issues we use to think about other issues; it matters what stories we tell to tell other stories; it matters what knots are tied, what thoughts think thoughts, what definitions define definitions, what ties bind ties". Therefore, questioning the habitual structures of architectural representation is crucial for exploring alternative ways of knowing and making.

The representational attempts (Figure 5.) in this work may be described as fragments of an ongoing research process. The knowledge gathered through different visits to the inn, composed of situated moments and partial narratives as manifestations of drawing, reveals relationships that are not yet fully visible. This study aims to continue the work with mixed media through further experiments that allow for material interaction. The experiments thus far have been shaped by the question of why soft components remain absent from architectural drawings. Architectural drawing, then, becomes not merely a representational technique, but also a critical tool a means of questioning how space, materials, and knowledge are constructed, and who or what is excluded in the process. Rather than assuming that architectural drawing exists solely to construct, this paper proposes drawing as a practice that is relational, speculative, open-ended, soft, partial, and capable of engaging with that which is not yet.

Figure 5. (Re)drawing Soft Components: Fragments of soft spatiality and unfinished stitching (Özbek, 2024).

Keywords: Retrofitting Techniques, Reinforced Concrete Buildings, Environmental Sustainability, Carbon Footprint, Cost-Benefit Analysis.

Aim

It is not possible to rebuild all reinforced concrete residential buildings in earthquake-prone areas due to city conditions. Therefore, strengthening the durability of buildings is of critical importance in terms of ensuring life and property safety. However, since a significant portion of the existing building stock was constructed according to outdated regulations, therefore, reconstruction or reinforcement works are a necessity. Strengthening existing structures has various advantages and disadvantages in terms of cost, sustainability and technical feasibility. This process offers the opportunity to extend the service life of structures and to minimize possible structural risks by increasing their durability. However, each strengthening method creates different economic and environmental impacts depending on the type of material used, labor requirements and long-term performance. In this context, the evaluation of strengthening strategies in terms of their technical adequacy and sustainability is important for the preservation of the existing building stock. This research analyzes in detail the techniques for strengthening reinforced concrete structures with different storey heights. The study aims to determine the most efficient option by comparing the economic and environmental effects of various strengthening methods. The evaluation process focuses on sustainability and durability criteria and takes into account the requirements of international environmental standards and building codes. In this context, it is aimed to develop optimal solutions for the protection and improvement of the existing building stock.

In recent years, the importance of sustainable retrofitting strategies has been increasingly emphasized due to their potential to reduce environmental impact and enhance the seismic resilience of urban areas (Shao & Billington, 2019). Studies suggest that reinforcement practices, when aligned with energy efficiency improvements, can generate significant lifecycle benefits compared to complete demolition and rebuilding (Comerio, 2004). Furthermore, environmental assessments indicate that targeted reinforcement methods often produce substantially lower embodied carbon emissions, especially when recyclable and low-carbon materials are prioritized (Colavitti & Usai, 2015). International guidelines also recommend that such strategies be cost-effective, performance-oriented, and adaptable to varying structural conditions, making them highly relevant for policymakers and urban planners (Kappos, 1996).

Material and Method

The main purpose of this study is to analyze different renovation methods applied in reinforced concrete structures in terms of cost and benefit and to compare them with the reconstruction process. The research considers three different building height groups: (1) low-rise, (2) mid-rise and (3) high-rise reinforced concrete residential buildings. For each group, techniques such as cladding, reinforcement with steel elements, use of fiber-reinforced polymer (FRP) and carbon fiber-reinforced polymer (CFRP), addition of shear walls, bracing with internal or external frames and foundation reinforcement are examined. These analyses are carried out on the basis of field studies, cost estimates and comprehensive literature reviews. The evaluation process is carried out based on international building safety standards such as Eurocode 8, ACI 318 and FIB.

Additionally, carbon footprint analyses of reinforcement techniques and reconstruction processes revealed significant differences in terms of environmental impacts. The indexing system created in line with the obtained data provided a comparative framework for sustainability assessments. In the context of environmental sustainability, examination of green

building certification criteria such as LEED and BREEAM revealed the importance of evaluating the ecological impacts of reinforcement methods. In order to minimize environmental damage, reinforcement strategies should be compatible with international sustainability standards, use low-carbon emission materials and be supported by energy-efficient solutions. With this way, detailed cost analyses were conducted to evaluate the structural performance of reinforced structures under different seismic scenarios, and the amount of carbon footprint was examined in detail, taking into account the production methods of the structural elements used. In this context, buildings were divided into three groups according to their heights and comprehensive calculations were made on the selected structures for each category.

Findings

This research aims to determine the most suitable reinforcement methods for buildings of different heights. In low-rise buildings, lightweight and economical solutions such as jacketing and carbon fiber reinforced polymer (CFRP) applications come to the fore. In medium-rise buildings, the addition of shear walls and the use of steel frame systems have been shown to be more effective in increasing structural strength. In the case of high-rise buildings, the application of foundation reinforcement and steel-supported systems provides the most successful results in terms of preserving structural integrity.

Recent studies have shown that reinforced concrete buildings with irregular geometries may not achieve sufficient structural improvement with standard strengthening methods. Such structures require specially developed solutions instead of generalized strengthening strategies due to irregularities in their load-bearing systems. In particular, it has been determined that methods such as the addition of shear walls and base isolation significantly increase structural strength in buildings with soft story effects. In this context, a unique analysis process is required for each building and detailed engineering evaluations are required to select the optimum strengthening technique.

Cost analyses show that in some cases, strengthening existing structures offers a more economical option than reconstruction, but under certain conditions, demolition and reconstruction may be a more viable solution. In particular, in cases where the costs of strengthening exceed 50% of the costs of reconstruction, reconstruction may become a more economically sustainable alternative in the long term, considering the advantages of increased structural durability and energy efficiency. However, when the production processes of the building materials used, the manufacturing of the elements required for storage, the emissions from industrial facilities, the environmental impacts of logistics activities and the implementation processes of all these elements at the building scale are taken into account, carbon footprint analyses may yield negative results. This situation may require a re-evaluation of a method that is considered advantageous in terms of environmental sustainability.

Carbon footprint analyses show that structural renovation is a more sustainable alternative in most cases, but this effect varies depending on the type of materials used. In general, renovation practices are associated with lower natural resource consumption and reduced greenhouse gas emissions compared to reconstruction. However, the environmental advantages of renovation can be significantly reduced when high-carbon materials such as steel and concrete are used. According to international environmental standards, the preference for recyclable and low-carbon materials increases the sustainability potential of renovation processes. For instance, composite materials such as FRP and CFRP, although they require high energy consumption in the production stages, can provide long-term environmental benefits by extending the service life of structures.

In addition, studies show that energy efficiency improvements can be integrated with structural renovation processes. In particular, the implementation of modern facade designs that increase insulation systems and thermal performance can contribute to the reduction of operational carbon emissions. Such improvements can make renovation methods more advantageous in terms of sustainability, providing both environmental and economic benefits in the long term.

Conclusion

Studies have shown that the most appropriate reinforcement methods vary depending on the height of the building and its current structural condition. While lightweight and easy-to-implement solutions are preferred for low-rise buildings, comprehensive and durability-enhancing reinforcement techniques are needed for taller buildings (Table 1). Cost-benefit analyses show that reinforcement is economically advantageous in some cases, while reconstruction offers a more suitable

solution in terms of long-term durability and sustainability for certain buildings. These analyses show that when reinforcement costs remain at approximately 50% of the reconstruction cost, reinforcement methods are a more rational option. However, when reinforcement costs approach the reconstruction cost, reconstruction becomes more advantageous in terms of longevity and energy efficiency.

In the context of environmental sustainability, reinforcement techniques generally result in lower carbon emissions, but the production processes of the materials used may increase this effect. The use of materials that comply with international environmental standards and are recyclable increases the sustainability of reinforcement methods by reducing the environmental burden caused by construction processes. In addition, integrating seismic reinforcement works with energy efficiency-enhancing measures can significantly improve the overall sustainability performance of buildings. In particular, the use of advanced insulation systems and high-performance façade technologies can contribute to minimizing environmental impacts throughout the building life cycle by reducing operational carbon emissions.

As a result, a holistic approach to evaluating cost, benefit and carbon footprint analyses reveals the need for a decision support system that will determine the most appropriate retrofit method for building owners and engineering firms. This system determines the most effective methods for different building types, allowing the implementation of the most economically and environmentally sustainable solutions. This decision support tool, which will be developed using mathematical modeling and formulation-based approaches, can support scientifically based decision-making processes for urban planners, architects and policy makers by providing real-time evaluation of various retrofit and reconstruction scenarios.

Table 1. Earthquake Resistant Concrete Structures (Kappos 1996).

TECHNIQUE	INITIAL COST LEVEL	DURABILITY IMPACT	CARBON FOOTPRINT	MATERIAL SOURCEABILITY
Steel Jacketing	High	High	High	Moderate
FRP/CFRP Wrapping	Moderate	Moderate-High	Low	Moderate-High
Shear Wall Addition	Moderate-High	High	High	Easy
Base Isolation	Very High	Very High	Moderate	Limited
External Bracing (Steel Frames)	Moderate	Moderate-High	Moderate	Moderate

Evaluation of the Seismic Performance of Traditional Akçakese Houses in Relation to Structural Deterioration

Zeynep Dikyer [a], Caner Göçer [b]

[a]Istanbul Technical University, Graduate School, Environmental Control and Construction Technologies, Türkiye
[b]Istanbul Technical University, Faculty of Architecture, Department of Architecture, Türkiye
dikyer22@itu.edu.tr

Keywords: Earthquake, Timber-Framed Structures, Akçakese Houses, Wattle And Daub Wooden Houses, Timber Structure Deterioration.

Aim

Turkey's location in a high seismic risk zone makes the preservation of traditional buildings and cultural heritage in regions along active fault lines a critical issue. Traditional residential buildings in Anatolia, constructed with timber-framed structural systems over generations, not only reflect local architecture and craftsmanship but also contribute to the sustainability of historical, socio-cultural, and economic structures (Göçer & Erarslan, 2020; Arun, 2012; Gündoğan, 2018). Preserving such buildings is of great importance not only in terms of aesthetics but also in ensuring the transmission of architectural heritage to future generations.

The traditional houses located in the Akçakese village of Şile are characterized by their wattle and daub infill technique and possess unique architectural features that are well adapted to the region's climate, geography, and locally available materials (Göçer & Erarslan, 2020). Chestnut wood, which is abundant in the region, has been used as the main material for the timber frame, contributing to the lightweight and flexible nature of these structures (Figure 1). Over time, however, these buildings have deteriorated due to environmental factors, leading to various structural damages. As a result, their overall structural integrity has begun to decline. Especially in the face of sudden and severe natural disasters such as earthquakes, these structural weaknesses pose a significant risk. Furthermore, the preservation of these buildings should not be viewed solely as an aesthetic or cultural concern but as an essential component of disaster risk reduction strategies within communities. With ongoing urbanization and the dominance of modern construction techniques, the conservation of traditional buildings has become increasingly challenging. Many such houses have been abandoned due to neglect. At this point, evaluating the seismic performance of traditional Akçakese houses becomes a crucial topic for scientific inquiry, as it contributes both to maintaining historical continuity and minimizing the potential impacts of future earthquakes.

Figure 1. Traditional Akçakese Houses, Göçer C.

The primary objective of this study is to comprehensively evaluate how the seismic performance of traditional timber-framed houses in Akçakese village has been affected over time due to deterioration caused by atmospheric and other

environmental factors. Within the scope of the study, the original construction techniques, material properties, and the wattle and daub infill system employed in these structures were thoroughly examined. Furthermore, an estimation was made regarding the seismic behavior of these buildings by considering the structural degradations that have occurred over time.

Material and Method

The materials utilized in this study include literature reviews, archival photographic documentation, and on-site observations. In order to understand the structural anatomy of the buildings, the durability of the materials used, the quality of the joints at connection points, and the deterioration that has occurred over time were analyzed in detail. Additionally, traditional buildings that sustained damage during past earthquakes were examined, and comparative assessments were made with the structures under study (Bozkurt, 2018).

As a methodological approach, the study evaluates the deterioration of traditional timber structures over time and assesses how these deteriorations compromise their resistance against seismic loads under current conditions. Initially, a comprehensive literature review was conducted on similar buildings in the region, followed by an examination of the observed damages. The types of damage, causes of deterioration, and structural weaknesses were thoroughly analyzed to identify vulnerabilities in the load-bearing systems. Throughout this process, the progressive degradation of timber elements and its influence on the seismic performance of the buildings were systematically evaluated.

Findings

Based on a literature review, the damages observed in traditional timber structures during the 1970 Gediz (Kütahya) earthquake, the Afyon (2002), Bingöl (2003), and Erzurum (2004) earthquakes, the 1999 Marmara (Kocaeli) earthquake, and most recently, the February 6, 2023 earthquakes centered in Pazarcık and Elbistan districts of Kahramanmaraş, have been examined. The analysis focuses on the type and causes of damage according to different structural classifications of traditional wooden buildings.

Figure 2. A rusty building damaged in the Gediz Earthquake, Güçhan, 2005.

The first image presents an observation of a traditional hımış structure damaged during the 1970 Gediz Earthquake. In this case, the lack of adequate connection elements between the structural systems prevented effective interaction between the building and the adjacent structure. This deficiency resulted in what is known as the "pounding effect," caused by the stiffness difference and pendulum-like movement between neighboring buildings during seismic excitation. The lightweight and flexible nature of the hımış structure rendered it

insufficiently resistant to such lateral impacts; the absence of proper connections led to displacement or damage of the exterior walls. This case serves as a significant example underscoring the importance of structural connections and adequate spacing between adjacent buildings in traditional architecture (Figure 2).

Figure 3. Partially demolished Timber-framed structure with infill, Aksoy D., Ahunbay Z.

The second image illustrates significant material degradation of the structural elements due to prolonged exposure to atmospheric conditions such as rain, humidity, temperature fluctuations, and UV radiation. In particular, biological deterioration—including decay, fiber separation, and loosening—has occurred in the wooden beams and columns located beneath the oriel (projecting bay) that supports the overhanging section on the exterior façade. This degradation process has led to a reduction in the structural load-bearing capacity, ultimately resulting in the failure and collapse of the oriel. In traditional buildings, when proper maintenance and protective measures are not implemented, wooden elements tend to lose their structural integrity, posing a serious threat to the overall safety of the building (Figure 3).

Figure 4. Demolished Timber-framed structure with infill, Göçer C., 2023.

The third image depicts a traditional hımış structure that sustained severe damage during the 2023 Kahramanmaraş Earthquake. It is observed that the external walls, particularly in the short direction, collapsed out-of-plane and separated from the main structure. Such a failure typically results from the insufficient stiffness of the infill material (adobe or brick), lack of composite action between the frame and the infill, and weakness

at the connection points. The image clearly shows not only the disintegration of the infill but also the failure of some joints within the timber frame, indicating a loss of structural integrity in the load-bearing system. This case reveals the inherent weaknesses of traditional construction systems in terms of seismic performance and highlights the necessity of reevaluating their behavior under lateral forces (Figure 4).

When reviewing past earthquake damage cases, it can be stated that Akçakese houses, built with chestnut timber known for its lightweight and flexible properties, exhibit a degree of resistance to earthquakes under normal conditions. Timber displays a ductile behavior under seismic loads, enabling energy dissipation and resulting in less damage compared to heavy masonry structures (Tomaževič, 1999; Ceccotti, 2008). Moreover, the wattle and daub infill system contributes to seismic resilience by providing a lightweight and flexible wall structure. However, it has been identified that over time, environmental factors have caused deterioration in various structural components. Timber elements have been found to decay, loosen, crack, or deform due to moisture, temperature fluctuations, and other external influences (Figure 5). Failures and loosenings in timber joints further compromise the overall stability of the building. Additionally, it has been observed that the mortar used in the infill has fallen off, negatively affecting the structural continuity of the walls.

Figure 5. Rotten wooden structural element detail, Göçer C.

The load-bearing systems of these houses are composed of timber members connected to each other primarily through nailing techniques. However, the absence of reinforcing components such as steel wedges or triangular wooden blocks at the joints results in weakened connection points. In order to mitigate this weakness in the walls, diagonal braces were implemented between the main vertical posts and bottom beams. These braces increased the in-plane stiffness of the walls and improved their seismic performance under lateral earthquake loads (Figure 6).

In addition to the braces, timber cladding panels made of chestnut wood also contributed to the structural behavior by acting as rigid diaphragms during seismic events, thus enhancing the overall stability of the buildings under horizontal loading (Figure 6). Field observations revealed that due to material degradation, some brace connections had loosened, and partial detachment of façade cladding was also identified. These forms of deterioration negatively affected the seismic performance of the structures.

Figure 6. Buttress and wood cladding detail, Göçer C.

In traditional masonry structures, the deterioration and cracking of the mortar binding the stone blocks due to atmospheric effects over time have resulted in a significant reduction in lateral stiffness. Particularly, intense rainfall and freeze–thaw cycles have caused erosion of the mortar joints in stone walls, leading to partial collapse in some structures. As a consequence of such deterioration, these buildings have become increasingly vulnerable to horizontal seismic forces.

Conclusion

The deterioration of Akçakese houses due to environmental effects negatively impacts their earthquake resistance. Although the lightweight and flexible structural system offers certain advantages under seismic loads, material degradation, weakened connections, and deformations in load-bearing elements compromise this advantage over time. Therefore, a scientifically grounded and conservation-conscious approach must be adopted in restoration practices to protect these structures from ongoing environmental damage.

First, structural components affected by deterioration should be identified and documented. Then, in accordance with conservation principles, repairs and reinforcements should be performed using timber materials of similar species. Strengthening of timber joints, replacement of decayed members, and reinforcement of critical load-bearing elements will enhance the long-term durability of the structures. Moreover, combining traditional building techniques with modern engineering principles in accordance with restoration ethics will not only preserve the authenticity of these buildings but also improve their seismic resilience.

It is essential for local authorities, academic institutions, and civil society organizations to collaborate and develop policies aimed at preserving traditional buildings. While the current Turkish Seismic Code provides comprehensive regulations for reinforced concrete and steel structures, expanding its scope to include timber structures is of great importance. Timber, with its low weight and inherent flexibility, can offer superior seismic performance, yet without proper design and construction standards, it may fail to meet expectations. Therefore, the seismic design provisions should incorporate detailed engineering assessments for timber buildings, standardized connection details, and robust material performance criteria.

In conclusion, preserving and strengthening the traditional timber houses of Akçakese is not only vital for transferring cultural heritage to future generations but also critical for ensuring public safety. The conservation of these structures contributes not only to the continuity of tangible heritage but also to sustainable local development.

Evaluation Of Light Steel Structured Housing According To Construction Systems

Burçin Fırtına[a], Caner Gocer[a]

[a]Istanbul Technical University/Graduate School, Architecture, Environmental Control and Construction Technologies, Turkey
firtina22@itu.edu.tr

Keywords: Light Steel Systems, Industrial Construction Systems, Residential Construction System, Building Construction Methods.

Aim

Light steel bearing systems, which emerged in the USA and Europe in the mid-20th century and whose production accelerated especially in the housing sector in North America after the 1970s, are one of the innovative construction systems increasingly preferred in today's construction sector. The system, which is based on the method of assembling coating materials on a carcass skeleton consisting of cold-formed light steel galvanized profiles, has various advantages over other traditional construction systems. Due to its basic features such as reducing the weight of the building, accelerating the construction process, continuity of the quality control system originating from industrial production and being made of recyclable materials, it provides various advantages such as cost effectiveness, energy efficiency, earthquake resistance and minimizing errors. Light steel structured housing constitutes the most common area of use. It offers an important opportunity to meet the increasing housing need, especially in cities, in a fast, economical, high-quality and sustainable way. (Harini et al., 2020; Veljkovic& Johansson, 2007)
The aim of this study is to examine in detail the different construction systems of light steel structured housing, to reveal the differences of these systems in terms of architecture, structure and economy, and to make a comparative assessment to determine the most suitable construction system that meets certain needs.

Material and Method

The data used in the research is based on literature review, sector research and field observations. This data was evaluated through qualitative and quantitative analysis; parameters such as cost, durability, time, energy efficiency and sustainability of different construction systems were examined comparatively. In the analyses, cold-formed galvanized light steel profiles, coating materials and insulation materials, which constitute the main materials of light steel structured housing structures, were evaluated.

Figure 1. Light Steel Framed Housing (Url-1).

Findings

Three different systems are used as a construction system in the production of light steel structured housing: linear (frame or rod) systems, panel systems and modular (cell) systems. (Ekinci, 2006; Yıldırım, 2010) In linear systems, horizontal and vertical carrier elements pre-produced in the factory are brought together on site to form carrier components. The production of linear systems is based on the construction site; The assembly phase is taken into consideration more than the production phase. In panel systems, structural elements such as floors and walls, which have been pre-installed in a factory, are transported as a whole or in parts and directly to the application area and assembled in a short time. Walls and floors can be manufactured as a single piece or as multi-piece modules. Panels can be brought to the construction site as a frame with one side coated, two sides coated or uncoated. The system based on the principle of producing the parts of a structure in the size of the space and then assembling them on the construction site is called the cellular system. This system, which emerged as a result of the development of linear and panel systems, has a high production percentage level in the factory. The structural working principles of the system are the same as the light steel frame system. However, each unit forms a rigid frame within itself. The structural rigidity of the building system is provided by the combination of the units. In the cell construction system, the units are in the form of "closed cells" or "open cells". In closed modular cells, all sides of the unit are completely limited and the space size is determined. The size of the cell is limited by the possibility of transportation. The width of the cells can be as much as the traffic laws allow during transportation by road. In this case, the length of the modules in one direction should not be more than 2.40 m. or 3.30 m. Since the space dimensions will be dependent on this width, it is generally more suitable for residential buildings. In open cells, the cells are not completely limited. The limited sides can be a load-bearing wall or a load-bearing interior wall. The unrestricted side of the cells allows for a larger space to be created by merging with the other cell. The purpose of this is to facilitate the transportation of the modular cell or to provide planning flexibility starting from a unit space consisting of a single cell module to large spaces formed by a large number of combined cells. Compared to linear and panel systems, the cellular system provides a large amount of labor and time savings during the assembly phase, although the production process in the factory is longer. As we move from linear systems to module systems, the level of industrialization increases, the production process in the factory is extended while the assembly process on the construction site is shortened.

Linear systems are more advantageous than other production types in terms of providing design flexibility and being able to cover wider openings. Linear systems are preferred in residential projects where flexibility of use, special designs and larger openings are required. However, due to the large number of assemblies on the construction site, the construction period is long and the rate of being affected by seasonal conditions is high in linear system housing production. Since it is the production type with the longest construction period, labor and construction site costs are also the highest. Thanks to its lightness and elements developed against earthquake loads, the linear system has at least as high resistance properties as other systems. At the same time, it is the most disadvantageous of all systems in terms of quality control processes. Panel systems have more flexible design opportunities compared to modular systems. The construction site process is shorter and labor costs are lower compared to the linear system. Transportation costs are more advantageous when compared to the modular system. High energy efficient detail solutions are possible. It has high durability performance with appropriate detail solutions. Thanks to prefabrication processes, material losses are lower and the quality control process is more effective compared to linear systems. The most important advantages of modular (cell) systems are the possibility of assembly in a short time, controlled production in a factory environment, reduced labor costs and low material losses. It is preferred in terms of time and cost in mass housing production, especially in post-disaster situations that require rapid production. The most important disadvantages can be seen as the high transportation costs and the logistical difficulties in transporting large modules and the flexibility limitations in the design. It has high performance in terms of durability, low material losses and a production system with high energy efficiency are important in terms of sustainability.

Conclusion

Research findings have shown that light steel structures are more resistant to earthquakes due to their lighter weight than traditional building systems. It has been determined that these systems reduce material loss and accelerate the construction process thanks to continuous quality control mechanisms. (Vitale et al., 2018) At the same time, it has been determined that

thanks to pre-production, significant time savings are achieved in production and assembly processes, but initial investment costs can be higher in some cases compared to traditional structures. In terms of energy efficiency, it has been observed that light steel construction systems can show high performance with the right insulation and insulation details. Using appropriate materials and producing effective detail solutions to ensure sound insulation and fire resistance can make the use of light steel construction systems, especially in residential structures, widespread. As a result, each production type can be more advantageous for certain usage scenarios. While cellular systems are an ideal option for residential projects that require fast and mass production, panel systems offer more flexible and economical solutions. Considering the advantages and disadvantages of these different systems, the most suitable production type should be selected depending on the project requirements.

Evaluation of Damage Mechanisms in Stone Structured Houses Due to Earthquakes

Sarvin Iravani Ghadim[a], Caner Göçer [a]

[a] Istanbul Technical University, Graduate School Institute, Environmental Control and Construction Technologies Program, Türkiye
ghadim22@itu.edu.tr

Keywords: Earthquake, Masonry Buildings, Earthquake Damage, Earthquake Damage Assessment, Stone Structures.

Aim

Turkey and its surroundings are tectonically very active and are located in the Alpine-Himalayan earthquake zone, one of the most important earthquake zones in the world. There are many fault lines in this region between the Anatolian plate, Eurasian and African plates. Masonry stone structures, especially those located in rural areas, come to serious damage during these earthquakes. At least one earthquake with a magnitude between Mw=5.0-6.0 occurs every year (AFAD 2025; Bikçe, 2017).

More than 100,000 people have lost their lives due to the devastating effects of earthquakes in Turkey in the past 60 years. 269 earthquakes have occurred in Turkey since 1900, causing loss of life or damage. The largest earthquakes in terms of loss of life are the 2023 Kahramanmaraş, 1939 Erzincan and 1999 Gölcük centered Marmara Earthquakes, respectively. Throughout the historical process, major earthquakes have occurred in the Aegean Sea and its surroundings. These earthquakes are, respectively, 1688 Izmir, 1739 Foça, 1778 Izmir, 1865 and 1867 Lesvos Island, 1880 Samos Island, 1883 Çeşme, 1899 Izmir, 2014 Gökçeada, 2017 Lesvos Island, and 2020 Samos Island Earthquakes (Güleç, 2023).

Stone masonry structures are traditional construction systems that commonly used in rural and historical regions of Turkey. In addition to their cultural and historical value, buildings constructed with stone material also ensure the effective use of local materials (Olğun & Karatosun, 2019). Ensuring the sustainability of architectural heritage is an important issue, considering that until the 1970s, stone was widely used as a structural material in building construction in rural areas of Turkey. After the 1970s, the increasing population and rising land costs led to the widespread construction of multi-story buildings and the use of fast construction systems. Accordingly, the construction of buildings with reinforced concrete skeleton structure systems has has become more dominant. Stone-structured buildings, often constructed without engineering services, suffer severe damage even from moderate earthquakes (Binici & Yakut, 2010). Therefore, evaluating the damage mechanisms caused by seismic effects in stone buildings is of great importance.

In this study, the effects of earthquakes that occurred in the last 50 years in Türkiye and its surroundings on stone-structured houses were analyzed and the resulting damage mechanisms were evaluated.

Material and Method

Within the scope of this study, the evaluation of damage mechanisms in stone masonry residential buildings due to the effects of moderate and large earthquakes in Turkey and its surroundings has been conducted based on literature data. First, the types and degrees of damage were identified, and then the possible causes of these damage types were evaluated. The number of stories, architectural plan characteristics, structural system, interior wall materials and system, type, form, and size of the stone material, masonry system, and mortar used in the masonry system were among the elements that were taken into consideration when conducting the assessments. Possible causes of damage associated with different damage types were identified and evaluated based on literature data, Turkish Earthquake Code (TEC), and comparative analysis principles.

Findings

The effects of past earthquakes have shown that stone masonry structures exhibit five different levels of damage: slight damage, moderate damage, severe damage, partially collapsed, and completely collapsed. In "slightly damaged" buildings, the types of damage observed include vertical fine cracks in the load-bearing interior and exterior walls, as well as diagonal fine cracks at the corners of door and window openings. Cracks defined as "thin" have a width of less than 10 mm. In slightly damaged buildings, stone fragmentation and dislodgement have been observed in the upper sections of chimneys. In the chimney areas of the exterior wall, some stones have detached from the thinned wall section. The vertical and diagonal cracks in "moderately damaged" buildings are 10 to 25 mm wide.

In buildings with the same damage level, the load-bearing wall is observed to have thinned due to stone detachment in the parapet below the window opening and the lintel area above it. In cracks wider than 25 mm, separations within the wall plane are observed. This condition elevates the damage level to a destructive category classified as "severe." Another type of damage seen in "severely damaged" buildings is the out-of-plane overturning of the exterior wall. In damage levels defined as "partially collapsed," the out-of-plane overturning of the exterior wall has occurred in two directions. As a result, it has been found that the wooden roof structure in buildings with the same damage level has also partially collapsed. In two-story buildings, along with out-of-plane overturning damage, partial fragmentation damage has been observed in the wooden construction floors and interior partition walls. Buildings with a damage level of "complete collapse" have been rarely detected (Figure 1).

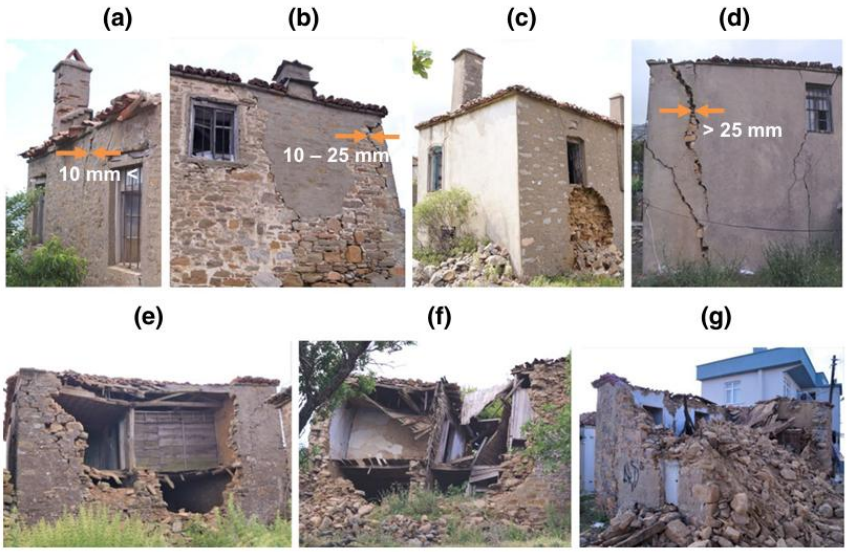

Figure 1. Building examples of the masonry structure according to the level of damage: a slightly damaged, b, c moderately damaged, d, e heavily damaged, f, g partially collapsed, (Göçer, 2020).

Conclusion

Evaluating the causes of the damage types based on the damage levels listed above is crucial both for strengthening the existing building stock with similar characteristics and for taking the necessary precautions in new constructions. In slightly damaged buildings, when the direction of the earthquake force is parallel to the wall, diagonal cracks occur, while horizontal and vertical cracks appear when the force is perpendicular to the wall. Cracks have occurred in high-tension zones. Shear stress, which occurs perpendicular to or along the plane of the wall, is the cause of the diagonal cracks that have developed at the corners of door and window openings.

The form of the stone blocks in the load-bearing wall, irregularities in the masonry system, and the lack of lintels on the load-bearing walls have caused vertical plane separations at some of the exterior wall corner joints due to the effects of the earthquake. According to the TEC (2018), there are certain limitations and dimensional characteristics for masonry structure

systems. According to the TEC (2018), in masonry buildings, reinforced concrete lintels must be applied at each floor level of the load-bearing walls, with a minimum width equal to the wall and a height of 30 cm.
Additionally, to ensure the "rigid diaphragm effect" in masonry buildings, the floor system must be made of reinforced concrete with a minimum thickness of 10 cm. At the junctions of exterior walls, stresses caused by horizontal forces become concentrated. No damage has been observed at the wall corners where large rectangular stone blocks are used. However, separation damage has occurred in some corner joints due to the use of smaller-sized stones. In buildings with lintel beams at intermediate levels, such damage is generally not observed. Another reason for this type of damage is the inadequate shear strength and wear resistance of the earth mortar that binds the stone blocks together.
In buildings with plastered exterior surfaces, protecting the mud mortar from water and moisture helps prevent a reduction in the mortar's strength. In structures with similar design features, where the masonry system uses cement mortar, the load-bearing walls generally show little or no damage, with only fine cracks that can be defined as slight damage.
In partially collapsed buildings, the main causes of the destructive effects can be listed as the absence of rigid lintels at the floor and roof levels of the load-bearing exterior walls, the use of rubble stone in the wall components, the non-homogeneity of the stone block size, the irregular masonry system, the low ductility of the mortar in the masonry system, and the presence of wooden construction for the interior partition walls.
In some buildings, due to the weak connection between the stone exterior wall and the wooden interior wall on the upper floors, the unsupported length of the load-bearing wall has been observed to reach levels of 6.00 - 8.50 meters in plan. This value exceeds the limit specified in the TEC (2018) (maximum 5.50 m). Destructive damage has also occurred due to the unidirectional load transfer of the wooden construction floor and roof structure. In the case of a floor and roof system that exhibits rigid diaphragm behavior, it can be said that the out-of-plane overturning of the exterior wall would be prevented.
Complete collapse damage in stone-structured masonry buildings due to earthquake effects is rarely observed. The main reason for this is the inflexible behavior of the non-homogeneous and brittle wall system.
The formation of damage mechanisms varies depending on the number of damage causes, plan characteristics, and certain structural features. According to the plan characteristics, an increase in the length of the unsupported load-bearing wall has led to the development of more destructive damage mechanisms in residential buildings.
In general, the lack of engineering services and the construction of most stone buildings in rural areas without supervision according to TEC principles are significant factors in the formation of destructive damage. The results of evaluating the damage mechanisms in stone-structured masonry buildings due to the effects of medium and large earthquakes in Turkey and its surroundings are important for the assessment of similar buildings under earthquake threat and for taking necessary precautions.

Impact of Deterioration Due to Environmental Factors on Seismic Performance of Traditional Timber Buildings in the Historical Peninsula in Istanbul

Abdüllatif Sarıkaya[a], Caner Göçer[b]

[a] Istanbul Technical University, Graduate School, Environmental Control and Construction Technologies, Türkiye
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Türkiye
sarikayaab@itu.edu.tr

Keywords: Timber Structure, Seismic Performance, Architectural Heritage, Traditional Architecture, Deterioration in Timber Buildings.

Aim

The Historical Peninsula is one of the key centers of Istanbul's cultural and historical heritage. The peninsula is included on the UNESCO World Heritage List. It is located within the administrative borders of Fatih district in İstanbul, at present. The Historical Peninsula is often referred to as "Sur İçi" (Inside the Walls). The peninsula is surrounded by the Sea of Marmara to the south, the Golden Horn to the north and the districts of Zeytinburnu and Eyüp to the west. Due to it is bordered by water on three sides, strong city walls were built throughout history to protect it. The land walls between Yedikule and Ayvansaray are still exist and have an important role in protecting the historical identity of the area. The area is significant for its civil and monumental buildings from both the Byzantine and Ottoman periods. This makes the peninsula an important place within the scope of global cultural heritage. Timber structures exhibiting characteristic features of traditional residential architecture possess significant architectural and historical value. Because of that, these structures are essential elements that require protection (Seçkin, 2012). These timber structures are not only important for their design but also for their symbolic meaning. These buildings reflect traditional construction techniques and give information about the craftsmanship, material choices and daily life of humans. These structures are seriously damaged because of environmental factors over time. Timber is sensitive to temperature and humidity changes, air pollution and damage from living organisms. This makes it risky to preserve these buildings for a long time (Wang et al., 2018; Lanata, 2015). This study aims to assess the long-term effects of environmental factors on the load-bearing elements of traditional timber buildings within Istanbul's Historical Peninsula, a site of significant architectural heritage. Focusing on how environmental deterioration compromises the seismic performance of these structures, the study offers preliminary recommendations to support the preservation of their structural integrity and architectural legacy.

Material and Method

In this study, the deterioration of traditional timber structures in Istanbul's Historical Peninsula, caused by environmental factors, was examined through fieldwork, on-site observations and a comprehensive literature review. An initial field survey was carried out across the Historical Peninsula to gain a general understanding of the condition of traditional timber buildings. Following this preliminary assessment, 24 buildings were subjected to detailed analysis. These buildings were selected based on visible signs of deterioration, such as material deformation, surface wear, and color changes. The common types of deterioration were identified during the study. A detailed assessment was then conducted to examine the relationship between environmental factors such as humidity, temperature fluctuations and air pollution. The impact of biological agents on the observed damages was also evaluated. The findings from the fieldwork were documented and compared with existing studies in the literature to highlight any recurring patterns of deterioration and to establish a deeper understanding of how environmental factors impact the structural integrity of these buildings. Furthermore, historical documents and previous research were reviewed to analyze how these buildings have withstood or succumbed to environmental conditions over time. This historical perspective allowed for a better understanding of the long-term effects of environmental stress on timber structures. The study also explored the impact of these deterioration processes on the earthquake performance of the buildings. The weakening of structural elements due to environmental damage was assessed

based on the collected data, taking into consideration both the current state of the buildings and their historical resilience to such factors. Lastly, based on the observations and the analysis of the deterioration processes, suggestions for conservation strategies were proposed. These recommendations aim to improve the sustainability and seismic resilience of these historic timber structures, emphasizing the importance of regular maintenance, moisture control, and the use of appropriate materials for restoration. The goal is to provide a comprehensive approach to the preservation of these culturally significant buildings, ensuring their longevity and structural safety in the face of environmental challenges.

Findings

Timber structures located in the Historical Peninsula are exposed to physical, chemical and biological deterioration over time as a result of environmental factors. These damage processes cause the structural parts to change shape. They also weaken the load-bearing system and reduce the overall strength of the structure. Among the primary factors directly influencing the durability of these timber buildings are humidity, temperature fluctuations, atmospheric pollutants and biological organisms (Yagci and Mazlum, 2016). Rain, snow, hail and frost cause physical damage to timber, leading to cracks, surface erosion and color changes. Because timber absorbs moisture, changes in humidity cause it to swell or shrink, which reduces the strength and stability of the load-bearing parts. Long exposure to sunlight causes the timber surface to lose its color and makes the fiber structure weaker over time. Chemical damage in timber structures is linked to air pollution and harmful gases like sulfur dioxide (SO_2) and nitrogen oxides (NO_x). These react with the timber and reduce its strength. This problem is worse in the peninsula because of increased pollution and traffic. Biological damage happens because high humidity helps fungi, insects and microorganisms grow, harming the timber. While they enter the building, water and moisture are big risks causing the timber to absorb water, deform and weaken.

Poor insulation, bad drainage, ignored condensation and hidden plumbing leaks make timber more open to fungi. If facade and roof damage are not repaired soon, the damage spreads to the load-bearing parts. Decay is common in parts like studs, sills, braces, floor joists and claddings, while metal fasteners usually suffer corrosion. This weakens the load-bearing system, making the building structurally deficient. To reduce moisture damage, moisture sources inside should be found and removed, timber parts dried well and timber kept away from damp surfaces. Proper insulation should be used to protect timber from moisture. In the traditional timber buildings of the historical peninsula, structural damage typically originates from deformations occurring in the roof covering and the failure to repair these deformations in a timely manner (Figure 1). The loss of the roof's functionality allows rainwater to infiltrate the structure. This situation accelerates moisture-induced deterioration in the timber load-bearing elements. Other components of the structure are subjected to various forms of damage. Moreover, the loosening of timber joints leads to the separation of structural elements. When this process continues without intervention, partial collapses have been frequently observed. Many buildings in the area have suffered complete structural failure over time because they were not properly maintained (Günay, 2007).

Figure 1. Inappropriate roof coverings.

Traditional timber frame systems are flexible and have some advantages in earthquakes. However, long-term exposure to weather weakens the connection points of the structural parts. Repeated loads and environmental effects reduce the stiffness

of timber over time, making it less effective. Floor coverings, staircases and joinery parts get worn out because of frequent use and friction and it weakens them. Insects and larvae that feed on timber damage it by making it porous. It leads to reducing the size of timber parts and their load-bearing strength. Timber exposed to sunlight, weather and air pollution for many years shows darkening, aging and loss of brightness. This mostly affects appearance and has less effect on earthquake performance. Long-term heat also causes expansion, texture separation and lower mechanical strength because of reduced density.

Poor workmanship and lack of maintenance cause damage in timber parts, such as cracking, splitting, and breaking, especially under side loads. Using materials that do not match the original during renovation, especially in cladding and wet areas, adds extra weight and speeds up the deterioration of timber elements. A related issue is the use of sheet metal on façades. Although it may protect the building from weather, adding sheet metal increases the load on timber structures and can accelerate deformation and damage. Therefore, careful consideration is needed when adding such materials to historic timber buildings (Figure 2). Effective moisture control, preventive measures against biological deterioration and appropriate fire safety strategies are of critical importance for ensuring both the sustainability and seismic performance of these traditional structures.

Figure 2. Extra load from inappropriate façade material replacement.

Conclusion

In the repair of timber structural elements, interventions can either replace damaged components or address issues in existing timber. When damage is detected in structurally significant timber elements, factors such as the extent of the damage, cost, aesthetic considerations, and reversibility should be carefully evaluated to ensure minimal disruption to the building's overall integrity. Decay-damaged timber requires the removal of compromised or weakened sections. These sections should then be replaced with treated, well-dried timber that matches the original in type, quality, and moisture content. If removal isn't possible, preservatives should be applied, and injection techniques used if necessary. However, many buildings in the Historical Peninsula are poorly maintained. Improper repairs weaken their structural integrity, particularly affecting seismic performance.

Interventions on historic timber structures should aim to preserve the building's original identity and integrity. Prior to intervention, the structure's current condition and load-bearing system must be thoroughly analyzed. The choice of methods, materials and chemicals must prioritize the building's preservation, avoiding harmful actions. Regular maintenance and periodic inspections are essential to detect and prevent deterioration early.

Traditional timber structures in the Historical Peninsula have suffered significant structural damage due to environmental factors, weakening load-bearing systems and decreasing overall durability. This damage affects the performance of buildings against dynamic loads such as earthquakes, posing a threat to both their safety and sustainability. Field studies show that timber materials deform from moisture, water, and atmospheric conditions, further compromising structural integrity. To protect these buildings and ensure their longevity, preservation strategies must be developed.

While the 12th Section of the Türkiye Building Earthquake Code provides detailed structural guidelines for traditional timber buildings, it lacks conservation principles focused on the long-term preservation and seismic performance of these

structures. Although the regulation specifies load-bearing system dimensions and connection details, it does not offer guidance on maintenance, repair, or material durability, which are crucial for ensuring the seismic performance of these structures.

The Timber Buildings Regulation, which came into force in 2025, takes a more complete approach to improving the performance of buildings, especially addressing deterioration through waterproofing. It emphasizes preventing water and moisture penetration in light-frame timber systems and building components exposed to environmental factors by ensuring the impermeability of the building envelope. Detailed solutions are proposed to avoid water ingress from the external environment into interior spaces, including proper design of facade slopes to ensure effective drainage and architectural features such as eaves and projections to redirect water away from the facade.

The preservation recommendations can be outlined as follows. Regular maintenance and inspections should be conducted, with periodic checks for early detection of deterioration. Moisture levels should be constantly monitored, and sources of water ingress should be eliminated. Decayed timber elements should be removed and replaced with similar, well-dried timber. Effective waterproofing should be applied, and roof covering should be regularly inspected. Preservatives should be applied to decayed timber to prevent further biological damage. Restoration methods should align with traditional techniques and scientific standards. Facade elements and drainage systems should be properly designed to prevent water accumulation.

In conclusion, insulation measures, improved drainage, and regular roof inspections are critical for preserving structural elements against moisture. Timber parts that are damaged by decay should be replaced with treated materials to enhance their resistance to biological damage. Restoration efforts should use methods compatible with traditional construction practices, prioritizing the structure's historical integrity. Preserving historic timber buildings ensures the sustainability of cultural heritage, and conservation efforts must adopt an interdisciplinary approach, supported by long-term strategies for the reinforcement and preservation of these buildings.

Developing One-part Geopolymer Binders by Using Ground Granulated Blast-furnace Slag and Ceramic Waste as Precursors

İlar Berfin İlbeyi[a], Ünal Anıl Doğan[a]

[a] Istanbul Technical University, Graduate School, Structural Engineering Program, Türkiye
ilbeyi17@itu.edu.tr

Keywords: Ceramic Waste, GGBS, One-part Geopolymer, Solid Activator, Waste Glass.

Aim

Concrete is the most widely used building material due to its durability, low cost and ease of handling. The main binding component of the concrete is Portland cement. According to studies, 0.8 tonnes of CO_2 are emitted into the atmosphere for each tonne of cement produced (Mohamada et al., 2022). Released greenhouse gas amount is 1.5 billion tonnes due to Portland cement production for each year (Singha et al., 2020). Since Portland cement has negative impact on the environment, improving an alternative greener material is very important. One of the promising option which can reduce consumption of Portland cement is using geopolymer binders. Geopolymers are formed by treating of aluminosilicate containing precursors with alkaline solutions or solids, known as activators. Geopolymers are classified as one-part and two-part according to the form of the alkali content. If the activator used in the geopolymer binder is solid, it is defined as one-part geopolymer, while if it is liquid, it is defined as two-part geopolymer. Using one-part geopolymers are more advantageous than that of two-part geopolymers in terms of ease of use and commercialization potential. The aim of this study is to develop one-part geopolymer binders, that can be a greener alternative to Portland cement, by using the waste materials.

Material and Method

Within the scope of this study, precursors and activator, which are the main components of the geopolymers, are derived from waste materials. Ground granulated blast-furnace slag (GGBS) and ceramic wastes were used as precursor materials, replacing each other in various proportions, while waste glass and NaOH were used for activator production. Instead of the hydrothermal method, which produces the activator in solution form, the thermochemical method was used to produce the activator in solid form.

According to the literature, for producing a solid activator used in one-part geopolymer, different molar ratio of SiO_2/Na_2O (silicate modulus), heating temperature and heating duration were examined. Studies have shown that, geopolymer mortars containing activator produced with silicate modulus of 1,0 and heating temperature between 150-300 ˚C, achieve higher compressive strength results (Vinai et al., 2019; Delgado Plana et al., 2024).

In this study, preliminary tests were conducted to observe the efficiency of solid activator. Different activators with silicate modulus of 0,5, 1,0 and 1,5 is produced at different temperatures of 150 ˚C, 250 ˚C, 350 ˚C and heating durations of 30, 75, 120, 150 and 180 minutes for preliminary tests. For making the NaOH and waste glass mixture homogenized, water was added to the blend by 25% wt of total mass of NaOH and waste glass. The efficiency of the produced activators were examined using geopolymer mortars containing only GGBS. The strength results of the geopolymer mortars produced to determine the appropriate temperature and duration for activator production are shown in Table 1.

Table 1. Strength results of mortars containing only slag, prepared with activators having different molar ratios, heating temperatures, and durations**.**

Mixture	$nSiO_2/nNa_2O$	Heating Temperature (ºC)	Heating Duration (min.)	Activator (wt.)	Flexural Strength (MPa)			Compressive Strength (MPa)		
					7th Day	14th Day	28th Day	7th Day	14th Day	28th Day
1	1,5	150	30	8,00 %	0,23	0,35	0,50	0,43	0,78	1,00
2	1,5	250	75	8,00 %	0,21	0,30	0,52	0,37	0,62	1,21
3	1,5	350	120	8,00 %	0,22	0,27	0,58	0,48	0,65	1,31
4	1,0	150	75	8,00 %	0,21	0,44	0,62	0,46	0,58	1,10
5	1,0	250	120	8,00 %	0,50	5,39	4,71	1,11	6,90	19,48
6	1,0	350	30	8,00 %	0,24	2,34	3,81	0,50	2,76	8,12
7	0,5	150	120	8,00 %	1,34	3,76	6,48	2,38	8,69	20,91
8	0,5	250	30	8,00 %	1,37	5,66	7,41	2,63	12,05	20,23
9	0,5	350	75	8,00 %	2,22	6,53	6,03	4,02	13,91	17,66
10	0,5	250	120	8,00 %	0,69	2,33	5,69	1,57	4,33	12,73
11	0,5	250	150	8,00 %	0,43	1,69	-	0,89	2,60	8,78
12	0,5	250	180	8,00 %	0,69	1,91	3,75	1,22	4,07	10,12

Twelve different mortars were prepared with a water/binder ratio of 0,45, containing 8% activator by weight, and were kept at room temperature until the testing age. After determining the flexural and compressive strengths of the mortars at 7, 14, and 28th day, it was found that the highest strength results were achieved with activators obtained by heating NaOH and waste glass at 250°C for 120 minutes, with a silicate modulus (SM) of 0,5 and 1,0.

After determining the optimum method for producing the activator with preliminary tests, ceramic wastes were introduced to the mixture as precursor in addition to GGBS. The obtained ceramic wastes were ground in a ball mill until it turned into powder and were made ready to use in the mixtures.

Precursor materials, waste ceramic and GGBS, were used to prepare geopolymer mortars by replacing each other at ratios of 20%, 40%, 60%, and %80 by weight. The water/binder ratio was fixed as 0,45, and the activator content in the mixture was kept constant as 15% by weight. The mixtures were produced for both silicate moduli of 0,5 and 1,0. Mix proportions of 8 different produced mixtures are given in Table 2.

Table 2. Mix proportions of geopolymer mortars containing GGBS and waste ceramics.

Mixture	GGBS (%wt)	Ceramic Waste (%wt)	$nSiO_2/nNa_2O$ (SM)
K1	80	20	0,5
K2	60	40	0,5
K3	40	60	0,5
K4	20	80	0,5
K5	80	20	1,0
K6	60	40	1,0
K7	40	60	1,0
K8	20	80	1,0

During the preparation of the mortars, the precursors and the activator were first mixed in dry form. Then, water was added to prepare the paste, and finally, sand was added to obtain the geopolymer mortar. Prepared mortars were placed in steel molds with the dimensions of 40x40x160 mm, and stored at room temperature until the testing age.

Findings

Figure 1 shows the compressive strength results of geopolymer mortars at 7, 14 and 28th day containing activator with SM of 0,5 and 1,0. The sample K1, containing an activator with a silicate modulus of 0,5 and a precursor composition of 80% blast furnace slag and 20% waste ceramics reached compressive strength of 20 MPa on the 28th day. The mortar produced with the same precursor composition but with a silicate modulus of 1,0, which was named as K5, achieved compressive strength of 12,4 MPa on the 28th day.

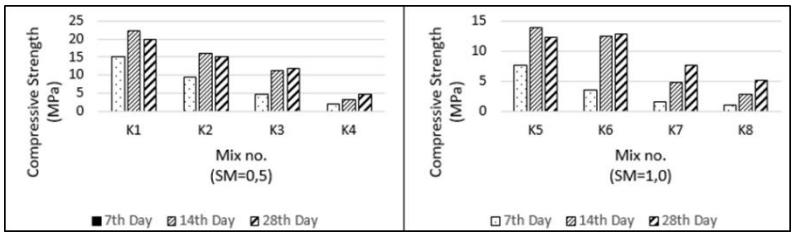

Figure 1. Compressive strength results of geopolymer mortars at 7, 14, and 28th day.

When comparing the strength values at 14th and 28th days, it was observed that mixtures produced with activators having a SiO_2/Na_2O molar ratio of 0,5 and a precursor composition containing 40%, 60%, and 80% GGBS, largely completed the geopolymerization reaction by the 14th day. From Figure 1, it can be seen that K1, K2 and K3 mixtures, containing 80%, 60%, and 40% GGBS, respectively, did not gain strength after 14th day, while mixture K4, having GGBS %20 by weight, gained 30% of its total strength after 14th day. Among the samples produced with an activator having silicate modulus of 1,0, K5 and K6, containing 80% and 60% slag by weight, respectively, did not gain strength after 14th day, while the K7 and K8 samples, containing 40% and 20% slag, respectively, gained 38% and 46% of their total strength after the 14th day.

Conclusion

This study aims to develop geopolymer binders by utilizing waste materials. The optimal silicate modulus and production process for the activator, using NaOH and waste glass, were determined through mixtures prepared with blast furnace slag. Mortars were prepared using waste ceramics and blast furnace slag as precursors, and their mechanical properties were assessed with flexural and compressive strength tests. As a result of the study, it was determined that the most suitable activator composition for blast furnace slag based mixtures was obtained with a silicate modulus of 0.5 and 1.0, with heating process at 250°C for 2 hours. It was seen that, increasing GGBS proportion in precursors results in higher strength values. It was also observed that increasing waste ceramic content in the precursor reduced early-age strength but, it allowed strength development at later ages.

Further studies should be conducted to commercialize geopolymer mortars, which are being developed as an alternative to reduce cement production.

This study includes the preliminary work of the project numbered 223M280, supported by TÜBİTAK.

Keywords: Past Earthquakes, Industrial Structure, Reinforced Concrete Earthquake Damage, Earthquake Performance, Structural Irregularity.

Aim

The fact that earthquakes are a sudden natural event and cause a large number of loss of life and property are the main reasons why earthquakes are seen as a greater threat than other natural disasters (Ataman & Tabban,1977). In the last thirty years, many earthquakes with magnitudes greater than M:6.0 have occurred in areas close to fault lines in different regions of Turkey. These large earthquakes have caused many casualties and many buildings to be destroyed or heavily damaged, resulting in large economic losses (Erdik vd., 2000). When the earthquakes in Turkey are analysed, it is understood that the industrial zones, which are the locomotive of the country, were also greatly damaged by the earthquake. In these industrial areas, which constitute a large share of the country's population and economy, significant structural damages, destruction, demolitions and loss of labor were experienced in industrial buildings. The fact that most industrial zones in Turkey are built on active fault lines necessitates the analysis of the earthquake performance of industrial structures in these regions. Especially the earthquake readiness of industrial buildings in the Marmara Region, which hosts about half of the industry in Turkey, should be determined.

Material and Method

Past major earthquakes provide important data to understand the causes of damage that the industry clustered in and around İstanbul, one of the most important cities in Turkey with its high population density and consequently a large number of buildings, industrial and commercial activities, may be exposed to in the face of a possible major earthquake. For this purpose, in this study, the types and causes of damage in reinforced concrete (RC) industrial structures in past earthquakes were examined. The main subject of the study is the evaluation of the architectural and structural earthquake performance and damage mechanisms of RC industrial buildings, especially in the earthquakes experienced in recent centuries. In this study, it is aimed to determine the structural irregularities in the horizontal and vertical directions in industrial buildings, structural faults that may affect the seismic performance of the structure and to reveal the important factors that cause damage and to emphasize earthquake-resistant building design.

Findings

The results of the research on the damage mechanisms of industrial structures affected by the 1999 Gölcük and Düzce earthquakes and the 2023 Pazarcık and Elbistan earthquakes provide important data that should be taken into consideration for the analysis of the seismic performance of industrial areas in Istanbul under the threat of earthquakes (Sezen vd., 2003). When the data on these damage mechanisms are analysed, it is seen that the damages in industrial buildings exhibit similar characteristics. In the field work carried out after the earthquake, destructive damages occurred in many buildings that were constructed in low standards and without receiving engineering services, especially without complying with the principles of the Turkish Earthquake Code (TEC). In regions with high earthquake risk, the most important feature required for structures is earthquake safety and ductile behaviour, adequate strength and limited lateral drift (lateral rigidity) conditions should be provided for earthquake performance. As it can be understood from the field investigations and research reports

in the past earthquakes, the design phase of the structures and the production process of the structure have a great importance in the RC structures to meet these conditions (Işık vd., 2024;Sagbas vd., 2024).

Ground and structure interaction should be carefully considered in building design and ground conditions should be accurately determined by in-situ geotechnical tests. Soil liquefaction led to settlement of structures in Adapazarı in the 1999 Kocaeli earthquake (Scawthorn &Johnson, 2000). In-situ observation studies and researches conducted in buildings that have experienced earthquakes show the importance of the behaviour of the ground in earthquakes and the need to consider the structure-ground interaction.

Major reinforcement failures such as missing or incorrect stirrup connections at joints, insufficient wrapping, incorrect clamping, etc. are the cause of devastating damage to structures in the 2023 Pazarcık and Elbistan earthquakes (Figure 1). 'According to TEC (2007), in all earthquake zones, columns of all RC systems with high or normal ductility level, column-beam joints, It is stated that the stirrups used in curtain end zones and beam hugging zones are special seismic stirrups and there must be 135 degree curved hooks at both ends of special seismic stirrups' and 'According to TEC (2018), It is stated in the regulation that the diameter of the transverse reinforcement should not be less than 8 mm and the spacing should not exceed 150 mm in enclosed joint and the diameter of the transverse reinforcement should not be less than 8 mm and the spacing should not exceed 100 mm in non-enclosed joint'. In most of the reinforced concrete structures examined after the earthquake, inadequate reinforcement ratio, weak reinforcement anchors, weak reinforcement detailing in column-beam joints, stirrup spacing up to 25-30 cm in column-beam joints and 90 degrees at the end of the seismic stirrups, insufficient length hooks are observed. Inadequate transverse reinforcement spacing in the plastic joint region and the absence of transverse reinforcement in column beam connections caused serious damage to the structures of industrial buildings.

Figure 1. Reinforcement failures (Sagbas vd.,2024).

Field data from the 1999 Gölcük and Düzce earthquakes show that deficiencies arising from the construction phase of RC buildings such as low concrete quality, unribbed reinforcement bars, corrosion and workmanship defects can also cause

different levels of damage. Many problems occurred in concrete mixing due to the use of unsuitable aggregates such as smooth and large sizes, high water/cement ratios and inadequate curing. In all earthquake zones, it is mandatory to use quality controlled, maintained and vibrator placed concrete according to the definition in TS-500. The use of vibrator is important in order to prevent segregation in concrete, otherwise excessive amount of air void remains in the concrete and this situation adversely affects the strength of concrete. Along with poor concrete quality, the use of unribbed bars in RC structures has further reduced the interlocking mechanisms between concrete and reinforcement details, leading to significant bond problems. In earthquake reports in relation to RC industrial buildings, severe corrosion was observed in most buildings, causing cracking and spalling of the concrete cover and exposing the reinforcement.

Structural irregularities seen in almost every earthquake zone are the main cause of earthquake damages and destructions. According to TEC (2018), structural irregularities are analysed in two groups as plan plane and vertical direction. Plan irregularities are A1-torsional irregularity, A2-floor discontinuity and A3-protrusions on the plan. Vertical irregularities are B1-weak floor irregularity, B2-soft floor irregularity and B3-discontinuity of vertical elements of the structural system. Soft storey, defined as the rigidity irregularity between adjacent floors, is a common cause of damage in RC industrial structures in past earthquakes. If the ground floor height in the structure is higher than the upper floors and the use of infill walls is removed on any floor, a sudden rigidity change occurs in the horizontal load distribution in the structure. The use of mezzanine floors, especially on the ground floor, seen in RC industrial buildings, causes floor discontinuity and soft floor irregularity. In past earthquakes, increasing the gap ratio on the ground floor facades of RC industrial buildings and reducing the use of infill walls to allow the use of large workshop areas caused weak floor irregularity, which negatively affected the earthquake performance. In order to prevent the complete collapse of RC buildings and to provide a ductile and strong structural behaviour, it is essential that the columns are stronger than the beams. This issue becomes more important especially in structures that are fragile due to soft and weak floors. One of the main reasons for pancake type collapse of structures in earthquakes is weak column- strong beam applications. The use of band windows, which is frequently encountered in industrial buildings, causes short column damages. Short column damage is one of the most important causes of damage in RC industrial buildings in past earthquakes (Figure 2). Joint gaps are left between adjacent building blocks due to different ground settlements and earthquake effects. 'According to TEC (2018), the minimum joint gap to be left considering temperature change, height difference and ground conditions shall be at least 30mm up to 6m height and at least 10 mm shall be added to this value for every 3m height after 6m'. In the design of adjacent buildings, sufficient joint space is left between the RC buildings to allow free displacement of the buildings during an earthquake. Otherwise, if there is not enough space between two buildings, these buildings collide and damage each other. Especially in adjacent buildings with different floor levels, examples of the floor slab at the floor level of one building causing serious damage to the column of the other building are encountered in earthquake field reports. As can be understood from the examples observed in the recent 2023 Pazarcık and Elbistan earthquakes, the use of mezzanine floors, single storeys at two storey heights, soft storey and weak storey damage mechanisms due to the difference in the infill wall ratio between the storeys and short column damage mechanisms due to the use of band windows in RC industrial buildings are the main reasons for the destructive effects on the structures and the decrease in the earthquake performance of the structures. In addition, inadequate functioning of the building control mechanism and incorrect applications due to lack of control are important factors in the occurrence of earthquake damages.

Figure 2. Short column damage (left) and soft- weak storey damage (right).

Conclusion

Important industrial cities such as İstanbul, Tekirdağ, Kocaeli and Bursa are under the threat of the northern fault. Most of the industrial buildings, which constitute a large share of Turkey's economic power, are located in these areas with high earthquake risk, and the fact that the majority of the population lives in this region increases the size of the danger. Although there are studies on determining the seismic performance of RC buildings, there is great benefit in enriching the literature on the subject with comprehensive research and studies by analysing the seismic performance of RC industrial buildings. In past earthquakes, the evaluation of the seismic performance of RC industrial buildings, which constitute a significant share of the building stock in Turkey, is very important in order to examine and understand the effects of structural features and irregularities on the seismic performance of existing RC industrial buildings. The evaluation data obtained after the researches in the past earthquakes are important in terms of strengthening the existing structures and taking the necessary precautions for the new structures to be built.

Evaluation of Exterior Cladding Materials in Educational Buildings in Terms of Embodied Energy

Dilfuruz Kara[a], Caner Göçer[b]

Keywords: Educational Buildings, Facade Cladding Materials, Environmental Impact, Carbon Emissions, Sustainable Architecture.

Aim

Türkiye is a geographically diverse country that encompasses various climate zones. This diversity makes it inevitable for climatic factors to have a direct influence on material selection in building design. In particular, exterior cladding materials are determined not only by aesthetic expectations but also by technical requirements such as climate conditions, durability, and energy efficiency. However, the increasing population and demand for construction have led to significant energy consumption in the production processes of building materials, resulting in considerable carbon emissions. In this context, it is of critical importance to develop strategies aimed at reducing carbon emissions associated with the production of exterior cladding materials, which constitute the largest surface area of the building envelope (IEA, 2023; Republic of Türkiye Ministry of Environment, Urbanization and Climate Change, 2023). A visual representation of this situation is provided in Figure 1.

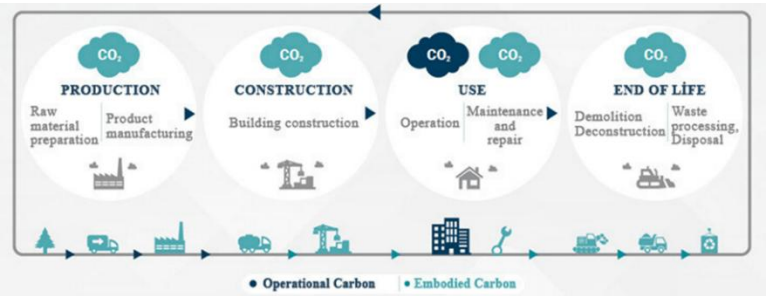

Figure 1. Decarbonization Roadmap for Türkiye's Building Sector, (Url 1).

As illustrated in Figure 2, the construction sector accounts for approximately 40% of global energy consumption and 36% of carbon emissions (IEA, 2023). These figures necessitate the adoption of sustainability-oriented material selection in the building industry.

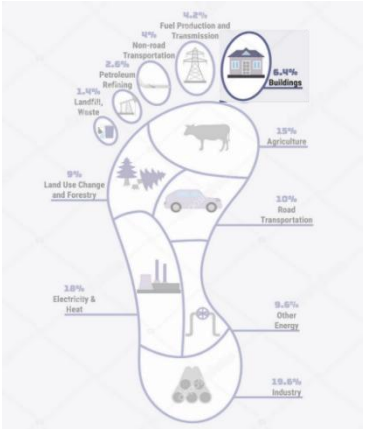

Figure 2. CO_2 Ecological Footprint Diagram (Url 2).

The environmental impacts of buildings are not limited to their direct energy consumption; they are also significantly influenced by the energy consumed during the production, transportation, and processing of materials—a factor referred to as embodied energy. Therefore, identifying and quantifying embodied energy values provides a scientific foundation for selecting environmentally friendly materials in the construction sector (Dixit et al., 2010).

Educational buildings, in particular, should be addressed with a focus on energy efficiency due to their significant share within the building stock and the high rate of user circulation they accommodate (Gökçen Akkurt et al., 2015). The exterior cladding materials used in such buildings should be evaluated not only based on physical attributes such as aesthetics, durability, and maintenance but also in terms of their environmental impacts. In this context, the use of materials with low embodied energy has become increasingly important (González & Navarro, 2006).

The primary aim of this study is to determine the embodied energy values associated with the production processes of exterior cladding materials used in educational buildings in Turkey, and to present an evaluation framework for sustainable material selection based on these data. By comparatively analyzing the carbon emissions produced during the manufacturing stages of various materials, the study seeks to support environmentally responsible design decisions.

Material and Method

In this study, the analysis was conducted by modeling the exterior façade surface of a typical classroom unit found in educational buildings in Turkey. The dimensions of the referenced façade module were assumed to be 7 × 4 meters (28 m²), with a transparency rate of 30%. Accordingly, calculations were based on a net 20 m² of opaque surface area. Material analyses were performed using the LCA One Click software. This tool provides data based on Life Cycle Assessment (LCA) methodology and calculates energy consumption during the production processes of building components in units of $kgCO_2e$.

To ensure realistic system modeling, not only the exterior cladding material but also all layers constituting the building envelope—including substructure systems, adhesives, fasteners, thermal insulation, and plaster layers—were incorporated into the calculation. In this way, the total embodied energy of the cladding systems was comprehensively determined. Figure 3 presents a screenshot from the software interface showing the layers included in the analysis.

Building Part	Resource Name	Details	Quantity	Unit	Thickness mm	Comment
External walls and facade	Aluminium profile (updated dataset), 2700 kg/m3, EN15804+A1, ref. year 2018		120	kg		
External walls and facade	Aerated concrete, 500 kg/m3, non-reinforced, P4 05, EN15804+A1, ref. year 2018		4	m3		
External walls and facade	Stone wool (mineral wool) insulation, unfaced, L = 0.03 W/mK, R = 1 m2K/W, 30mm, 2.1 kg/m2, 70 kg/...		20	m2	30	
External walls and facade	Gypsum plaster for interior applications, 10 mm, 8 kg/m2, 1004.74 kg/m3, Rimano UNI (Saint-Gobain ...		18	m2		
External walls and facade	Aluminum composite panel, curtain walling/facade, mineral filled, 4 mm, 5.85 kg/m2, B2 (Saray)		20	m2	4	

Figure 3. Screenshot taken from the LCA One Click Interface.

The exterior cladding materials evaluated in this study are as follows:

- Cement plaster
- Aluminum composite panel
- Solid wood cladding
- Wood composite panel
- Granite cladding
- Ceramic cladding
- Sinterflex

Given that educational buildings constitute a significant portion of the building stock in Turkey, the environmental performance of the materials used in these structures is crucial—both for reducing the current carbon footprint and for defining long-term sustainability strategies. Therefore, in this study, a system cross-section was developed for each analyzed material, and the associated carbon emissions were comparatively examined through the software interface.

Findings

According to the calculations, cement plaster exhibited the lowest level of embodied energy consumption among the exterior cladding materials analyzed. Cement plaster was found to emit only 1257 $kgCO_2e$ of carbon emissions. In contrast, aluminum composite panels ranked highest, with a carbon emissions value of 4522 $kgCO_2e$. This significantly high figure is attributed to the aluminum production processes, which require intense heat and complex refinement procedures.
Materials with medium levels of carbon emissions are as follows:

- Solid wood: 1393 $kgCO_2e$
- Wood composite: 3625 $kgCO_2e$
- Ceramic cladding: 2818 $kgCO_2e$
- Granite cladding: 2495 $kgCO_2e$
- Sinterflex: 3565 $kgCO_2e$

These values are illustrated in the graph presented in Figure 4 below.

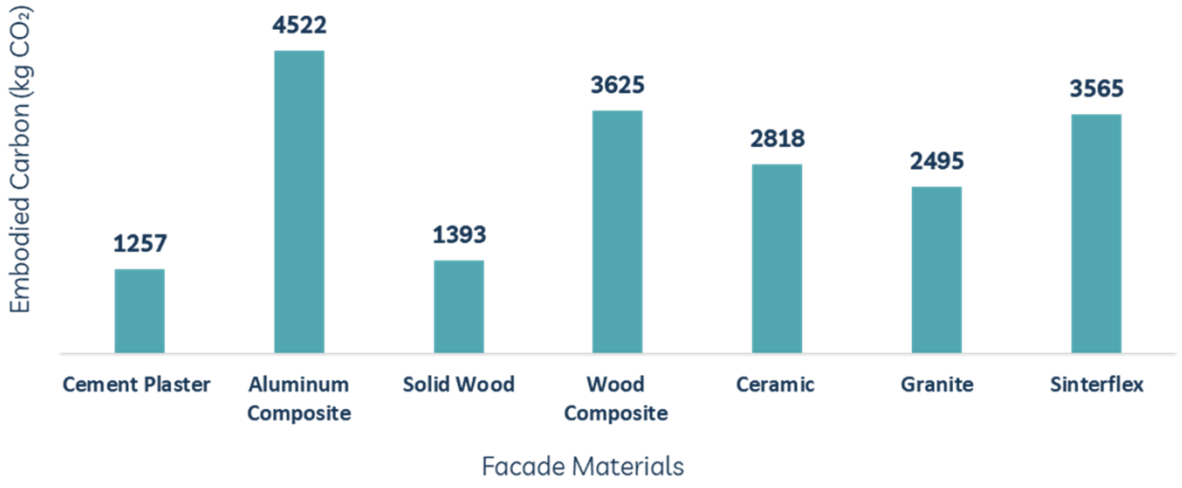

Figure 4. Carbon Emissions Totals for a 20 m² Classroom Unit.

These findings indicate that wood-based materials derived from natural sources are environmentally advantageous due to their lower carbon emissions during the production process. On the other hand, materials such as ceramic and sinterflex, despite exhibiting higher levels of carbon emissions, may offset this impact through performance-related advantages such as durability, ease of maintenance, and longevity.

Therefore, material selection should not be based solely on carbon emissions; rather, the overall contributions of materials throughout their life cycle must be considered holistically.

Conclusion

The results obtained reveal significant variations in the carbon emissions generated during the production processes of exterior cladding materials. The lowest carbon emission value was observed in cement plaster, whereas the highest value was recorded for aluminum composite panels. This disparity is primarily due to the intensive thermal treatments and refinement processes required in aluminum production. Materials such as solid wood, wood composite, granite, ceramic, and sinterflex exhibited moderate levels of embodied energy consumption.

Comparative analysis indicates that cement plaster produces approximately 72.2% less carbon emissions than aluminum composite, solid wood 69.2% less, granite 44.8% less, ceramic 37.7% less, and sinterflex 21.2% less. These figures highlight the critical importance of using low-carbon-emission materials in the building envelope to reduce environmental impacts.

Furthermore, the intensive usage of educational buildings necessitates that selected materials be evaluated not only in terms of energy performance but also through multidimensional criteria such as durability, maintenance requirements, longevity, recyclability, and fire resistance. Therefore, sustainable architectural approaches must encompass holistic performance goals beyond merely low carbon emissions.

In conclusion, material selection strategies that incorporate embodied energy considerations in exterior cladding represent a vital tool for reducing the environmental burden of the construction sector. Conscious choices in educational buildings will contribute significantly to both short-term energy savings and long-term carbon reduction targets.

The Impact of Façade Cladding Materials on Carbon Emissions in Urban Renewal Projects: The Case of Istanbul

İkranur Sena Akkaya[a], Caner Gocer[a]

[a] Istanbul Technical University, Department of Architecture, Environmental Control and Building Technology Program, Turkey
akkayaik23@itu.edu.tr

Keywords: Urban Renewal, Façade Cladding Materials, Embodied Energy, Carbon Emissions, Environmental Sustainability.

Aim

The rapid growth of cities and population growth have significantly increased energy demand. Increased energy consumption leads to a substantial increase in carbon emissions. Consequently, ensuring environmental sustainability has become a primary agenda item for expanding urban areas (Durguter, 2012). It is emphasized that the negative effects on the environment should be reduced with sustainable urbanization policies, especially the need to protect natural ecosystems and transform existing areas in accordance with sustainability principles (Hamurcu and Buldurur, 2017; Tezangi, 2014).
The main aim of urban renewal projects is to renovate buildings that pose earthquake risks and have reached the end of their physical lifespan and to build more safer and modern buildings in accordance with zoning regulations. However, energy consumption and environmental impacts must also be considered during the urban renewal process. Existing buildings often have inadequate thermal insulation in their exterior walls, leading to high energy consumption for heating and cooling (Lo, 2015). Urban renewal projects have the potential to address this issue by offering energy-efficient exterior wall systems. In addition, the production phase of the construction materials can lead to consumes a significant amount of energy and high carbon emissions. Therefore, the selection of materials, which constitute the majority of the building envelope is an important issue to be considered in urban renewal projects and requires a detailed evaluation in terms of sustainability.
The selection and production processes of façade cladding materials hold significant importance in terms of sustainability. The majority of carbon emissions in the construction sector occur during the production phase of building materials. Therefore, the energy consumption and carbon emissions in the production processes of facade cladding materials are key factors for making more environmentally sustainable material choices. This study aims to calculate and compare the embodied energy of commonly used façade cladding materials in urban renewal projects in Istanbul. Design parameters in residential buildings—such as plan typologies, façade arrangements, and building heights—directly influence the volume of the external shell, leading to variations in embodied energy ratios. Therefore, this study analyze and compare the embodied energy values of selected façade cladding materials under different architectural parameters. Developing strategies to reduce the impact of the building sector on global carbon emissions and establishing a scientific basis for sustainable architectural approaches are also among the main objectives of the research.

Material and Method

This study examines a total of 169 buildings from low-rise, mid-rise, and high-rise urban renewal projects in Istanbul. The commonly used façade cladding materials in these buildings were identified, and their floor plans and façade arrangements were analyzed.
The most commonly used aluminum composite, wood composite, ceramic coating and sinterflex panels were evaluated in the facades of the buildings examined. Within the scope of the calculations, the energy consumption per unit volume of the materials was determined and the unit production energies were calculated in accordance with the researches and standards accepted in the literature. According to the data, the embedded energy values of the materials examined are: Aluminum Composite (150 MJ/kg), Wood Composite (12 MJ/kg), Ceramic Cladding (12 MJ/kg), and Sinterflex (14 MJ/kg).

In this study, using the manual calculation method, the analyses were carried out by multiplying the building facade areas with the embedded energy values of the materials. The façade area was determined based on the impact of architectural parameter variations on the volume of the external shell, and calculations were performed accordingly.
The architectural parameters identified in the analysis of buildings were classified: linear and square forms in terms of building shape; parapeted and non-parapeted window types in terms of façade arrangement; and , frame-vertical band, horizontal band, and flat façade layouts in terms of façade elements.
Façade arrangements were categorized into eight different scenarios based on combinations of , frame-vertical band, horizontal band, and parapeted/non-parapeted window designs. Plan typologies were classified into two scenarios: linear and square forms. Building height was categorized as low-rise, mid-rise, and high-rise, with corresponding heights of 4, 8, and 16 stories, respectively, while the floor height was assumed to be 3.20 meters.
Since these parameters directly influence the volume of the building envelope, they were used as fundamental variables in carbon emission calculations. In the scenarios created with the manual calculation method, the structural properties of the wall layers are kept constant and calculations are made only for each façade cladding material. The embodied energy per unit area of the materials are calculated to determine the total carbon emissions for different building scenarios.
Different façade materials were compared based on design parameters, and solutions with the lowest carbon footprint are identified. Additionally, the differences in carbon emissions among various material types have been analyzed for their impact on architectural design decisions.

Findings

The initial findings of the study clearly demonstrate the impact of façade cladding materials, building design, and façade arrangements on carbon emissions.
The calculation data shows that there are significant differences in the embodied energy values of façade cladding materials. Aluminum composite exhibited the highest embodied energy value, making it the material with the greatest carbon burden. Conversely, ceramic cladding and sinterflex panels offered more environmentally friendly alternatives due to their lower embodied energy values.
Plan typology, building height, and façade arrangement variables directly affect embodied energy values. Notably, embodied energy levels increased significantly in high-rise buildings. This phenomenon can be explained by the increase in façade surface area and the corresponding rise in the amount of cladding material used as building height increases.
While flat façade designs exhibited lower embodied energy values compared to other façade elements, non-parapeted façades with , frame-vertical band resulted in lower carbon emissions than other design solutions. However, scenario that include parapeted-horizontal bands and frame-vertical bands exhibited higher embodied energy consumption. This situation can be explained by the use of additional facade elements, such as horizontal band and frame-vertical band, which increase the exterior surface area of the building and, consequently, the amount of material used.
Regarding building shape, square-plan buildings had slightly lower embodied energy values than linear-plan buildings due to their more compact structures.
Figure 1 shows the embodied energy values for each scenario and material used in the study. The corresponding design scenarios are defined and coded in Table 1, based on variations in architectural design parameters such as building form, height, façade arrangement, and parapet presence.

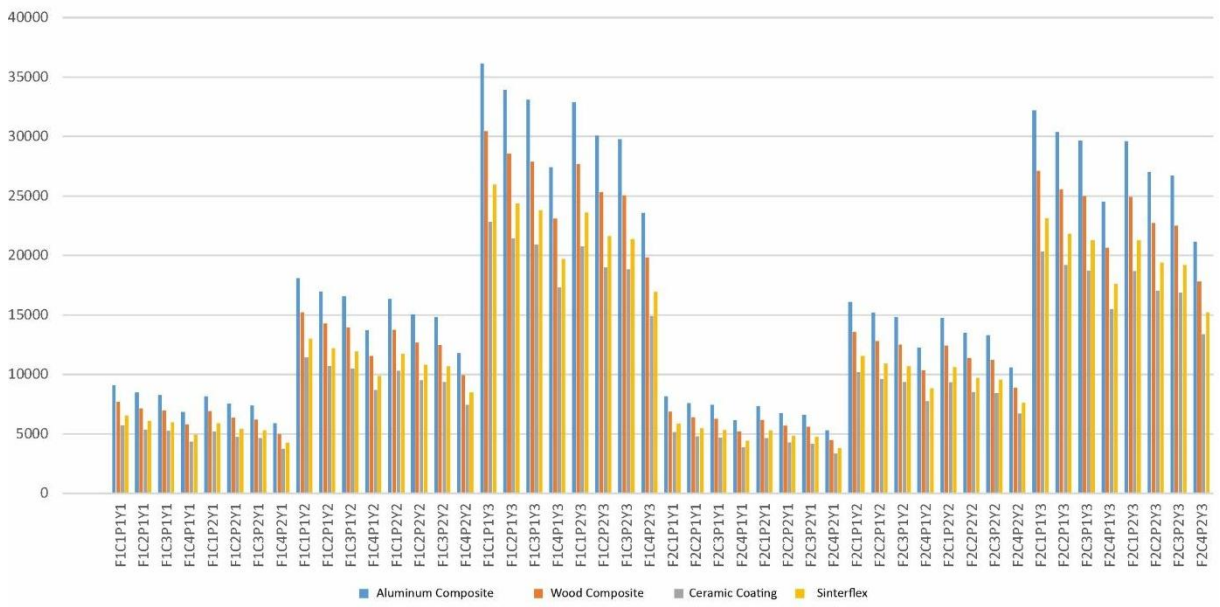

Figure 1. Embodied energy values of each scenario and material.

Table 1. Scenario Definitions Based on Architectural Design Parameters.

Design Parameters	Scenarious
parapet present (h:85 cm)	P1
no parapet	P2
horizontal-vertical band	C1
horizontal band	C2
vertical band	C3
flat façade	C4
linear form	F1
square form	F2
4 story (h:12.8 m)	Y1
8 story (h:25.6 m)	Y2
16 story (h:51.2 m)	Y3

Conclusion

This study highlights that material selection is a critical factor in sustainable building design, and embodied energy values must be considered. Replacing high-embodied-energy materials such as aluminum composite with alternatives like ceramic cladding and sinterflex panels, which have lower carbon footprints, will support environmental sustainability.

It was determined that design decisions related to building height, geometric form, and façade arrangements directly impact energy consumption and carbon emissions. More compact square-plan buildings enhance energy efficiency and reduce the use of unnecessary façade elements, thereby minimizing embodied energy consumption. In this context, the use of low-embodied-energy materials and the adoption of simplified façade designs in sustainable urban transformation projects will significantly contribute to reducing environmental impact.

Future research should not be limited to embodied energy but should also comprehensively examine operational energy consumption. The total carbon emissions of a building are directly related not only to the embodied energy of materials used during construction but also to the energy consumed throughout the building's lifespan. Therefore, heating, cooling, and other operational energy components should be analyzed in detail within sustainable building design processes.

Considering that façade materials' thermal insulation performance, site placement, and architectural characteristics significantly influence operational energy consumption, material selection should not only prioritize low embodied energy but also enhance energy efficiency.

In conclusion, achieving a sustainable construction process requires selecting low-carbon-emission materials, optimizing building geometry and façade design for energy efficiency, and implementing strategies to minimize natural resource consumption. This holistic approach will help reduce the environmental impact of the construction sector and contribute to the development of more sustainable and livable cities.

Ottoman Brick Stamps

Nevriye Öztürk[a], Gülsün Tanyeli[b]

[a] Istanbul Technical University/Graduate School, Department of Architecture, Restoration Program, Türkiye

Keywords: Ottoman Bricks, Flat and Modern Bricks, Brick Stamps, Inscriptions and Symbols of the Stamps.

Aim

Bricks have been one of the fundamental construction materials, which were used by various civilizations throughout the ages. This durable material, which could be easily, inexpensively, and rapidly produced, was also employed during all periods of Ottoman architecture.

Studies associated with the Ottoman bricks have been mainly carried out in the academic field of architectural history, and the building elements and masonry bonding techniques in which bricks were used have been examined. Whereas, the majority of brick related studies, which have been conducted in the academic discipline of restoration, have determined the current condition and the existing problems of brick masonry structures and developed conservation proposals for these buildings. The scholars and specialists, who have published research on Ottoman architecture, have devoted very little attention to the brick material itself and its properties. Their interest in the material has been limited to brick sizes, and the relationship between these dimensions and the periods of Ottoman architecture. However, there are other characteristics of Ottoman bricks that need to be focused on and investigated. The brick stamps, in particular, have not been sufficiently researched. The first scholar who revealed the existence of the practice of stamping bricks during the Ottoman era was Semavi Eyice in the early 1980s. He stated that the presence of various stamps on Byzantine bricks had been widely known, but there had been no evidence of Ottoman brick stamps and no publications on the subject until that time. He also pointed out that researchers should conduct studies on these stamps in the future, and emphasized that it would be possible to obtain detailed information about the Ottoman brick industry by increasing the number of studies on this matter (1981). Since then, stamped bricks of Ottoman era have attracted increasing attention from both private collectors and researchers. While a few articles related to this topic were published, it must nevertheless be pointed out that, no comprehensive and systematic study has been conducted on the issue at hand.

Ottoman stamps are significant and merit further research because they provide diverse, robust and reliable data about the historical bricks on which they appear. The first-hand information gained from the stamp is essentially related to the production of that brick. For instance, the place, the facility, and sometimes the date of manufacturing can be determined from the inscriptions of Ottoman brick stamps. Therefore, the inscriptions have the ability to confirm a certain place and, in rare examples, a certain time. It is considered that by benefiting from stamped bricks' potential for validation, even unstamped ones can be associated with the details of their production. One can argue that the data received from Ottoman brick stamps may constitute a credible reference for research undertaken in other fields (history of architecture, archaeology, building materials and technologies, etc.), other periods (Byzantine era bricks, etc.), and other materials (tiles, archaeological ceramics, etc.) as well.

Ottoman bricks have two main types: one of which is flat bricks in the form of thin plates with a square or rectangular plan, and the other one is modern bricks in the form of rectangular prisms. These two fundamental types of bricks differ from each other not only in their shapes but also in their sizes, subordinate types and production technologies. However, stamps can be observed on both of them. These stamps range from simple finger markings to sophisticated inscriptions and symbols.

The aim of this article is to examine and classify the Ottoman brick stamps in terms of form and content.

Material and Method

In order to achieve the goals of the study, field work and archival research methods were used and documentation was made. A number of private collectors were interviewed, several collections were evaluated, and on-site examinations of brick masonry buildings were made within the scope of field work. Historical documents, periodicals and books with regard to the Ottoman bricks and their manufacturing were found and translated from French, Italian, and Ottoman Turkish into contemporary Turkish in the context of archival research. For the purpose of identifying the characteristics of the stamps; brick samples were collected from masonry buildings and procured from different people and institutions, photographs were taken, and detailed survey drawings of the samples were made.

Findings

After examining hundreds of bricks, the stamped brick types, distinct positions of the stamps, characteristics of inscriptions, and symbols were determined.

Flat and modern bricks have numerous subtypes, but not all of them were stamped. An attempt was made to identify the stamped ones by using archival research and fieldwork. It is stated in a 19th century document that brickmakers were instructed to imprint stamps on Beylik, Çarşu, Topaç, and Kebir bricks (BOA.C.İKTS.9/428). The only stamped flat brick sample that was found was broken, so its exact dimensions and form could not be specified. But it is thought that it could be a Beylik or Çarşu brick. The other stamped flat brick example that was observed in Eyice's article has a rectangular form (1981). From its shape and dimensions, it is thought that it could be a half brick, which is called "kuzu tuğla" in Ottoman terminology. Pressed, yard, machine, chamfered, and frogged bricks are subtypes of solid modern bricks, and three and six holed bricks are subtypes of perforated modern bricks, on which stamps were encountered during the fieldwork. However, it is thought that the stamped flat and modern brick types are not limited to these. Since brick is a material used in the load-bearing system, stamp detection is difficult and generally possible in partially or completely damaged structures and during restoration.

There are three main positions where stamps were applied on brick surfaces: the upper bed face, the bottom bed face, and the stretcher face. The detected stamps of flat bricks were positioned only on their upper bed faces. However, on modern bricks, stamps can be observed on all three faces.

Inscriptions can be classified into five categories depending on their content and the information they provide. These categories are inscriptions with names, letters, numbers, places, and statements. The names in the inscriptions may be the name and surname of the manufacturer or the name of the company. The two capital letters in the inscriptions are the initials of the brickmaker's name. Inscriptions with 1-, 2-, and 4-digit numbers were encountered during research. One- and two-digit numbers are thought to be some kind of identification numbers given to the brickyards to distinguish their products from others in regions where many manufacturers were located together. Four-digit numbers indicate a year that may represent the production time of the brick. The place names seen in the inscriptions indicate the locations of factories or brickyards. Some examples include the names of the cities, while others provide more details, such as district names or even the full addresses. Some inscriptions consist of promotional and complimentary expressions. These statements can be considered as advertisements placed on the product.

The symbols can be divided into five groups according to their form: symbols that include animals, floral patterns, celestial bodies, geometrical shapes, and common objects. It can be said that the most preferred symbols were the bee, the butterfly and the moon and star.

The compiled information also led to secondary findings regarding the Ottoman brick making industry. Important brick production centres, especially the hubs in which industrial establishments were accumulated, were specified. Moreover, the names of high-profile manufacturers and companies in the Ottoman brick industry were distinguished. Additionally, a catalogue that consists of the photographs, the dimensions, and detailed information of the bricks that were subjected to inspection was prepared. The entire catalogue in question will be included in the appendix section of the relevant PhD thesis from which this article was created.

Conclusion

In conclusion, Ottoman brick stamps can be classified into different groups according to their location, content and form. But more importantly, the value of the data received from Ottoman brick stamps should be underlined. Finally, it should be pointed out that this study was carried out with the hope that it would contribute to a better understanding of the Ottoman bricks and brick industry, as suggested by Eyice nearly half a century ago.

Keywords: Kırklareli, Yayla Square, Urban Conservation Area, Architectural Conservation, Restoration.

Aim

According to the Architectural Heritage Conservation Charter of ICOMOS Turkey, urban sites are areas that contain cultural and natural environmental elements (such as structures, gardens, vegetation, settlement patterns, walls) that have architectural, historical, artistic, and local characteristics, and their value increases due to their presence together and their integrity [1]. The urban fabric of Yayla Square and the surrounding neighborhoods constitute the traditional historical settlement of the Kırklareli province. With the decision taken by the Edirne Regional Council for the Conservation of Cultural Heritage in 1996, Yayla Square and its surroundings were designated as an Urban Conservation Area. Following this designation, in 2000, a Conservation Zoning Plan and Implementation Provisions were prepared at scales of 1:1000 and 1:500. With the Conservation Plan, some buildings were registered as examples of civil architecture that should be preserved. In the decisions regarding the site area, there are decisions made for registered structures, traditional structures, new structures, and their surroundings. In 2004, within the scope of the Conservation Project-II course of the ITU Restoration Master's Program, detailed analytical studies were carried out on the basis of street textures and parcels in and around the Urban Conservation Area, and as a result, a conservation project was created. The site protection project carried out for Yayla Square and its surroundings, which has undergone changes over the years, constitutes an important data for evaluating the current site area decisions and practices, identifying the transformation in the area, and detecting the structures that have not survived to the present day.

In this study, research and fieldwork started in 2022. Analytical studies at a 1:1000 scale were conducted based on inventory, documentation, and map drawing. In 2004, an evaluation was conducted by comparing the fieldwork and parcel-based analytical studies carried out as part of the ITU Conservation Project-II course within the scope of the ITU Restoration Master's Program with the analytical studies performed in 2022. This paper aims to present the transformation processes of the area by comparing the data from 2004 to 2022 and to develop recommendations for sustainable conservation planning for the future. These recommendations aim to preserve the cultural heritage values found in the urban site and its surroundings.

Material and Method

In this study, Yayla Square and its surroundings have been considered at the scale of the site. The study area encompasses the site area and its surroundings (Figure 1). Research and fieldwork were conducted in 2022. Documentation work was carried out through observations and photographs. It was determined that the cadastral map of Yayla Neighborhood and its surroundings does not accurately reflect the current situation. The area's plan was updated by processing the 2021 aerial photograph obtained from the Directorate General For Mapping. To document the transformation in the area, analytical studies were conducted at a 1:1000 scale. The analytical studies include environmental condition analysis, cadastral and inventory data, fill-gap analysis, floor count analysis, construction system analysis, registration status analysis, property status analysis, usage status analysis, function and preservation status analysis.

An evaluation was made by comparing the fieldwork and parcel-based analytical studies conducted in 2004 as part of the ITU Restoration Master's Program Conservation Project-II course with the analytical studies performed in 2022. In addition

to these studies, the conservation zoning plan and implementation provisions were examined, along with aerial photographs taken between 1956 and 2021, obtained from the Directorate General for Mapping, to assess the development and transformation of the urban conservation area.

The decisions made by the Edirne Regional Council for the Conservation of Cultural Heritage, approved projects and inventory forms have been reviewed. There are numerous written sources related to Kırklareli province and Yayla Neighborhood. Academic studies containing the texture of the urban site area, civil architectural elements, and restoration works applied have been examined. The book Kırklareli and Traditional Houses, prepared as part of the summer school project conducted by the Architectural Restoration Program of Mimar Sinan Fine Arts University, with its survey drawings, has served as a reference source.

Studies prepared in the field of architectural and urban conservation have been reviewed to understand the concept of urban conservation areas, their architecture, and construction techniques. Additionally, laws, regulations, and agreements related to architectural conservation have been examined to assess the current situation in the area.

Figure 1. Urban Conservation Area and Study Area (Adapted from a 2021 aerial photograph [2]).

Findings

The urban site area located in the central district of Kırklareli province is part of the Yayla and Demirtaş neighborhoods. Yayla Square is situated at the border of these the two neighborhoods. Yayla Square has been used as a gathering and event space from the 19th century to the present day [3]. Around the square, there are photographs from the time of gathering in a building that was used as a school during its period.

The site area and its surroundings contain buildings made with different architectural traditions, including masonry construction systems, wooden frame systems, and mixed construction systems (Figure 2). In addition to the majority of two-story houses with gardens, single-story buildings showing the character of rural settlements with courtyards have also been observed. Most of the buildings are currently used as residences. It has been observed that some of the traditional buildings are no longer in use. To protect the unused buildings from external factors, garden walls have been raised, and the entrances to the buildings have been closed (Figure 3).

Figure 2. Examples of Masonry and Timber Frame Construction Systems.

Figure 3. Example of Traditional Building with Closed Entrances.

As a result of the comparison of the analytical studies prepared within the scope of the ITU Restoration Master's Program, it has been observed that the residential function density has been preserved in the buildings. Although some buildings suffer from the problem of becoming ruins due to neglect, it has been observed that many buildings have been re-functionalized and are in use through restoration and reconstruction practices (Figure 4). It has been determined that most of these buildings have been converted into museums. An example of restoration practice is the transformation of Vali Faik Üstün Primary School into a hotel after its restoration (Figure 5). Although the conservation project suggested maintaining the same function, it has created an important accommodation area for visitors from outside the city and abroad in the area.

Figure 4. Neglect and Deterioration of Buildings Example.

Figure 5. Example of a Restored Building.

It has been observed that the existing terrace roofs have been closed. The analysis revealed that the original paving, which was shown as road coverings, has not survived to the present day. Additionally, the majority of courtyard pavings in registered and traditional buildings have also not survived. The demolition of the building along with its courtyard, the removal of the courtyard paving, and the pouring of concrete are among the reasons for this. Although most of the traditional garden walls have been preserved to the present day, some have had brick or concrete block additions made on top of them. In the new buildings constructed within the site area, it has been observed that the number of floors is three, including the ground floor. It has been observed that the rural character buildings surrounding the site area have gradually been demolished and replaced with high-rise structures. Some buildings have been demolished due to neglect, and their plots remain vacant (Figure 6).

Figure 6. Registered Parcel.

The compared analyses have been evaluated in line with the conservation zoning plan and implementation provisions. These provisions include a decision to prevent the construction of terrace and attic floors in newly built structures. Although there has been a decrease in the number of existing terrace roofs, there is also an example of a terrace roof application in the new building. Additionally, there are buildings where the condition of using traditional roof tiles as roofing material has not been applied. It has been observed that changes have been made in the area designated for preserving the road paving, and the original material is no longer present. It has also been determined that the garden gates, which were to be preserved, have not survived to the present day. In the new construction outside the site area, it has been found that the number of floors has increased, and no buffer zone has been designated in the zoning plan for these areas. A decision was made to relocate the transformer building in Yayla Park to another location, but it has been determined that no changes have been made in the current situation.

Conclusion

It has been observed that the cultural heritage value of the Kırklareli Urban Conservation Area has been maintained, while significant changes and various conservation issues have arisen in the area, particularly due to new constructions in recent years. Thanks to the conservation project prepared in the past, inventory studies, and published academic works, the transformation of Yayla Square and its surroundings over the past eighteen years has been examined. Based on the data obtained from the research, the conservation issues within the site area have been identified. Although zoning decisions have been made for buildings with a rural settlement character, they have not been registered, leading to conservation issues. The non-use of traditional buildings, along with neglect, has initiated the process of decay and demolition. These buildings have been proposed for registration to ensure the protection and transfer of cultural values for the future. Additionally, the concepts of "Interaction-transition zone" in Law No. 2863 and "Buffer zone" in the Valletta Principles should be included in the site area decisions [4][5]. As a result of decisions made under these concepts, a transition area in line with the conservation approach should be created from the site area to its surroundings.

The Rural Settlement Structure and the Challenges of Preserving Traditional Housing in Tokat Bağbaşı (İbibse) Village

Erva Köşker[a], Zeynep Eres Özdoğan[b]

[a] Istanbul Technical University, Graduate School, Restoration Program, Turkey
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture, Turkey
kosker16@itu.edu.tr, eresze@itu.edu.tr

Keywords: Bağbaşı, Conservation, Cultural Heritage, Restoration, Tokat.

Aim

Bağbaşı (İbibse) Village is a rural settlement located in the central district of Tokat province. The village's old name is recorded as "İbibse" or "İlbis" in sources. The name "İbibse" is still used by the local population. It is believed that a city from the Roman period existed in this region and that the village name originates from there. During the Republican period, village names began to be changed to Turkish names. The village took the name "Bağbaşı" due to the abundance of vineyards and gardens. It is located 20 km from the central city of Tokat. The village is situated between two creek beds that feed the Yeşilırmak River, and its settlement pattern is oriented towards the north, built on a sloping area. The historical street layout and traditional buildings have been preserved to this day. Recently, archaeological remains from the Roman period were discovered in a region within the village settlement. Therefore, it can be said that the village is a multi-layered rural settlement area. Due to its representation of rural settlement, Bağbaşı Village has been considered worthy of examination in this paper.

The villagers make their living through agriculture and small-scale livestock farming. Each family also provides its daily needs with vegetables and fruits grown in their gardens. The population of Bağbaşı Village has significantly decreased because the majority of its residents have migrated to the city center. Those who remain in the village are mostly abandoning their traditional houses and building new living spaces on the outer edges of the historical settlement area. Most of the new buildings are used seasonally. The abandoned structures are mostly used as storage, and over time, these neglected buildings deteriorate.

This paper aims to define the historical significance of Bağbaşı Village, identify the cultural values that need to be preserved, document its historical settlement fabric, and propose sustainable conservation recommendations for the preservation of the rural settlement. In this context, the physical, social, and economic characteristics of the village and the central district of Tokat, to which the village is affiliated, as well as the historical development process, are examined.

Material and Method

In this study, the historical settlement fabric of Bağbaşı Village has been documented, with both its architecture and traditional village life considered together. Through field studies conducted in 2023, the architectural layout of the village and the physical characteristics of the buildings were examined, and analytical maps at the site scale were created. The entire study area was documented with photographs between 2023 and 2024. It was determined that the cadastral map of Bağbaşı Village is up to date, and new buildings constructed in recent years have been added. The built environment, architectural, and rural elements were thoroughly analyzed, and a 1/500 environmental condition analysis was developed. To reveal the architectural identity of the area and its conservation issues, 1/1000 scale analytical studies were conducted.

In addition to the analysis of the historical settlement, the architectural features of traditional houses have also been studied at the scale of individual buildings. A total of 24 traditional buildings, selected from those at risk of destruction, were examined in detail. The buildings were documented using traditional survey techniques and original floor plans were completed at a 1/100 scale, while rural architecture inventory forms were filled out. The architectural features, such as the positioning and orientation of the buildings, building entrances, and additionals, have been examined. Typology have been

conducted to better interpret the documented buildings in the village. By examining the architectural changes of traditional buildings over time, conservation issues were explained.
Documents related to the village were scanned at the Presidential Archives of the Republic of Turkey, and the "Temettuat Defteri" was translated from Ottoman Turkish to Turkish and examined. Historical maps covering the province to which the village belongs and documents regarding the change of the village's name were reviewed in the relevant sources. Oral interviews were conducted with the villagers, and information was gathered about the village's history and buildings. Traditional rural architecture, construction techniques, and building materials were interpreted by reviewing previous studies prepared in the field of conservation.

Findings

The traditional single-storey buildings in Bağbaşı Village are generally constructed using stone materials. In two-storey buildings, the ground floor consists of stone walls, while the upper floor features a timber frame system with adobe filling. The buildings' plots include attached or separate structures such as barns and haylofts. The village settlement is oriented to the north, and there are entrances to the buildings from every facade.
The Georgian House, known to be the oldest structure within the historical settlement fabric, consists of a two-storey construction with stone and timber frame system. There is a barn attached to the building. According to oral sources, the original windows on the building's facade has been changed and recently the building has been divided to accommodate two families. However, the original doors on the upper floor and the closets in the rooms have been preserved to this day. The building is currently used seasonally.
The migration of the majority of the village population to the city center has had significant effects on traditional buildings. This particularly caused changes in village life and the abandonment of traditional buildings. Due to neglect, these traditional structures have deteriorated and become unusable over time. As a result, traditional buildings are increasingly at risk of destruction. Some villagers, however, have chosen not to completely abandon village life but instead have constructed new houses using modern construction techniques and materials on their own plots. The abandoned traditional buildings on the same plots are typically used as storage. Some users who continue to live in the village seasonally have abandoned traditional structures and built new living spaces outside the historical settlement area. These new settlements, built on agricultural land, are causing a transformation in the traditional structure of the village and historical settlement fabric.
The village settlement includes a mosque, primary school, village wedding hall and a health clinic. The old mosque of the village has collapsed over time. However, the minaret, built using traditional construction techniques with bricks, has been preserved to this day. Recently, a new mosque has been constructed on the site of the old mosque. The primary school, located at the entrance of the historic settlement area. Afterward, children from the village continue their education at schools in the city center. An archaeological excavation in the schoolyard has recently uncovered pots and artifacts dating back to the Late Roman Empire. This area has been registered as a 3rd Degree Archaeological Conservation Site. On the opposite side of the archaeological site, there are wall remains believed to belong to an inn. The village wedding hall and health clinic have lost their functionality in recent times.
The water channels found in the study area hold significant importance in the village settlement and agricultural lands. They are primarily used for irrigation in traditional village life. The water channels are generally open, but in locations where roads pass over them, they have been covered. The old mill located to the south of the historical settlement area has been lost to the present day. There is a pool near that area. Two different water sources, one in the southeast and one in the southwest outside the settlement area, have endured to the present day.
The main source of income for the villagers is agriculture and their daily life is largely spent working in the fields. They also provide their daily needs from the vegetable gardens within the village settlement. In addition to agriculture, small-scale livestock farming is also common.

Figure 6. The Interior of the Georgian House in Bağbaşı Village: Original Examples of Closets and Doors.

Figure 7. An Example of Traditional House Interior in Bağbaşı Village.

Conclusion

Based on the data obtained from the research, the architectural conservation issues of Bağbaşı Village have been identified. The easy access to electricity and water for the villagers has significantly impacted the traditional way of life. The interior structure of the houses is being changed to adapt to new requirements. Some buildings are being modified with additions that are far removed from traditional materials and techniques, or existing spaces are being reshaped. This results in the destruction of the original architecture of the interior. Roof repairs made with new materials and the replacement of windows and doors with new materials of different sizes on the facade are among the repairs made without proper consideration.
In the development of the conservation approach for Bağbaşı Village, ICOMOS's Charter on The Built Vernacular Heritage (1999) has been examined. The traditional houses and barns identified within the historic settlement will be proposed for registration. Inappropriate additions that disrupt the facade design and do not conform to the architectural layout should be removed. Additions should be made in accordance with new requirements, without altering the original form of the traditional structure.

After the large-scale migration to the city center, the abandoned traditional houses are left neglected and are at risk of destruction over time. Many families living in the village are abandoning their traditional structures and building new living spaces on the outer edges of the historical settlement. These new settlements are being constructed without the use of traditional materials and techniques. As a result, they are disrupting the historical settlement fabric. However, new settlement should be designed in a way that does not damage the historical settlement fabric and does not affect agricultural land. The agricultural economy of the village should be revitalized. In this way, different incentives should be provided to motivate the population who moved to the city center to return to their village.

Keywords: Architectural heritage, Modern building materials, Renders.

Aim

Discussions on authenticity have significantly influenced architectural conservation theory. Material authenticity is now internationally recognized. Since the Venice Charter of 1964, various documents have presented the importance of original materials in the preservation of cultural heritage (Polat-Pekmezci, 2024). An important example of these documents is the 'Nara Document on Authenticity'.

Today, architectural conservation theory has a perspective that covers buildings, materials and construction techniques from all periods. Conservation interventions are being carried out on twentieth-century buildings and widely used cement mortars as they are the documents of the modern construction culture. The Madrid New Delhi document of ICOMOS ICS20C is an important guide on 20th century buildings. According to the document the 20th century was characterized by innovative structural solutions, building materials and construction techniques and there is a need to research and develop specific repair methods to modern buildings (Docomomo International, 2017). More than a hundred twentieth-century buildings are on the World Heritage List and the preservation of these structures is on the agenda. When carrying out conservation efforts on modern buildings, it is essential to determine a suitable function for re-use and also to sustain the material characteristics of the buildings. The effective conservation of 20th century buildings requires a comprehensive knowledge of the materials used. This paper aims to document, analyze, and discuss the current state of conservation and the potential for conserving materials used in the architectural surfaces and finishes of modern architectural heritage in Istanbul, Türkiye.

Material and Method

The study focuses on buildings constructed in the first half of 20th century in the districts of Beyoğlu, Şişli, Fatih, and Kadıköy where the registered buildings of the Republican period are prominent in İstanbul (Kudde, 2024).

The research methodology was divided into three stages. In the first stage, academic sources from the relevant period were compiled and evaluated to gather information on the construction techniques, materials used, and architectural details. The primary source of information was the architectural journal, Mimar/Arkitekt, which offered valuable insights into the building materials and construction methods through its articles and photographs.

The second stage involved examining the current condition of the materials referenced in the publications, enabling a better understanding of the terminology and techniques used during that period. Fieldwork included locating the buildings, capturing detailed photographs, and creating sketches to document construction techniques and details. The final stage involved assessing the conservation status of the buildings by comparing their original condition with their current state.

Findings

The Arkitekt Journal, established in the 1930s, is a valuable resource for information on modern buildings, their materials and construction techniques. In the early years, the focus was predominantly on residential buildings, with architects Abidin Mortaş, Seyfi Arkan, Mimar Hüsnü, Adil Denktaş, Zeki Sayâr, Emin Onat, and Rebii Gorbon contributing to the design and construction. Multi-storey apartment buildings were common in neighborhoods like Ayazpaşa, Maçka and Nişantaşı, while two-storey garden houses were built in Suadiye, Kalamış and Moda. The buildings are constructed using reinforced concrete systems and cementitious materials. The floors are finished with decorative cement tiles, terrazzo or terrazzo tiles especially

in circulation and wet areas. Prefabricated stair treads can be made of cement mortar containing colorful aggregates. The facades were enhanced with various application techniques (Shown in Figure 1.).

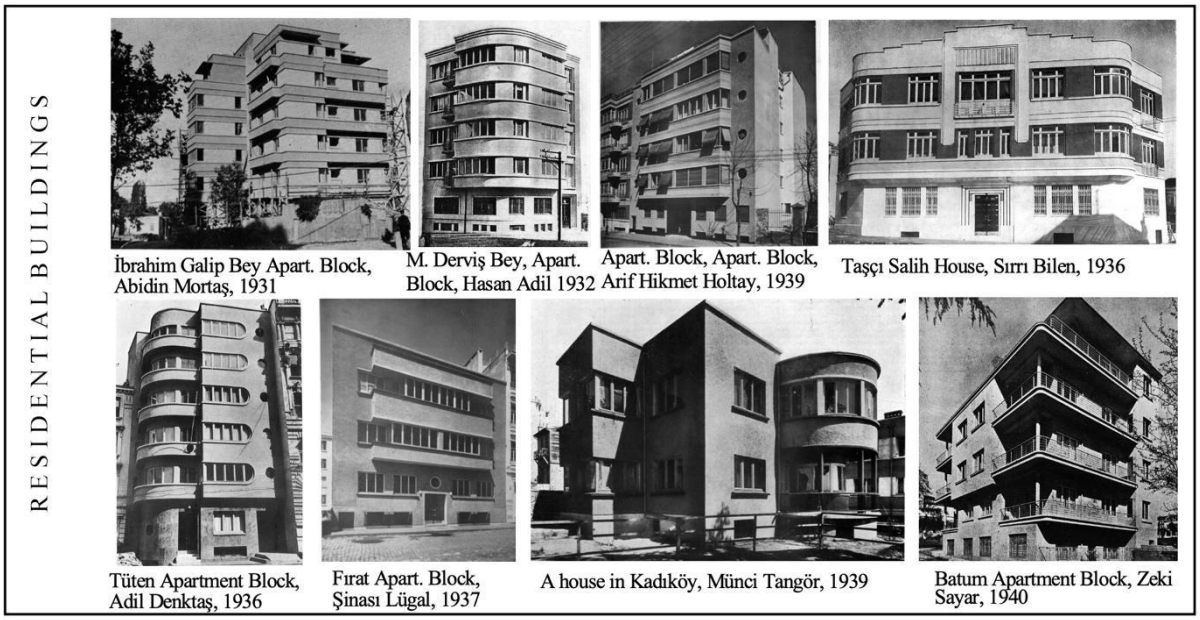

Figure 1. Examples of residential buildings constructed between 1930-1950 (Source: Arkitekt Journal).

In the 1940s, the focus shifted to the construction of commercial and public buildings including ministerial buildings, telephone central offices and public facilities. Notable structures from this period were the Valide Hanı in Sirkeci, Şişli Telephone Central and Zeki Sayâr's apartment building in Kadıköy. The ministerial buildings were constructed with similar materials and construction techniques by Construction Offices of the Ministry (Anonim, Hocapaşa Maliye Şubesi, 1938) (Anonim, Telefon Santralı Binası, 1940). Unlike residential buildings, the facades of public buildings lack projections but they feature curvilinear corners, horizontal lines and rhythmic window arrangements, as illustrated in Figure 2.

Figure 2. Examples of public buildings constructed between 1930-1950 (Source: Arkitekt Journal).

The first issue of Arkitekt Journal, published in 1932 featured an article that highlighted the significance of color composition in modern architecture. The author emphasized the use of exterior plasters to achieve the desired color effect. Painting lime or cement plaster or adding various crushed stone powder or mineral paint into the mortar are suggested as affordable solutions (Shown in Figure 3.). Terranova and Edelputz plasters gained popularity in Ankara, Bursa, and Istanbul in the 1930s and were favored for their crack resistance, color retention, breathability, and water repellent properties (Mimar Hüseyin, 1932).

Figure 3. Façade textures (Mimar Hüseyin, 1932).

The article published in Arkitekt in 1941 is a translated version of Eduard Jobst Siedler's "Lehre vom Neuen Bauen" and 1937-12 issue of "Deutsche Bauzeitung". The text provides insights into the various aspects of plastering, including the tasks performed by exterior plasterers, the requirements for good plastering, and the composition, application, and color of plaster mortar. The text also describes dry mortars, which are high-quality plasters manufactured in factories and then applied on-site by adding water. These dry mortars contain water-repellent additives. Additionally, the article describes renders that are processed by stonemasons. Notably, the recipes used by manufacturers in Germany are registered, and the hardness of these renders can exceed that of natural stones (Anonim, Binalarda Dış Sıva Tekniği, 1941).

Figure 4. Original surfaces of 20th century heritage.

36 articles containing significant information about buildings from Beyoğlu, Şişli, Kadıköy and Fatih districts have been selected. Today, 30% of these buildings are in situ and most of the preserved buildings are located in Beyoğlu. Amongst these buildings all of them except 5 are residential. 16 of them are garden houses, 15 of them are apartment blocks.
Façade finishing materials may vary on the ground and upper floors. Typically, marble stone and less commonly, cement plaster were used for ground floor façades. In contrast, all upper levels were covered with cement plaster. A smooth surface was generally created for the sills, moldings and jambs. On the front façades, various cement mortars were employed to produce different textures. Terranova, Edelputz and stone imitation plasters were widely used on the exterior facades of these buildings. Surfaces were created by craftsmen with hand tools. The facade design of these buildings includes a range of textures and color choices (as shown in Figure 4).
Cement plasters were made with colorful mortars. Color information of the buildings from 30's also compiled from articles. According to the articles in Arkitekt Journal, colorful finishing mortars were commonly in cream, beige, and grey tones. While some buildings utilized a pure cement color without any color additives, others showcased monochromatic surfaces (Sayâr, 1937) (Gorbon, 1937) (Denktaş, 1936). Additionally, there were examples of polychromatic surfaces (Adil, 1932) (Santur & Mortaş, 1932) (Anonim, İstiklâl Apartmanı, 1932).

Conclusion

Modern buildings have different kind of conservation problems from older buildings. Firstly, they are not yet protected in the way they deserve, as they are often not evaluated as heritage by decision-makers. It was observed that the facades of the buildings exemplified in the text have been painted over the original material, which disrupted their authenticity. Furthermore, the additional layers of paint can conceal structural and material deteriorations, allowing significant problems to develop unnoticed.
When making any interventions, it's important to consider the original materials, textures, and colors to ensure that the buildings maintain their historical value. Original materials used in the interior or exterior facades of modern buildings should be preserved to sustain modern architectural characteristics. Yet, various methods have been tried to protect surfaces of modern buildings. The World Heritage Site, Walter Gropius's Bauhaus Dessau of 1926 (Markgraf, 2006), and the buildings of Le Corbusier and Pierre Jeanneret (Fentzloff & Arnold, 2013) (Balletti, 2017) exemplifies projects that focus on preserving original surfaces. Similarly, Adalberto Libera's Malaparte House constructed in 1938, demonstrates an archaeological approach when planning intervention to 20th century buildings (Pittaluga & Quiros Castillo, 2024). These vibrant surfaces are not only aesthetic, but also important documents that convey the building techniques and material knowledge of the period. Such details play a decisive role in understanding modern architectural heritage.

Keywords: Concrete Waste Management, Smart Recycling Systems, Sustainable Building Technology, Urban Environmental Control.

Aim

The construction industry is responsible for major contributions to the global economic development of a nation, however, is also one of the leading causes of environmental degradation. Urban cities such as Istanbul generate high levels of urbanization, urban renewal work, and constant building activities that yield enormous amounts of construction and demolition (C&D) waste. Studies indicate that 3-5 million tons of concrete waste are created annually in Istanbul. With the anticipated large-scale urban transformation projects, especially considering the city's vulnerability to earthquakes, this number could rise dramatically, potentially reaching 320 million tons.

Despite the magnitude of the waste amount, existing waste management practices remain inefficient. The conventional methods are high in cost, environmentally damaging and logistically impractical. Current recycling processes often require extensive land use, involve high transportation costs, and increase significantly to carbon emissions. Furthermore, conventional recycling processes do not recover the cement content of concrete, resulting in more CO2 emissions and wasted material. The aim of this study is to introduce an entrepreneurship proposal named "UrbanReCrete" as a greener alternative to conventional recycling practices. UrbanReCrete proposes a new vision that recycles demolition waste back into reusable materials of concrete that have lower carbon emissions and increased efficiency in construction waste management. This research examines the potential of UrbanReCrete's approach, evaluates its economic and environmental benefits, and presents a roadmap for its implementation in Istanbul's construction field.

Material and Method

UrbanReCrete as an entrepreneurship project proposal has an approach that is based on a comprehensive examination of the state of affairs concerning construction and demolition waste management, using the contrast between traditional practices and emerging technologies, to assess their economic and environmental impacts. The approach is developed with a mixed-method study including four key components: Quantitative Analysis of the Current Scenario, Comparison of Traditional Methods and Contemporary Technology, Analysing Its Economic and Environmental Benefits, Strategic Plan for Large-Scale Valorisation.

The study takes into account the volume of construction waste generated annually in Istanbul and its anticipated growth due to urban transformation. Quantitative analysis provides a precise image of the scale of the problem. A comparative analysis of traditional recycling techniques and UrbanReCrete's SmartCrusher technology is provided. Traditional and modern methods are compared in terms of efficiency, environmental and financial aspects. The economic viability of the deployment of SmartCrusher technology in terms of opportunity in the marketplace, computational costing, operating model, and financial viability is also considered. Furthermore, the way its implementation could contribute to ensuring sustainability goals in terms of a reduction in carbon emissions and resource utilization is addressed. UrbanReCrete's valorisation roadmap facilitates industry integration through policy support and incentives, leveraging SmartCrusher technology to optimize concrete recycling, reclaim cement fines, and reduce CO2 emissions.

Findings

The findings of this study indicate that the use of UrbanReCrete's SmartCrusher technology presents significant environmental, economic, and logistical advantages. Current concrete recycling methods are inefficient due to high capital

needs, energy-intensive processes, and no capacity to recover cement fines. UrbanReCrete overcomes these shortcomings by a technologically advanced, mobile, and cost-effective system.

The key aspects of the strategies developed by UrbanReCrete, an entrepreneurship project proposal, can be listed as mobile recycling units, increased material recovery, sustainability incentives and carbon footprint reduction. Unlike conventional recycling plants that require significant infrastructure and fixed bases, UrbanReCrete mobile units enable on-site treatment. This reduces transportation costs significantly and greenhouse gas emissions from trucking construction waste to distant recycling plants. SmartCrusher technology recovers high-quality aggregate and fine particles to be reused in new concrete production, achieving the highest level of material efficiency with minimal use of virgin resources. Through being aligned with government policies and sustainability programs, UrbanReCrete is rewarded with fiscal incentives such as tax credits and green funding incentives. Cement fines recovery results in significant CO2 savings. For example, with a processing rate of 80,000 tons annually, UrbanReCrete can recover up to 11,200 tons of CO2-free cement fines annually, offsetting cement plant emissions directly. In addition, the methodology considers economic and logistic aspects, assuring sustainability in the regulatory framework of Istanbul. UrbanReCrete collaborates with İSTON, a municipal construction subsidiary, to ensure the utilization of recycled concrete in municipal infrastructure projects. Cost-benefit analysis and return on investment is conducted to determine economic feasibility.

The estimated revenue stream model created based on these feasibility studies consisted of service fees that recycle waste concrete for İSTON and generate revenue from the recycling services themselves; and recycling fees aimed at selling recycled aggregates and cement-sand components to contractors based on municipal policies that encourage contractors to consume recycled concrete in construction. The model operates with an annual revenue of more than 135% of its total costs, with profitability and payback period of just 1.6 years. Additionally, UrbanReCrete also has sustainability benefits like reduced urban disturbance, better waste management, and lower carbon emissions. As the construction sector is being more and more entrusted with meeting sustainability goals, adopting UrbanReCrete's approach is also aligned with industry and government initiatives towards circular economy strategies. On the other hand, UrbanReCrete's ecological impact is likely its biggest selling point. Cement production accounts for roughly 8% of worldwide CO2 emissions. With the potential to recycle cement fines through SmartCrusher technology, these emissions are reduced and UrbanReCrete is an essential tool in climate change protection. The reduced amount of natural aggregates used also cuts down on habitat loss and resource consumption, adhering to broader sustainability goals.

From a commercial point of view, the market for green building materials is increasing very rapidly. The global market for green building materials is projected to grow each year at 9.5% until 2031, which is a very good opportunity for UrbanReCrete. Because Istanbul is undergoing large-scale urban renewal, the city is a significant market for green building solutions.

Conclusion

UrbanReCrete provides an innovative entrepreneurship to the construction waste management challenges of Istanbul. Using the latest technology, mobile recycling capability, and environmentally friendly business models, the scheme has the potential to reduce carbon emissions enormously, make recycling more efficient, and support urban sustainability goals. The scalability of this approach goes beyond Istanbul and offers a template that can be rolled out for other metropolitan cities with comparable waste management issues.

UrbanReCrete's future potential lies in the rationalization of the SmartCrusher technology to enhance efficiency and reduce costs, increasing market coverage through collaboration with municipalities and the private sector, and integrating automation and artificial intelligence-based sorting technologies to optimize recycling processes. By addressing both economics and environmental factors, UrbanReCrete presents a new solution for circular economy interventions in the construction sector, minimizing the environmental impact of urbanization while promoting sustainable development.

Reduction of Cooling Loads in Office Buildings in Hot Climates Using Radiant Cooling

Yasemin Kılıçoğlu[a], Gülten Manioğlu[b]

Keywords: Radiant cooling, Chilled Ceiling, Cooling Load.

Aim

The increase in global average temperatures due to the effects of global warming has led to a rise in cooling demands in buildings to ensure occupant comfort. Consequently, energy consumption for cooling purposes has significantly increased. Office buildings, due to their high internal heat gains resulting from a large number of occupants and extensive use of equipment, tend to be energy-inefficient. This inefficiency is further exacerbated by contemporary façade designs, which frequently incorporate a high proportion of glazed surfaces. Excessive heat gains through these façades contribute to elevated indoor temperatures, necessitating the operation of active cooling systems to maintain thermal comfort, particularly in office buildings located in hot climates. As a result, a considerable amount of energy is consumed for cooling purposes.

It is well known that 38% of the total global energy consumption is attributed to meeting the cooling demands of buildings. With the increase in the number of buildings and, consequently, rapid urbanization, the rising demand for cooling has led to the continuous expansion of cooling system usage. According to energy efficiency reports, more than 66% of the energy consumed in the building sector is used for HVAC systems and lighting. Since cooling systems release the heat extracted from buildings into the surrounding environment, they contribute to the enhancement of the urban heat island effect. As a result, rising temperatures due to global warming are further exacerbated by the waste heat generated from active cooling systems, leading to an even greater dependence on cooling technologies. This increasing reliance on cooling systems creates a self-reinforcing cycle, highlighting the need for innovative solutions to break this pattern.

The Sustainable Development Goals (SDGs), particularly SDG 7 under the theme of "Affordable and Clean Energy," encourage universities to develop sustainable solutions. One such sustainable approach aims to reduce high energy consumption in buildings while ensuring thermal comfort through efficient cooling strategies (Villar-Ramos et al., 2022). In this context, research has been conducted on passive cooling systems as potential alternatives to conventional HVAC systems.

One of these passive systems, radiant systems, can provide heating and cooling through pipes filled with cold or hot water. In these systems, ventilation and humidity control requirements are met by a DOAS (Dedicated Outdoor Air System). In offices, conditioning and ventilation of spaces account for 41-51% of the total energy load. The use of water to transport and remove heat in a building is more efficient than air, which makes it possible to reduce this energy expenditure with radiant systems. Water transfers thermal energy approximately 7 times more effectively than air (Ali & Naik, 2016). There are different versions of radiant cooling, and their types can be integrated into building components (Vivek & Balaji, 2023). Ceiling-based radiant cooling is more energy-efficient for cooling in summer. The direction of convection currents developed is consistent with the temperature gradient, meaning that cold air falls, facilitating the upward movement of warmer air from the heat source at the floor level (Fairconditioning, n.d.).

The Chilled Ceiling system is a ceiling-mounted system designed to cool the space beneath it in a silent, draught-free manner. Each unit consists of small-diameter chilled water pipes arranged in an S-shape, which are attached to the upper surface of a ceiling panel. The ceiling panels are typically made of thin metallic material, though they may also be made of gypsum board. In some systems, the chilled water pipes are embedded within the ceiling panel. During operation, the panel is cooled through contact with the chilled water piping and cools the space through convective and radiant heat transfer (approximately 40% of the cooling is radiant). Chilled ceiling systems require a separate ventilation system for the supply

of fresh air. Condensation of air within or on the chilled ceiling can be prevented by cutting off the chilled water flow, depending on the room's dew point (DesignBuilder Software, n.d.-a).
The study area is determined as the Bayraklı district of İzmir. Bayraklı is known as a developing business center in İzmir. The region predominantly consists of office buildings, and high-rise buildings with curtain wall facades are commonly constructed. In this context, the increasing number of curtain-wall office buildings in the İzmir Bayraklı region is considered a significant issue in terms of cooling. The lack of sufficient decisions regarding passive design strategies, such as the materials used for office building facades, the orientation of the building, and the thermal performance of the building envelope as determined by regulations, has led to office buildings becoming increasingly dependent on ventilation systems and air conditioning units, further exacerbating cooling loads. Therefore, this study aims to develop solutions to reduce the cooling loads of office buildings in a hot, humid climate region such as İzmir. To achieve this goal, the chilled ceiling system, which provides ceiling-based radiant cooling, will be compared with the commonly preferred Fan Coil system in office buildings.

Material and Method

This study aims to propose solutions to reduce cooling loads for office buildings in the İzmir Bayraklı District by creating façade options with different material choices. To achieve this goal, various scenarios have been developed, and simulations have been conducted through the DesignBuilder simulation program, which is an extension of EnergyPlus.
Primarily, a three-story office building with dimensions of 20x20m and a floor height of 3.5m. Plan is shown on Figure 1. The ofice building was modeled in the DesignBuilder program. The building features a 90% glazing façade on the north, east, south, and west sides. The perspective view of the design builder model is shown in Figure 2.

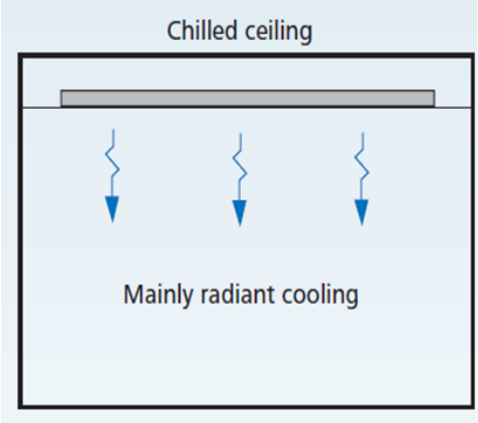

Figure 1. Chilled ceiling schematic representation
Note. Reprinted from Editing zone chilled ceiling, by DesignBuilder Software, n.d., https://designbuilder.co.uk/helpv7.2/Content/Detailed%20HVAC/EditingZoneChilledCeiling.htm. © DesignBuilder Software.

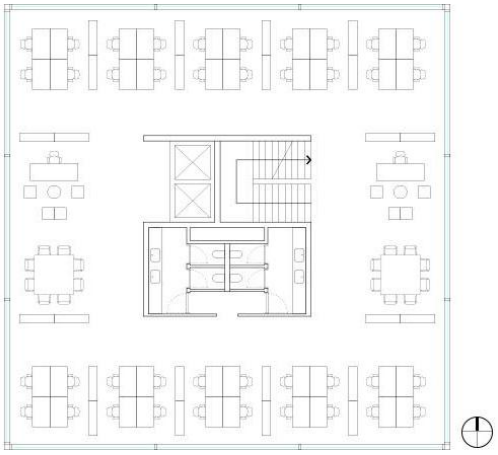

Figure 2. Open Ofice Plan.

Designed as an open office, the building includes enclosed areas only for the stairs, elevator, and restrooms. The walls of these areas were defined as adiabatic surfaces in the DesignBuilder software. Adiabatic surfaces prevent heat transfer through them and are generally applied to simulate interfaces with other spaces whose temperatures are approximately equal to that of the zone (DesignBuilder Software, n.d.-b). Office working hours are set from 8:00 AM to 6:00 PM on only weekdays, and the simulation period is defined to represent the cooling season from May 15th to September 15th. The office building model was simulated using two different types of glazing (G1: Double Glass, G2: Double LoE Elec Ref Bleached) (Table 1) with Fan Coil and Chilled Ceiling systems. The set points were determined according to the ASHRAE adaptive comfort model standard, where comfort levels range between 26°C and 28°C for cooling and between 19°C and 21°C for heating (ASHRAE, 2020).

Materials were defined in the simulation program according to the U-values specified for Zone 1 in the TS825 (2013) Standard, which includes İzmir. The U-value for the walls in Zone 1 is 0.66 W/m²K, the U-value for windows is 1.8 W/m²K, the U-value for the floor is 0.66 W/m², and the U-value for the roof is 0.43 W/m²K (Turkish Standards Institution, 2013). The U-values specified are shown in Tables 2.

For the first mechanical system main office zone, a "fan coil air-cooled chiller was selected as a suitable system for İzmir's climate. Fan coil units operate through a water loop connected to chillers and boilers, providing hot or chilled water for heating and cooling. An air handling unit was added to the system. The fan coil datas was simulated as autosize in DesignBuilder.

The second mechanical system evaluated is the chilled ceiling system. For the chilled ceiling system, parameters such as hydronic tubing length and maximum chilled water flow rate were set to autosize in DesignBuilder. The hydronic tubing inside diameter was specified as 0.013 meters. Additionally, the zone temperature control type was set to operative temperature.

The .epw format Typical Meteorological Year (TMY) 2007-2021 weather data file for İzmir was imported from the Climate.org website and used for energy calculations in the simulation tool (Climate Institute, n.d.). It is assumed that the building under consideration is located on a flat terrain and is not shaded by any surrounding structures.

Findings

The office building model created for İzmir was simulated separately for two different types of glass with Fan Coil and Chilled Ceiling systems. According to the calculation results, when the G1 option is used, the total energy consumption for cooling is 165,873.1 kWh with the Fan Coil system and 146,721.42 kWh with the Chilled Ceiling system. This indicates

that the Chilled Ceiling system reduces the total cooling energy by 11.54% for G1. When the G2 option is used, the total cooling energy consumption is 125,213.55 kWh with the Fan Coil system and 104,581.24 kWh with the Chilled Ceiling system. This shows that the Chilled Ceiling system reduces the total cooling energy by 16.47%. The calculation results are shown in Figure 3. The highest cooling load was observed in the Fan Coil and Glaze 1 configurations, while the lowest cooling load was observed in the Chilled Ceiling and Glaze 2 configurations.

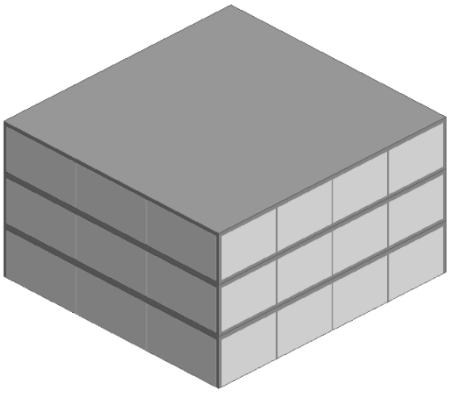

Figure 3. Building Perspective.

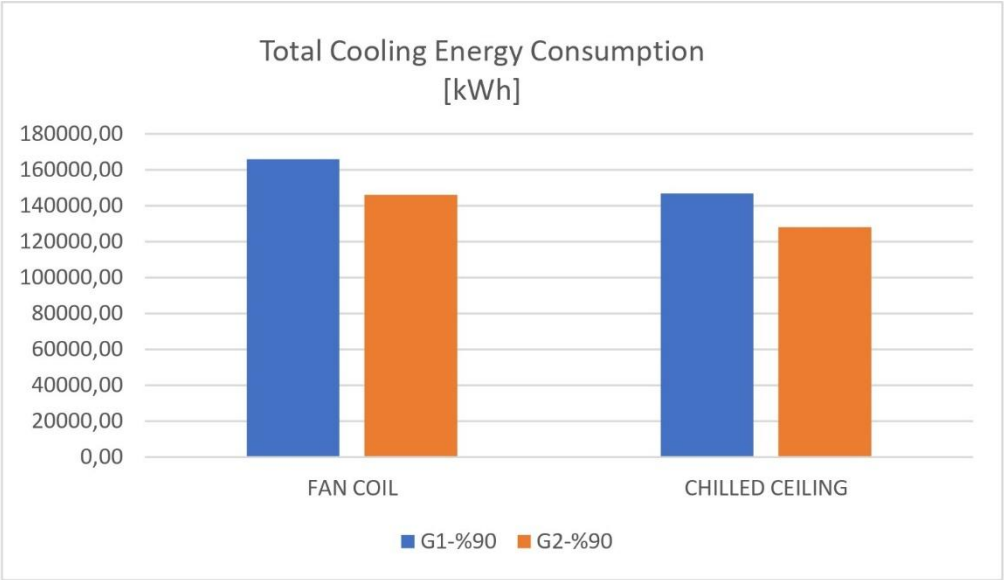

Figure 4. Total Cooling Energy Electricity Consumption.

Conclusion

In hot climate regions, cooling is regarded as a basic necessity that directly influences the quality of life. User comfort is significantly affected by high temperatures. In buildings, effective cooling strategies are required to maintain indoor temperatures at acceptable levels. With the ongoing effects of increasing urbanization and global warming, cooling demands are being continuously raised. However, serious problems are caused when this demand is met through traditional, energy-dependent methods. Therefore, the development of cooling solutions that enhance energy efficiency in hot climate regions is considered highly important.

As a result, it has been observed that the Chilled Ceiling system is an energy-saving system compared to the Fan Coil HVAC system. It was found that the type of glass can be even more critical than mechanical systems in affecting the building's cooling loads. When a better glass with a lower Solar Heat Gain Coefficient value is selected, it has been shown that this ratio can achieve even better results.

As limitations and possible directions for further research, different types of glass with varying transparency levels can be compared. Other façade systems used in office buildings could also be examined. The study focused on a building type with open facades on all four sides (N-S-E-W), but this could be expanded by simulating the building with different orientations. Additionally, the study could be conducted for various climate types.

Multi-Stage Space-Adaptive Shelters: An Alternative to Post-Disaster Shelters

F. Berke Cilesizoglu [a], Oguz C. Celik [b]

[a] Istanbul Technical University, Graduate School, Environmental Control & Construction Technology, Turkey

Keywords: Space-Adaptive Structure, Post-Disaster Shelter, Computational Design.

Aim

On February 6th, Earthquake doublets of M_w=7.8 Pazarcık and M_w=7.6 Elbistan/Ekinözü (Ding et al., 2023) have devastated the southeast Turkey by damaging the existing building stock and urban infrastructure, affecting nearly 13.5 million people living in the region. (Celik et al., 2024) A reconnaissance has taken place in the aftermath of the earthquakes to assess the damage and disaster-relief sheltering situation. The immediate need for shelters in abundance caused a strain on manufacturing and construction, with tents and containers being the main solutions. After 2 years, official documents show that 650.000 people still live in 395 container sites in the region, which shows that emergency actions taken in face of catastrophes can have long-lasting effects (Presidency of Strategy and Budget, 2025).

There are various widely recognized post-disaster shelter types offering solutions to different sheltering issues such as emergency, upgradability, durability or comfort. (IFRC/RCS, 2013) In the context of this research, sheltering can be summarized in three important and distinct stages based on both core and recent literature (Quarantelli, 1982; UNHCR, 2021). An immediate stage that answers the emergency need for sheltering, deployed quickly and intended to be habitable for a short time. An interim stage that answers basic requirements and partial comfort until next stage. Finally, an intermediate stage offering temporary housing with adequate comfort conditions. While current solutions suffice the requirements for each stage, their temporary nature and immense numbers creates an abundance of material waste, energy waste and occupied plots (Rios et al., 2015). Ongoing studies aim to bridge the gap between stages; however, an all-encompassing solution is not available due to unique properties of each stage (Abu-Aridah & Ligler, 2024; Shahkar, 2022). Authors aim to improve the workflow of disaster-relief sheltering by offering an alternative sheltering solution based on space-adaptive systems that progressively answer the aforementioned three stages. Multi-Stage Space-Adaptive Structures (MSSAS) are structures that can respond to the changing needs and environmental effects whose spatial qualities can be altered through their structural parts, deployment or replacement. Authors aim to employ MSSAS and their inherent adaptive attributes (Abdullah & Al-Alwan, 2019; Maierhofer & Menges, 2019; McCoy & Duffy, 2022) to answer different needs and challenges of these stages using computational design methods, and a combination of durable high-tech materials and local low-tech materials (Antonini et al., 2020).

Material and Method

Adaptability (Kronenburg, 2013; Matheou et al., 2023; Mitsimponas & Symeonidou, 2024; Schmidt III & Austin, 2016) serves as a crucial aspect of architectural practice to respond to environmental (Loonen et al., 2013) and social transformations (van Ellen et al., 2021), emerging crisis situations (Valcárcel, 2024) and other unforeseen circumstances. Computational design (Caetano & Leitão, 2024; Menges & Ahlquist, 2011) represents a methodology that incorporates generative algorithms, integrated structural analysis and computational design tools into the creative process (Fleischmann et al., 2012; Menges & Ahlquist, 2011; Yazici & Tanacan, 2020). This method proves suitable for adaptive design frameworks, as this approach aligns with the concept of designing systems with multiple variations and configurations that can respond to changing parameters. MSSAS are intended to be established both theoretically and technically by research-through-design method (Roggema, 2016).

A case study is designed for Buruncayir Village in Adiyaman, southeastern Turkiye, in order to observe the effects of site-specific design elements: soil, earthquake, wind and climate. Design was created in NURBS-based CAD environment

(Rhinoceros3D) with visual algorithm tools (Grasshopper) and integrated multi-objective optimization, and structural analysis tools (Karamba3D). Functionality and transformation of structure were tested using a 3D-printed PLA functional prototype. In order to evaluate applicability and feasibility of the case study, spatial, material and construction standards, has been established through analysis of universally accepted guidelines (Sphere Association, 2018), local regulations (TS498, 2021; TBEC, 2018) and 53 well-documented works (IFRC/RCS, 2011, 2013; UNHCR, 2016, 2021) built in the 21st Century (Table 1.).

Table 1. Requirements (maximum values) for three sheltering stages.

	Immediate Stage	Interim Stage	Intermediate Stage
Lifespan	1 Year	5 Years	10 Years
Construction Time	1 Day	7 Days	10 Days
Cost	€500	€2000	€2500
Covered Living Area	12 m^2- 18 m^2	12 m^2- 24 m^2	16 m^2- 24 m^2
Cargo Weight	5000 kg	10000 kg	50000 kg
Cargo Volume	5 m^3	10 m3	40 m3

Construction	Pre-fabricated	In-situ	In-situ
Earthquake Resistance	Lightweight Structure/ Adequate Rigidity		
Wind Resistance	Deep Foundation		
Flood Resistance	Elevated Floor		
MEP Services	Not Mandatory	Mandatory	Mandatory

Findings

MSSAS is a deployable progressive structure with modular elements and reconfigurable parts. MSSAS is deployed to create a self-supporting single-layer shell structure **(Figure 1)**. Main structural elements are steel tubular elements and steel hinge connections. The hinged connection details were designed in a way to accommodate eight connections in four axes and, when in free motion, rotation around X-axis in order to fold/unfold the structure. Z-axis allows direct connection to cladding, effectively transferring the loads directly to the joints (**Figure 2)**. Form finding algorithms based on hanging chain model were computed using multi-objective optimization algorithm with minimum weight, minimum displacement (in relation to minimum stresses), maximum living area goals. The structural elements are parametrically generated through their geometric relationality according to site-specific needs. Due to its modularity and transformable form, different-sized shelters for different functions can be built with the same elements **(Figure 3**).

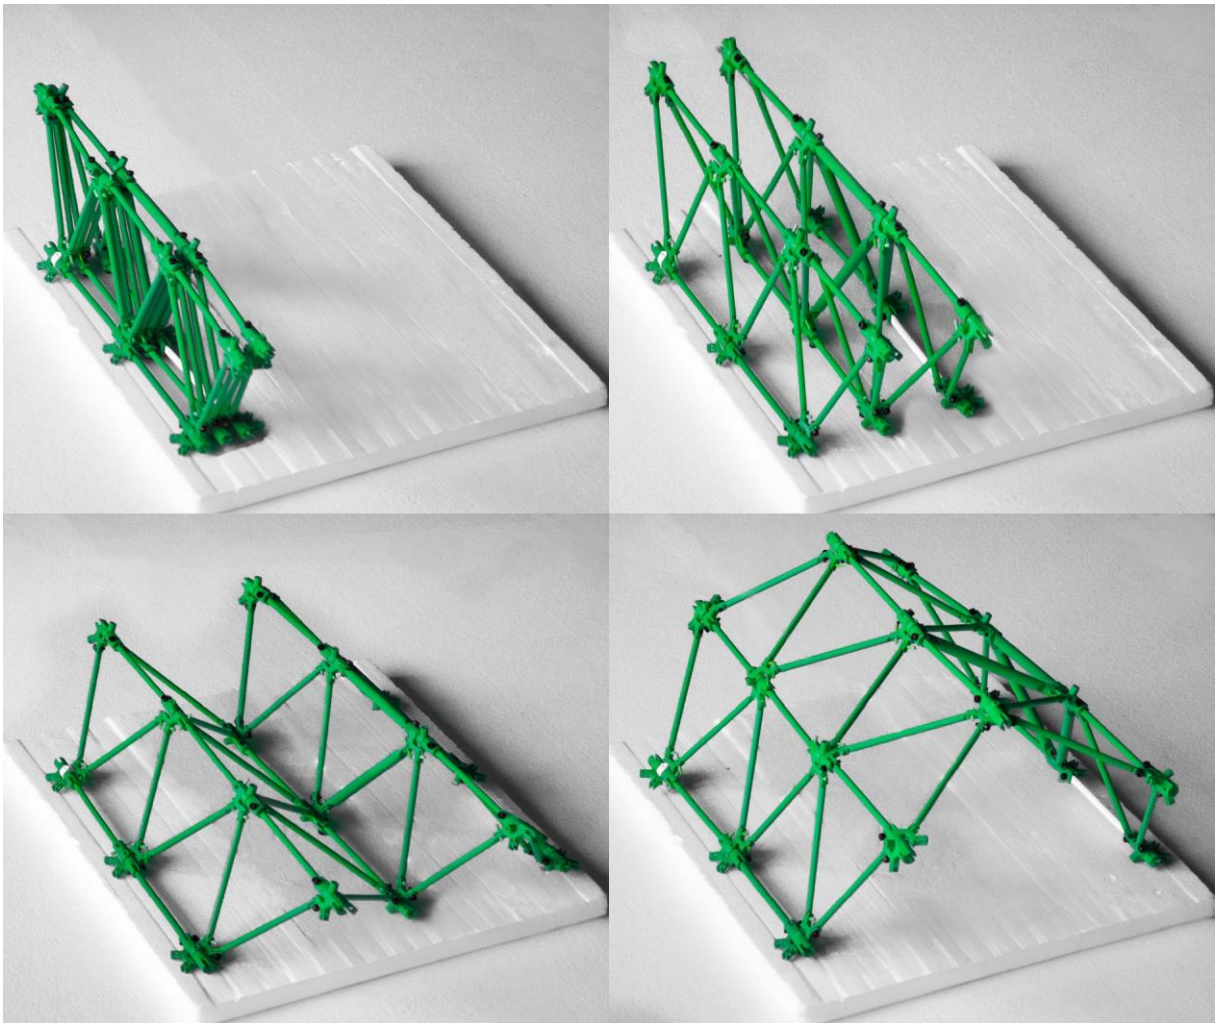

Figure 1. 3D printed functional prototype.

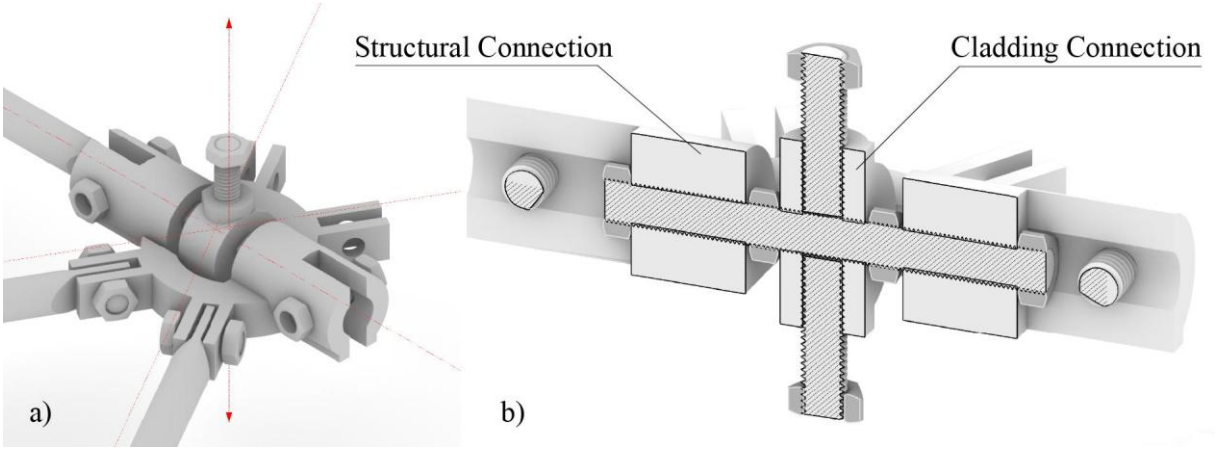

Figure 2. (a) Axonometric perspective, (b) section of detail.

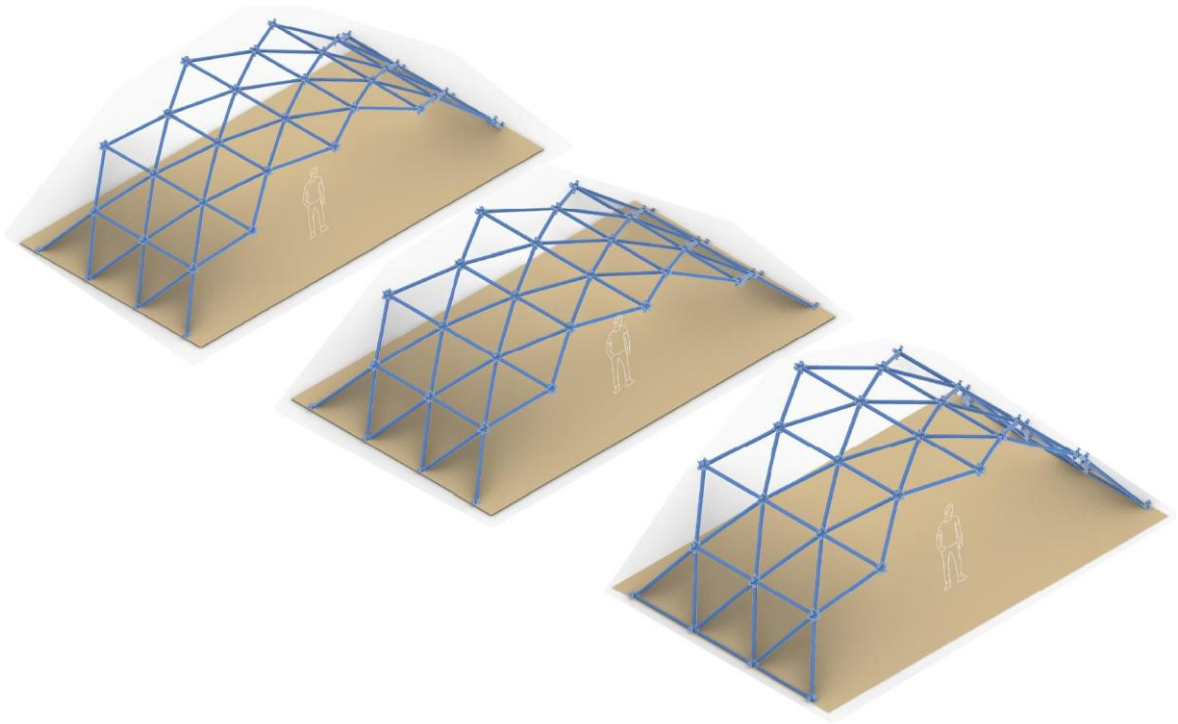

Figure 3. Diagrams showing different forms created by the same modules.

The floor must be elevated using adjustable steel footing to level living area, provide flood protection and create crawl space to be used for MEP installation in interim stage. Immediate stage, consists of deployable shell with lightweight cover, like plastic sheeting, and basic cladding. Deployment mechanism of the structure accelerates the construction, offering the advantage of quality-controlled detailing and construction, which helps with avoiding problems associated with poor workmanship. Interim stage, utilizes common or low-tech materials to upgrade the structure and improve living conditions. Thatching can be used for roof, while plywood, bamboo, and straw mats can be used for both flooring and cladding. Intermediate stage brings living conditions close to a temporary housing standard. Bracings are added increase stability of the structure. Double-layered cladding and roofing with insulation enhance climate conditions for the shelter. A second MSSAS can be added to create rooms, kitchen, and bathroom areas. MSSAS, supplies all the basic needs of three stages **(Figure 4)** while remaining feasible **(Table 2)**.

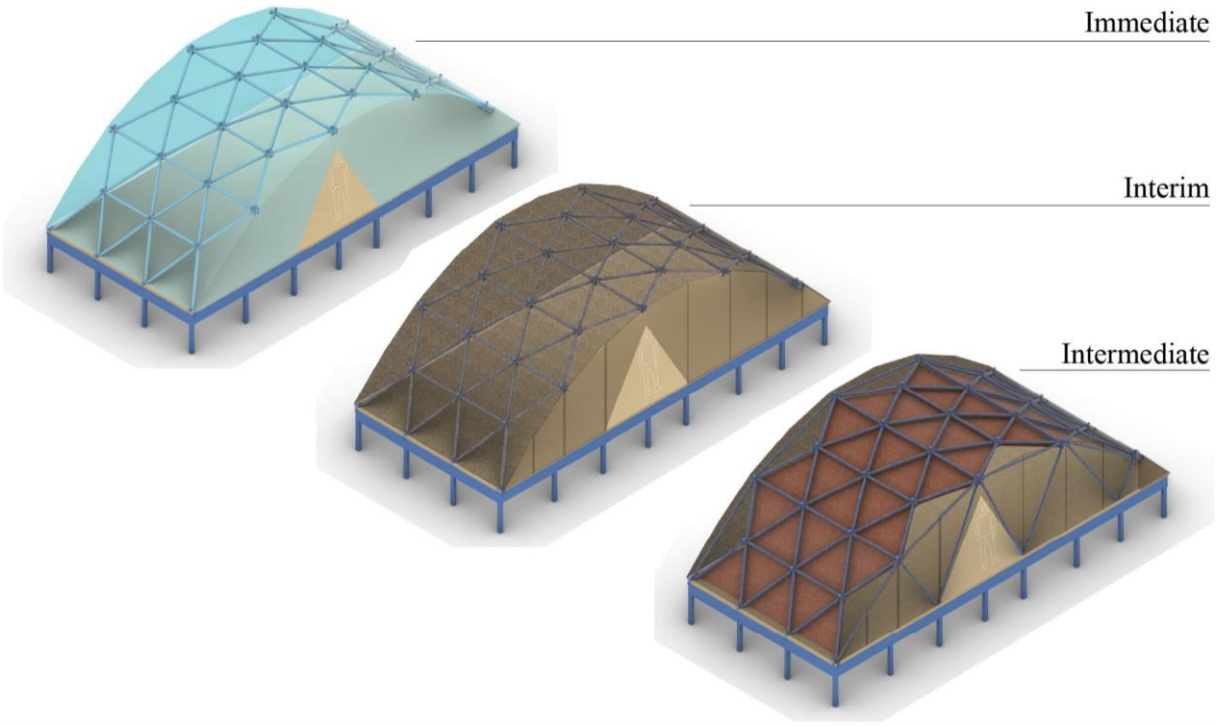

Figure 4. Immediate, interim and intermediate stages.

Table 2. Evaluation of MSSAS.

	MSSAS Initial	MSSAS Total	Three Stages Total
Lifespan	1 Year	15 Years	15 Years
Construction Time	1 Day	7 Days	15 Days
Cost	€2000	€4000	€5000
Covered Living Area	26 m^2		24 m^2
Cargo Weight	3000 kg	5000 kg	50000 kg

Cargo Volume	9 m^3	15 m3	50 m3
CO_2 Footprint	5000 kg	9000 kg	15000 kg
Cost/ Lifespan	€ 250/ year		€ 350/ year
Cost/ Lifespan/ Area	€ 10/ year/ m^2		€ 15/ year/ m^2
Cargo Weight/ Area	200 kg/ m^2		2000 kg/ m^2
Cargo Volume/ Area	0.6 m^3/ m^2		2 m^3/ m^2
CO_2/ Lifespan/ Area	25 kg/ year/ m^2		40 kg/ year/ m^2

The case study is designed for Burunçayır Village in Adıyaman. Gridshell consists of steel tubes (50mm diameter and 5mm wall thickness) and it spans 8 meters. NPI220 and NPI180 beams are used for floor beams. Structure has 26 m^2 living area with additional 16 m^2 covered areas reserved for storage and installation. Structural analysis (FEA) was conducted with Karamba3D for S235 steel material (σ=23,5 [kN/cm²], E=21000[kN/cm²], and checked for displacement ($\delta < L/250$), axial stress and buckling **(Figure 5).** Dead loads (self-weight), live loads (2 kN/m^2), snow loads (1 kN/m^2) and wind loads (28 m/s) were calculated according to TS498 (2021). Earthquake loads were calculated per TBEC (2018) (soil condition ZD, building importance coefficient BKS=3, building height value BYS=8) for DD-3 values received from AFAD Seismic Map (S_S=0.349, S_1=0.088, S_{DS}=0.531, S_{D1}=0.211, PGA=0.153 PGV=8.879).

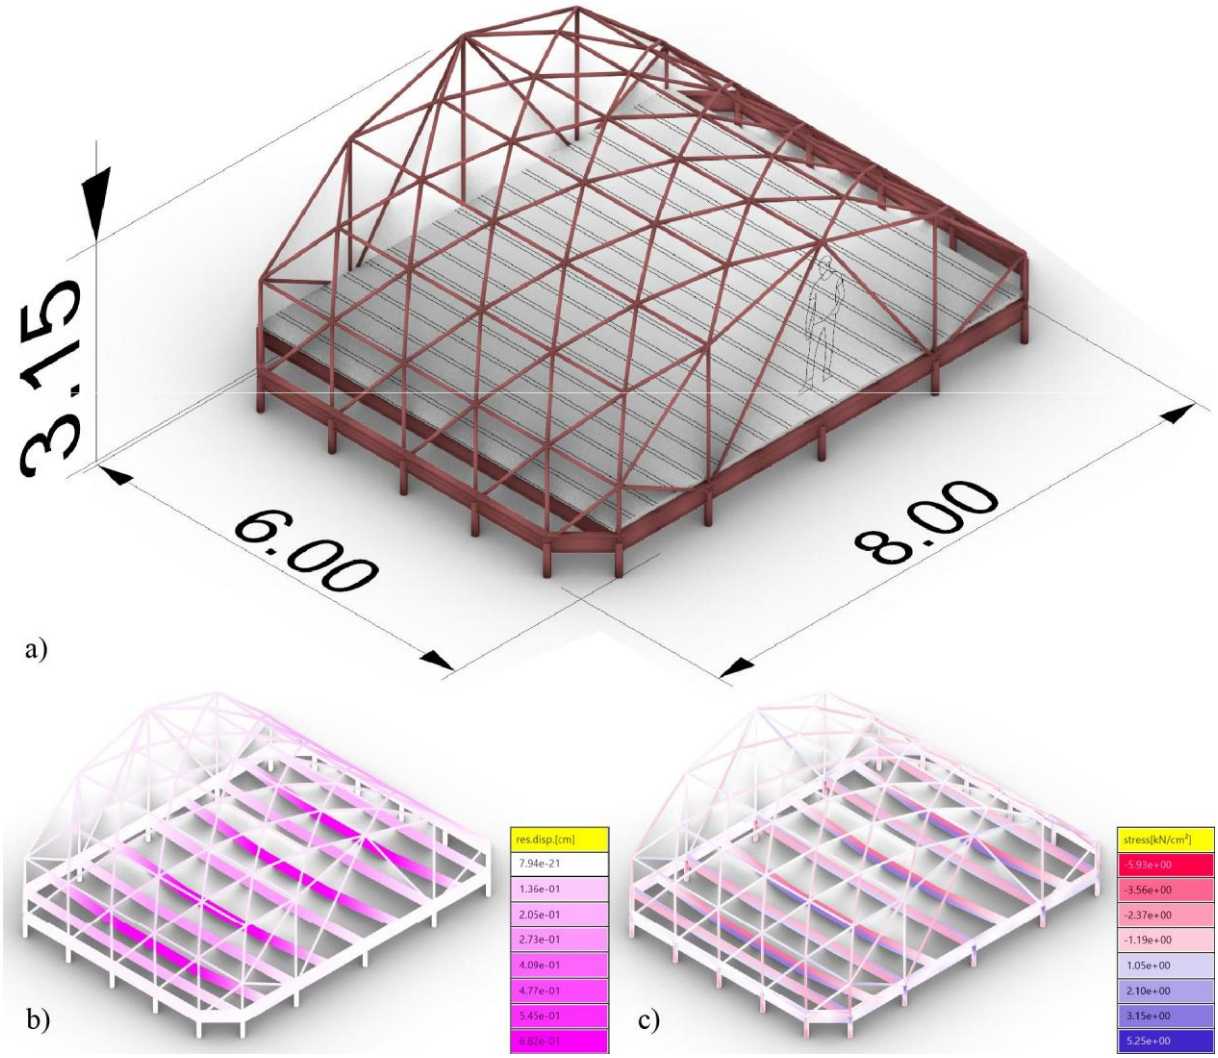

Figure 5. (a) Case study for Buruncayir Village, (b) displacement analysis, (c) stress analysis.

Conclusion

MSSAS displays that deployability with an embedded capacity for progressiveness improves the sheltering workflow. Though initial cost, transportation volume, mass and material usage for SAS are higher than regular emergency shelters, design itself accommodates multiple stages, addresses multiple settlement situations and multiple socio-spatial parameters in one single modifiable structure. When compared to three individual shelters combined, it is estimated that MSSAS decreases costs, transported volume, transported mass, and carbon footprint by a considerable amount. Although available materials and costs can change based on location and situation, study represents a design principle. In conclusion, MSSAS's ease of transportation, usage of local materials and engineered structural and climate performance make it a durable, ecologically and socially sustainable and psychologically sensitive alternative to current shelters.

Aim

Artificial intelligence (AI) has been present in various areas of human life for many years; although it has been perceived as a "science fiction product" for many years, it has recently become an ordinary part of everyday life. Efforts to imitate human intelligence through machines began with great hopes, but the progress has been paused periodically for various reasons. Nevertheless, over time, AI has been adopted as an important transformation tool in a wide range of fields.
In this study, the features to be used in the context of architectural materials education were examined and discussed through the findings based on literature research. The historical development of the concept of AI since it first emerged, how the capacity of AI changed over time and how AI was applied especially in education were discussed. In addition, the contributions of AI to educational processes, the opportunities it offered and the limitations that may have been encountered, ethical and legal regulations regarding the use of AI in education were examined within the scope of the literature study findings and it is aimed to discuss the requirements for the sustainable and reliable implementation of this technology.

Material and Method

This study is based on literature review findings to discuss the historical development of AI, the phases and sub-concepts of its capability, current practices that can be taken as examples for integration into material education in architecture, the opportunities it offers as well as the limitations that may be encountered, and the ethical and legal regulations regarding the use of AI in education.
The main sources are academic articles, reports, international regulations, scientific research on past and current AI applications and studies on the use of AI in various fields. The data were categorized and evaluated in terms of types of AI, learning models, its use in education, ethical/legal dimensions, and the opportunities and risks it presents.

Findings

Although the concept of AI was previously expressed under different names, it became widespread at the Dartmouth Workshop in 1956. The workshop was an important turning point where the theoretical foundations of AI were established. (Nilsson, 2005; p.77-79) Within the scope of the workshop, the concept of AI was addressed by McCarthy as the problem of creating machines that behave similarly to human intelligence. (McCarthy et al., 1955)
This early period witnessed significant advances in research on symbolic AI, focusing on cognitive processes. Alan Turing proposed the Turing Test, which assesses a machine's ability to behave intelligently at a level indistinguishable from a human, and the test was used as a standard benchmark for years. (Turing, 1950) Studies such as Samuel's checkers program and Newell and Simon's General Problem Solver (GPS) demonstrated the development potential of AI in learning and problem solving. (Samuel, 1959; Newell et al, 1963) In Turkey in 1959, Cahit Arf's conference titled "Can Machines Think and How Can They Think?" offered insights for AI and the future (Uğur et al, 2025).
The first International Conference on AI (IJCAI) in 1969 was an indication of its growth. In the same period, there was an increase in courses and literature on AI, and academic communities began supporting AI studies. However, during the

1970s, the Mansfield Amendment in the US and the Lighthill Report in the UK resulted in funding challenges for AI researches, which led to a slowdown in the progress (Nilsson, 2005).

Although these difficulties, funding continued thanks to the interest in applications, and expert systems attracted great interest. The period 1975-1985 was considered a "boom period" for AI. The revival period and the successes achieved increased the interest of researchers. With this increasing interest, the American Association for Artificial Intelligence (AAAI) was founded and large companies invested in AI. Although interest in the field increased worldwide, there was a setback in the 1980s when AI failed to deliver the promised success, and this period was called the "AI Winter." (Nilsson, 2005)

In the late 1980s, a revival period began with the development of machine learning technologies. Studies on the applicability of biological structures to machine learning and the development of multilayer neural networks led to significant developments. In the 1990s, artificial neural networks started to give successful. The early 21st century represents the beginning of a new era in AI, the era of deep learning. With advances in computing power and technical capabilities, especially the development of powerful graphics processing units (GPUs), deep learning has enabled the identification of complex patterns from big data using multilayer artificial neural networks (Burkov, 2019; Doğan et al, 2019; Kaplan et al, 2019).

Neural networks provide solutions to various types of problems with supervised, unsupervised and reinforcement learning methods. While supervised learning aims to make predictions using labeled data, unsupervised learning aims to make sense of unlabeled data sets. Reinforcement learning focuses on learning the best strategy through reward mechanisms. Unsupervised learning is used in speech recognition applications such as Apple's Siri or Amazon's Alexa, while Reinforcement learning is used in Microsoft's MSN.com headline selection (Burkov, 2019; Kaplan et al, 2019).

Today, these networks are used in many areas such as classification, prediction, diagnosis and diagnosis, and different models are preferred according to the structure of the data and the type of problem. Deep learning has led to groundbreaking developments in a wide range of fields such as computer vision, classification, object detection, audio processing, medical image analysis and industrial processes (Doğan et al, 2019).

The advancements in technology in the 21st century have significantly impacted educational practices as well. One of the notable developments is the emergence of generative AI, which uses machine learning to create new content based on analysis of existing content. Two key generative AI models are Generative Adversarial Networks (GAN) and Generative Pre-Trained Transducers (GPT). GAN utilizes two neural networks to distinguish between real and artificial content and has found widespread use in visual and audio production. GPT models, on the other hand, employ natural language processing techniques to produce human-like text by analyzing large datasets. These GPT-based models have diverse applications, including customer service chatbots and character development in video games. In recent years, tools like ChatGPT have gained attention in various fields, from education to engineering, journalism, medicine, and economics. (Baidoo-Anu et al., 2023)

AI is being used in various universities and positive results are being achieved. At Georgia Tech University, an AI-based virtual teaching assistant is used to answer student questions; AI-powered chatbots are used to speed up teaching processes at Berlin Technical and Carnegie Mellon Universities. Major academic publishers such as Elsevier and LexisNexis use AI to automate systematic literature searches, detect plagiarism and identify statistical misuse. In online education, facial expressions from webcams can be analyzed to determine which students are paying attention to the lecture and which are not. It is thought that in the future, the RENNE system can support faculty members in determining the most effective coaching strategies or detecting cheating in exams by reading student emotions. Studies show that AI in education has the potential to enrich teaching and learning methods, offer students a more in-depth learning experience, and provide instructors with more effective process management. AI has the potential to revolutionize education by providing personalized learning experiences and automating tasks such as grading. This allows teachers to focus more on individual interactions with students. (Kaplan et al., 2019; Zawacki-Richter et al., 2019; Baidoo-Anu et al., 2023; Kovari, 2025).

On the other hand, there are still uncertainties and ethical concerns surrounding the use of AI in education. It is unclear if students will prefer AI-driven education, if universities will view AI as a substitute for human teachers, and how the quality of education will be affected. To address these concerns, it is recommended that universities offer courses on "AI and

Humanity" to explore issues such as ethics, privacy, and data ownership in AI education. By addressing these issues, the potential benefits of AI in education can be maximized while safeguarding the well-being and values of students. (Kaplan et al., 2019).

Globally, advancements in AI are rapid, but legal frameworks are still developing (Bird et al., 2020). The European Union (EU) established its first international AI strategy in 2018 and published ethical guidelines for trustworthy AI in 2019 (European Commission, 2019). EU member states continue to develop national strategies (European Commission, 2021). In Turkey, the "2021-2025 National AI Strategy" and ethical guidelines by the Council of Higher Education (YÖK) promote responsible AI use in education and research (URL-1; URL-2; URL-3; URL-4; URL-5; URL-6; URL-7). AI's integration into education gives rise to challenges such as data privacy, algorithmic biases, and ethical risks. Ensuring fair, transparent, and responsible AI integration in education is imperative (Zhang et al, 2021).

While AI is developing rapidly around the world, legal regulations have not kept pace. The European Commission established its first international AI strategy in 2018 and set ethical criteria for trusted AI in 2019. In developing their national strategies, EU countries are investing in AI applications in various sectors such as health, education, transportation. For example, Finland aims to use AI in public services, while Germany is focused on developing data protection and ethical frameworks. The United Kingdom has established a data ethics and innovation center that promotes the safe and ethical use of AI (Bird et al., 2020). The European Union adopted its AI regulation in 2021. The regulation, which is the first AI law adopted in the world, focuses on protecting human rights and prohibits harmful AI systems while encouraging socially beneficial applications. In the field of education, ethical use is supported. (Url-1; Url-2; Url-3; Url-4; Url-5)

In Turkey, the "2021-2025 National Artificial Intelligence Strategy", prepared in cooperation with the Presidential Digital Transformation Office and the Ministry of Industry and Technology, has entered into force. This strategy promotes the development and application of AI technologies in areas such as health, industry, education and public administration. Furthermore, the Council of Higher Education (YÖK) published a guideline in 2024 setting out ethical principles for the productive use of AI in scientific research and publication activities (Url-6; Url-7).

AI brings challenges such as data privacy and ethical risks. Issues such as data breaches and student-teacher autonomy are important ethical issues to be considered in the use of AI in education. Therefore, it is of great importance to use AI in education in a fair, transparent and responsible manner (Zhang & Aslan, 2021).

Conclusion

AI refers to the development of algorithms to perform tasks that require human intelligence. The goal of AI is to create software that mimics and, if possible, even surpass human cognitive abilities. Just like the replacement of human muscle power with machines in the Industrial Revolution, the AI transformation enables the automation of cognitive processes and their execution by machines.

Wide range of applications shows that AI will become even more widespread in the future and will play a transformative role in many disciplines such as materials education in architecture. It is seen that it can enrich education with personalized learning experiences, automated tasks and adaptive feedback systems as well as simulating material behavior, predicting performance based on material properties and function, and providing efficient feedback to help students make design decisions with materials that are appropriate for project requirements.

However, in the integration of AI into material education, issues such as data privacy, variability of information according to the data being processed, and over-dependence on technology should be considered. It is important that AI should be used as a tool which plays a complementary role to human abilities by supporting critical thinking and creativity in architectural education.

In conclusion, AI has the potential to transform material education in architecture, enhancing learning and decision-making processes and becoming a helpful, supportive tool for students and instructors when integrated responsibly and ethically. Successful integration of AI in education depends on strengthening ethical and legal frameworks. In this process, collaboration between educators, researchers and policy makers will play a critical role to maximize the potential of AI in education while minimizing potential risks.

A Literature Review On Organizational Structures In The Construction Industry

E. Gamze Sentuna[a], F. Pinar Cakmak[a]

[a] Istanbul Technical University, Architecture, Project and Construction Management Program, Turkey
sentuna16@itu.edu.tr

Keywords: Construction Industry, Construction Project Management, Literature Review, Organizational Structure.

Aim

A company's organisational structure can have a pronounced impact on its performance. It influences a wide array of metrics such as productivity, decision-making agility, information sharing, employee retention, and problem-solving ability, all of which directly or indirectly impact the organization's profitability. The construction industry's project-based nature means that the organization's profitability is often determined at the project level, thus making understanding how organizational structures influence projects crucial.

This research focuses on organizational structures and their impacts on the construction industry. Given the industry's project-based nature, understanding how organizational structures influence projects is crucial. By examining existing research on organizational design, this paper explores the fundamental principles, key characteristics, and implications of different structures within a specific industry context.

Existing studies on construction industry organizational structures have approached the topic from multiple perspectives. While project stakeholders operate within their respective organizations, simultaneously, they function within temporary project organizations. As a result, research on the topic often examines structures at the project team level.

Turner and Muller (2003) redefine projects by emphasizing the project team as an organization: "a project is a temporary organization to which resources are assigned to undertake a unique, novel and transient endeavor managing the inherent uncertainty and need for integration in order to deliver beneficial objectives of change".

Unlike permanent organizations, temporary project organizations exhibit certain characteristics, such as temporariness, uniqueness, heterogeneity, short-term orientation, and lack of organizational routines, which pose challenges to management (Hanisch and Wald, 2011). These traits contribute to the inherent complexity of temporary organizations (Geraldi et al., 2011).

Organizational structure by Daft (2007) is stated as ''social entities that are goal-oriented and deliberately designed to coordinate activities so as to link the system to the external environment." Organizational structure by Mahmoudsalehi (2012) is "a formal allocation of work roles and administrative mechanisms for controlling and integrating work activities". Noorderhaven (1995) argues that organizational structure is "the formal pattern of how jobs are allocated to people and divisions, how communication flow is structured and how hierarchical relationships between people are connected". As the primary output of construction projects is the product delivered, project success is inherently linked to the effectiveness of the organizational structure.

Purpose of the Study:

This paper aims to systematically map and analyse existing academic contributions on organizational structures in the construction industry. Rather than presenting new empirical findings, it synthesizes prior research to identify key structural dimensions, thematic patterns and dominant research methods. It is aimed to establish a foundation for further empirical investigation - specifically to develop a research framework for evaluating how organizational structures influence project outcomes in real-world construction settings. To achieve this, the paper first details the research methodology and approach to gathering literature. Then, it presents the findings, categorizing the reviewed literature in terms of levels of analysis, research methods, and key recurring concepts in the topic.

Material and Method

A comprehensive literature search was conducted using Scopus, a database providing access to over 23,500 peer-reviewed titles from more than 5,000 international publishers covering science and social science subjects (Leiringera, 2021).
The search string is as follows: TITLE-ABS-KEY ("organizational structure") AND TITLE-ABS-KEY ("construction industry" OR "construction sector" OR "construction management") AND (LIMIT-TO (DOCTYPE, "ar")). This search yielded 153 articles related to the topic for further review. These articles have been reviewed and categorized depending on their relevance to the research question.

Findings

Out of the 153 identified articles, 52 articles have been deemed relevant to the research topic. Of these, 30 articles have been cited in the thesis draft. The remaining 22 articles provided contextual background without directly contributing to the research question.
Out of the 30 articles, 17 articles examine construction project organizations as temporary entities where multiple actors collaborate for a limited time. The other 13 articles focus on internal organizational structures within individual construction companies. In the thesis research, temporary project organizations are the focus.

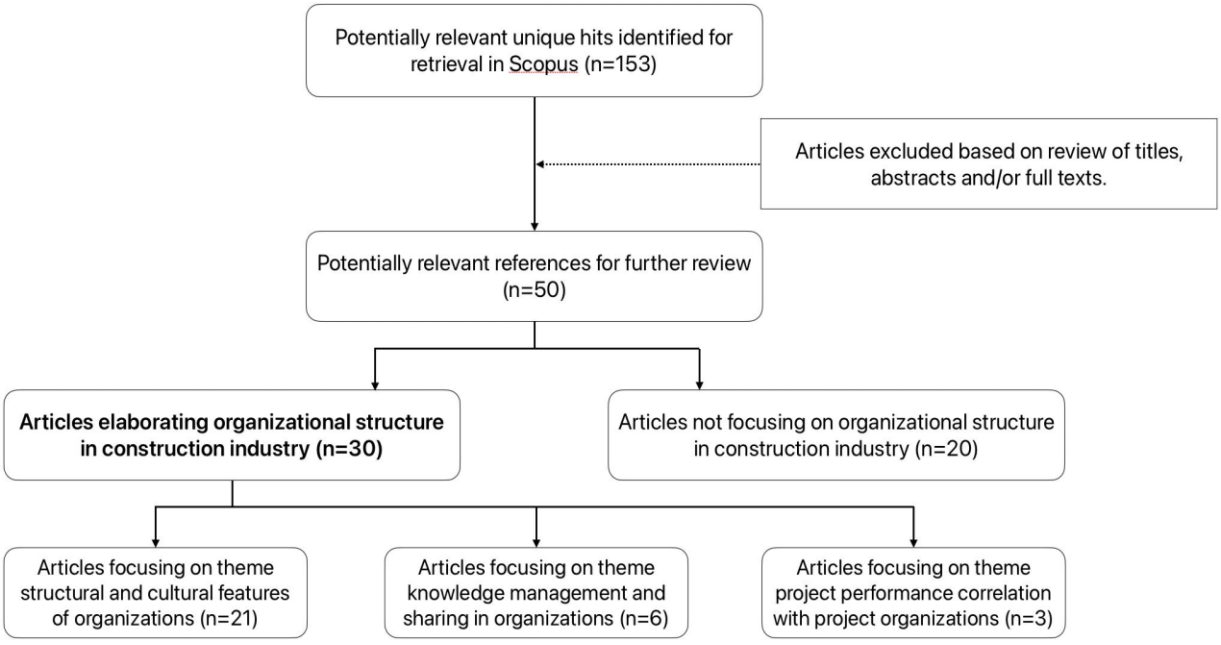

Figure 1. Flow diagram of sample selection process.

As captured in Figure 1, three dominant research themes have been identified within the sample of articles explicitly mentioning organization structures in the construction industry. Out of the 30 key articles, 21 studies explore theoretical frameworks such as centralization, formalization, specialization, complexity, horizontal and vertical schemes, network organizations, and relationships.
The second theme in six articles is knowledge management and sharing practices in project organizations and how organizational structures facilitate or hinder these. Only a small subset of studies (three articles) explicitly investigates the link between organizational structures and project performance outcomes.

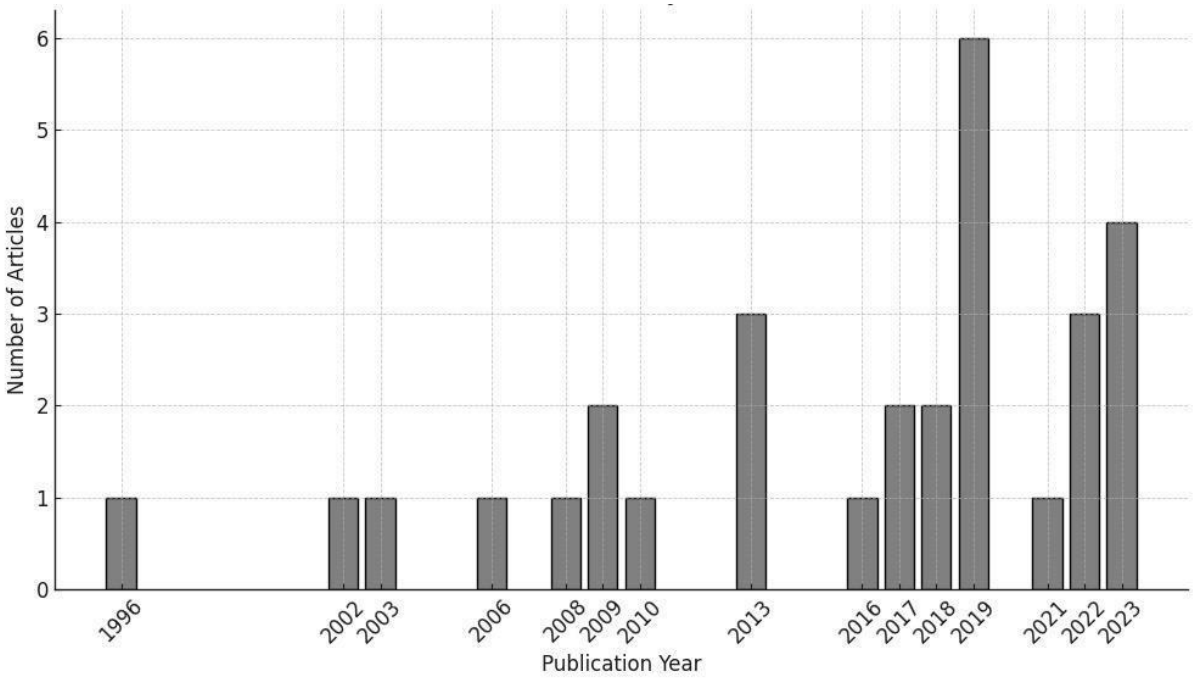

Figure 2. Distribution of articles based by publication year.

Most studies on organizational structure in construction have been published after 2013, reflecting a growing interest in recent years (Figure 2). The project-based organizations (PBO) are mostly reviewed in articles after 2019.

Table 1. Distribution of articles based on level of analysis and research method.

Level of Analysis (n=30)	
1. Individual Level	1
2. Project Level	6
3. Organisational Level	10
4. Multi-level (combining individual, project and organizational levels)	13
Research Method (n=30)	
1. Case Study	4
2. Survey	18
3. Mixed Method	8

The articles analyse the concept of organizational structure at several different levels, i.e., individual, project, and organisational. Approximately one-third of the articles in the sample focus on the organizational level, while 60% employ survey-based research methods (Table 1). Sample survey selection often includes clients, contractors, consultants, subcontractors, manufacturers and other project stakeholders.

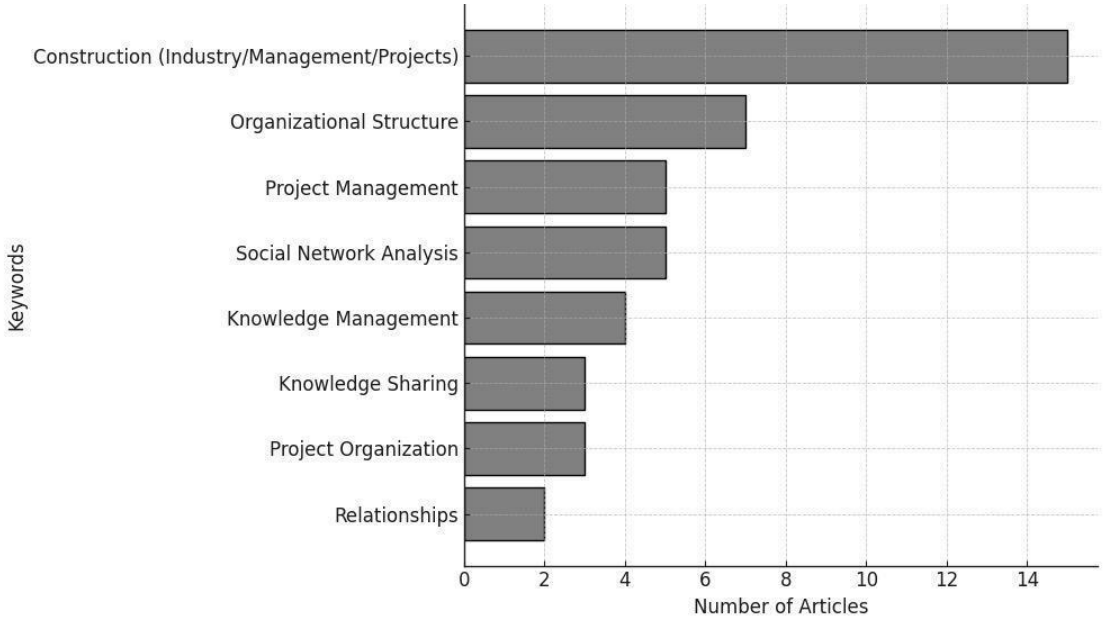

Figure 3. Distribution of most frequently used keywords in sample articles (n=30).

As reflected in Figure 3, 50% of the articles focus on construction organizations, emphasizing their structural and managerial strategies. 23% of the literature highlights knowledge sharing and management, underlining their importance in project organizations' success. Relationships among actors is another function that influences the organizational structures in construction projects.

Conclusion

This literature review provides an initial systematic analysis of research on organizational structures in the construction industry, highlighting key themes, methodologies, and gaps. Over 90% of the articles in the sample have an empirical component, utilizing various data collection methods.

A number of observations can be made as follows: Most research is quantitative, with case studies and surveys being the dominant methodologies. The research focus and objectives vary significantly, with limited evidence of knowledge accumulation or theory building. The majority of studies target the organisational level. 'Enhanced' performance is commonly alluded to, but most articles do not define performance outcomes explicitly or show how the outcomes are in direct correlation with organizational structures.

The insights gained from this review will support the thesis study on the research question: Is there a correlation between organizational structure and project outcomes? The categorization of themes, level of analysis, and research methods derived from this review will directly inform the design of the thesis research. Specifically, it will guide the development of a theoretical framework and the data collection, such as survey questionnaire, to evaluate how organizational structures influence performance in temporary project organizations.

A notable limitation of this review is that the literature search is still ongoing, and relevant references cited within reviewed articles have not yet been fully explored. As the thesis progresses, additional studies may provide further depth and support the refinement of the research approach.

A Systematic Review of BIM and the Circular Economy: Key Research Areas and Findings

Merve Cellek[a], Fatma Pınar Çakmak[a]

[a] Istanbul Technical University, Graduate School, Project and Construction Management, Turkey
cellek19@itu.edu.tr

Keywords: Building Information Modelling (BIM), Circular economy, Literature review.

Aim

In the modern construction industry, the circular economy is becoming increasingly prominent in reducing resource consumption and increasing sustainability. Circularity aims to efficiently use materials and resources, minimizing waste and promoting reuse throughout the life cycle of buildings. In this context, digital technologies such as Building Information Modeling (BIM) significantly contribute to circularity by supporting material tracking, life cycle analysis and sustainable design processes. This meta-analysis aims to systematically assess the academic literature examining the integration of BIM with the circular economy, categorizing the main research areas, methods used and prominent findings.

Material and Method

First of all, Scopus was used to examine the existing studies on BIM and circularity. A systematic data selection procedure based on the keywords TITLE-ABS-KEY("building information model*" OR "BIM" OR "bim") AND TITLE-ABS-KEY("construction sector" OR "construction industr*" OR "construction manage*") AND TITLE-ABS-KEY("circularity") OR TITLE-ABS-KEY("circular economy") was adopted. The search resulted in 137 articles, two of which were removed because they were not in English, leaving 135. The oldest article was published in 2019, and new ones will continue to appear until 2024. We selected 30 articles that addressed the transition to circularity and the inclusion of digitalization. A meta-classification system was developed for the reviewed articles based on research output, data source and content variables. The meta-analysis framework is shown in Table 1 below:

Table 1: Meta-analysis framework.

Category	Attributes Included
Article Info	Article Name, Publication Date, Keywords, Number of Citations
Author & Journal Info	Author(s), Author(s) Background, Country, Journal Name, Publisher
Content & Methodology Info	Research Focus, Topics, Gaps, Methods, Outputs, Data Sources, Geographical Distribution, Recommended Research Areas

Findings

The publications are primarily in sustainability and environmental journals, published in 20 journals and two conference series. The number of publications on BIM, sustainability and circularity is rapidly increasing, with significant increases expected in 2022 and 2024. This increase results from concerns about environmental sustainability and global climate change, which are increasing the importance of circularity and related technologies such as BIM. The increase in 2024 suggests that these topics will continue to be important focuses of future studies.

As stated in Figure 1, keywords such as BIM, circular economy, and life cycle assessment (LCA) are among the most commonly used. Among other keywords, sustainability and waste management also stand out in frequency.

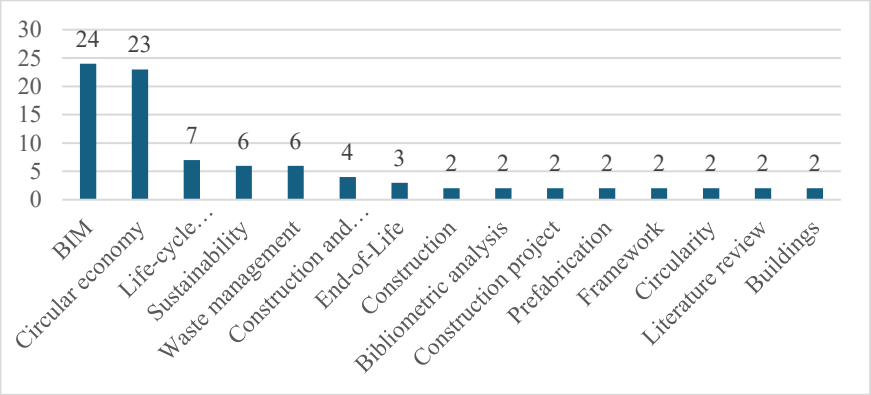

Figure 1: Keyword frequency.

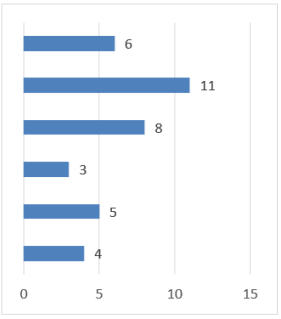
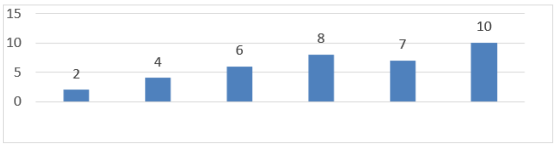
The most cited paper, "Uses of building information modeling for overcoming barriers to a circular economy" received 109 citations. Papers focusing on circular economy, digital transformation and construction supply chain processes significantly impact other research. In particular, studies on the challenges and opportunities of circular economy adoption supported by digital transformation serve as key references. These citation trends highlight the growing importance of the circular economy and digital transformation in the construction industry and their impact on academic research.

In order to classify the research focus, the articles were classified into six categories according to their content. Some articles were included in 2 areas as they were suitable for two categories. The most popular topic, circular economy integration with BIM, was examined in 11 of the 30 articles. These papers are mainly about developing theoretical BIM-based frameworks and exploring BIM use cases supporting circular economy applications (Charef, 2024). The second popular topic is construction, demolition, and waste management with BIM, which was analyzed in 8 papers. These articles generally cover the integration of BIM and JIT to develop environmentally friendly and efficient methods in construction demolition processes (Andriyani et al., 2024), BIM-Lean interaction for developed demolition processes (Torgautov et al., 2021). The third category includes circular economy and strategies, with six articles. These articles generally include identifying circular economy strategies in the construction sector and the factors affecting them (Chen et al., 2022). The fourth category is asset management and life cycle assessment, with five articles on this topic. These papers generally discuss topics such as developing a flexible life cycle assessment framework with a high level of detail (LOD) (Mowafy et al., 2023). The fifth category is circular economy barriers and challenges, with three articles. The articles in this category mainly address the barriers of the circular economy approach in the construction industry (Charef et al., 2021). The last category, named other, includes green business models, integrated/mixed Technologies (Lamptey et al., 2020), and bibliometric analysis (Linglin, 2023). Table 2 shows the categories, articles and years of publication.

Table 2: Research focus distribution by years.

Research Focus	2019	2020	2021	2022	2023	2024	Total
Circular Economy and Strategies		1	1	3		1	6
Circular Economy Integration with BIM	1	1	1	2	1	5	11
Construction Demolition and Waste Management with BIM	1	1		1	2	3	8
Circular Economy Barriers and Challenges			2	1			3
Asset Management and Life Cycle Assessment			2	1	1	1	5
Other (Green Business Models and Integrated/Mixed Technologies, Bibliometric Analyses, etc.)		1			3		4
Total	2	4	6	8	7	10	37





Among the data sources used in the articles, reviews, and surveys are among the leading sources. Reviews showed an increase after 2019, reaching 19 articles in 2024, followed by 12 articles based on surveys. Analysis of the articles by data sources reveals that most of the data used in this field is secondary data and/or data collected from sector professionals.

The 30 publications of the meta-analysis were divided into four categories: statistical results (4 articles), general views (9 articles), experimental/prototype model (8 articles), and conceptual/theoretical model (10 articles). Despite the increase in articles, the categories of research outputs did not change significantly over time.

The 30 articles analyzed were prepared in 16 countries, on a global scale and within the European Union, revealing the global interest in the field. Globally, 11 articles, four articles in the UK, Australia and Italy with two articles each, and Brazil, Indonesia, Ghana and India with one article each, indicating global interest and growing research on the topic.

Conclusion

BIM strengthens circular economy concepts in the construction industry by facilitating efficient management in areas such as material recovery, waste management and life cycle assessment. Research shows that BIM-based component tracking and data management support circularity. Through assessments, interviews and case studies, the literature contributes to the body of knowledge for further studies by investigating how BIM and the circular economy can work together.

Investigating the Role of Data Management for AI Utilization for Decision-Making in Construction: A Literature Review

Hansa Eusmanaga[a], Fatma Pınar Çakmak[a]

[a] Istanbul Technical University, Graduate School, Project and Construction Management, Turkey
eusmanaga23@itu.edu.tr

Keywords: Artificial Intelligence, Machine Learning, Construction Management, Decision Support, Data Management.

Aim

The integration of Artificial Intelligence (AI) and Machine Learning (ML) in the construction industry has gained attention due to its ability to support the leverage of advanced technologies, enhance decision-making, analyze data, optimize project execution, automate processes, improve safety and mitigate risks (Chenya et al., 2022). However, the effectiveness of AI-driven decision models is highly dependent on the quality, structure, availability and management of data related to construction (Chenya et al., 2022).

This study aims to examine how AI and machine learning applications can be effectively implemented in the construction industry in general through enhanced data management strategies and, more particularly, to improve on-site decision-making processes in construction management. The study collects findings from 62 scholarly articles and identifies AI applications based on their use in optimizing workflows, enhancing risk assessment, and improving predictive analytics. The paper focuses on primary enablers, challenges, and future opportunities in AI-powered data management for the construction industry.

This extended abstract contains the literature review for a thesis study about the applications of AI and ML in the construction management industry. It provides the foundation for understanding the recent progress and identifying the gaps for future studies. The following work will build upon these insights and explore the topic in-depth, thus potentially proposing a structure for handling data for construction management AI and ML integration.

Material and Method

A systematic literature review was conducted, analyzing 62 peer-reviewed articles. A Scopus database was used to search the articles using a keyword-based search; the keywords used were "construction management," "artificial intelligence," and "decision-making." The search was refined to include only English-language journal articles published between 2013 and 2025 to ensure that the works are up-to-date and have high-quality research contributions.

Initially, 203 articles were identified through the structured search. The first screening phase involved analyzing abstracts to determine relevance to AI applications in construction, reducing the selection to 102 articles. The second phase involved a more in-depth evaluation based on the information that can benefit the search, data-driven AI applications, and relevance to data management in construction, resulting in 62 final articles. These selected papers offer a comprehensive perspective on AI integration in construction, covering risk management, decision support systems, cost optimization, site monitoring, digital twin applications, scheduling improvements, and explainable AI models. While most of the selected papers focus on AI applications within the construction industry, some articles are from manufacturing and supply chain management. These industries were included because they provide valuable insights into AI-driven data integration, decision support, and risk management strategies, which can be adapted to enhance AI applications in construction. By leveraging cross-industry findings, this study broadens its scope to identify best practices in AI implementation and benefit from other industries.

The selected papers were categorized into seven thematic areas: AI and ML for risk management and safety, AI-based decision support systems (DSS), AI in construction cost management, AI for site monitoring and process automation, AI and digital twin integration, AI for construction scheduling and resource optimization, and Explainable AI (XAI) in construction decision-making.

Key technological enablers, methodologies, and challenges were extracted from each article and synthesized to develop a framework for AI-driven data management in construction. Figure 1 shows the overall process of the structured literature review.

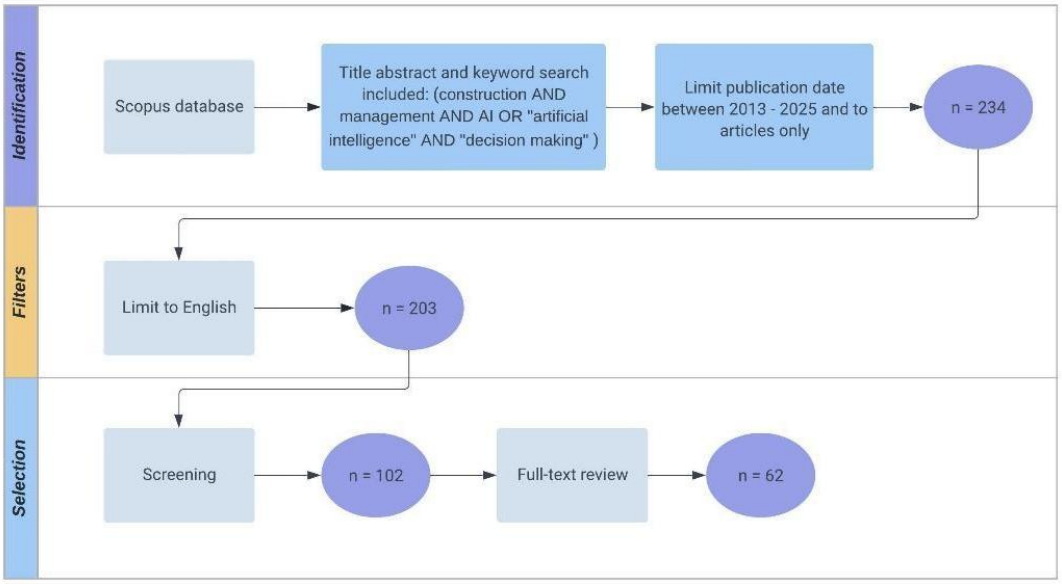

Figure 1: The process of the systematic review.

Findings

The analysis revealed key insights into AI-driven data management in multiple areas. AI-driven risk prediction models using ML and neural networks significantly improve accident prevention and hazard identification (Chenya et al., 2022). However, the lack of structured safety data limits AI model accuracy and makes it more difficult to integrate on a large scale. Data management frameworks that standardize safety data collection and ensure real-time accessibility can significantly improve the effectiveness of AI models.

Explainable AI (XAI) can also enhance model transparency, ensuring reliability in risk assessment and making data-driven insights more interpretable for decision-makers (Love et al., 2024). AI-based DSS enhance construction planning by integrating predictive analytics and real-time site monitoring (Love et al., 2024). However, the effectiveness of these systems is often compromised by inconsistent data formats and missing project information. Proper data management procedures can overcome these constraints, such as real-time data synchronization and standardized reporting systems.

AI-driven cost estimation models using neural networks outperform traditional financial forecasting techniques (Yi & Luo, 2024). However, challenges in data standardization and integration with existing financial systems hinder widespread AI adoption. Implementing a structured database that combines historical project costs and integrates real-time financial data from multiple sources can enhance the predictive accuracy of AI models, ultimately improving budgeting and financial planning.

AI-based computer vision and IoT-enabled monitoring systems improve real-time construction site tracking (Bozorgzadeh & Umar, 2023) (Rafsanjani & Nabizadeh, 2023). The primary obstacle to their scalability lies in fragmented data sources and a lack of integration with BIM systems. Establishing a centralized data-sharing platform that merges real-time site data with BIM models can facilitate predictive maintenance and workflow optimization. However, high computational costs remain a concern, requiring further research into cost-efficient AI processing solutions.

AI-enhanced Digital Twin models facilitate real-time construction monitoring and lifecycle management (Rafsanjani & Nabizadeh, 2023). The biggest challenge in leveraging digital twins is the interoperability between Digital Twin, AI, and BIM platforms, which leads to fragmented insights and inefficient decision-making. A standardized data exchange protocol

that enables seamless data flow between these systems can significantly enhance decision-making capabilities. Additionally, ensuring data accuracy and consistency across different platforms will be key to the success of AI-driven Digital Twins in construction.

AI-powered scheduling models optimize construction timelines by analyzing historical data and project constraints. However, many scheduling models lack real-time adaptability due to delays in data updates and information gaps between on-site activities and digital planning tools (Yi & Luo, 2024). By integrating AI scheduling models with IoT-enabled real-time data feeds, construction managers can make more informed, data-driven adjustments to project timelines, reducing delays and cost overruns.

Table 1 provides an overview of the mentioned AI applications in construction, highlighting their impact, used technologies, and the critical data-related challenges that affect their implementation in the industry.

Table 1. Key AI Applications, Challenges, and Their Impact on Construction Management.

AI Application Area	Impact on Construction	Key Technologies Used	Challenges
Risk Management & Safety	Enhances hazard prediction and safety compliance	Machine Learning, Explainable AI (XAI)	Limited availability and quality of risk data
Decision Support Systems	Optimizes planning and resource allocation	Neuro-Fuzzy Models, Predictive Analytics	Inconsistent data formats and missing project details
Cost Management	Improves budget accuracy and financial forecasting	Neural Networks, Ensemble Learning	Lack of standardized cost data and integration issues
Site Monitoring	Real-time tracking and predictive maintenance	Computer Vision, IoT, BIM	Fragmented real-time data sources and high processing costs
Digital Twin & BIM	Enhances lifecycle management and project visualization	AI-Driven Digital Twins, Smart Sensors	Interoperability and data exchange limitations
Scheduling	Reducing delays and cost overruns	Machine Learning, IoT	Real-time data gaps

Conclusion

This study highlights the transformative impact of AI and ML in construction management, emphasizing the importance of adapting data management frameworks to maximize AI efficiency.

To effectively deploy AI in construction, the following must be addressed: standardized data management to ensure consistency in data formats across AI applications, integration of AI with BIM and IoT to enhance real-time monitoring and predictive analytics, and adoption of Explainable AI to increase transparency and stakeholder trust in AI-driven decision-making. Future research should improve AI model adaptability to unstructured construction data and enhance interoperability between AI, Digital Twin, and BIM platforms. The findings contribute to developing a structured approach to managing data within the construction industry to adapt the use of advanced technologies such as AI-enabled decision support systems.

Keywords: Built environment, Case study, Circularity assessment tool, Circular economy, Sustainability.

Aim

Although the circular economy (CE) has garnered increasing global interest within the AECO industry, its applications largely remain confined to conceptual frameworks and literature reviews. This highlights a critical gap in the translation of circular economy principles into structured design strategies. In this regard, there is a need to develop comprehensive frameworks that integrate circular design strategies and its components, enabling practical implementation and fostering systemic change within the industry. This study aims to develop an assessment tool to measure the circularity of the buildings; to implement circular strategies and design thinking into the built environment, particularly to the buildings.

According to the literature, circularity assessments are developed at four systemic levels: starting from the macro-level (cities, urban areas); followed by meso-level (buildings), micro level as building components, product components, and at the nano-level which is materials, individual products elements (EASAC, 2016; Tecchio et al., 2017; Boyer et al., 2021; Shevchenko et al., 2022). However, existing tools have some certain limitations: some of them (Giorgi et al., 2019; Zhai, 2020) only focus on waste and / or energy, and some of them are only conceptual circular design tools.

This study focuses on developing meso-level building scale circularity assessment tool. Moreover, developing a circularity assessment tool will increase the applicability and awareness of CE among the AECO community which will open the way to wider adoption of CE on the built environment. The overall perspective of this study is to contribute in smartening and improving the built environment with digital technologies within the current and future projection of climate change and energy crises.

The novelty of this study lies in its holistic approach to circular economy within the built environment, emphasizing architectural characteristics such as plan layouts, detail drawings as key determinants of the circularity. Unlike existing studies that primarily focus on energy efficiency or material choices, this research evaluates alternative life scenarios and the reuse potential of buildings, components and materials. By integrating these dimensions, the study aims to provide a more comprehensive framework for assessing and enhancing the adaptability, resiliency, and circularity of architectural designs.

Material and Method

Methodology of this study consists of three stages: (1) Evaluating buildings according to the Shearing Layers, (2) Developing a novel CE-integrated metric, and (3) Implementing the Method on a case study and reaching the building Circularity Score. The workflow of the methodology is shown in the Figure 1.

As the first step of the Methodology, buildings are analysed considering the Brand's (1994) Shearing Layers: Site, Structure, Skin, Services, Space Plan, Stuff. Sub-categories are developed for each layer as criteria for circularity score. Duffy (1992) distinguished building layers into four: Shell, Services, Scenery and Set which was called 4S. Shell is the structure; Services are the Mechanical-Electrical-Plumbing (MEP) related functions; Scenery is the internal partitions and finishings; Set is the furniture. Brand (1994) extended Duffy's 4S model into "Shearing Layers" concept with 6S: Site, Structure, Skin, Services, Space Plan and Stuff. Site is considered eternal. Structure is the load-bearing elements of the buildings that last fifty to three hundred years depending on the structural material. Skin is the façade, roof and the external layers which can last twenty-thirty year. Services are related to MEP: wiring, plumbing, fire sprinkler systems, HVAC, and circulations like elevators and escalators, with a lifespan of 15-20 years. Space Plan is the general layout—the spatial functionality of the

interiors which last long approximately 30 years depending on the buildings' function. Stuff is the elements of daily life, mainly furniture.

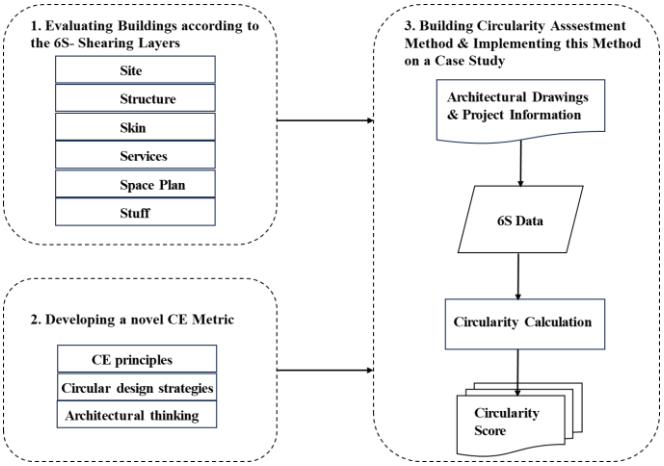

Figure 1. Workflow of the study.

For the second stage of the Methodology, 6S principles divided into sub-categories (Figure 2) considering the circular design strategies, such as designing the end-of-life cycle, reuse and repair potential, disassembly, sharing potential. All the sub-categories have certain value, 1 or 0 that will turn into a scoring system in calculation circularity score.

SITE	Empty	Green Area
		Construction Area
	Demolition	
	Excavation	
STRUCTURE	Life Span	<50-60 years, >60 years
	Material	Bio-based or technical
		GHG value
		Reused material
	Dissassembly	
	End-of-Life Cycle	Reuse as a component
		Reuse as a material
		Recycle
	Safety	Lateral forces, earthquake
SKIN	Life Span	<20-30 years, >30 years
	Material	Bio-based or technical
		GHG value
		Reused material
		Repair potential
	End-of-Life Cycle	Reuse as a component
		Reuse as a material
		Recycle
	Thermal Comfort	Wall section
	Ventilation	Cross ventilation, wind chimney, double skin env.
	Energy Production	
SERVICES	Life Span	<15-20 years, >20 years
	Flexibility	Zoning, modularity, seperate sys., premade instal.
	Material	Dissassembly
		Reused material
		Repair potential
	Smart Digitalized Systems	
	End-of-Life Cycle	Reuse as a component
		Reuse as a material
		Recycle
	Water Management	
	Energy Production	
SPACE PLAN	Function	Residential / Office / Public / Industrial
	Life Span	Residential: <30 years, 30-50 years, >50 years
		Office: <30 years, 30-60 years, >60 years
		Public: <75 years, 75-100 years, >100 years
		Industrial: <25 years, 25-50 years, >50 years
	Dissassembly	Wall Systems
		Floor Systems
	Material	GHG value for wall material
		GHG value for floor material
		Reused material
		Repair potential
	Sharing Potential	Multi-user
		Multi-function
STUFF	Furnitures	Local
	Second Hand	
	End-of-Life Cycle	Reuse potential
		Repair potential
		Remanufacture potential

Figure 2. Criteria and sub-categories of the metric.

Site has the following sub-criteria: situation and status, being empty (green area (0) or construction area (1)) or demolished (valuable (0) or weak (1)) and excavation information (few (1) or sloped area- many (0)). Structure has five sub-categories and nine sub-subcategories: material (bio-based (1) or technical (0); GHG value <100 (1) or >100 (0); reused / waste material (1), not (0)); life-span (<50-60 years (0), >60 years (1)); disassembly (yes (1), no (0)); end-of-life cycle (reuse a component (1 or 0), reuse a material (1 or 0), recycle (1) or waste (0)); safety (1 or 0) is related to being resistance to lateral forces such as earthquake, wind. Skin has six sub-categories and eleven sub-subcategories: material (bio-based (1) or technical (0); GHG value <100 (1) or >100 (0); reused / waste material (1), not (0), repair potential (1 or 0)); life-span (<20-30 years (0), >30 years (1)); energy production (yes (1), no (0)); end-of-life cycle (reuse a component (1 or 0), reuse a material (1 or 0), recycle (1) or waste (0)); thermal comfort according to wall section (1 or 0); natural ventilation (1 or 0) is related to cross ventilation, wind chimneys, double skin envelope. Services has seven sub-categories and eleven sub-subcategories: life-span (<15-20 years (0), >20 years (1)); flexibility (zoning / modularity / separate systems / premade installations (1), none (0)); material (disassembly (1 or 0); reused / waste material (1), not (0), repair potential (1 or 0)); water management system (1 or 0); energy production (yes (1), no (0)); end-of-life cycle (reuse a component (1 or 0), reuse a material (1 or 0), recycle (1) or waste (0)); smart digitalized systems (1 or 0). Space Plan has five sub-categories and ten sub-subcategories: selecting the function (residential / office / public / industrial); according to the function life-span will be marked (shown as Figure 2); disassembly (for walls (1 or 0) and for the floors (1 or 0)); material (GHG value for wall,

GHG value for floor, reused / waste material (1), not (0), repair potential (1 or 0)); water management system (1 or 0); energy production (yes (1), no (0)); sharing potential (multi-user (1 or 0), multi-function (1 or 0). Stuff has three sub-categories and five sub-subcategories: furniture (local (1) or not (0)); second-hand usage (1 or 0); end-of-life cycle (reuse potential (1 or 0); repair potential (1 or 0); remanufacture potential (1 or 0)).
The final stage of the Methodology is Implementing the method on a case study and reaching the building Circularity Score. Calculating the circularity score depends on the core principles of mathematics and the measuring tool is applied by using Python. The scoring based on a binary system as 1 / 0 or yes / no. This is called closed-ended dichotomous scale, and have certain advantageous on providing a straightforward and easily quantifiable response. According to the criteria on the Figure 2, site can take up to 2, structure up to 9, skin up to 11, services up to 11, space plan up to 9 and stuff up to 5 points.

Findings

The selected case study is steel frame 6 storey office building (Figure 3) which is completed in 2015, constructed on an empty construction area. Spanning six floors, the structure is steel, made of HEB240 columns and IPE200 beams ensuring durability while complying with seismic performance standards. Table 1 and Figure 3 describe the buildings' characteristics- materials, building elements, systems, etc.

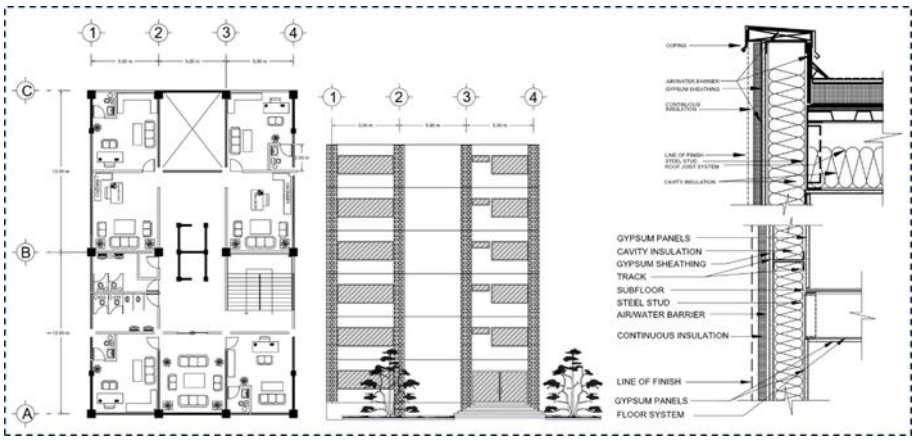

Figure 3. Plan, section and detailed drawings of the selected case study.

The facade features glass panels combined with brick cladding and painting. Internally, modular panel partitions made of gypsum are chosen for the walls and ceilings. The building integrates centralized HVAC systems including zoning and premade wirings, smart lighting solutions, enhancing user comfort and energy efficiency. Each room or area act as a thermal zone. 40% of wall area is window opening for each four façades; and the glass-frame ratio is 10%. Wirings are copper; plumbing is PVC, and ventilations are galvanized steel. Rainwater harvesting system and grey water transformation are adapted as part of water management. For the furniture, local suppliers are used.

Table 1. Project information of the selected case study.

Function:	Office Building
Construction Year:	2015
Number of Floors:	6
Construction Area	2300m2
Site Status:	Construction Area
Excavation:	2500m3
Structure:	HEB240 Steel Columns, IPE200 Steel Beams
Facade:	Brick + Painting + Glass

Insulation:	XPS (8cm) + Air Barrier
Interior Partition:	Vinyl Gypsum Modular Wall Panels
	Vinyl Gypsum Modular Ceiling Panels
MEP:	Centralized Heating / Cooling + Zoning + Premade Wiring
Lightening:	Smart + Led
Water Management:	Rain water harvesting + Smart Control
Energy Production:	No.
Furniture:	Local suppliers.

Implementation of the framework and answers for each criteria are shown in Figure 4. Based on the results; from site 2 points, from structure 7 points, from skin 3 points, from services 8 points, from space plan 6 points and from stuff 4 points are gathered. Considering the circularity percentage calculation in the Methodology, the analysed case study is 59,55 % circular according to the proposed framework. According to EU (2015), EMF (2014), CCD (2024); reaching 40-45% circular is an achievement. In this regard, the selected case study can be accepted as a circular for the analysed aspects.

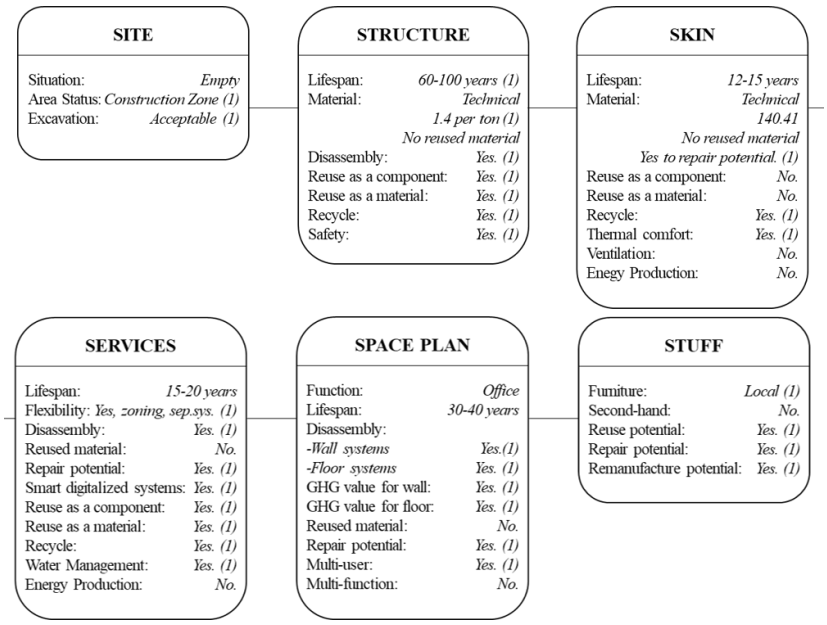

Figure 4. Implementation of the metric on the case study.

Conclusion

To conclude, this study investigates the possibility of developing a building circularity assessment tool in order to contribute circular built environment vision. In this study, circular built environment is considered as "restorative or regenerative by intention and design". Therefore, the building assessment tool is structured focusing on 6S Shearing layers and circularity design strategies such as assembly, disassembly, reuse potential, repair potential, lifespan, for each building layers. The proposed assessment is applied on a new construction steel frame office building and the final circularity score, 59,55%, is considered as acceptable.

This study's insights aim to provide valuable guidance on circular design and inspiration for the future research. This circularity assessment framework aims to be used by architects, policy makers, and the other professionals of the AECO industry that targets to learn the current conditions of the existing buildings or design the new buildings considering the circular economy. The subsequent research will compare the projects with different structural materials and functions, especially comparison of reinforced concrete, steel and timber frame buildings are expected to highlight the heavy effect of

the structure and materials in circularity. Also, existing material database can be extended. This process could retain the diversity of buildings during circularity assessment.

The Role of Digital Technologies in Museum Storytelling: Ephesus Experience Museum

Hilal Kesikci[a], Zeynep Kuban Tokgöz[b]

[a] Istanbul Technical University/Graduate School, Art History Program, Istanbul, Türkiye

kesikci23@itu.edu.tr

Keywords: Cultural Heritage, Digital Storytelling, Experience Museum, Interactive Exhibitions, Visitor Engagement.

Aim

Museums are places where cultural heritage is preserved and presented, offering visitors a glance into the past through artifacts, documents, and exhibitions. In recent years, the role of museums has expanded beyond static displays, focusing on creating immersive and engaging visitor experiences. This shift has led to the emergence of a new category known as "experience museums." Experience museums use advanced technologies such as Augmented Reality (AR), Virtual Reality (VR), 3D modeling, and interactive installations to go beyond traditional exhibitions. They aim to transform storytelling by actively engaging visitors, allowing them to connect with historical, cultural, or scientific narratives on a deeper, often emotional level. Unlike traditional museums, where visitors are mainly observers, experience museums place them at the center of the story, making them active participants. One of the most notable examples in Turkey is the Ephesus Experience Museum, which combines cutting-edge digital tools with Ephesus's rich archaeological history. It seeks to recreate the past in a way that is both captivating and informative. This study explores the role of digital techniques in transforming storytelling in museums, focusing on the Ephesus Experience Museum as a case study. It examines how these museums are conceptualized and designed, their goals, and how effectively they achieve them. The research aims to analyze the broader impact of digital storytelling in museums by comparing archaeological and non-archaeological contexts and evaluating the economic and cultural factors influencing their development.

Material and Method

The research employs a qualitative approach based on literature review, expert interviews, and comparative analysis. Data were collected through interviews with museum professionals, exhibition designers, and a game designer working on cultural heritage projects. Each interview focused on key topics such as the role of digital technologies in storytelling, the challenges of integrating digital tools into museums, and visitor engagement strategies. The questions explored various aspects, including how digital technologies enhance storytelling in museums, the balance between traditional curation and digital innovation, the challenges faced during digital experience design, and the impact of digital experiences on visitor engagement and education. A thematic analysis was conducted on the interview responses, identifying recurring themes such as immersive engagement, accessibility concerns, and content-driven approaches in digital museum experiences. This analysis helped shape the findings of the study. Publications from the creators of the Ephesus Experience Museum were examined, alongside statistics from the Izmir Provincial Directorate of Culture and Tourism, which supported the interpretation of the findings. Additionally, a review of various digital storytelling techniques employed by museums worldwide was conducted. Key terms such as "digital archaeology," "museum storytelling," and "visitor experience and technology" were used to search relevant databases. The study also compares museums that offer a "digital experience" to explore different storytelling approaches in cultural institutions.

Findings

Digital technologies are widely used in museum storytelling, transforming visitor experiences from passive observation to interactive engagement. Ephesus Experience Museum serves as a case study illustrating this transformation. In order to analyze the museum, first examining the narrative and presentation methods was the beginning of the shaping of the

findings. The museum is housed in a newly constructed building located right next to the ancient city of Ephesus. It employs digital projections, sound, and interactive installations to reconstruct elements of ancient Ephesus. The storytelling follows a structured sequence presented through three immersive rooms. The first room introduces myths associated with Ephesus, such as the Oracle of Delphi (Pythia) and the goddess Artemis. The second room represents the Roman period, offering a digital reconstruction of the ancient streets of Ephesus. The final room focuses on Artemis, highlighting her role in the city's spiritual heritage. One of the key findings is that despite utilizing advanced digital techniques, the museum has notable limitations. The experience is entirely projection-based, relying on pre-designed content rather than interactive or participatory elements. Unlike museums that integrate physical artifacts or allow visitors to explore at their own pace, the Ephesus Experience Museum follows a fixed narrative sequence, restricting independent discovery. As well, the historical context provided is minimal, making it difficult for visitors to fully understand the broader archaeological significance beyond the visual displays.

Interviews conducted to further elaborate the findings were also effective. A common perspective gathered from the interviews is the necessity of avoiding applications that use digital technologies as tools without placing humans at the center. Striking a balance between digital tools and content depth will create a more comprehensive and educational experience for visitors. Additionally, the interviews provided a different perspective while reviewing the literature, helping to refine the comparative approach in a more accurate direction. In the literature, the Ephesus Experience Museum is often compared to other digital or immersive museums, such as the Van Gogh The Immersive Experience, which uses large-scale digital storytelling techniques. In this example, comparisons can only be made in terms of the technologies used. However, considering its location within an archaeological site, a more suitable comparison would be with visitor centers at similar heritage locations. Visitor centers typically provide background information, historical context, and sometimes physical exhibits as an introduction to the archaeological site. Among the examples considered, the Çatalhöyük Visitor Center stands out due to both its architectural design and the interactive experiences it offers. This comparison is crucial in assessing whether digital storytelling alone is sufficient in effectively conveying cultural heritage or if complementary elements are necessary. From another perspective, visitor centers also play a role in increasing visitor numbers at archaeological sites. According to the statistics published by the Izmir Provincial Directorate of Culture and Tourism, Ephesus Ancient City already accounts for more than half of all cultural and tourism activities in Izmir. Currently there is statistical data until July 2023. Interpreting future statistics to see the impact of the Ephesus Experience Museum, which opened in October 2023, will also be an important finding.

Besides, the term "experience museum" in Turkish presents conceptual challenges. It may imply that traditional museums do not provide experiences, which is not entirely accurate. In the case of the Ephesus Experience Museum, "experience" mainly refers to digital engagement rather than broader museum practices. This distinction is important when discussing the effectiveness of digital storytelling in museums. A museum established under the title of experience museum should clearly state in its name exactly what experience it offers. A good example of this, naming it "Schloss Schönbrunn VR" to describe the digital experience offered to visitors within Schönbrunn Palace. This example, which is not near an archaeological site, can be compared in terms of its location and naming within a historical architectural structure.

Conclusion

In conclusion, the study highlights the impact of digital technologies on museum storytelling. Ephesus Experience Museum demonstrates the potential of immersive digital tools in engaging audiences and enhancing historical narratives. However, for digital storytelling to be effective, it must balance technology with meaningful content. Museums should prioritize visitor engagement through well-structured narratives rather than relying solely on technological innovations. Digital storytelling should not be viewed as a mere addition to exhibitions but as an integrated approach that enriches the visitor experience. Future developments in digital museum experiences should focus on accessibility, interactivity, and content-driven storytelling to maximize educational and cultural impact. Museums should consider hybrid approaches that combine traditional exhibition methods with cutting-edge technology, ensuring that historical authenticity is maintained while offering modern engagement strategies. By striking this balance, museums can enhance visitor understanding, foster deeper emotional connections, and create lasting impressions that extend beyond the physical museum space. The success of digital

storytelling depends not only on the technology used but also on how well it aligns with the museum's educational and cultural mission.

Keywords: Art Collectives, Turkish Art History, Commoning, Commons.

This study critically examines the historical trajectory of art collectives in Turkey, analyzing their evolution through the lens of commoning practices. Commoning refers to the collective management of resources through participatory and decentralized governance. Within the sphere of contemporary art, commoning is not merely the redistribution of material assets but an ongoing process that fosters relational dynamics, community-driven sustainability, and alternative forms of artistic labor. By exploring early collective artistic movements in Turkey, such as the Community Centers (*Halkevleri*), the Independent Painters and Sculptors Association (*Müstakil Ressamlar ve Heykeltıraşlar Birliği*), the Newcomers Group (*Yeniler Grubu*), the Ten's Group (*Onlar Grubu*), the d Group and the Attic Painters (*Tavanarası Ressamları*), this research investigates the structural, ideological, and artistic continuities and fractures that have shaped contemporary art collectives since the founding of the Turkish Republic in 1923.

Aim

The primary aim of this research is to analyze how Turkish art collectives have historically navigated socio-political and economic structures while developing collective practices of artistic production, resistance, and sustainability. By investigating historical ground, the study seeks to identify patterns of collaboration, resource sharing, and communal engagement that have either persisted or transformed over time. This examination situates Turkish art collectives within broader global discourses on the commoning, artistic labor, and collective agency in cultural production.
The emergence of art collectives in Turkey, particularly in the late 20th and early 21st centuries, reflects a broader global tendency towards participatory and collaborative artistic practices. However, these collectives operate within a distinct socio-political and economic framework, shaped by local conditions and historical contingencies. By exploring the motivations, organizational structures, and artistic strategies of these collectives, this study aims to reveal the ways in which they negotiate autonomy, sustainability, and visibility within the Turkish art scene. Unlike institutionalized art platforms, collectives prioritize horizontality, non-hierarchical decision-making, and fluid membership structures. This study argues that such practices align with the principles of commoning, where resources, knowledge, and creative labor are collectively generated, managed, and distributed. By analyzing pioneering examples of early Turkish art collectives, this research investigates how they develop mechanisms of shared authorship, co-creation and collective agency by challenging conventional narratives of artistic production.

Material and Method

This study employs a multi-method qualitative approach to provide a comprehensive understanding of the historical dynamics of art collectives in Turkey. This research integrates historical analysis, literature review, and case study methodologies. The study is structured around four primary components. The primary methodological component includes historical analysis, which is an examination of archival materials, including state records, exhibition catalogs, and artist manifestos, to reconstruct the ideological, aesthetic, and organizational frameworks of early Turkish art collectives.This literature review systematically examines theoretical and empirical studies on Turkish art collectives, commoning practices, and alternative cultural economies. Drawing from perspectives in art history, sociology, and political theory, it aims to

provide a comprehensive understanding of how these collectives function and evolve over time. In the case study section, a comparative analysis of selected Turkish art collectives from different historical periods will be conducted. This analysis will focus on their modes of operation, their engagement with commoning practices, and how they have responded to socio-political shifts. By highlighting these aspects, the study seeks to reveal the dynamic nature of art collectives and their role in shaping alternative cultural economies in Turkey. By synthesizing these methodologies, the study constructs a historical and theoretical framework that situates Turkish art collectives within a broader discourse on commons-based cultural production.

Findings

The findings highlight significant continuities and ruptures in the history of Turkish art collectives. While early Turkish art collectives were often state-supported or embedded within nationalist cultural policies, they nevertheless laid the groundwork for alternative and cooperative artistic production models. The Community Centers (*Halkevleri*), established in the early Republican period, functioned as an enlightenment project that sought to integrate art into public life. Though state-led, these centers emphasized art as a public good, a notion that closely aligns with contemporary commoning principles. Similarly, the *Müstakil Ressamlar ve Heykeltıraşlar Birliği* and *Yeniler Grubu* pioneered non-institutional exhibition practices, challenging the centralization of artistic production and prefiguring the DIY ethos of today's independent art collectives. Another critical finding is the evolving conceptualization of commoning in artistic contexts. Early Turkish art collectives engaged with commoning primarily through shared physical resources (such as exhibition spaces and studios). By situating Turkish art collectives within the global discourse on commoning, this study underscores their role in reconfiguring artistic agency, community-building, and knowledge production beyond traditional institutional frameworks.

Conclusion

In conclusion, this study underscores both the continuities and transformations within Turkish art collectives, illustrating how past artistic movements have influenced contemporary commoning practices. While early collectives functioned within centralized structures, today's initiatives prioritize decentralized, grassroots organizational models. This shift reflects broader transformations in artistic labor, cultural production, and strategies for sustainability amid increasing institutionalization. By historicizing Turkish art collectives through the lens of commoning, this research contributes to ongoing debates on cultural production, artistic precarity, and collective agency. By bridging historical and contemporary perspectives, this study provides valuable theoretical and practical insights into the evolving role of commoning within artistic practice in Turkish Art History. By historicizing Turkish art collectives through the lens of commoning, this research contributes to ongoing debates on cultural production, artistic precarity, and collective action.

Finally, this research critically examines early Turkish art collectives within the framework of commoning, revealing how they functioned as pioneering models of artistic collaboration and social engagement. Emerging in the early to mid-20th century, these collectives were often formed in response to political, economic, and cultural challenges, positioning themselves as counter-narratives to dominant institutional structures. They operated through shared artistic production, collective authorship, and an ethos of mutual support, laying the groundwork for contemporary formations. Groups such as the *Yeniler Grubu* and *On'lar Grubu* exemplified an early commitment to artistic solidarity, navigating state policies, economic constraints, and shifting ideological landscapes to sustain alternative creative spaces.

The study thus provides valuable insights into the transformative potential of collective artistic practices in contemporary Turkey and beyond, demonstrating their capacity to reshape the landscape of cultural production while fostering a sense of solidarity within artistic communities. By linking these historical precedents to present-day collectives, this research underscores the persistent relevance of commoning as a mode of resistance, innovation, and artistic renewal.

Keywords: Pot, Ceramic Art, Alev Ebüzziya Siesbye, Imaginary Expression, Functional Form.

Aim

Throughout the history of civilisation, pot and ceramic objects are important mediums that are the carriers of the culture in which they are produced. The place of ceramics among small handicrafts, which started with the production of pots and vessels from the B phase of the Neolithic Age and paved the way for mass production with the invention of the potter's wheel, is undeniable. While ceramics initially stood out with its purely functional characteristic, in time it transformed into a decorative object and became an important part of human life. It is one of the important research areas of archaeology and art history as its raw material is clay, the ancient methods used in its processing, shaping and decoration are passed down from generation to generation, and it is the earliest material used in every region of the world other than wood and stone. In a sense, the history of ceramics is also the history of humanity and technology, and the relationship between ceramics and craftsmanship should not be overlooked.

In this paper, first of all, the definition of 'functional object' is clarified. Then the concept of 'imaginary' is analysed. The theoretical framework is shaped in the context of Heidegger's views that categorise objects into types. According to Heidegger, there are three types of object groupings which dominate the Western thought: the pure object, the equipment and the art object. These types are three states of being that appear in different forms. The pure object is that which exists in nature in its own state. An equipment is an object of use produced with appropriate material selection and correct design. The art object, on the other hand, is distinguished from other objects by its characteristic of an act of knowing that includes imagination. (Heidegger, 2011: 24). For Heidegger, a work is the recreation of the essence of a being. This 'essence' of the work of art is recreated by the artist, the 'techne' is revealed by means of [tékʰnɛː]. (Heidegger, 1998: 53). In a general sense, "the word techne, as used by Plato, is a "making" activity in ancient Greek culture in which the distinction between craft and art, as we do today, is not in question, and it includes a basis based on direct knowledge (episteme)." (Haşlakoğlu, 2016:17) Techne is defined as any state of making; the rational method used to produce an object or to realise a goal or purpose. This concept emerged in Ancient Greece at a time when there was not yet a distinction between craft and art and covers everything produced by hand. In this paper, the art practice of Alev Ebüzziya Siesbye (b. 1938), one of the artists who uses the pot form in its simplest form as a way of imaginative expression, will be discussed in the context of imaginative expression.

Material and Method

The minimalist and conceptual approach in the artist's ceramic works will be evaluated; how she transforms the pot form, a traditional object of use, into an art object will be analysed. Biography, work analysis, formal analysis and comparison methods will be used in this analysis which focuses on the transformation of the pot from a functional object into an imaginary object. In addition, oral history practice will also be used by obtaining first-hand data through an interview with the artist.

Findings

In the research, which is limited in scope with ceramic artifacts, the effects of the relationship between the object of use and the material on the process of imaginary form creation are discussed. Since the early periods, ornamental elements have been added to ceramics with various methods. The evaluation of ceramics as a work of art rather than an object of daily life is associated with Modernity. The emergence of imaginative expression forms in ceramics started with Modernity. The history of ceramics, which is obtained by firing 'clay', a natural and easily shaped raw material, dates back to 30,000-32,0000 years ago. The first finds are small-sized objects such as figurines found in excavations in Central Europe and idols thought to be used as talismans. The first examples of ceramic objects used as pots and vessels made 19.000 years ago are found in Central Asia. (Yoleri, H. and Öztürk, Ş. 2023: 57)

In this paper, the concept of image is important. Its literal meaning is 'something conceived in the mind and longed to be realised; imagination'. Imaginary is an adjective derived from this word. The analysis of the transformation of ceramics, an object of use with a certain function, into an imagined form is a process that can only be analysed by plastic evaluation methods. Some evaluation criteria used in ceramic art are raw material, space-occupancy, volume, balance, colour. In this context, first of all, artists who have chosen the path of expression with pure imaginary forms in ceramic art have been analysed. These people work on the transformation from function to image, sometimes intuitively and sometimes planned. Among ceramic forms, the pot stands out. Because the earliest functional ceramic is defined as 'pot', which is also an archaeological term. In his work "The Meaning of Art' (2014), Herbert Read says of ceramic, 'ceramics (pot) is the most difficult because it is the most abstract form of art". (Read, 2014: 22). Although it is one of the simplest forms, it is the most difficult to specialise in, and studies on the pot are concentrated in areas such as form, decoration and glaze.

Alev Ebüzziya Siesbye who will be discussed in the context of imaginative expression was born in 1938 in Istanbul, studied sculpture at the İstanbul State Academy of Fine Arts and ceramics at the Füreya Workshop between 1956-58. In the following years, she continued her studies at the Eczacıbaşı Ceramic Factory in Istanbul and the Royal Danish Porcelain Factories in Copenhagen. In 1969, Ebüzziya established her own studio in Copenhagen and moved her studio to Paris in 1987. Her artistic career spans more than fifty years and she has around three thousand works in various collections, including the Royal Collections in Denmark and England, the Imperial Palace of Japan, the Boymans van Beuningen Museum and the Victoria & Albert Museum. In her exhibition in Denmark in 1974, Siesbye transformed pots, which are functional objects and have been visible for thousands of years, into an imaginary form.

The main subject of this paper is Alev Ebüzziya Siesbye's works from 1974, when she had her first solo exhibition as an artist, until 2024, as a result of the compilation of publications on her pots. While analysing the elements that influenced Alev Ebüzziya Siesbye's works produced between 1974 and 2024 and their reflections on her pots, the place of the concepts of form, space, lightness, simplicity and time in the artist's approach is also discussed. Ebüzziya Siesbye reproduces ceramic pots in their simplest form, without differentiating them with any additional decorative elements; in the process of creation, she carries the pot form to the imaginary level with the concepts of negative space, volume and repetition; she uses these concepts as plastic elements. Her unique 'levitating pots' are the group of works that will be analysed formally and semantically in this paper. In addition, the concepts of imaginative expression, artistic creation process, minimalism and conceptual art will be traced in Alev Ebüzziya Siesbye's art practice. The change, transformation and development of the artist's 'levitating pots' over a period of half a century will be observed retrospectively and the research will deal with the visual analysis of the artist's works with a qualitative method. Qualitative analysis contributes to the evaluation of Ebüzziya Siesbye's works in terms of colour, texture and glaze in addition to form, material and space.

Conclusion

In conclusion, the content of this study reveals how Alev Ebüzziya Siesbye presents an original interpretation on the axis of tradition, Minimalism and Conceptual Art by transforming the pot form, a functional object, into an artwork. The artist, who builds a bridge between thousands of years ago and contemporary art, invites the viewer to think about form, space

and existence through objects that have been de-functionalised. Ebüzziya Siesbye's ceramics not only present a visual aesthetic, but also bring new insights into the meaning of the art object.

Keywords: Activated Carbon, Biomass, Chemical Activation, Supercapacitor Electrode.

Aim

The increasing demand for energy is leading to the rapid depletion of fossil fuels and environmental pollution. To meet energy demand, it is essential to use renewable energy sources such as solar and wind energy. However, these sources are often intermittent, requiring energy storage solutions (Aziz & Shah, 2023). Supercapacitors, as an energy-storage device bridging the gap between batteries and conventional capacitors, offer advantages such as long cycle life, high power density, and fast charging/discharging (Zhang & Li, 2023). Light rail systems, military services, wind turbine systems, aerospace, and electric vehicles are some of their applications (Aziz & Shah, 2023). The electrochemical performance of a supercapacitor is directly related to the capacitive performance of its electrode material. Carbon materials with hierarchical macro/meso/micropores, used as electrode materials, enhance supercapacitor performance (Xu et al., 2021). Macropores, mesopores, and micropores each play distinct roles in the electrochemical charge/discharge process. Macropores serve as ion storage reservoirs for mesopores and micropores, while mesopores provide transport channels for ion diffusion. Although some regions of micropores may be inaccessible for ion adsorption, they affect the charge state by controlling ion diffusion and exhibiting molecular sieve effects (Yang et al., 2019). Activation is the key method to obtain a hierarchical structure with a large specific surface area (Xu et al., 2021). Commercial activated carbons are still the most commonly used electrode materials today; unfortunately, they are mostly derived from fossil fuels, and their precursors are not environmentally friendly and are expensive (Zhang & Li, 2023). Biomass waste is being extensively investigated as high-performance supercapacitor materials due to its abundance, availability, low cost, and environmental friendliness (Yue et al., 2022). For this purpose, activated carbon was produced from waste biomass under different activation temperatures and using various activator ratios. To evaluate the effect of various operating conditions on porosity, analyses were performed on activated carbon samples, and electrochemical performance tests were conducted on supercapacitor electrodes prepared from activated carbon (Zhang et al., 2022).

Material and Method

Corn stalk (CS), one of the three main agricultural waste products worldwide, was used as the biomass precursor. Potassium hydroxide (KOH) was used for the chemical activation. Figure 1 shows the preparation process of activated carbon from corn stalk. To obtain activated carbon from corn stalk, carbonization was first performed, followed by chemical activation. The corn stalk was ground to a particle size of ≤250 μm. It was heated to 600 °C at a rate of 10 °C/min in a tube furnace under a nitrogen atmosphere and subjected to pre-carbonization by keeping at this temperature for 1 hour. The carbonized corn stalk and KOH were mixed in a 1:3 ratio. The mixture was then heated to the desired temperature (600, 700, 800, 900 °C) at a rate of 10 °C/min in a tube furnace under a nitrogen atmosphere and subjected to chemical activation by keeping at this temperature for 1 hour. The electrochemical measurements of these four samples were conducted, and since better results were obtained at 800°C, subsequent productions were carried out at this temperature. The carbonized corn stalk and KOH were mixed in the determined ratios (1:1, 1:2, 1:3, 1:4) and heated in a tube furnace under a nitrogen atmosphere at a rate of 10 °C/min to 800 °C, keeping at this temperature for 1 hour. The activated carbon was first washed with 1 M HCl to remove residual chemicals, then washed with distilled water until the pH became neutral. It was then left to dry in an oven at 60 °C overnight. The samples were named according to the activation temperature and activation chemical ratio as

CS-600, CS-600-K3, CS-700-K3, CS-800-K3, CS-900-K3, CS-800-K1, CS-800-K2, and CS-800-K4. To observe the effect of activation on the material, the CS-600 sample was only subjected to carbonization without activation. The characterization of the activated carbon samples is being carried out using FTIR, TGA, SEM, Raman Spectroscopy, XRD, XPS, and BET analyses. The proximate, elemental and structural analysis of corn stalk was carried out. For the preparation of the supercapacitor electrode, a weight ratio of 8:1:1 of activated carbon, carbon black, and PVDF was used. First, PVDF was dissolved in NMP using a magnetic stirrer at 30 °C. Then, activated carbon and carbon black were added to the mixture and stirred further. PVDF, carbon black, and NMP were used as a binder, conductivity enhancer, and solvent, respectively. The resulting mixture was drop-cast onto a stainless-steel current collector and dried in an oven at 60 °C. Electrochemical measurements of the electrodes were performed in a three-electrode cell. For the three-electrode cell, Ag/AgCl was used as the reference electrode, Pt as the counter electrode, and a 6 M KOH aqueous solution as the electrolyte. Cyclic voltammetry (CV), galvanostatic charge-discharge (GCD), and electrochemical impedance spectroscopy (EIS) were used to measure the electrochemical performance of the electrodes.

Figure 1. The preparation process of electrode from corn stalk.

Findings

The capacitance values, calculated from the GCD curves shown in Figure 2, were used to evaluate the electrochemical performance of the samples. It was found that the CS-600-K3, CS-700-K3, CS-800-K3, and CS-900-K3 samples, obtained at different temperatures, exhibited specific capacitance values of 43 F/g, 111 F/g, 170 F/g, and 100 F/g, respectively, at a current density of 0.5 A/g. The highest specific capacitance was achieved with the sample produced at 800 °C. Further optimization was conducted at this temperature by varying the KOH ratio in the activation process. The CS-800-K1, CS-800-K2, and CS-800-K4 samples, with different KOH ratios, showed specific capacitances of 105 F/g, 208 F/g, and 129 F/g, respectively, at the same current density of 0.5 A/g. The highest specific capacitance was achieved with the sample produced with a 1:2 KOH ratio at 800 °C. It was also found that the specific capacitance of the non-activated CS-600 sample was 3 F/g at 0.5 A/g. The non-activated sample showed a much lower specific capacitance, confirming the

importance of the activation process in improving the material's electrochemical properties. The activation increased the surface area and charge accumulation by enhancing the porosity, resulting in an extended CV behavior. The GCD curves indicated enhanced charge/discharge performance in activated carbon samples, attributed to increased ion diffusion and storage capacity.

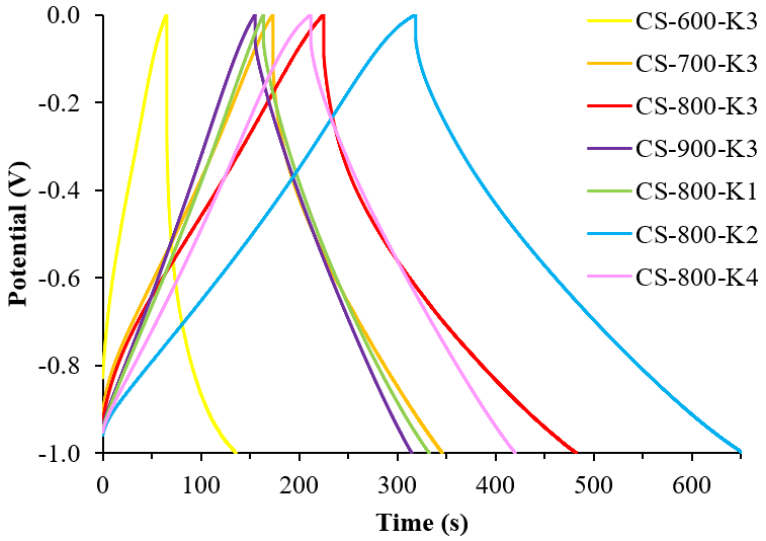

Figure 2. GCD curves at 0.5 A/g.

Conclusion

These results demonstrated that corn stalk-derived activated carbon can serve as a sustainable and cost-effective electrode material for supercapacitors. The findings showed that the activation temperature and activator ratio significantly influenced the porosity and electrochemical performance of the resulting carbon material. Among the tested samples, CS-800-K2, produced at 800 °C with a 1:2 KOH ratio, achieved the highest specific capacitance of 208 F/g at 0.5 A/g, highlighting the optimal activation conditions for corn stalk. In conclusion, this study highlights the potential of biomass-derived activated carbon as a promising alternative to conventional electrode materials, contributing to the development of sustainable energy storage technologies.

Machine Learning-Based Prediction of FTIR Spectral Peaks for Biomass Characterization

Fahreddin Talha Sağiş[a], Anıl Yılmaz[a], Hanzade Haykırı-Açma[a], Serdar Yaman[a]

[a] Istanbul Technical University/Graduate School, Faculty of Chemical and Metallurgical Engineering, Chemical Engineering Program, Türkiye

sagis22@itu.edu.tr

Keywords: Biomass Characterization, FTIR Spectroscopy, Machine Learning, Multi-Label Classification, Spectral Peak Prediction.

Aim

This extended abstract focuses on accelerating lignocellulosic biomass characterization by integrating Fourier Transform Infrared (FTIR) spectroscopy with machine learning (ML) techniques. Lignocellulosic biomass is composed primarily of cellulose, hemicellulose, and lignin, plus minor constituents like extractives and ash, all of which influence its suitability for bioenergy or bioproduct applications. Conventional chemical analyses—such as Soxhlet extraction for extractives, the Klason method for lignin, and other gravimetric or chromatographic assays—are accurate but demand significant time and labor. Hence, there is a pressing need for rapid, high-throughput analytical methods capable of capturing biomass composition. FTIR meets this need by producing spectra (4000–450 cm^{-1}) that reveal chemical "fingerprints" in the form of characteristic absorption bands for O–H, C=O, and aromatic ring vibrations. However, overlaps among these bands, baseline drifts, and broad peaks complicate manual interpretation.

To address these challenges, this study leverages machine learning models that can parse and interpret FTIR data more efficiently. Specifically, we investigate three distinct phases. In Phase 1, multi-output regression models (Partial Least Squares, Ridge Regression, Random Forest, and Multi-Layer Perceptron) aim to predict every wavenumber intensity (~3551 points) from a small set of nine input features (including moisture, ash, volatile matter, lignin, and holocellulose). Phase 2 transitions to a more tractable approach: broad-range classification, where each defined spectral interval (e.g., 3700–3000 cm^{-1}) is labeled as "peak present" or "peak absent." Finally, Phase 3 narrows the classification scope to only three chemically pivotal windows (e.g., 1800–1500 cm^{-1}), hypothesized to yield clearer relationships between known functional groups and predicted outcomes. By comparing model performance across these phases, we clarify how the level of spectral detail—ranging from entire-spectra regression to interval-based classification—impacts accuracy, interpretability, and computational feasibility.

Material and Method

We acquired 56 biomass samples from woody, herbaceous, and agricultural residues to cover a wide range of lignocellulosic compositions. Each sample underwent proximate analysis to determine moisture, ash, volatile matter, and fixed carbon, followed by compositional assays for holocellulose, lignin, and extractives. FTIR spectra were recorded between 4000 and 450 cm^{-1} at a resolution that yielded approximately 3551 wavenumbers per sample.

Preprocessing involved baseline correction to remove sloping artifacts from inhomogeneities or ATR contact issues (Mokari et al., 2023), followed by normalization to zero-mean, unit-variance so that features with large numeric ranges (e.g., percent ash or extractives) would not skew training. An optional polynomial feature expansion was also tested to capture non-linear interactions among numeric inputs, such as moisture–ash synergy.

In Phase 1 (Full-Spectrum Regression), we used nine input features per sample to predict all 3551 wavenumbers of the FTIR spectrum. We compared Partial Least Squares (PLS), which creates latent factors maximizing covariance with high-dimensional outputs; Ridge Regression, a fundamentally linear model that applies L2 regularization; Random Forest Regressor, an ensemble of decision trees designed to capture non-linear relationships; and an MLP Regressor, a neural network with hidden layers (using ReLU or tanh activation) and a final linear output layer for multi-output tasks, with hyperparameters tuned via grid search.

For Phase 2 (Broad-Range Classification), we converted spectral outputs into 8–10 wide intervals (e.g., 4000–3700 cm^{-1}, 3700–3000 cm^{-1}), labeling each interval as "1" if a strong absorbance peak crossed a chosen threshold or "0" otherwise. We then applied multi-label classification using Classifier Chain wrappers on Logistic Regression, Random Forest, Gradient Boosting, and SVM (RBF kernel).

Phase 3 (Narrow-Interval Classification) targeted three narrower intervals (3000–2800, 1800–1500, 1150–900 cm^{-1}), each closely associated with critical functional groups such as aliphatic C–H, lignin/carbonyl signals, or carbohydrate bands. Models were again multi-label classifiers distinguishing "peak" from "no-peak." Across all phases, we used five-fold cross-validation. Phase 1 results were evaluated by RMSE and R^2, while Phases 2 and 3 were assessed by Hamming Accuracy (1 − Hamming Loss), Micro-F1, and confusion matrices.

Findings

Phase 1 (Full-Spectrum Regression) demonstrated the challenge of mapping only nine input features onto 3551 wavenumber intensities. Among the models, Ridge Regression had the highest RMSE (~1.10) and the lowest R^2 (~0.04), suggesting that a purely linear approach with L2 penalty fails to capture non-linear or interaction effects in spectral data. PLS performed moderately better (RMSE ~1.03, R^2 ~0.17) by extracting latent factors tailored to spectral variance. Random Forest improved over Ridge (RMSE ~1.06, R^2 ~0.13), but still faced difficulties with the large output space. MLP achieved the best scores (RMSE ~1.00, R^2 ~0.21), albeit the R^2 remained relatively small, highlighting the complexity of full-spectrum predictions.

Phase 2 (Broad-Range Classification) saw a jump in multi-label accuracy compared to Phase 1's direct intensity mapping. Logistic Regression sometimes led with a Hamming Accuracy of ~0.75 and Micro-F1 ~0.79, indicating more reliable detection of peak presence/absence in broad spectral ranges. Random Forest and SVM also posted competitive performance, though the choice of parameters (e.g., C and gamma for SVM, max_depth for Random Forest) influenced results. Some intervals (like 3700–3000 cm^{-1}) were less frequently misclassified, presumably due to distinct O–H stretching peaks, whereas intervals with more overlap or fewer "1" samples (like ~2000–1800 cm^{-1}) showed greater confusion.

Phase 3 (Narrow-Interval Classification) targeted intervals known to correlate strongly with lignocellulosic traits: 3000–2800 cm^{-1} (aliphatic C–H), 1800–1500 cm^{-1} (aromatic/carbonyl signals linked to lignin), and 1150–900 cm^{-1} (carbohydrate fingerprint). Random Forest excelled, reaching ~0.81 Hamming Accuracy and ~0.88 Micro-F1. Confusion matrices revealed fewer false positives/negatives in these constrained windows, implying a sharper chemical link between input features and FTIR dips. Even if MLP and SVM were close behind, the ensemble-based approach of Random Forest often captured subtle non-linearities beneficial in narrower spectral domains.

Overall, Phase 1's comprehensive goal proved the hardest with limited data. Aggregating or restricting spectral outputs in Phases 2 and 3 yielded progressively better classification metrics, supporting the strategy of simplifying the output space to major or high-value spectral signals.

Conclusion

This study confirms that integrating FTIR spectroscopy with machine learning can expedite and refine biomass characterization. Predicting the entire FTIR spectrum (Phase 1) underlined the challenge of a massive output space: while

an MLP outperformed other models, absolute R^2 remained modest, indicating that hundreds of samples or more advanced modeling might be needed for highly accurate full-spectrum regression. By transitioning to broad-interval classification in Phase 2, the modeling complexity reduced significantly, leading to higher accuracies in detecting whether a peak existed in each region. Phase 3's targeted classification approach further improved results and interpretability, as focusing on narrower intervals strongly linked to functional groups (e.g., lignin's aromatic region) delivered the best classification metrics.

From an industrial or research standpoint, these findings suggest that if one only requires confirmation of certain functional groups (e.g., lignin presence around 1510 cm^{-1}), narrower intervals with an ensemble classifier (Random Forest) or a well-tuned neural network can yield a fast, robust solution. On the other hand, if a complete spectral reconstruction is desired, more sophisticated or data-intensive approaches may be necessary. Future expansions could include deeper architectures, transfer learning between different biomass categories, or larger multi-feedstock datasets to enhance generalizability. In essence, this multi-phase methodology spotlights a flexible framework: from exhaustive spectrum modeling to selective peak detection, enabling a range of FTIR-based solutions that balance accuracy, speed, and interpretability.

The Design And Application of Novel Post-Metallocene Catalysts For Olefin Polymerization

Önder Güneş[a], Ozan Sanlı Şentürk[a]

[a] İstanbul Technical University, Departmant of Chemistry, Türkiye
guneso18@itu.edu.tr

Keywords: Catalysts, Polyolefins, Post-Metallocene, Tailor-Made-Polymer.

Aim

Polyolefins are macro molecules that are made of many smaller molecules which contain C=C in their structure. Those polymeric materials possess properties like being durable, resistant towards harsh chemicals and heat according to their molecular structure. It is also known that polyolefins are one of the major plastics that is made for many applications in a wide range. Although, plastic materials are among the most widely produced man-made products, with nearly 400 million tons manufactured annually. It is estimated that around 150 million tons of polyethylene (PE) and 85 million tons of polypropylene (PP) account for the vast majority of these polymeric materials.

The distibution of produced plastics are; 21% low density polyethylene (LDPE), 18% of poly(vinyl chloride) (PVC), 17% poly(ethylene teraphthalate) (PET), 15% polypropylene (PP), 14% lineer low density polyethylene (LLDPE), 10% high density polyethylene (HDPE) and 5% polystyrene (PS) which shows the polyolefins as a group are the main backbone of the arrangement.

This research focuses on designing and synthesizing new post-metallocene catalysts for producing tailor-made polyolefins with ultra-high molecular weights (UHMW). UHMWPE is a kind of plastic that has a molecular weight over 1,5 million Da (Malpass, 2010). Within this high of a molecular weight, it has the potential of producing extra strong and durable materials. However, production of UHMWPE requires special kinds of methods. Since it is a polymer within a specific molecular weight (tailor-made), its synthesis necessitates a prescribed pathway (Severn and Chadwick, 2008).

To synthesize polyethylene with ultra-high molecular weights, three key components are needed, the monomer (ethylene gas), the catalyst and a co-catalyst (Kaminsky et al. 1985). All three compounds must be as pure as possible to achieve the maximum catalytic activity. The polymerisation yield is also dependent on other factors like pressure of ethylene gas and temperature of reaction chamber. When these criteria are met, a successful polymerisation can be done according to Natta et al. (1957). Among all of these, most important component in this scenario is the catalyst, since this polymerisation is exceptional when it is compared to the traditional methods. Within a proper catalyst, not only homopolymers but also co-polymers with different olefins can be obtained (Severn and Chadwick, 2008).

Synthesis of UHMWPE can be achieved with presence of a sharp catalyst such as post-metallocene catalysts. According to Matsugi and Fujita, these catalysts are called as 'Constrained Geometry Catalysts' due to their molecular structure (2008). In these molecules, there is a transition metal centre that is surrounded by an organic. When this structure is investigated, it is seen that organic ligand has two main duties. First, it makes the molecule soluble in organic solvents. Second, it balances the electronic interaction in coordination complex. The ligand must also contain electron donating and electron withdrawing groups because coordination polymerisation mechanism involves steps that requires both of them (Johnson et al. 1995).

One of the factors that affect the activity of these catalysts is the energy gap between the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) energy levels. Therefore, the design of the ligand and selection of centre atom takes a critical place according to the ligand field theory. In this context, a coordination complex that consist of a tetradentate organic ligand to coordinate transition metals titanium, zirconium and hafnium is designed in this work. The organic ligand has two imine and two pyrrole functional groups having nitrogen atom as a donor in a chelate form. It is believed that, this structure provides the electronical flexibility to the complex while having the proper energy gap between HOMO and LUMO when it is compared to the literature (Check the previous work in appendices 1-3).

Aim of this research is actualisation of synthesis, characterisation and proving the activity of new post-metallocene catalyst and comparing their activity with corresponding literature examples.

Material and Method

Production of post-metallocene catalyst heavily relies on air-free methods such as, Schlenk Technique and employment of glove box. The reason behind this requirement is this kind of molecules are highly air and moisture sensitive. To prevent losing their activity, all synthesis, analysis and purification works are done under nitrogen atmosphere.
To synthesize the ligand, following chemicals are used:
- Pyrrole-2-carboxyaldehyde
- 1,2-ortho-phenylene diamine
- Ethyl alcohol
- Diethyl ether

This is carried out in Schlenk flask with nitrogen atmosphere. In first step a determined amount of pyrrole-2-carboxyaldehyde and 1,2-ortho-phenylene diamine was weighted according to 1:2 molar ratio (1 eq. Of diamine and 2 eqs. Of pyrrole). After that, solid materials are dissolved in ethyl alcohol in the flask and stirred overnight at room temperature. Continuity of reaction is investigated with thin layer chromatography. To terminate the reaction, firstly, the solvent was evaporated via application of vacuum with heating. When remaining solid was cooled to the room temperature, cooled diethyl ether was added to the flask. Final desired product precipitated from solution as yellowish-white solid and filtered through filter paper and washed several times with diethyl ether again. NMR and IR analysis results showed that product is highly pure and reaction yield is around 55%.

Findings

In this work, afore-mentioned ligand is successfully synthesized and characterized. Characterisation of this molecule is done by the 1H-NMR, 13C-NMR and IR analyses. When results are compared, it could be said that mentioned compounds are highly pure according to cross-comparing different methods. It is believed that, this ligand is ready to be used in further reactions to synthesize novel post-metallocene catalyst which is not done yet. In future, it is aimed to synthesize the desired coordination compound and use it for polymerisation reaction afore mentioned before.

Conclusion

In conclusion, it could be said that, electronically flexible and constrained geometry ligands are decisive elements of production of UHMWPE. This work is focused on synthesis and characterization of the ligand which would be used in later for production of post-metallocene catalyst. When this is achieved, our proposal will be accepted for synthesis of polymeric materials which is promising for many uses in a wide range of industries such as chemistry, automotives, material and mechanical engineering, agriculture, naval and defense industry.

Investigation of Fluorescence Properties of ZIF-8 Structures Modified with Graphitic Quantum Dots

Hilal Nazan Ağar[a], Caner Ünlü[a]

[a] Istanbul Technical University, Faculty of Science and Letters, Department of Chemistry, Türkiye
agar16@itu.edu.tr

Keywords: Graphitic Quantum Dots, ZIF-8, Fluorescence, Surface Properties, Nanomaterials.

Aim

In recent years, studies in the field of nanotechnology have offered significant opportunities for the synthesis and development of next-generation materials. Graphitic quantum dots (GQDs) have attracted considerable interest in various areas such as sensors, optoelectronic devices, and biomedical applications due to their excellent optical properties, large surface areas, high photoluminescence efficiency, and chemical stability (Li et al., 2021). These unique characteristics make GQDs promising candidates for a wide range of scientific and industrial applications, including biosensors, energy conversion, and drug delivery. Modifying the structures of GQDs to form hybrid systems with different materials is an important strategy contributing to the development of functional materials. Metal-organic frameworks (MOFs) are widely used in applications such as gas storage, catalysis, drug delivery, and separation technologies, owing to their high surface areas, regular porous structures, and chemical flexibility (Zhou et al., 2020). Among these, the zeolitic imidazolate framework (ZIF-8) stands out due to its high thermal and chemical stability. However, the optical properties of ZIF-8 are limited, and enhancing its fluorescence characteristics is important for sensor and optoelectronic applications (Wang et al., 2019). In this study, it was aimed to fluoresce ZIF-8 structures using GQDs and investigate their effects on surface properties.

Material and Method

GQDs, with their small sizes, high photoluminescence efficiency, and chemical stability, can modify the optical and surface properties when integrated into MOF matrices. ZIFs (zeolitic imidazolate frameworks), known for their porous structures and chemical stability, are a class of MOFs used in various applications such as gas storage, separation, and catalysis. The combination of GQDs and ZIF-8 structures is significant in enhancing fluorescence properties and improving surface characteristics. In this context, rendering ZIF-8 structures fluorescent through GQDs and investigating their absorbance properties presents an important approach for the development of potential applications. Evaluating the effects of GQD integration into ZIF-8 structures on fluorescence properties also highlights the importance of characterizing surface features. The integration of GQDs into ZIF-8 structures not only reveals their fluorescence properties but also enables the arrangement of active groups on their surfaces. These active groups facilitate the formation of interactions and catalysts for targeted applications. Such interactions play a crucial role in applications requiring selective adsorption, controlled release, and enhanced photocatalytic activity. The interaction between GQDs and ZIF-8 not only improves optical properties but can also optimize the porous structure within the material, increasing its gas storage capacity (Wu et al., 2019). This combination offers broad application potential, especially in areas such as environmentally friendly technologies and sustainable energy production.

GQDs were synthesized via a microwave-assisted method using boric acid, urea, and varying amounts of citric acid. The microwave method offers high efficiency and low energy consumption, making it advantageous for controlled synthesis (Zhao et al., 2022). Varying the amount of citric acid demonstrated that the fluorescence behavior could be tuned by affecting the distribution of GQDs within the structure and their optical properties.

The synthesized GQDs were dissolved in methanol and incorporated into the ZIF-8 synthesis process. ZIF-8 structures were synthesized via controlled precipitation of 2-methylimidazole and zinc acetate dihydrate. The integration of GQDs into the ZIF-8 matrix and the resulting optical and structural changes were examined. Careful control over synthesis parameters

ensured uniform GQD dispersion and optimal interaction with the ZIF-8 framework. During synthesis, the pre-prepared GQD solution was added to the system in appropriate ratios to integrate them into the ZIF-8 matrix. ZIF-8 structures were synthesized using GQDs containing different citric acid ratios to investigate the effect of GQD concentration on the modification.

The obtained pure and GQD-modified ZIF-8 structures were analyzed using various characterization techniques, including X-ray diffraction (XRD), Fourier-transform infrared spectroscopy (FTIR), scanning electron microscopy (SEM), photoluminescence (PL), and UV-Vis spectroscopy.

Findings

FTIR and XRD analyses confirmed the presence of the ZIF-8 crystal structure with GQDs, while SEM analyses revealed changes in surface morphology. XRD was conducted to examine changes in the crystal structure. FTIR was used to determine alterations in chemical bonding structures. SEM was applied to study surface morphology and structural changes. UV-Vis spectroscopy was employed to evaluate fluorescence properties and analyze dye adsorption behavior. The characterization results demonstrated successful integration of GQDs into the ZIF-8 structure. XRD results indicated that GQD incorporation did not significantly alter the crystal structure of ZIF-8 but could affect its porosity.

FTIR analyses confirmed that the characteristic vibration bands of imidazole groups were preserved in the GQD-modified ZIF-8 structures. SEM images revealed significant changes in surface morphology due to GQD addition, especially in the porous surface structure. UV-Vis spectroscopy analyses showed that the fluorescence properties of ZIF-8 structures were significantly enhanced with the inclusion of GQDs. The fluorescence emission intensity could be controlled by changing the GQD concentration, allowing tunability in optical properties. This suggests that the modified structures may be suitable for sensor and optoelectronic applications. Dye adsorption experiments showed that the inclusion of GQDs altered the ability of ZIF-8 to adsorb dye molecules. Particularly, analyses using methylene blue (MB) dye demonstrated that GQD-modified structures exhibited higher adsorption capacity compared to pure ZIF-8. This is attributed to the increased surface area and altered electrostatic interactions due to modification.

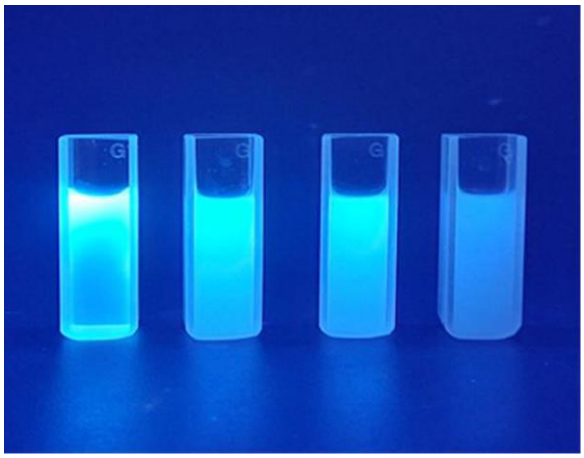

Figure 1. The emission color of carbon dots fluorescent under GQD, ZIF8-GQDs I, ZIF8-GQDs II, ZIF8-GQDs III are shown from left to right, respectively.

Conclusion

This study comprehensively investigated the changes in optical and surface properties of ZIF-8 structures modified using GQDs. The results showed that GQD incorporation significantly imparted fluorescence properties to ZIF-8 and altered its surface to improve dye adsorption capacity. The findings highlight the potential of such hybrid materials for developing efficient adsorbents, photocatalysts, and luminescent probes. Non-fluorescent ZIF-8 structures were converted into fluorescent materials through this method. Such hybrid structures have broad application potential in sensor technologies,

optoelectronics, and environmental pollutant removal. Future studies may focus on further enhancing material properties using different types of GQDs and MOF combinations, enabling more detailed optical tuning and investigation of selective adsorption mechanisms. This study highlights the improvements in optical properties of ZIF-8 structures modified with GQDs and their potential applications in fields such as sensing, optoelectronics, and dye technologies.

Synthesis Of Polymers Containing Supramolecular Components In The Pendant Or Main Chain

Hafize Reva Bayraktar[a], Abdullah Aydogan[a]

[a] Istanbul Technical University, Faculty of Science and Letters, Department of Chemistry, Turkey
rebayraktar@itu.edu.tr

Keywords: Polymer, Polyurethane, Supramolecular Chemistry.

Aim

The aim section should be written in Times New Roman font, justified-alignment and in 10-point size. Supramolecular chemistry differs fundamentally from classical covalent chemistry by emphasizing non-covalent interactions and complexation, including hydrogen bonding, π-π stacking, van der Waals forces, and metal coordinations. These dynamic and reversible interactions enable the spontaneous self-assembly of intricate molecular architectures, a key feature that underpins the development of advanced functional materials. One particularly significant application of supramolecular chemistry is in the design of self-healing materials, where non-covalent bonds facilitate autonomous repair mechanisms. By incorporating host–guest interactions and hydrogen bonding networks, these materials can undergo reversible cross-linking, allowing structural integrity to be restored after damage shown in figüre 1. This inherent adaptability and responsiveness make supramolecular systems highly promising for applications in biomaterials, soft robotics, and smart coatings (Sinawang et al., 2020).

Calix[4]pyrroles (C4Ps) were initially synthesized by Baeyer in 1886 through a condensation reaction between pyrrole and acetone, with hydrochloric acid serving as the catalyst. The cyclic tetrameric structure was later proposed by Chelintzev and Tronov (Gale et al., 1998) . In 1955, the synthesis process by substituting the catalyst with methane sulfonic acid is enhenced (Rather et al., 2019). The study of it's ion recognition and binding properties gained attention in 1996 (Gale et al., 2001) , (Rather et al., 2019b) . Calix[4]pyrroles (CPs), including octamethylcalix[4]pyrrole shown in Figure 2, and their derivatives are easily synthesized and functionalized. These compounds selectively bind anions in organic solvents. The selectivity order for anion binding by CPs is as follows: $F^- > CH_3COO^- > Cl^- > Br^- > CN^- > NO_3^-$. (Akar & Aydogan, 2005).

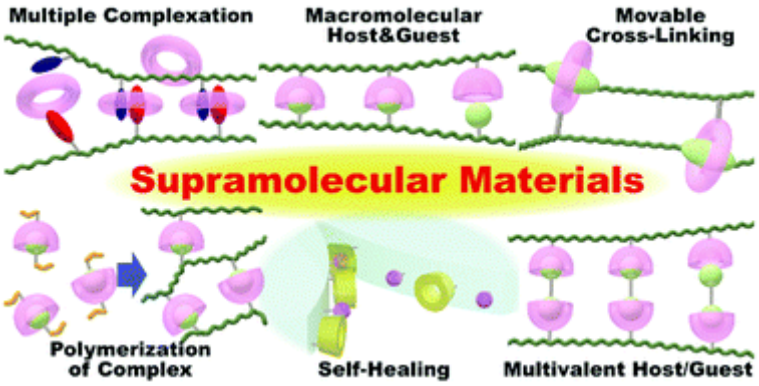

Figure 1. Cartoon representations illustrating the supramolecular complexation concepts (Gale et al., 1998).

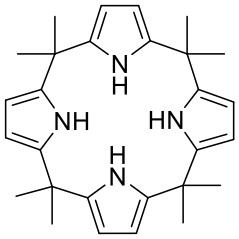

Figure 2. Octamethylcalix[4]pyrrole.

Researchers have continuously investigated the use of polyurethane for the removal, pre-concentration, and separation of various substances such as phenols, phthalates, polychlorinated biphenyls, carboxylic acids, pesticides, and dyes. The use of polyurethane as an adsorbent for organic dyes traces back to the 1990s .The extraction of azo dyes using polyester- and polyether-based types of polyurethane foam has been studied. Now, there are numerous independent reports on the use of polyurethane for the treatment of textile waste water with both model and real waste (Werbowesky & Chow, 1996) .
In this study, polyurethane polymers containing calix[4]pyrrole (C4P) units in the main chain or as pendants, cross-linked either physically or covalently, will be synthesized. The resulting polymer will be used in the extraction studies of organic dye waste,in the formation of supramolecular polymer gel networks and self-cross linking supramolecular polymers. The structural analysis and properties of the new polymers will be carried out using NMR spectroscopy, FTIR spectroscopy, viscosity and conductivity measurements, UV-VIS spectroscopy, and rheological measurements.

Material and Method

The material and method section should be written in Times New Roman font, justified-alignment and in 10-point size. First, the CP-Diester compound, which has an ester functional group at the meso position and serves as a starting compound to bis-alcohol-calix[4]pyrrole (C4P) monomer was synthesized for the preparation of calix[4]pyrrole-based polyurethanes. The obtained CP-Diester was then reduced to a diol monomer for use in polyurethane synthesis. Polyurethanes are formed through a polyaddition reaction between diisocyanates (e.g., TDI, MDI) and polyols (e.g., ethylene glycol, propylene glycol). The reaction between isocyanate (-NCO) and hydroxyl (-OH) groups results in the formation of urethane bonds (-NH-COO-). The properties of the resulting polymer can be tuned by varying the types and ratios of reactants. The synthesis was carried out in dry THF solvent in the presence of dibutyltin dilaurate (DBTDL) as a catalyst. Viscous reaction solution was then diluted with THF and precipitated into hexane, filtered, and washed with hexane, dried under vacuum. Resulting product was a pale yellow powder like solid.The characterization of P-CP was performed using NMR and FTIR techniques. In this study, the diisocyanates IPDI, MDI and TDI were used.

Findings

The findings section should be written in Times New Roman font, justified-alignment and in 10-point size. One of the methods used to demonstrate the formation of suprapolymers is NMR spectroscopy. NMR is used to determine molecular structure and functional groups. The reaction between calix[4]pyrrole-diol and various diisocyanates (IPDI, MDI) occurs between isocyanate groups (-NCO) and hydroxyl groups (-OH), forming urethane bonds (-NH-COO-). This technique is used to identify the –NH and –CH2– groups in the polyurethane structure.
The most significant indication of polymerization is the disappearance of isocyanate group peaks and the appearance of urethane bond peaks in the NMR spectrum. In addition FTIR spectroscopy is used to confirm the presence of functional groups. To analyze polyurethane formation, the presence of characteristic functional groups specific to the polyurethane structure and the disappearance of other groups during the reaction process is examined.
Post-Reaction (Polyurethane Formation):
^{1}H-NMR detects the protonic groups (–H) of the polymer. Below are the key peaks indicating the progress of the polyurethane synthesis based on calix[4]pyrrole-diol and various diisocyanates: Urea (NH) groups:The urea bonds formed in the polyurethane structure generally produce a broad and sharp peak around 4.0–7.0 ppm. This indicates that the

isocyanate has reacted with the diol to form urea bonds. Recently formed –NH–CH2– groups:The protons of these groups appear in the range of 3.0–4.0 ppm. Aliphatic bonds –CH2–CH2–: Due to polymerization with isocyanate, the protons of aliphatic methylene (–CH2–) groups between urea bonds may appear in the region of 2.5–3.5 ppm. The isocyanate group (–NCO) shows a peak in the FTIR spectrum around 2270-2250 cm-¹. This peak will disappear when polymerization is complete. The NH groups will form a broad band in the range of 3300-
3500 cm-¹ upon polyurethane bond formation. The urethane carbonyl groups (–NH–C=O) will produce a peak between 1640–1730 cm-¹ confirming the formation of the polyurethane structure. Additionally, characteristic peaks of aromatic rings and alcoholic hydrogens should appear in the FTIR spectrum. FTIR used to determine whether the isocyanate is present in the reactant and whether polyurethane bonds have formed.

Conclusion

The conclusion section should be written in Times New Roman font, justified-alignment and in 10-point size. In this study, polyurethane polymers incorporating calix[4]pyrrole (C4P) units in the main chain or as pendant groups were successfully synthesized using diisocyanates (IPDI, MDI). The reaction between hydroxyl (-OH) and isocyanate (-NCO) groups resulted in the formation of urethane bonds (-NH-COO-), as confirmed by structural characterization techniques. Characterization via ¹H-NMR spectroscopy provided key evidence for polymer formation by identifying shifts in chemical shifts corresponding to –NH, –CH_2, and aromatic protons. The disappearance of the isocyanate (-NCO) peak and the emergence of urethane (-NH-COO-) and urea (-NH) bond signals confirmed successful polymerization. Complementary FTIR spectroscopy further validated the reaction progress, demonstrating the loss of the isocyanate functional group at 2270-2250 cm-¹ and the appearance of characteristic peaks for polyurethane structures, including broad NH stretching bands at 3300-3500 cm-¹ and carbonyl (C=O) peaks at 1640-1730 cm-¹. The polymer properties were influenced by the choice of diisocyanate and polyol, allowing tunability in terms of viscosity, cross-linking density, and mechanical behavior.Further studies will explore the potential applications of these polymers in supramolecular gel networks, self-cross-linking polymer systems, and organic dye waste extraction.
Overall, this research provides a foundational approach to designing calix[4]pyrrole-based polyurethane materials with tunable properties for specific applications. Future studies aim to focus on optimizing polymer properties by varying monomer ratios, assessing mechanical stability, and exploring real-world applications such as micropollutant adsorption.The synthesized supramolecular polyurethane materials will be evaluated to the broader field of functional supramolecular polymers and their role in environmental benefits in the removal of micropollutants and organic dyes.

Dual Radical and Singlet Oxygen Pathways in Polybutadiene Photovulcanization: A Novel Approach Using Phenylacylbromide under UV-A Irradiation for Advanced Crosslinked Films

Ragib Talha Uzun[a], Baris Kiskan[a]

Keywords: Oxidation, Phenylacyl Bromide, Photo-crosslinking, Polybutadiene.

Aim

Polybutadiene (pBD) is extensively utilized in various industrial sectors due to its excellent elasticity, abrasion resistance, and durability, making it indispensable for automotive tires, conveyor belts, footwear, and other industrial products [1]. Traditional methods for crosslinking polybutadiene, such as thermal vulcanization, rely heavily on energy-intensive conditions, including elevated temperatures, prolonged reaction times, and high-pressure setups, resulting in increased operational costs and environmental impacts [2]. Consequently, there is a growing need for alternative methods that provide more sustainable and efficient pathways to achieve similar or enhanced material properties.

Photocrosslinking has emerged as a promising solution, offering milder reaction conditions, reduced energy consumption, shorter processing times, and better environmental compatibility [3]. Nevertheless, conventional photoinitiators predominantly facilitate either radical-induced crosslinking or oxidation-based reactions separately, limiting the overall effectiveness and versatility of these methods. Thus, the development of multifunctional photoinitiators capable of simultaneously triggering both radical and oxidative mechanisms represents an important advancement in photocrosslinking technology.

Polybutadiene contains highly reactive pendant 1,2-vinyl groups and sensitive allylic positions in its 1,4 segments, making it particularly susceptible to radical-induced and oxidation-mediated crosslinking reactions [4–6]. This study builds upon previous research by investigating an improved photocrosslinking strategy utilizing phenylacylbromide (phABr) as a novel photoinitiator under UV-A irradiation. PhABr uniquely combines direct radical generation via homolytic cleavage and indirect generation of singlet oxygen through its photodegradation product, acetophenone [7]. Our research aims to explore the dual-mechanism functionality of phABr comprehensively, evaluating its potential to produce advanced polybutadiene films with superior mechanical, thermal, and surface characteristics suitable for demanding industrial applications.

Material and Method

Polybutadiene (pBD M_n = 5000, %80 cis-trans %20 vinyl, Sigma-Aldrich),2-bromoacetophenone (phenacyl bromide) (phABr, Sigma-Aldrich, 98%), acetophenone (Sigma-Aldrich, >98%), chloroform ($CHCl_3$, Sigma-Aldrich, 99.8%) deuterated chloroform ($CDCl_3$, Sigma-Aldrich, 99.8% atom % D, contains 0.03% (v/v) TMS), potassium bromide (KBr, Sigma-Aldrich, >99%), were all used as received.

Polybutadiene and phABr mixtures (1 g pBD, 25–100 mg phABr) were dissolved in chloroform under dark conditions to prevent premature initiation. Films were formed by solvent casting onto a Petri dish and dried initially in air for 45 minutes, followed by vacuum drying at 40 °C to eliminate residual solvents. UV-A irradiation was performed using Philips TL-36W BLB lamps emitting at 365 nm with an intensity of approximately 100 $mW \cdot cm^{-2}$, and reaction progress was monitored at predetermined intervals (0, 15 min, 30 min, 1 hr, and 2 hrs). Real-time spectroscopic monitoring was conducted via ^{1}H and ^{13}C NMR spectroscopy (Agilent VNMRS 500 MHz, in $CDCl_3$ at 25 °C) and FTIR spectroscopy using KBr pellet and ATR techniques. Film properties will be extensively characterized, including thermogravimetric analysis (TGA), differential scanning calorimetry (DSC) rheological testing, mechanical testing (strain-stress analysis), morphological assessment (scanning electron microscopy, SEM), and wettability evaluation via contact angle measurements with water and olefins.

Findings

Real-time ^{1}H NMR spectroscopy provided detailed insights into the reaction mechanism of polybutadiene (pBD) photocrosslinking under UV-A irradiation with phenylacylbromide (phABr). As can be seen at Figure 1. initial spectra (t=0) revealed only characteristic peaks of $CDCl_3$, 80% cis-trans pBD, and phABr. Upon 15 minutes of irradiation, new signals emerged at 2.63, 7.47, 7.58, and 7.98 ppm, indicative of acetophenone formation. This formation was further confirmed by comparison with reference spectra, showing slight downfield shifts attributed to increased polarity in the reaction medium. Over the reaction period, the gradual disappearance of the methylene peak at 4.48 ppm (phABr) and concurrent rise of the acetophenone-related methylene peak at 2.63 ppm clearly demonstrated phABr consumption and acetophenone production.

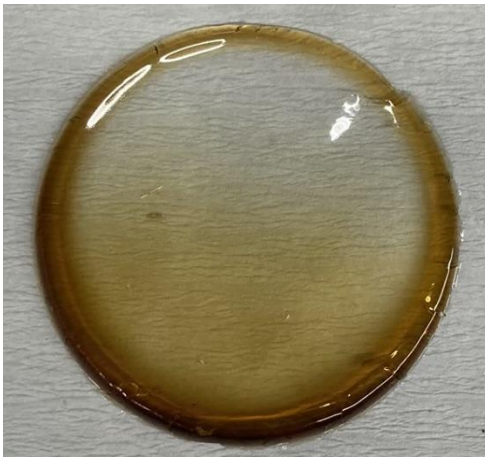

Image 1. Crosslinked film within 2 hours of irradiation.

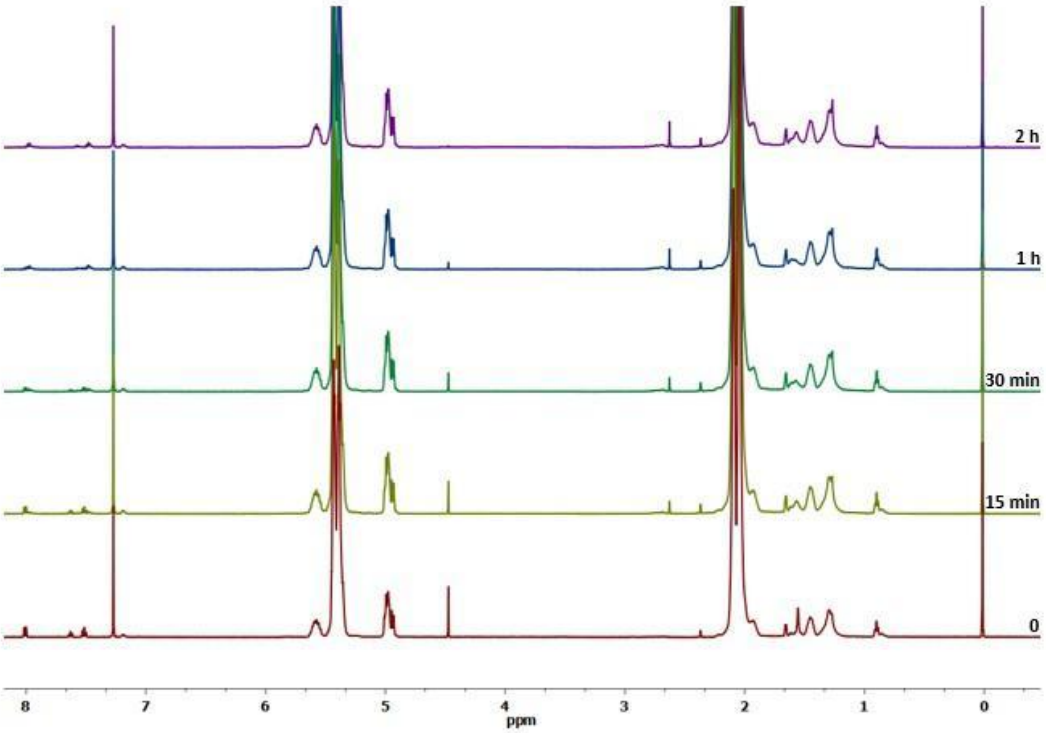

Figure 1. Real-time ^{1}H-NMR investigation of photovulcanization of pBD irradiation with phABr in d-Chloroform.

Analysis of characteristic hydrogen peaks from the 1,2-vinyl double bonds showed a decrease in the non-terminal double bond signal at 5.58 ppm, while an unexplained increase was noted at the terminal double bond at 4.98 ppm, highlighting the crucial role of the 1,2-vinyl units in crosslinking. Additionally, systematic monitoring of cis-to-trans isomerization via ^{1}H NMR exhibited a distinct reduction in cis-alkene signals at 5.39 ppm and an increase in trans-alkene signals at 5.43 ppm. This phenomenon, systematically observed here for the first time by NMR spectroscopy, emphasizes the reactivity of cis units in the photocrosslinking process.

Complementary ^{13}C NMR studies (see Figure 2.) corroborated the ^{1}H NMR findings, with the methylene peak of phABr at 30.83 ppm gradually decreasing and new signals at 26.6 ppm and 133.07 ppm confirming acetophenone formation. The spectral data further showed significant intensity changes, particularly a notable decrease in cis-1,4 methylene groups at 27.39 ppm and a slight increase in trans-1,4 groups at 32.71 ppm. Olefinic carbon signals associated with the 1,2-vinyl unit (114.31 ppm and 142.69 ppm) both exhibited reduced intensity, underscoring their active role in network formation. Additionally, the cis-olefinic carbon peak at 128.42 ppm diminished considerably, while the trans-olefinic peak at 130.13 ppm slightly increased, further validating the cis-to-trans isomerization mechanism.

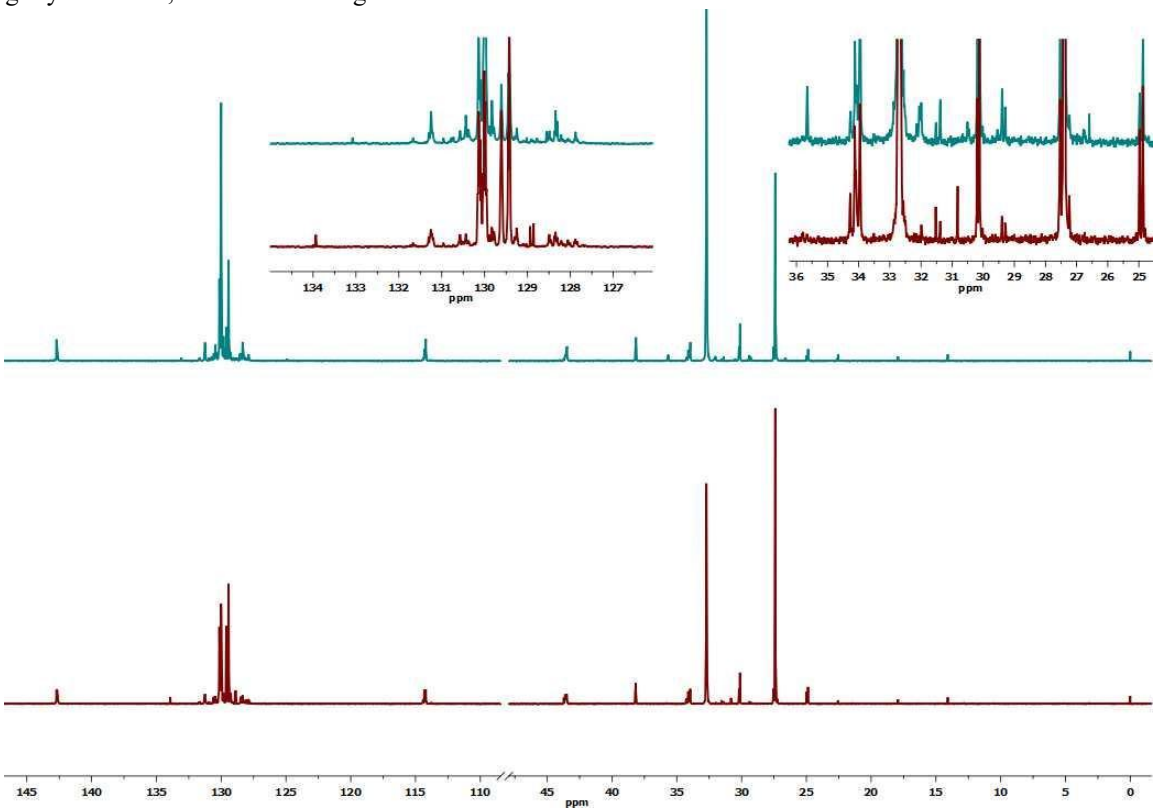

Figure 2. ^{13}C NMR investigation of photovulcanization of pBD irradiation with phABr in d-Chloroform; while the lower spectrum represents the sample at 0 h (before irradiation),the upper spectrum corresponds to the sample after 2 h of irradiation.

FTIR spectroscopy, utilizing KBr pellet method, provided complementary evidence supporting NMR results and offered additional mechanistic clarity. Gradual disappearance of phABr-specific bands (C–Br at 551 cm^{-1} and aromatic C–H bending at 729, 709, and 694 cm^{-1}) indicated its full photolysis within 2 hours. Concurrently, the emergence of a new carbonyl stretching band at 1720 cm^{-1} reflected the formation of saturated ketone oxidation products. Moreover, an increase in the broad O–H stretching band (3200–3600 cm^{-1}), coupled with intensified C–O stretching at 1075 cm^{-1}, confirmed the formation of oxidative functionalities, highlighting the involvement of radical and singlet oxygen pathways.

To conclude, the combined ^{1}H, ^{13}C NMR, and FTIR analyses distinctly characterized the complex dual-mechanism photocrosslinking process involving radical initiation and singlet oxygen-mediated oxidation. The detailed spectral changes demonstrated active participation and structural evolution of polybutadiene, confirming the efficiency of the novel phABr photoinitiator system in achieving robust crosslinked networks suitable for advanced material applications. Comprehensive mechanical and thermal analyses will be conducted in subsequent studies to further evaluate the performance and practical applicability of these crosslinked materials.

Conclusion

This study successfully demonstrated the dual radical and singlet oxygen-mediated photocrosslinking of polybutadiene using phABr under UV-A irradiation, highlighting phABr's exceptional multifunctional characteristics as a novel photoinitiator.. Real-time spectroscopic analyses confirmed the distinct roles of radical and singlet oxygen pathways, enhancing our understanding of photocrosslinking mechanisms. This dual-mechanism approach provides a versatile and efficient alternative to traditional thermal vulcanization methods, opening pathways for advanced elastomeric applications.

COMMUNICATION SYSTEMS

Antennas

Design and Inter-Element Spacing Optimization of GNSS Array

Muhammed Yusuf Şahin[a], Mesut Kartal[a]

[a] Istanbul Technical University, Faculty of Electrical and Electronics Engineering, Department of Telecommunication Engineering, Turkey
sahiny15@itu.edu.tr

Keywords: GNSS, Patch Antenna, Antenna Array, Circular Polarization, Mutual Coupling.

Aim

In this study, a compact GNSS antenna array operating in the GPS L1 frequency band (1575.42 MHz) is designed and optimized for applications requiring small form factor and robust signal performance. GNSS signals are inherently weak, so antennas must provide sufficient gain and have right-hand circular polarization (RHCP) with a good axial ratio. Furthermore, there is an increasing need to install these GNSS antennas on compact platforms such as unmanned aerial vehicles (UAVs), autonomous ground vehicles, and other small devices. To meet the demands for size, gain, and bandwidth, antenna designs must aim to reach the theoretical limits of miniaturization. Mutual coupling is one of the challenges that compact GNSS antennas must overcome after design. Although it is ideal for the distance between antenna elements to be less than half of the wavelength, this can lead to mutual coupling and its effects. These effects include reduced antenna array performance, distorted antenna patterns, the loss of signal-to-interference-plus-noise ratio (SINR), and steering vector non-compliance. Mutual coupling also negatively affects the jammer suppression ratio and degrades beam-nulling performance and null depth, especially in compact GNSS arrays used for CRPA applications. This study aims to design a compact GNSS antenna with high bandwidth, high gain, and low mutual coupling. The goal is to achieve high performance while ensuring suitability for GNSS applications, particularly in size-constrained environments.

Material and Method

The antenna structure employs a single-layer patch element fabricated on a high-dielectric Rogers TMM10 substrate (εr = 9.8, $\tan\delta$ = 0.002), which allows for significant miniaturization without sacrificing bandwidth or gain. The RHCP behavior is realized through corner truncations on the patch and further enhanced by an extra upper-left corner cut to improve impedance bandwidth. Four rectangular slots are added along the patch edges to improve the axial ratio and extend the circular polarization bandwidth. A substrate thickness of 2.5 mm is selected to support bandwidth needs. CST Microwave Studio is used for simulation and optimization of both the unit element and the antenna array. The optimized unit patch serves as the building block for a 4-element array. The unit elements are spaced at intervals between 50 mm and 70 mm and rotated 90 degrees for sequential rotation-based feeding. Two feeding schemes are considered: independent excitation and simultaneous excitation. The latter accounts for mutual coupling effects and enables more realistic performance analysis through active S-parameters.

Findings

The optimized unit antenna exhibits strong performance at 1575.42 MHz with axial ratio consistently below 3 dB and a realized gain exceeding 4 dBi. When integrated into the 4-element array and excited simultaneously with phase differences, the system demonstrates RHCP gain over 8 dBi. The radiation pattern remains stable, and axial ratio variation within the 3 dB beamwidth is minimized. Mutual coupling is found to significantly degrade array performance when element spacing is less than 60 mm. Optimal spacing is identified near 65 mm, balancing compactness and electromagnetic performance. Simulations of active reflection coefficients (S11) show close agreement between the array-fed and standalone element behaviors. The 90° phase-shifted excitation improves axial ratio distribution across the beam coverage. These findings confirm that compact GNSS arrays can maintain beam integrity and polarization quality when element spacing and excitation strategy are carefully optimized.

Table 1. Single Element Antenna Parameters.

Notation	Defination	Value
s_w	Substrate Width	40 mm
s_l	Substrate Length	40 mm
p_w	Patch Width	29.68 mm
p_l	Patch Length	29.68 mm
g_w	Ground Plane Width	$3 \times p_w$
g_l	Ground Plane Length	$3 \times p_l$
h_s	Substrate Height	2.5 mm
t	Feed Inset	9.78 mm
c_{rhcp}	Truncation Width for Circular Polarization	2.76 mm
c_m	Truncation Width for Matching	1.29 mm
rld	Right and Left Slot Depth	0.74 mm
rlw	Right and Left Slot Width	0.62 mm
tbd	Top and Bottom Slot Depth	0.65 mm
tbw	Top and Bottom Slot Width	1.30 mm
e_r	Relative Permittivity	9.8
tan δ_k	Tangent Loss of Dielectric	0.002

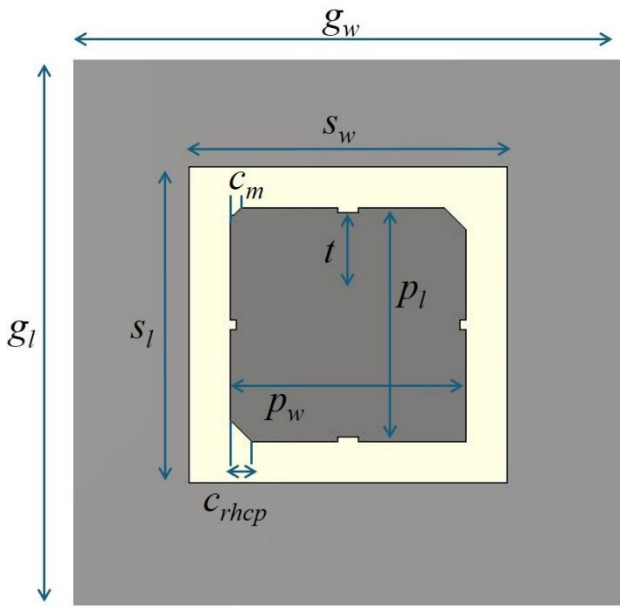

Figure 1. Single-Element Patch Antenna.

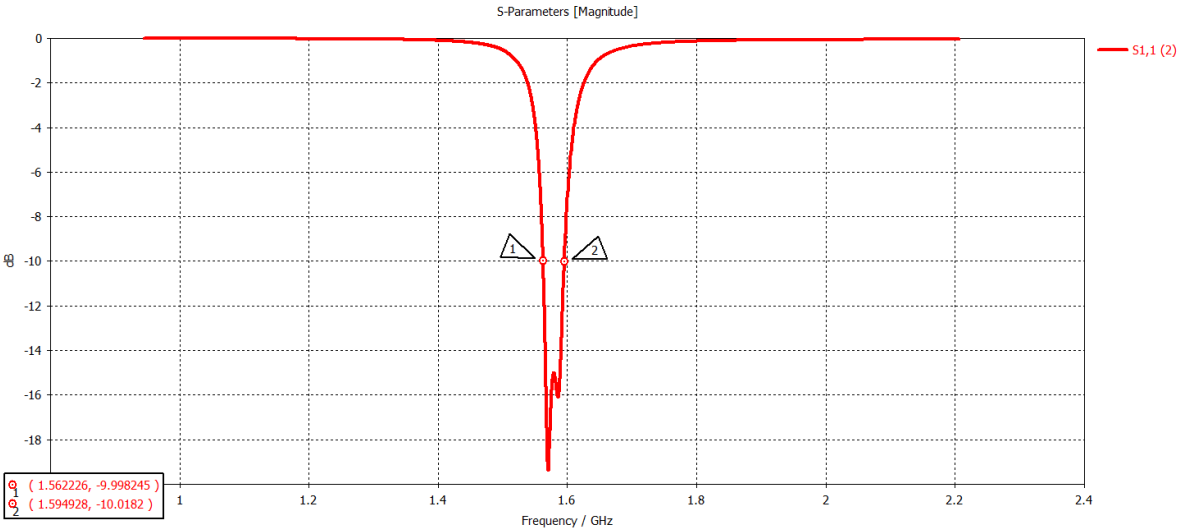

Figure 2. Input reflection coefficient of single element GNSS antenna (S11).

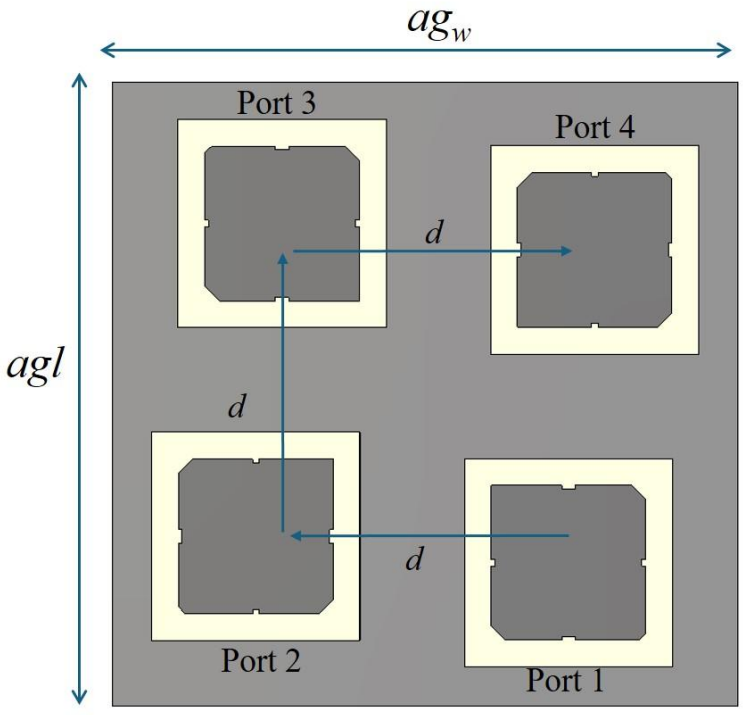

Figure 3. Sequentially Rotated Square Array with Four Elements.

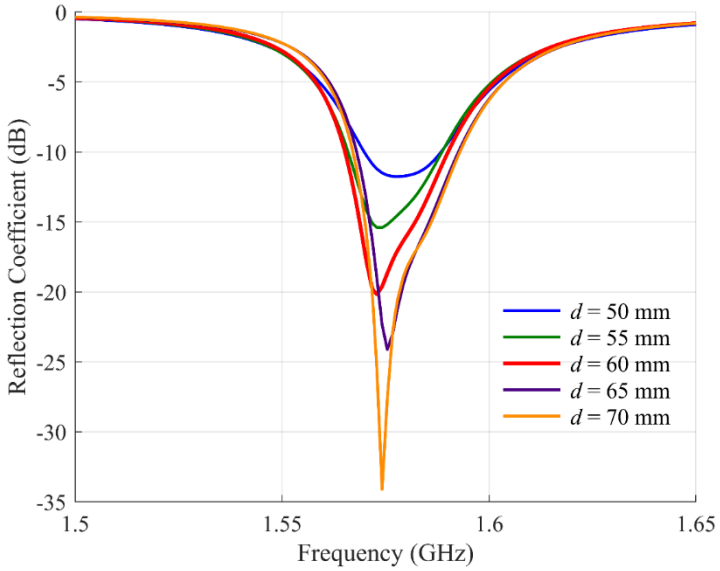

Figure 4. Effect of inter-element spacing on reflection Coefficient (S11) for Distances Between 50 mm and 70 mm in GNSS Array.

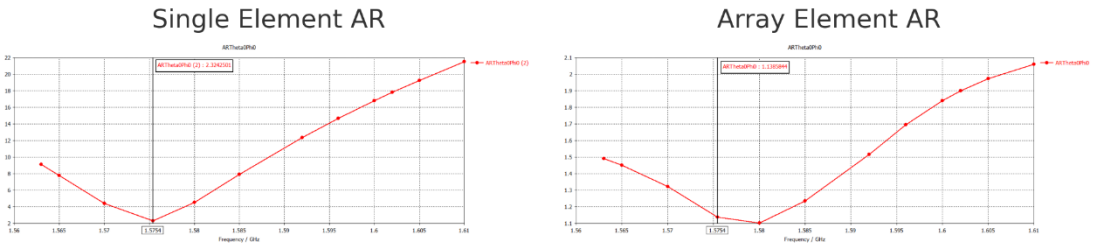

Figure 5. Maximum Axial Ratio of Single Element Antenna vs 4-Element Antenna Array.

Conclusion

A high-performance, compact GNSS antenna array operating at the GPS L1 frequency band is developed, featuring high gain, wide bandwidth, and strong RHCP performance. The combination of high-dielectric substrate selection, patch geometry optimization, and controlled inter-element spacing leads to a compact design suitable for integration into UAVs and other small-scale GNSS platforms. Mutual coupling effects are mitigated through optimized spacing and excitation schemes, resulting in a reliable antenna array capable of maintaining stable radiation patterns and polarization integrity under constrained deployment conditions.

Keywords: Breast Cancer, *CHK2*, DNA Repair, DNA Mutations, Molecular Dynamics Simulations.

Aim

Checkpoint kinase 2 (CHEK2) is an emerging tumor suppressor gene that plays a critical role in maintaining genomic stability and preventing DNA damage. It encodes the CHK2 protein, a serine/threonine kinase involved in DNA repair pathways and cell cycle regulation. CHK2's importance is underscored by its participation in the cellular response to DNA damage as a central mediator in the DNA damage checkpoint pathway. Mutations in CHK2 have been linked to several cancers, including breast, colon, kidney, prostate, and thyroid, making it a promising target for cancer therapy.

Human CHK2 is a single-chain protein of approximately 65 kDa, composed of 543 amino acids. It contains three principal functional domains: The serine-glutamine (SQ) and threonine-glutamine (TQ) cluster domain (SCD), the forkhead-associated (FHA) domain, and the serine/threonine kinase domain (KD*)* (Cai et al., 2009;).The SCD domain is located at the N-terminus of CHK2, and its SQ and TQ motifs are phosphorylated by phosphoinositide 3-kinase–related kinases (PIKKs), such as ATM and ATR (Buscemi et al., 2006;). The FHA domain mediates interactions with phosphorylated proteins, including the phosphorylated SCD of another CHK2 molecule, and demonstrates high specificity for phosphorylated threonine(Almawi et al., 2017; Zannini et al., 2014). At the C-terminal of the protein there is a kinase domain (KD) between residues 213-501. The kinase domain (KD), located at the C-terminus (residues 213–501), adopts a typical Ser/Thr kinase fold consisting of an N-terminal lobe (residues 213–305), which is rich in β-sheets, and a larger, mostly α-helical, C-terminal lobe (residues 306–501). The ATP-binding site lies in the cleft between these two lobes (C lobe; residues 306-501) mostly α-helical (Cai et al., 2009).

Under normal conditions, CHK2 exists as an inactive monomer in the nucleus. Upon DNA double-strand breaks, CHK2 is phosphorylated by ATM, causing significant structural rearrangements that include homodimerization and A-loop phosphorylation upon ATP binding. These events lead to further conformational changes and subsequent dissociation of the CHK2 homodimer into fully active monomers, enabling CHK2 to carry out its DNA repair and cell cycle checkpoint functions effectively.

Molecular dynamics (MD) methods are widely used computational tools for investigating the structural and dynamic properties of proteins at atomic-level spatial and femtosecond-level temporal resolutions. MD simulations model the spatiotemporal behavior of all atoms within a molecular system—including proteins, surrounding water molecules, ions, and ligands—by utilizing physics-based force fields. These simulations provide detailed, real-time molecular insights that are often challenging to obtain through experimental methods alone. In this study, all-atom MD simulations were conducted to examine five point mutations located in the C-lobe of the kinase domain (KD) of CHK2: D438Y, R474H, R318C, R318H, and T476M (Akcay et al., 2021; Baloch et al., 2014; Kleiblová et al., 2019; Momozawa et al., 2018; Xie et al., 2018). The primary aim of these simulations and hence our study was to investigate how these specific mutations affect the structural stability and dynamic behavior of the CHK2 kinase domain, thus enhancing our understanding of their potential roles in tumorigenesis and cancer progression.

Material and Method

To generate the active wild-type (WT) CHK2 structure, an initial structural model for MD simulations was created by integrating structural information obtained from the crystal structures with PDB identifiers 3I6U (Cai et al., 2009) and 2CN5 (Oliver et al., 2006). Specific residues (S379, T383, T387, and T389) within the activation loop of CHK2 were phosphorylated. Moreover, an ADP molecule, two Mg^{2+} ions, and crystallographic water molecules extracted from the 2CN5 structure were incorporated into the model. Structures carrying mutations (D438Y, R474H, R318C, R318H, and T476M) were generated using the Mutator plugin in VMD (Humphrey et al., 1996). All structures were solvated in a TIP3P water box with padding dimensions of 28 Å (x-axis), 20 Å (y-axis), and 28 Å (z-axis). Systems were neutralized, and ionic concentrations were set to 210 mM KCl and 20 mM NaCl. All systems were prepared by using VMD.

All simulations were carried out in NAMD 3.0 (Phillips et al., 2020), and CHARMM36 all-atom additive protein force field (Best et al., 2012). A 12 Å cutoff was applied for van der Waals interactions, and a 2 fs time step was used. Long-range electrostatic interactions were calculated using the particle-mesh Ewald (PME) method. The simulations were run under NPT conditions at 310 K and 1 atm. Temperature was maintained using Langevin dynamics with a damping coefficient of 1 ps^{-1}, and pressure was controlled via the Langevin Nosé-Hoover method with an oscillation period of 100 fs and a damping time scale of 50 fs.

To assess structural stability and flexibility differences between mutant and WT CHK2 proteins, Root Mean Square Deviation (RMSD) (Phillips et al., 2020) and Root Mean Square Fluctuation (RMSF) (Karplus & McCammon, 2002) analyses were performed. RMSD measures the average structural deviation of atoms from a reference structure over the simulation trajectory, quantifying overall conformational stability. RMSD is calculated using the formula:

$$RMSD(t) = \sqrt{\frac{1}{N}\sum_{i=1}^{N} \left(r_i(t) - r_i(0)\right)^2}$$

Equation 1: RMSD equation

where N represents the total number of atoms considered, $\mathbf{r}_i(t)$ denotes the position of atom i at time t, and $\mathbf{r}_i(\text{ref})$ is the position of atom i in the reference structure. Higher RMSD values indicate greater structural deviations from the initial conformation.

RMSF measures the local flexibility and dynamic behavior of individual atoms or residues over the course of the simulation. RMSF is defined as:

$$RMSF = \sqrt{\frac{1}{T}\sum_{t=1}^{T} \left\|r_i(t) - \langle r_i \rangle\right\|^2}$$

Equation 2: RMSF equation

where T represents the total number of trajectory frames analyzed, $\mathbf{r}_i(t)$ is the position of atom i at time t, and $\langle \mathbf{r}_i \rangle$ is the average position of atom i over the entire simulation period. Higher RMSF values reflect increased flexibility or movement, while lower values indicate structural rigidity.

Both RMSD and RMSF calculations enabled comparison of mutant and WT CHK2 proteins, providing valuable insights into how the studied mutations may influence the structure, stability, and dynamic properties of the CHK2 kinase domain. For the RMSD and RMSF analyses, only the coordinates of C_α atoms were considered. The reference structure is the initial build CHK2 protein structure that was build as a combination of crystal structures having PDB IDs 3I6U and 2CN5.

Findings

Two independent sets of MD simulations, each lasting 300 ns, were performed for every mutant. RMSD and RMSF analyses were conducted separately for each MD trajectory. From RMSD analyses (Figure 1), the D438Y, T476M, and R474H mutants showed higher RMSD values compared to the WT CHK2 protein, suggesting structural deviations compared to WT.

RMSD

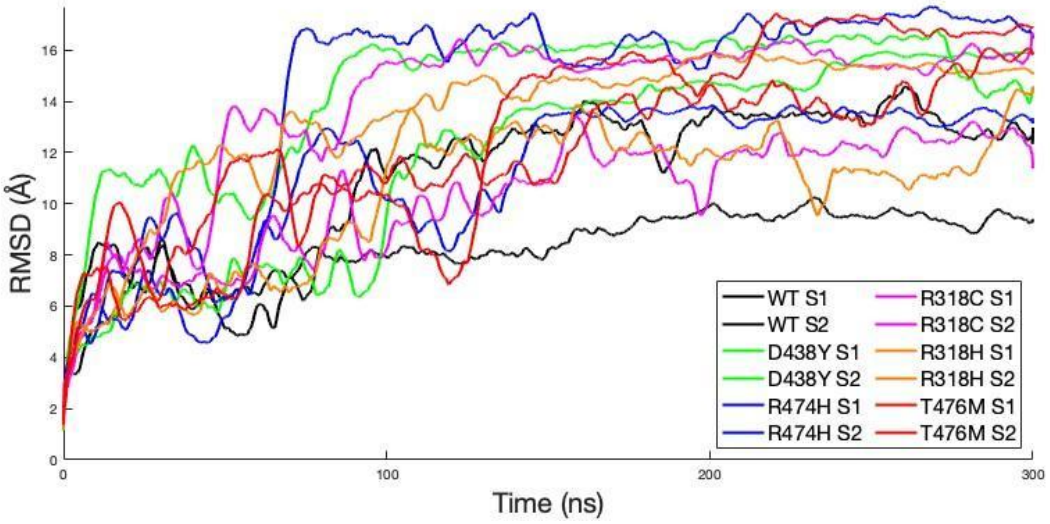

Figure 1. RMSD calculations of mutant and wild type proteins.

Figure 2 shows the RMSF analysis of WT and mutant CHK2 proteins. The R318H mutant exhibited reduced RMSF values between residues 96 and 160. Similarly, in the residue range 208–266, the R318H and T476M mutants demonstrated lower RMSF values compared to WT. Within the residue range 257–264, the R318C mutant showed increased RMSF, whereas the other mutants (R474H, D438Y, R318H, and T476M) exhibited decreased RMSF values. Additionally, in the residue range 371–391, all mutants displayed higher RMSF values relative to the WT. Overall, the R318H mutant displayed consistently lower RMSF values throughout the entire protein compared to the other mutants.

RMSF

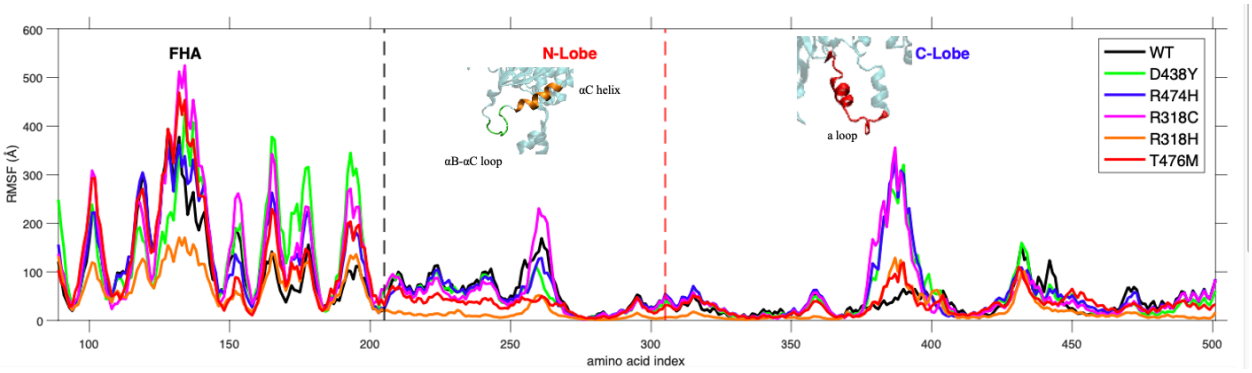

Figure 2. RMSF calculations of wylde type and mutant proteins.

Conclusion

This study utilized all-atom MD simulations to investigate the structural and dynamic consequences of five cancer-associated point mutations (D438Y, R474H, R318C, R318H, and T476M) located in the C-lobe of the CHK2 kinase domain. RMSD analyses indicated that the D438Y, T476M, and R474H mutations induced considerable structural deviations, which may impact protein stability and function. Furthermore, distinct alterations in protein dynamics were also observed through RMSF analysis. In particular, the R318H mutant displayed pronounced dynamic changes throughout nearly the entire protein structure. All five mutations altered RMSF profiles compared to WT CHK2, with notable changes concentrated in the residue ranges 257–264 and 371–391. Within the residue range 208–266, the R318H and T476M mutants exhibited greater dynamic alterations than the other studied mutants. Collectively, these simulations highlight how specific mutations in the CHK2 kinase domain's C-lobe can profoundly influence protein structure and dynamics. These findings provide molecular insights into potential mechanisms through which CHK2 variants may contribute to cancer progression, contributing to guiding future experimental validation and informing potential therapeutic strategies.

Keywords: Aeroacoustic, Aerodynamic, Computational Fluid Dynamics, Multi-Objective Optimisation.

Aim

In many turbomachinery applications, such as wind turbines, military and industrial aerospace applications, computer fans, and even cooling fans in electric vehicles (Qin et al., 2020), which cause the highest noise generation, both high aerodynamic performance and low noise level, thus high aeroacoustic performance have become important. Many aerodynamic optimisation studies have been conducted to achieve high C_l (lift coefficient) and high C_l/C_d (aerodynamic efficiency) values (Hicks et al., 1974; Obayashi & Takanashi, 1996). In addition to aerodynamic performance, there have also been studies to improve aeroacoustic performance by predicting flow separation (hence laminar separation bubbles, LSB) or trailing edge induced noise. However, this study was undertaken because it was observed that studies that address both aerodynamic and aeroacoustic concerns have rarely been carried out.

However, with the inherent contradiction between both aerodynamic and aeroacoustic objectives, optimisation studies create a multidimensional design problem. Increasing the lift force results in increased surface flow velocities. However, flow separation in the boundary layer induces turbulence, resulting in stronger noise generation in the far field, whereas noise improvements can be achieved by sacrificing aerodynamic concerns. Although multi-objective optimisation studies have been studied until recently (Lyu & Xie, 2016), the integration of aerodynamic and aeroacoustic optimisations, especially using flexible geometry parameterisations, is still limited.

As mentioned in the review article by Salunke et al (2014), there are many airfoil parameterisations in the literature such as NACA and PARSEC. In this study, Bezier curves are used and the geometry is left free by using only control points. This study aims to make 4 main contributions. The first is to provide airfoil shape manipulation with Bezier curves. The second is the integration of aerodynamic and aeroacoustic outputs. The third is the use of genetic algorithms for multi-objective optimisation in aerodynamic and aeroacoustic optimisation. Fourth and lastly, pareto-optimal solutions between the obtained results and C_l, C_l/C_d and SPL values are found.

Material and Method

In this study, two different independent Bezier curves were used for the suction and pressure surfaces of the airfoil geometry (Figure 1). In both curves, the points PLE and PTE, which define the traling edge and leading edge, are kept constant. On the other hand, as a preliminary assumption, the position of the intermediate points on the chord axis was kept fixed, while their vertical position was left free within the optimisation limits.

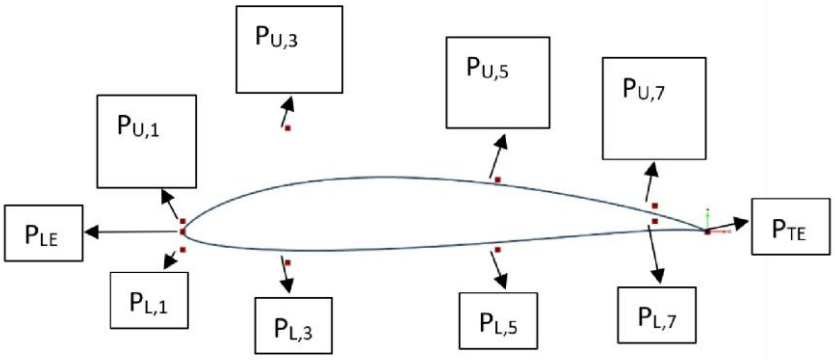

Figure 1. Bezier control points on airfoil, as upper and lower.

In contrast to definitions such as NACA 4-Digit, airfoils defined by Bezier curves can be parameterised more flexibly. In addition, although alternative parametrisation methods are presented in the paper compiled by Salunke et al. (2014), Bezier points are directly included in the optimisation to directly observe the effects of each control point on the optimisation outputs.

In the first stage, Sobol sequences were used to extract the design space. Sobol sequences were first introduced by Ilya Sobol in 1976, and the use of Sobol sequences in the computational environment of high-order applications and optimisation methods was introduced by Bratley and Fox (1988). They showed that by creating low-dispersion and homogeneously distributed solution points with Sobol sequences, the solution space can be created in a large and balanced way without increasing the sampling density. NSGA-II, used in the second and third stages of this study, is a genetic algorithm commonly used in multi-objective optimisation applications (Coello Coello et al., 2007). In addition to preserving optimisation and diversity, it allows to create a new Pareto front in each generation thanks to the mutation parameter while transferring good designs between generations thanks to the 'crowding distance' mechanism (Deb et al., 2002). In the third stage, the final optimisation process was completed by defining constraints on C_l, C_l / Cd and SPL values. With this structure, the solution quality focused on increasingly narrower regions in the design space was improved and the interaction between global exploration and locale improvements was analysed. Unlike single-objective optimisation, multi-objective optimisation searches for a Pareto optimal set of parameters. Genetic algorithms such as NSGA-II are convenient tools for multi-objective optimisation problems such as aerodynamics and aeroacoustics, as they can provide a population of solutions, as opposed to the single solution point search of traditional optimisation algorithms (Obayashi et al., 1997).

Aerodynamic analyses were carried out with XFOIL, an open source panel method commonly used for performance measurement of low and medium Reynolds number wing airfoils. (Drela, 1989). Acoustic analyses were performed using NAFNoise (NREL AirFoil Noise), an open source software that is adept at acoustic measurements by analysing boundary layer and far field properties. Since NAFNoise is a code written with data obtained from experimental studies, it is particularly successful in analysing turbulent boundary layer trailing-edge noise and separated flow noise. In this study, the acoustic signal was measured from a single point and the microphone was placed at theta = 90° and r = 8 chords away on the trailing edge of the airfoil.

Finally, all this work was carried out on a commercial optimisation tool called CAESES. CAESES contains three main parts: Parametric design, software connection and optimisation. It was used in this study as it automates the updating of geometry variables, running the software, setting up the optimisation loop to minimise manual effort while trying to achieve the main objectives of the study.

Findings

At the end of the three-stage optimisation process, significant results on the behavioural effects between the aerodynamic and aeroacoustic outputs were obtained. Design space sampling using the Sobol array yielded 300 airfoil designs, with a wide range of geometric characteristics, angle of attack and performance metrics. C_l values ranged between 0.4 and 1.6,

while the C_l/C_d ratio was between 40 and 150. SPL values were mostly above 130 dB, but a wide range of results was obtained. On the other hand, when the interaction between the control points defining the airfoil and the performances is analysed, the performance metrics showed higher sensitivity to the points on the suction side (airfoil hump, thickness and thus flow separation), although the correlations of the points controlling the pressure side of the airfoil were low. In particular, increasing U_{y3} led to positive effects on both C_l and C_l/C_d output , while increasing U_{y5} and U_{y7} led to a negative effect on SPL output (Figure 2). However, it was observed that the performances were sensitive to these parameters, whether positive or negative.

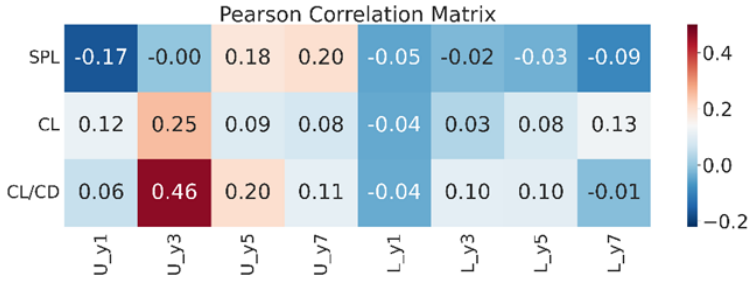

Figure 2. Pearson correlation matrix of SPL, C_l and C_l/C_d targets with upper and lower surface geometric control points (U_{y1} – L_{y7}). Positive correlations are shown in red, negative correlations in blue. Each cell contains the correlation coefficient between the corresponding control point and the target metric.

The second phase of the study analysed the effects between the performance metrics and the pareto surfaces of 1200 design points obtained with NSGA-II without constraints. While analysing the correlations of the performance metrics in this scan, significant clustering was observed. At different ranges of the angle of attack (AoA), the behaviour of the SPL varied in response to both the angle of attack and metrics such as C_l and C_l/C_d.

The SPL values, which have a non-monotonic behaviour (Figure 3), show high values (>60 dB) at relatively low AoA (0° – 6°), while at relatively high AoA (9° – 12°) they show a downward trend at intermediate levels (<60 dB). This can be explained by the appearance of the Laminar Separation Bubble (LSB) effect as the angle of attack increases. The unstable structure caused by LSB in the wake region can cause stronger noise at low angles of attack. As the angle of attack increases, the turbulent flow in the wake can transform this tonal noise into a more balanced noise with broadband character. This behaviour demonstrates the consistency of SPL values that a separation-oriented acoustic solver such as NAFNoise can analyse.

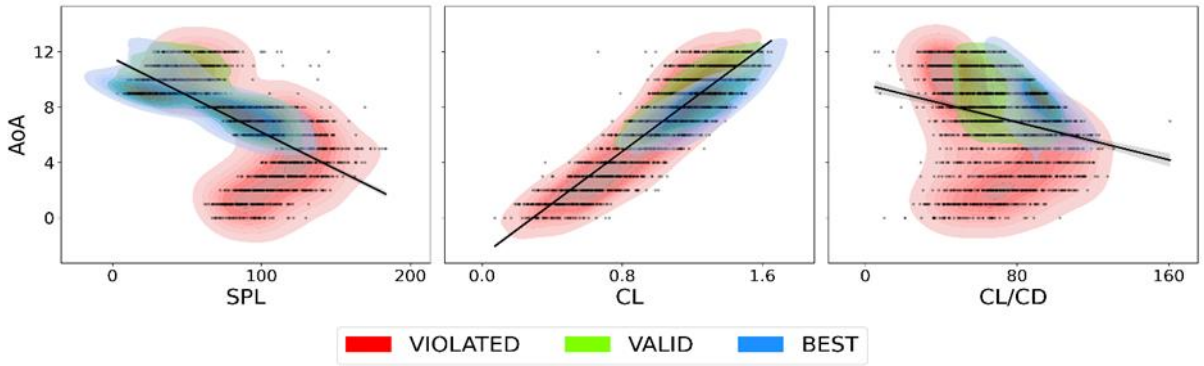

Figure 3. Scatter plots showing the relationships between angle of attack (AoA) and SPL, C_l, and C_l / C_d targets. Dots are shown in black, with KDE (density) clusters for each class colored: red (VIOLATED), green (VALID), blue (BEST). Black lines represent regressio.

In the third stage, some constraints were applied. C_l value min 1.0, C_l/C_d value min 80 and SPL value max 120 dB were started to search for more feasible results. The 120 dB limit for SPL is recommended as an acceptable upper limit for the design of small-scale UAVs. Thanks to the NSGA-II algorithm, non-constraint inputs are penalised and constrained inputs are passed on to the next generation. The designs marked in red are the penalised ones, the green ones are the ones close to the constrain values, and the ones marked in blue are the best design points (Figure 4).

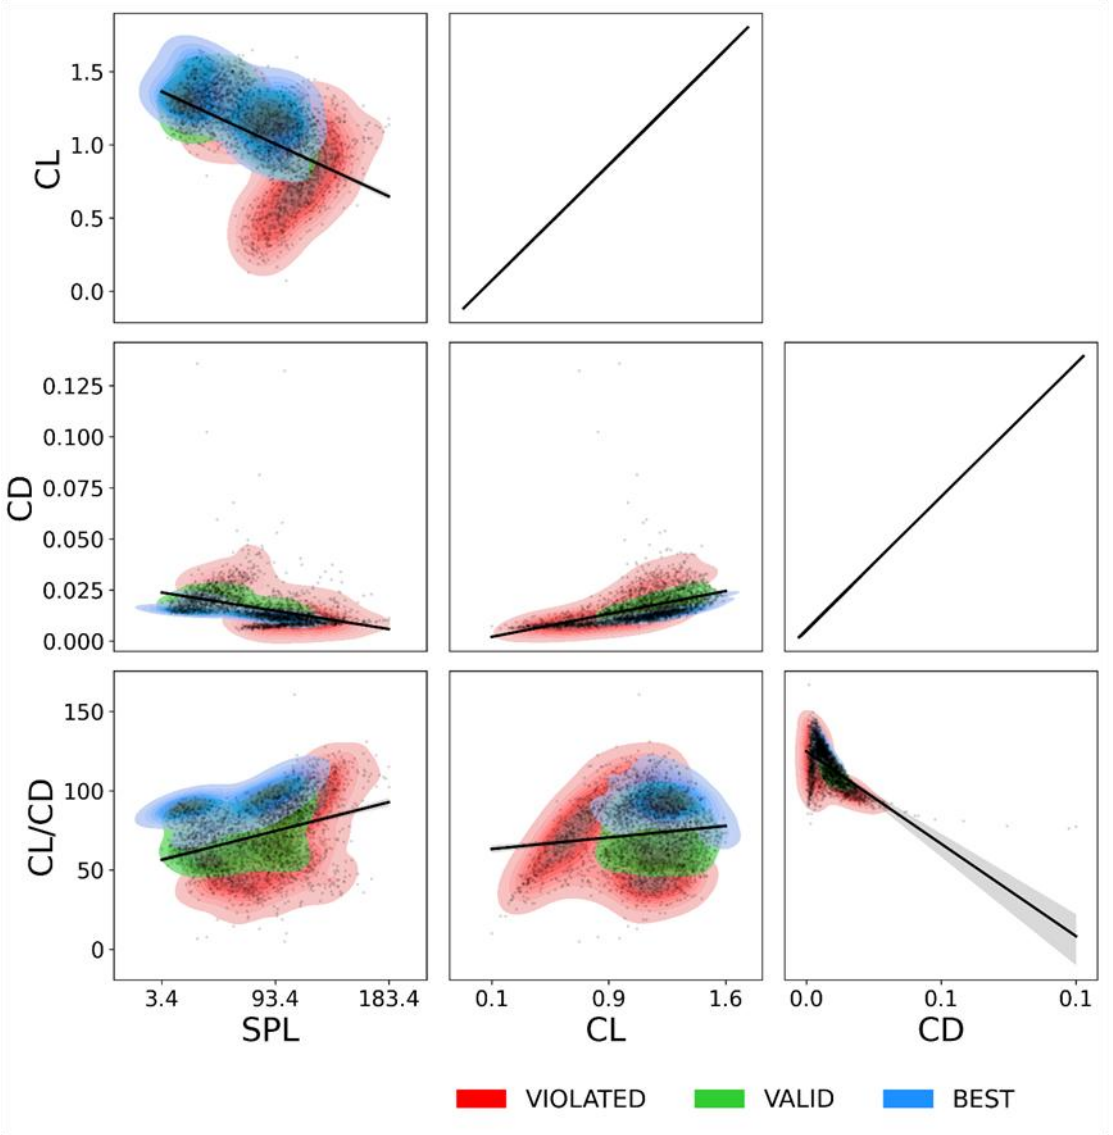

Figure 4. Scatter and intensity plots showing the pairwise relationships between SPL, C_l, C_d, and C_l/C_d targets.

Conclusion

In this study, both aerodynamic (C_l, C_d, and C_l/C_d) and aeroacoustic (SPL) performances of airfoils defined by Bezier curves are examined together in the optimisation process and both geometric and fluid parameters (only angle of attack in this study) are presented as input to the optimisation. The results obtained in this study show that only aerodynamic concerns are not sufficient in airfoil designs where acoustic concerns are pursued, and aeroacoustic objectives should also be taken into consideration.

In particular, the fact that the SPL follows different phenomena at different ranges of the angle of attack is a point to be considered in turbomachinery design. It was also observed that the geometrical design of the suction side, in particular, dominates the results. The nature of the fluid and the airfoils can lead to unexpected positive results.
This study also shows that parameterised and automated processes, such as genetic algorithms or local minimum/maximum searches, can lead the researcher to innovative and unexpected points in order to obtain the design space.
For future studies, additional research could be carried out in several different directions. SPL measurements of pre-designed airfoils obtained from aeroacoustic analyses can be made with higher accuracy with LES or RANS (RANS may be sufficient in this study since measurements are made at farfield) turbulence models in a FVM-based CFD solver. Finally, in geometry parameterisation, control points can be increased; instead of Bezier curves, alternative methods such as NURSB or Free Form Deformation (FFD) can be tried.

An Intelligent Jamming Environment: Reinforcement Learning Approach

Ömer Faruk Dikmen[a], Hasari Çelebi[a]

[a] Gebze Technical University, Computer Engineering, Türkiye
o.dikmen2023@gtu.edu.tr

Keywords: Adaptive Jamming, Dynamic Spectrum Access, Intelligent Jammer, Reinforcement Learning.

Aim

In wireless communication systems, which are indispensable in today's life, information is subject to deliberate various types of intentional or unintentional jamming as it is carried on electromagnetic waves along communication channels. Deliberate jamming attemps to reduce signal-to-interference plus noise (SINR) ratio as much as possible so that the information is partially or completely prevented from reaching the receiver [3]. On the other hand, the transmitter side aims to transmit information to the receiver in the safest and fastest way possible. This situation, known as electromagnetic spectrum (EMS) confrontation, makes the signal distortion problem in wireless communications an important area of research and study. Traditional strategies such as fixed frequency, comb type, barrage, and sweeping [1] are insufficient in a dynamic EMS environment, particularly when considering today's 5G and near future 6G communication technologies. Smarter systems are required. The literature predominantly features investigations on anti-jamming techniques [2]. Because wireless communication systems in highly dynamic environment only access the EMS at short intervals, a jammer can capture only a minimal amount of data. The question then becomes: Is it possible to have a real-time model that learns continually by interacting with the environment, without the requirement for labeled data, and so adapts to variations?
In this work, we seek a response to the aforementioned question and focus on the most appropriate strategy for intelligent jammer tuning. For this objective, the Q-Learning methodology, one of the RL methods, is tested in four EMS simulation scenarios and simultaneously contrasted with four conventional jamming techniques.

Material and Method

The simulation environment is presented in Figure 1. Here, the agent is an intelligent model that is always learning and making decisions. To facilitate calculation and analysis, the communication time is separated into equal discrete time periods Each time slot has N channel sets C = {0,1,2,....,N}, with each element being a frequency channel index that the CU and jammer can select. To avoid the jammer, the CU employs a frequency-hopping approach. In each time slot, the transmitter sends data over the next communication channel in a predetermined sequence (Figure 2).

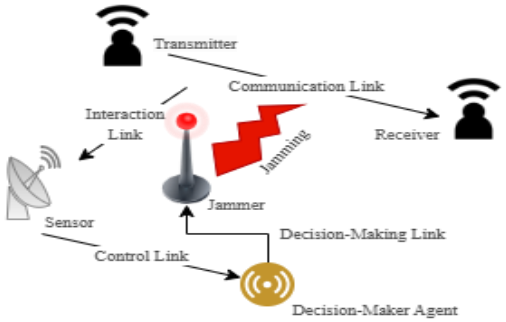

Figure 1. System Model.

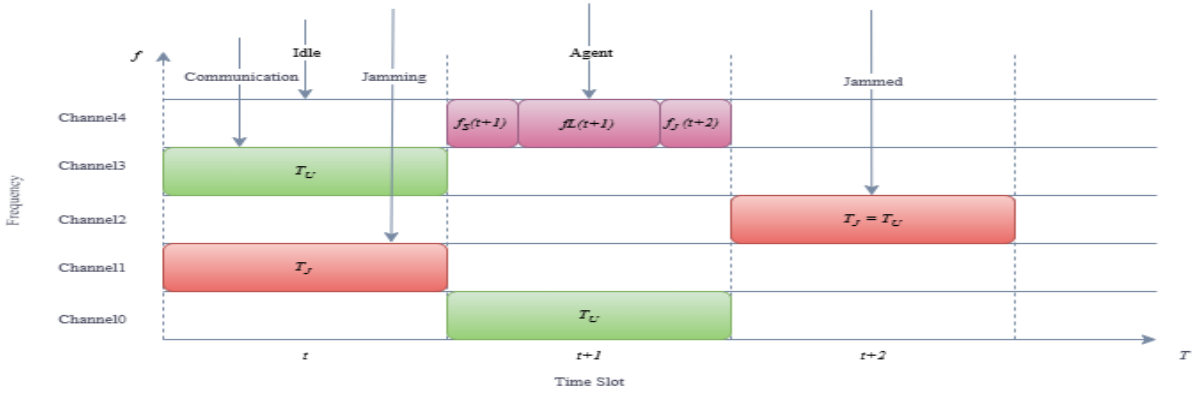

Figure 2. Spectrum model.

Five jamming mechanisms were used in the simulations: comb, sweeping, dynamic, pseudo-random, and RL. Comb jammers provide jamming signals to many communication bands at the same time. Sweeping jammers scan a specific range of communication bands at a set speed; dynamic jammers use both comb and sweeping techniques; pseudo-random jammers determine a target based on randomly generated values in a specific sequence; and RL-driven jammers learn by continuously interacting with the environment in real time without prior knowledge. The simulation assumes that both the transmitter and the jammer send signals across the same communication channel. If the signal emitted by the jammer to the frequency range chosen by the decision-maker agent's communication channel set overlaps with the communication channel of the CU, the SINR ratio is calculated. Since the scenario assumes one jammer and constant noise for each channel, the SINR formula can be simplified as shown in Equation 1. The SINR ratio is compared to a predetermined threshold value to create the indicator function. g_u is the transmitter's channel gain ratio, and p_u is its power value. On the divisor side, n represents channel noise, g_j represents the jammer's channel gain ratio, and p_j represents the jammer's power level.

$$SINR = \frac{g_u p_u}{n + g_J p_J} \tag{1}$$

If the indicator function value exceeds or equals the SINR threshold value, it is set to one; otherwise, it is set to zero (Equation 2). Here, β is the threshold value and $I(t)$ is the indicator function at time t. If the value of $I(t)$ is one, the transmission is successful, otherwise it is unsuccessful.

$$I(t) = \{1, SINR \geq \beta \; 0, SINR < \beta \tag{2}$$

The main goal of jammer is to minimise the value of the target function Λ in total (Equation 3). $\gamma \in (0,1)$ is the discount factor used to reduce the added value of future indicator values.

$$min\ \Lambda\ =\ \sum_{t=0}^{\infty}\quad \gamma^t I(t) \tag{3}$$

The suggested model is designed to learn the CU's frequency hopping technique by constant interaction with the environment, with no prior knowledge. As illustrated in Figure 2, the green signal represented by T_U is transmitted by the CU, while the orange signal represented by T_J is sent by the jammer. The figure clearly shows that T_J equals T_U. The purple colour represents the jammer's agent phase as a training phase, which consists of the sensor's spectrum sensing f_s, the agent's CU communication channel prediction in the previous time slot t compared to the actual communication channel detected, rewarding and punishing the agent, updating the Q-value at time t, and predicting the communication channel on which the jamming signal will be sent in the next time slot. Learning is denoted by f_L, and prediction by f_J.. This method is repeated until the Q-values for each communication channel are finalised. The Q-values for each communication channel are kept in a Q-table. The Q_values are updated using the formula in Equation 4.

The convergence of the Q-values indicates that the jammer has learnt the CU's communication strategy and has exited the learning process. It then determines whether it needs to synchronise its time slot with the CU's time slot.

The symbol A_{t+1} in Equation 4 represents all action options in the state at time $t+1$, which in our case is the CU's communication channel, and this is where Equation 4 takes its maximum. The sensor continuously analyses the surroundings to ensure that the channel of the mixing signal matches the current channel. If a mismatch is discovered in two consecutive time slots, the jammer switches to learning mode and begins learning the new model.

$$Q(s_t,a_t) \leftarrow Q(s_t,a_t)+\alpha[r+\gamma maxQ(s_{t+1},A_{t+1})-Q(s_t,a_t)] \tag{4}$$

Findings

In the experiments, the full frequency bandwidth for both CU and jammer is assumed to be 40MHz and the signal transmission bandwidth is assumed to be 4MHz. Thus, there are ten communication channels $C = \{0,1,2,3,4,5,6,7,8,9\}$ corresponding to a frequency bandwidth (Table 1).

Table 1. Bandwidth frequencies and frequency hopping sequence.

Channel Index	0	1	2	3	4	5	6	7	8	9
Cntre Frequency (MHz.)	2	6	10	14	18	22	26	30	34	38
Current Frequency (MHz)	2	6	10	14	18	22	26	30	34	38
Next Hop (MHz.)	18	10	2	34	38	26	22	14	30	6

Communication link parameters are set to p_u = 30dBm, p_j = 30dBm, n = -100dBm and β = 10dBm. If more than one communication channel is jammed in the same time period, as in the case of Comb-type jamming, the value of p_j is automatically reduced for each channel. The values of g_u and g_j are randomised in the range (0.1, 1.0) for each experiment run.

The comb jammer is intended to jam 6MHz, 14MHz, 22MHz, and 30MHz concurrently. Sweeping jammer speed was set to 0.8 GHz/s. Every 100 milliseconds, the dynamic jammer switches from comb jamming to sweeping jamming. The random jammer jams at random in each time period. The RL-driven jammer, on the other hand, lacks a pre-plan and instead learns the CU pattern through interaction with the environment before developing an adaptive jamming approach. The settings are as follows: ε = 1.0 for epsilon initial value, ε_{decay} = 0.90 for epsilon decay, ε_{min} = 0.01 for minimum epsilon, α = 0.1 for learning rate, and γ = 0.9. The waterfall spectrograms of conventional jammers are shown in Figure 4a.

Experiment 1: The CU frequency hopping sequence was initiated at 18 MHz (Table 2). After 24 iterations, Q values converged, and the RL-driven jammer model learnt the entire sequence (Figure 3). The waterfall spectrogram in Figure 4c shows how the RL focussed jammer behaves. Every 30 iterations, the success rate of each jammer is monitored to determine its performance. The RL jammer's first 30-slice moving average success rate is little less than 0.6 and quickly approaches

1.0. Conventional jammers remain at 0.2 or below (Figure 5a-5b). The RL jammer resulted in 983 successful jammings, compared to 200 or less for the other traditional approaches (Table 2).

Experiment 2: We employed the same frequency hopping mapping as in the prior experiment, but varied the hopping sequence's initial frequency every 20 iterations. The goal here was to see if the RL agent could learn the pattern completely correctly. The results demonstrated that the model could continue jamming without any issues. The jammer success rate also tended to approach 1.0 (Figure 5c). Figure 4b clearly depicts the model's change in behaviour. The prior experiment's success was 0.95, which became 0.98, and the objective function remained at the expected level of 7.50 (Table 2). Figure 5d shows a 1/10 scaled target function plot.

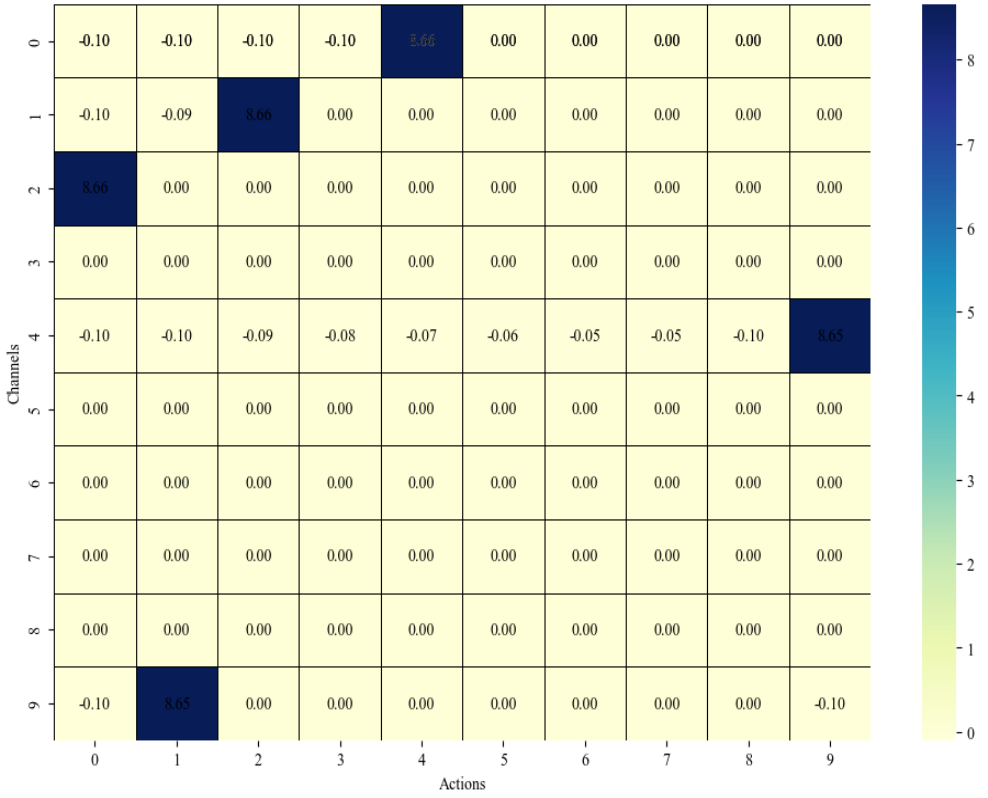

Figure 3. Spectrum Model.

Table 2. Performance table of jammers for experiment 1-2-3.

Experiment 1	Number of Success jams	Succes Rate of Jammer	Target Function
RL Driven Jammer	983	0.98	6.55
Random Jammer	113	0.11	9.52
Comb Jammer	200	0.20	9.99
Sweep Jammer	100	0.099	9.47
Dynamic Jammer	200	0.20	9.53
Experiment 2			
RL Driven Jammer	951	0.95	7.50
Random Jammer	101	0.10	8.21
Comb Jammer	600	0.60	9.99
Sweep Jammer	50	0.05	9.56
Dynamic Jammer	599	0.59	9.60
Experiment 3

Figure 5. Performance comparison of jamming techniques.

Experiment 3: In this experiment, to imitate a continually changing environment, the frequency hopping mappings were modified every 40 iterations. Thus, it was determined how adaptable the RL jammer was, and it was also compared to other approaches. The RL jammer agent's ε_{decay} was adjusted to 0.7, limiting exploration and enhancing model adaption. The agent's ε is set to 1.0 after two consecutive incorrect predictions (Figure 4d).

When the experiment's findings are evaluated, it is clear that, while the number of correct predictions and success rate has decreased significantly, it is still far more successful than other conventional methods. It was discovered that it created a 12% difference compared to the second successful one (Table 2). The values for comb, sweep, and dynamic jammer overlap on the target function graph in Figure 5f.

Experiment 4: In this experiment, two pairs of CUs are supposed to be operating in the spectrum, implying that the transmitters occupy two different frequency bands at the same time. Tables 3 describe the frequency hopping approach of two CUs. While traditional jammers follow the same technique as in prior studies, the RL jammer agent must estimate two distinct frequency bands at the same time. In this case, there are 100 action sets and a 100x100 matrix for the Q-table. Of course, the RL jammer is unaware of the scenario. First, the agent must identify which channels are currently active. It can accomplish this by arranging two Q-tables in a hierarchical structure.

Table 3. Frequency hopping sequences for communication user 1-2.

Current Frequency (MHz)	2	6	10	14	18	22	26	30	34	38
Next Hop (MHz.)	6	34	22	10	38	30	18	14	2	26
Current Frequency (MHz)	2	6	10	14	18	22	26	30	34	38
Next Hop (MHz.)	34	2	18	6	38	22	30	10	26	14

The number of simultaneously occupied channels will be estimated first, followed by a determination of which channels are occupied. For the sake of simplicity, it will be assumed that the number of channels employed is first determined and remains constant throughout the communication process, which in this experiment consists of two channels operating simultaneously. Because the action set is 100, the agent first initiates the learning process and begins jamming when it has learnt 40% of the pattern. Two incorrect predictions in a row means starting the learning process all over again.

The learning process raises ε to 0.90 (Figure 4e). The first transmitter's initial frequency is 34 MHz, while the second is 26 MHz (Table 3). After 1000 cycles, RL Jammer completed 858 successful jams, comb jammer 350, dynamic jammer 349, random jammer 214, and sweeping jammer 100 (Table 4). As shown in Figure 5g, the RL jammer outperformed other conventional approaches, with an 86% success rate. Because it did not jam during the learning period, the objective function value was near to zero, at 0.47 (Figure 5h).

Table 4. Performance table of jammers For experiment 4.

Performance Table of Jammers	Number of Success jams	Succes Rate of Jammer	Target Function
RL Driven Jammer	858	0.86	0.47
Random Jammer	214	0.21	9.71
Comb Jammer	350	0.35	11.72
Sweep Jammer	100	0.10	17.56
Dynamic Jammer	349	0.35	23.45

Conclusion

In the experiments, as many different environments as possible were created, and it was investigated whether the reinforcement learning model, particularly the Q-learning model, can provide a good solution for the design of an intelligent jammer that can quickly adapt to variability and work in real time without prior knowledge in varying environments. Four tests demonstrated that reinforcement learning offers significant potential as a solution to this problem. This study also provides a good platform for future research into developing intelligent anti-jamming devices to combat intelligent jammers.The conclusion section should be written in Times New Roman font, justified-alignment and in 10-point size.

The Role of Artificial Intelligence in Enhancing Software Quality: A Multivocal Literature Review

Melis Toksoy[a], Murat Yılmaz[b]

[a] Gazi University, Informatics Institute, Department of Information Systems, Türkiye
[b] Gazi University, Faculty of Engineering, Department of Computer Engineering, Türkiye
melis.toksoy@gazi.edu.tr

Keywords: Artificial Intelligence, Software Engineering, Software Quality.

Aim

With the rapid advancement of technology, software has become a critical component of modern technological products and the fundamental building block of technological systems (Thota, Shajin, & Rajesh, 2020). As software plays such a significant role, the necessity for it to be error-free and of high quality has increased. Low-quality software not only negatively affects system performance but also creates various risks such as security vulnerabilities and data loss. Especially in safety-critical domains such as healthcare, aviation, and automotive, software errors can severely disrupt system operations and lead to large-scale operational losses. Software engineering is a dynamic discipline that encompasses methods, tools, and techniques for the design, development, testing, and management of software products (Yu, 2018). Software engineers aim to not only develop software that works properly, but also to design reliable, scalable, and user-friendly systems. As software development processes become increasingly complex, changing requirements and increasing quality standards make traditional methods inadequate (Syed Adnan Afaq, 2023). This situation causes companies to turn to new technologies to make their software development processes more efficient in an increasingly competitive environment. At this point, artificial intelligence comes into play as a powerful solution partner for software engineers. Artificial intelligence (AI), which was founded with Turing's idea of "thinking machines" and gained a scientific identity with McCarthy's term "artificial intelligence", was initially based on a theoretical framework, but today it is creating significant change in different industries with its concrete applications (Turing, 2007; McCarthy, 1959). In the software development life cycle, various AI-based algorithms are effectively used at different stages. For example, machine learning algorithms are widely preferred to predict software errors and anticipate user needs (Yüksel & Çetin, 2020). Natural language processing technology is an artificial intelligence discipline that aims to transform human language into a form that computers can understand, process, and produce (Geetha, Gomathy, Yagn, & Praneesh, 2023). This technique extracts and interacts with text or audio data by analyzing grammar rules, word meanings, and context relationships. Deep learning and artificial neural networks are used to detect software errors at early stages and accelerate software optimization by processing more complex data sets (Shrestha, Krishna, & Von Krogh, 2020). These AI-based algorithms significantly enhance software quality by making the development process faster and more efficient. AI-powered tools enhance the efficiency of software development processes by making significant contributions in areas such as error detection, test automation, and predictive analysis. While traditional software engineering focuses more on functionality and performance, AI expands this focus, enabling software systems to become more intelligent and adaptable. Thus, software developers have the opportunity to design more flexible, dynamic, and continuously improving systems. Some of the AI-powered tools widely used in software development processes today are: SonarLint is a tool that detects security vulnerabilities and quality issues at an early stage by performing static analysis of the code. In this way, developers can make their software more reliable and maintainable by developing it in accordance with quality standards Yeboah & Popoola, 2023). GitHub Copilot is an AI-powered code assistant powered by OpenAI's Codex model and accelerates the software development process by offering features such as automatic code completion, function suggestions, and direct code generation (Baralla, Ibba, & Tonelli, 2024).These tools not only save software developers time, but also facilitate long-term maintenance of software projects by improving the readability, maintainability, and quality of the code. This study aims to comprehensively address

the contributions of artificial intelligence to software development processes and software quality. Although research on the integration of artificial intelligence into software development and quality assessment processes is increasing, a comprehensive study that addresses the effects of this technology on software processes and quality with a holistic approach has not yet been included. The current gap is not limited to academic literature but also leads to inadequate evaluation of applied knowledge and practical experiences. In this context, this study aims to present a systematic analysis by bringing together leading research on the subject and to contribute to the development of the field.

Material and Method

In this study, the Multivocal Literature Review (MLR) method will be applied. This method aims to better understand the different dimensions and practical applications of the subject by expanding the traditional Systematic Literature Review (SLR) approach and using gray literature sources such as industry reports, technical blogs, and industry articles in addition to academic literature (Ogawa & Malen, 1991). The literature review will enable us to evaluate the potential of AI to contribute to software quality from a broad perspective. This approach will provide a deeper understanding of AI's impact on software quality by bridging the gap between academic and industry perspectives. The data to be used in the study will be collected from the following sources: Academic Databases: IEEE Xplore, ScienceDirect, ACM Digital Library, Springer, Google Scholar academic databases will be scanned for peer-reviewed articles on artificial intelligence and software quality. The articles collected from these databases will form the scientific basis of the study and will allow us to evaluate the quality-enhancing effects of artificial intelligence in software development processes. Gray Literature: It refers to materials containing sector-specific information that are not included in official academic publications (Akl et al., 2019). This type of literature can be examined at three different levels of reliability:

1. First-level gray literature (high reliability): Books, journals, government reports, technical reviews.
2. Second-level gray literature (medium reliability): Annual reports, news articles, presentations, videos, Q&A platforms, and Wiki content.
3. Third-level gray literature (low reliability): Blogs, emails, social media posts (Adams, Smart, & Huff, 2016).

Research Questions and Search Strategy

In accordance with the MLR methodology, the search will be carried out according to the following steps: Determining research questions, defining search terms, searching academic databases, searching Google and other search engines, removing duplicate articles, determining inclusion/exclusion criteria, data extraction, data synthesis. The main research questions are listed in Table 1.

Table 1. Research questions.

ID	Question	Search Strings
RQ1	In which phases of the software development lifecycle are AI techniques most commonly applied?	("Artificial Intelligence" OR "AI Techniques" OR "Machine Learning" OR "Deep Learning") AND ("SDLC" OR "Software Engineering Phases" OR "Agile Development")
RQ2	How do AI techniques impact software quality metrics?	("AI Techniques " OR "Machine Learning") AND ("Software Quality Metrics" OR "Software Quality" OR "Quality Assurance")
RQ3	How do AI-powered tools impact software developer's productivity?	("AI-powered tools" OR "Machine Learning tools") AND ("Developer productivity" OR "Software development efficiency" OR "AI in software development productivity")

Inclusion and Exclusion Criteria

The literature to be included in this study consists of peer-reviewed journal articles, conference papers, and industry reports published between 2010 and 2025, as well as gray literature sources in both English and Turkish. The sources used must address the impact of artificial intelligence techniques on the software development lifecycle and software quality. Literature to be excluded includes studies published before 2010, articles written in languages other than English and Turkish, and content that does not address the research questions. Considering the reliability level of gray literature, only industry-contributing works directly related to the topic will be included.

Findings

To answer the research questions, the integration of artificial intelligence into software development processes will be examined comprehensively. The use of AI in various stages such as requirements analysis, design, coding, testing, and maintenance will be investigated, and the reasons behind its application in each stage will be explored. The advantages provided by AI in each phase will be explained in detail. Based on the initial research, the contributions of artificial intelligence to different stages of the software development lifecycle have been identified. In the requirements analysis phase, AI-based natural language processing techniques analyze user feedback, enabling more accurate and comprehensive requirements to be gathered. In the design and coding processes, AI-powered tools guide developers in code optimization by predicting errors, thus improving code quality. In the testing and debugging phase, AI-supported automated testing tools assist manual testing processes, accelerating error detection and enhancing software reliability. Finally, in the maintenance and deployment stages, AI-powered predictive analytics can identify potential issues that may degrade system performance in advance, ensuring an uninterrupted user experience. It has been observed that artificial intelligence techniques have a positive impact on software quality metrics. These effects may vary depending on the type of AI techniques used, the quality of the data, and the system integration. Therefore, the impact of AI on software quality may not be at the same level in every case, but generally, beneficial outcomes are expected in this area. In the context of the third research question, the effects of AI-powered tools on the productivity of software developers will be evaluated. AI-based tools enhance productivity by enabling developers to accomplish more in less time through features such as automatic code completion suggestions, providing tips, and conducting risk analysis with pre-error warnings. Additionally, AI-based predictive analytics guide developers in project management and resource planning, supporting decision-making processes.

Conclusion

This study aims to provide a valuable source of information that will guide software teams in developing higher-quality, reliable, and high-performance software by examining the effects of integrating artificial intelligence into software development processes. Literature reviews and initial findings show that AI techniques and AI-powered tools bring significant advancements in various stages of the software development lifecycle and can enhance software quality. The study is expected to contribute to a better understanding of the role of AI in software development processes and serve as a guiding resource for both academic research and industrial applications. The outcome of the study is anticipated to introduce a holistic perspective on the relationship between artificial intelligence and software, raise awareness about the impact of AI on software quality, and provide insights for future research.

Multi-Lead ECG Classification Using a Mixture-of-Experts Transformer Model

Atalay Çelik [a], Mehmet Ali Ergün [a]

[a] Istanbul Technical University, Data Engineering and Business Analytics, Big Data and Business Analytics Program, Türkiye
celika17@itu.edu.tr

Keywords: Classification, Ecg, Moe, Transformer.

Aim

The aim of the study is to conduct and experiment with a transformer-based mixture-of-expert (MoE) model architecture in the health field to classify electrocardiography (ECG) records into their possible diagnosis. The records are time-based data that vary in length and frequency.

Material and Method

The dataset to be used in the study is one of the datasets used in the Physio Challenge 2020 (Alday et al., 2020) called the CSPC dataset (Liu et al., 2018). George B. Moody PhysioNet Challenges are challenges prepared annuay about specific questions or use cases about ECG records. The Physio Challenge 2020 primarily focused on the classification of the ECG records for diagnosis. These records are ECG signals that are taken from 12 different nodes that are placed on the human body at different specific positions. These nodes measure the signal of the electrical activity around it and record the signal strengths to observe the heart activity or irregularities.
The records are labeled with diagnosis with a specific coding schema called the SNOMED CT Code (SNOMED International, n.d.). These codes refer the specific diagnosis. Across 5,570 records a total of 8 different unique SNOMED CT codes, hence diagnoses are present in the dataset. A single record can be labeled with multiple diagnosis. The dataset characteristics are given in Table 1. All the records have a metadata attach to it to read the diagnosis and other metadata in a specific format WFDB header file format (Moody, 2022).

Table 1. Diagnosis distributions.

SNOMED CT	Diagnosis Name	Number of Records
426783006	Sinus Rhythm	918
164889003	Atrial Fibrillation	1221
270492004	1st Degree Av Block	722
59118001	Right Bundle Branch Block	1857
284470004	Premature Atrial Contraction	616
164909002	Left Bundle Branch Block	236

In the dataset, the length of the records are 15.4 seconds in average. The frequency of the records is 1000 Hz. To feed into the model all the records preprocessed to have the same time interval and frequency by resampling, cropping or padding the records. Records are cropped if they are longer than 10 seconds. This results in all the records having the same number of samples. The time interval is decided by the most common time interval for all the datasets. The frequency is decided by doing an analysis of the signal-to-noise (SNR) ratio for different frequency options. Since these records are electrical signal

there are inherent and outside noise present in the records. To denoise the records filters such as Butterworth filter and finite impulse response (FIR) are used. Resampling and filtering steps are further analyzed in combination to select the best set of parameters to preprocess the records based on SNR values.

Some record show unidentifiable patterns or peaks that indicate a clear mismeasurement, these patterns are detected by a combination of three methods; Z-score for ECG records, principal component analysis (PCA) and Isolation Forest. These three methods vote on possible outliers and if there are records that have 2 out of 3 votes they are flagged as outlier. The methods are applied separately for different diagnosis. For the diagnosis that have more than 20 records the outlier analysis is done within the diagnosis group, but for rare diagnosis that have less than 20 records are grouped together and analyzed as a group. These filtering steps ensure that the data is similar across the same diagnosis and are detached from any outside effect.

Some diagnosis codes are representing similar diagnosis, for this reason they are concatenated to be a single diagnosis. These diagnosis pairs are taken from Physio Challenge evaluation repositories. (Alday, 2020) As a result, 6 unique diagnoses are present if diagnosis pairs are counted as one diagnosis.

Transformer architecture is a commonly used state-of-the-art architecture in fields such as large language models and image processing tasks. Since its first appearance it the literature by Vaswani et al., it has impacted the deep learning architectures with its subcomponents (Vaswani et al., 2017). Even though several subcomponents have changed since its first version, the main design has remained the same. One of the most significant alteration in the architecture has become the mixture-of-expert and router approaches (Shaazer et al., 2017). Original transformer implementation uses a dense model, where every neuron is used for a single inference cycle; however, with the MoE models the models are used sparsely to activate only a portion of the model. This mechanism is applied with the router logic. The router, routes the inputs to different experts according to its characteristics. The experts are fully connected layers that do the computation work. In the context of LLMs, these inputs represent tokens. The MoE architecture also introduces new loss components to ensure the uniform activation of routers and distribution of inputs across the experts.

Adoption of this architecture to the time series domain is still being actively explored in recent studies (Shi et al., 2024). However, most of the studies are focusing on the forecasting scenarios. The classification of the time series with an MoE architecture is still a developing area. The ECG classification task has become a great experimentation area for any classification-based implementation. The multi-feature characteristic of the data, a wide range of diagnosis with different characteristics, and the importance of the field due to critical health implications of a diagnosis present a great challenge.

In this study, a mixture-of-expert transformer model with an auxiliary loss that predicts the possible diagnosis of multi-lead ECG records is worked on.

The model architecture is a transformer architecture multi-head attention and RoPe positional encoding. layers that alternate between normal feed forward layers and MoE layers, the first and third layers are feed forward and second and last layers are MoE layers.

The model consists of multiple specialized experts and a learned routing network that dynamically assigns inputs in the sequence to the most appropriate experts. To mitigate the effect of expert collapsing, where only a small subset of experts receives the majority of sequence tokens, auxiliary losses is added to penalize the routing inefficiencies. The z-loss (Zoph et al, 2022) is implemented to inhibit the extreme routing to some experts and balance loss (Shaazer et al., 2017) is applied for uneven expert utilization, resulting in more efficient use of model capacity.

The architecture also includes a classification token (CLS) similar to BERT class models (Devlin et al., 2019), where a learned token is prepended to the input sequence and used for final classification in the last step of the model. The age and sex features are fed to the model with a projection layer to the model dimension. The training includes several optimization techniques to ensure stability, such as learning rate warmup, cosine annealing for learning rate, early stopping, and gradient clipping. The material and method section should be written in Times New Roman font, justified-alignment and in 10-point size.

Findings

The model which the architecture of it has been described has been trained for 30 epochs. The model is configured with a dimension of 48 and utilizes 4 attention heads across 4 layers. The Feed Forward Network (FFN) size is set to 192, and the model employs 8 experts. Regularization includes a Z-loss coefficient of 0.001 and a balance loss coefficient of 0.005. Training parameters include a batch size of 64, with gradient accumulation over 2 steps with early stopping. The initial learning rate is set to 7e-5 with 100 warm-up training iterations.
To find the best candidate hyperparameters, several runs are conducted for each parameter combination and it is concluded that a model with lower number of parameters learn the representations of the model better than a larger model. The results of the evaluation on the test set are presented at Table 2.

Table 2. Evaluation metrics of the model.

Component	Value
Exact Match Accuracy	54.93 %
Top 1 Accuracy	66.05 %
Top 2 Accuracy	85.06 %
Top 3 Accuracy	93.54 %
F1 Score	72.20 %

The experts that are present for the layers one and three are further analyzed to observe their utilization rate as seen in Figure 1.

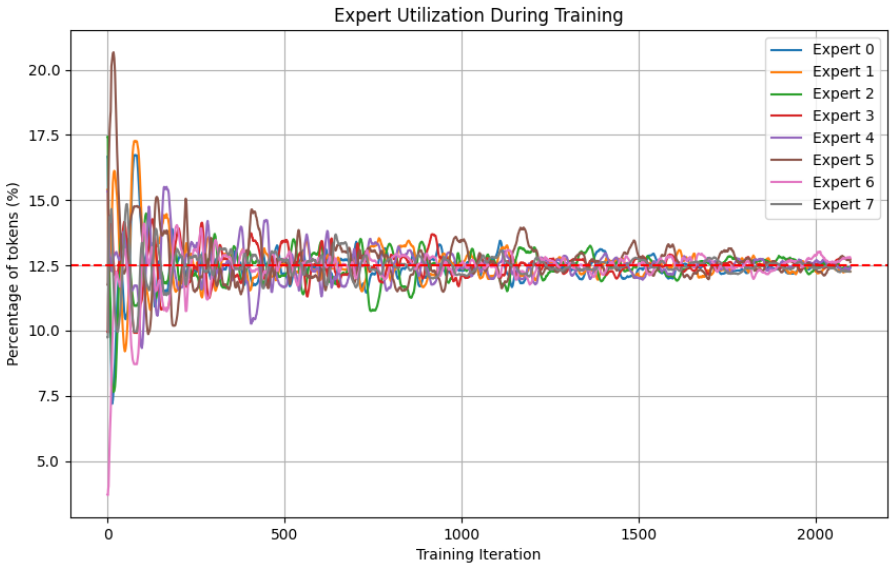

Figure 1. Expert utilization rates during training.

The model exhibits an adequate level of exact diagnosis detection and a high degree of accuracy for the top 3 predictions.

Conclusion

The mixture-of-expert approach to a time sequence data for classification is a great challenge to test this approach in the time series domain. One of the main challenges of this problem is the presence of multi-label diagnosis for the records. The model training demonstrated that it has the capability to learn to recognize different diagnosis with experts in place. Future research topic includes ingestion of extracted features from the ECG records, and implementation of further training on a larger dataset.

Adaptive Consensus Algorithms for Blockchain Networks

Esin Küçükmeriç[a], Adnan Ozsoy[a]

[a] Hacettepe University, Computer Engineering, Master's Program, Turkey
esinkucukomeroglu@hacettepe.edu.tr

Keywords: Dynamic Consensus, Hyperledger Fabric, Kafka, Parallel Channel Approach, Raft.

Aim

Blockchain technology has garnered significant attention in recent years due to its ability to provide reliability and transparency in distributed systems. However, one of its most critical components, consensus algorithms, directly impacts the performance and flexibility of the network. It is important to note that consensus algorithms exhibit varying priorities, such as speed, security, and capacity. This diversity complicates achieving an optimal balance between performance and security in different application scenarios. For instance, a financial application requiring high transaction throughput may prioritize speed and scalability, whereas a supply chain management system processing sensitive data may place greater emphasis on security and the fault tolerance of the consensus mechanism. In conventional blockchain architectures, addressing these diverse requirements with a single consensus algorithm often necessitates compromises in one area [7]. Ideally, a system capable of dynamically selecting the most appropriate consensus mechanism based on the network's current state and requirements could enhance both efficiency and security. For example, the system could prioritize speed during peak hours and subsequently prioritize security. Thus, in enterprise-level blockchain platforms like Hyperledger Fabric, the need to dynamically switch consensus algorithms arises [1, 2]. Although Hyperledger Fabric provides a modular and extensible blockchain infrastructure, its current architectural design does not support dynamically changing the consensus mechanism after the blockchain network has been initiated. As clearly stated in the official Hyperledger Fabric documentation, the chosen consensus algorithm is considered a foundational component of the orderer nodes' configuration at network startup and remains constant throughout the lifecycle of the blockchain network. Therefore, if there is a requirement to change the consensus mechanism, it necessitates fully stopping the running network, cleaning the previous configuration thoroughly, and restarting the network with new settings.This study focuses on a parallel channel architecture to overcome these existing limitations and provide a more flexible solution. This approach allows the network to switch between different consensus algorithms without downtime while maintaining transaction consistency and performance [5, 6]. This study aims to overcome the inherent limitations of dynamic consensus algorithm switching in blockchain networks, with Hyperledger Fabric as our selected use case. Currently, Fabric does not support changing the consensus algorithm, such as from Raft to Kafka or vice versa, without restarting the network [6]. This limitation introduces significant latency and operational overhead, making it impractical for real-time applications that require flexibility in consensus mechanisms based on varying workloads or network conditions. To overcome this challenge, we propose a novel parallel channel architecture where two channels—one using Raft and the other using Kafka—run simultaneously. This approach aims to enable seamless consensus switching while minimizing latency, ensuring transaction consistency, and maintaining high availability across channels. Additionally, we aim to quantify the latency introduced by consensus switching and synchronization between channels, providing a comprehensive analysis of the proposed solution's performance. This study also explores the potential of this architecture to support other consensus algorithms in the future, further enhancing the flexibility of blockchain networks [5, 6].

Material and Method

In the initial setup, a Hyperledger Fabric network is configured with Raft as the consensus algorithm. Chaincode operations are performed to establish a baseline for transaction processing latency and throughput. Kafka is then integrated into the network to evaluate the feasibility of consensus switching [3, 4]. The process of changing the consensus algorithm consists

of several critical stages, as illustrated in Figure 1 and Figure 2. The first stage involves cleaning up ("cleanup"), which includes stopping the current network's Docker containers, removing associated configuration files, and deleting previously generated cryptographic materials. This stage is represented in the "Cleanup" step in the graphics. The second step involves generating cryptographic materials ("crypto generation") tailored specifically for the newly selected consensus mechanism, as seen in the "Crypto Generation" phase. Subsequently, the initial state of the blockchain, represented by the genesis block, is generated ("genesis block generation"), followed by the creation of configuration files necessary for channel formation ("channel TX generation"). These stages are represented in the "Genesis Block Generation" and "Channel TX Generation" sections of the graphs.

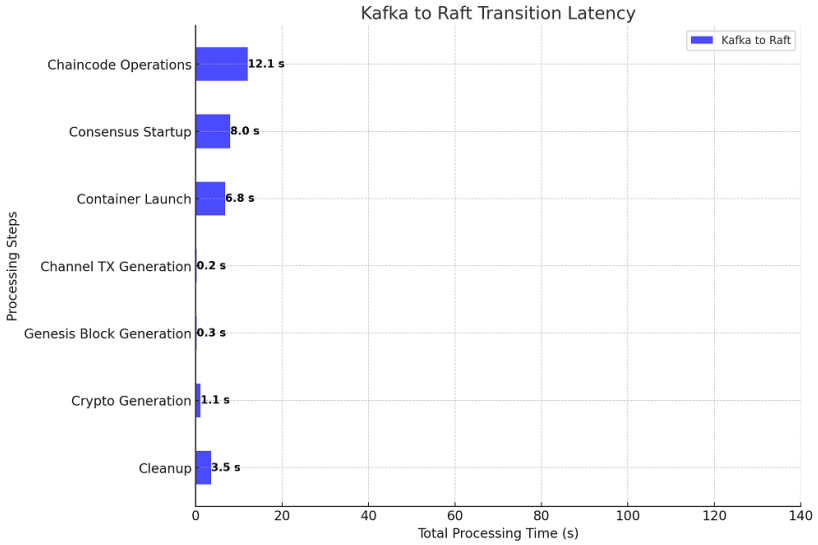

Figure 1. Kafka to Raft transition latency.

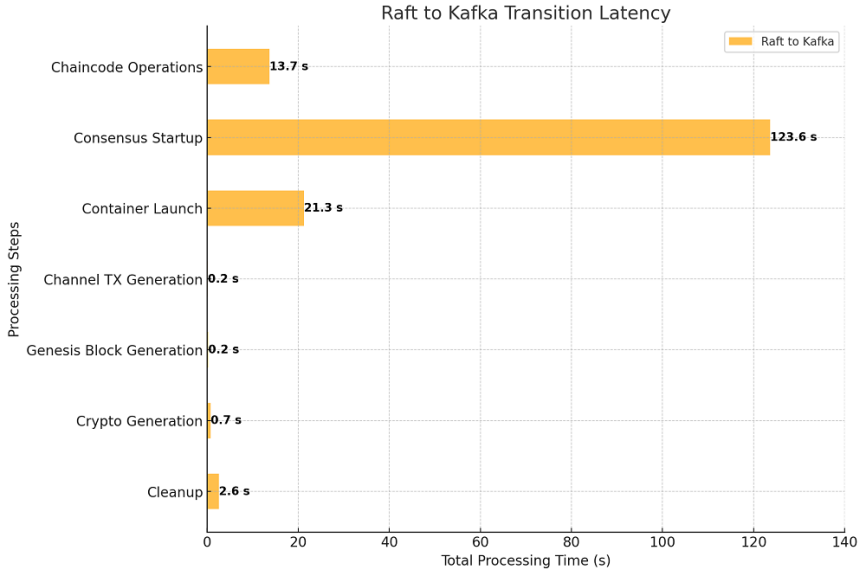

Figure 2. Raft to Kafka transition latency.

In the next phase ("container launch"), the network containers are started using Docker Compose configurations specific to the selected consensus mechanism, which is illustrated in the "Container Launch" phase. Following these general configuration steps, additional mechanism-specific preparations are required depending on the consensus type. For instance,

when initializing a Kafka- based network, the system waits until all Kafka brokers have fully become operational. During this waiting period, the statuses of Kafka brokers are periodically verified to ensure their readiness before initiating any blockchain transactions or channel creations. Similarly, a Raft- based network requires a leader election process among the orderer nodes to become operational. During this stage, periodic checks are performed on the orderer nodes' logs to confirm that a leader node has been successfully elected. This leader election phase is crucial for ensuring that the new consensus algorithm can reliably handle and order transactions across the network. These additional preparation steps significantly contribute to latency during consensus transitions. Once these foundational configuration stages were completed, chaincode operations became essential to bring blockchain functionality online. Chaincode operations involve four primary steps: packaging the chaincode ("chaincode package"), installing it on nodes of relevant organizations ("install"), organizations approving the installed chaincode ("approveformyorg"), and finally committing the chaincode to make it operational on the network ("commit"). After these operations, the chaincode became active, initial states (e.g., creating assets named A and B) were defined, and a simple token transfer was executed to verify the chaincode functionality. This process included instantiation ("instantiate"), asset initialization ("initialize assets"), invoking a transaction ("invoke"), and finally querying ("query") the assets to confirm transaction correctness. However, during these transitions, the necessity of shutting down and restarting the blockchain network inevitably leads to service interruptions. Such disruptions pose serious risks, particularly for blockchain applications requiring high availability and continuous operation. Network outages negatively affect service continuity, potentially reduce network reliability, degrade performance, and diminish user trust. Additionally, interruptions may result in increased transaction delays, growth in transaction queues, and elevated risks of data inconsistency.

As shown in Figure 1 and Figure 2, the latency introduced during the transition phases, especially in the "Consensus Startup" step, contributes significantly to overall transition time. To mitigate the high latency and negative impacts of these network interruptions, a parallel network operation approach has been proposed. In this approach, two separate blockchain networks—one using Raft consensus and the other Kafka consensus—are simultaneously launched and operated.

As shown in Figure 3, the Raft and Kafka networks operate independently but in parallel, with each network performing transaction processing simultaneously. Specifically, one network (the active network) processes transactions, which involve chaincode operations such as asset creation, token transfer, and querying, and immediately writes the processed transaction data into a file. The other network (the passive network) continuously reads the transaction data from this file and synchronizes these transactions internally, ensuring consistency across both networks. This parallel architecture allows for continuous operation during consensus transitions, with both networks mirroring each other's transaction processing and maintaining synchronization. The active network handles transaction processing and records it, while the passive network ensures that the state of both networks remains consistent by processing the same data from the file, effectively mirroring the operations of the active network. This methodology reduces latency, prevents service interruptions, and enhances overall system performance and reliability during consensus algorithm transitions.

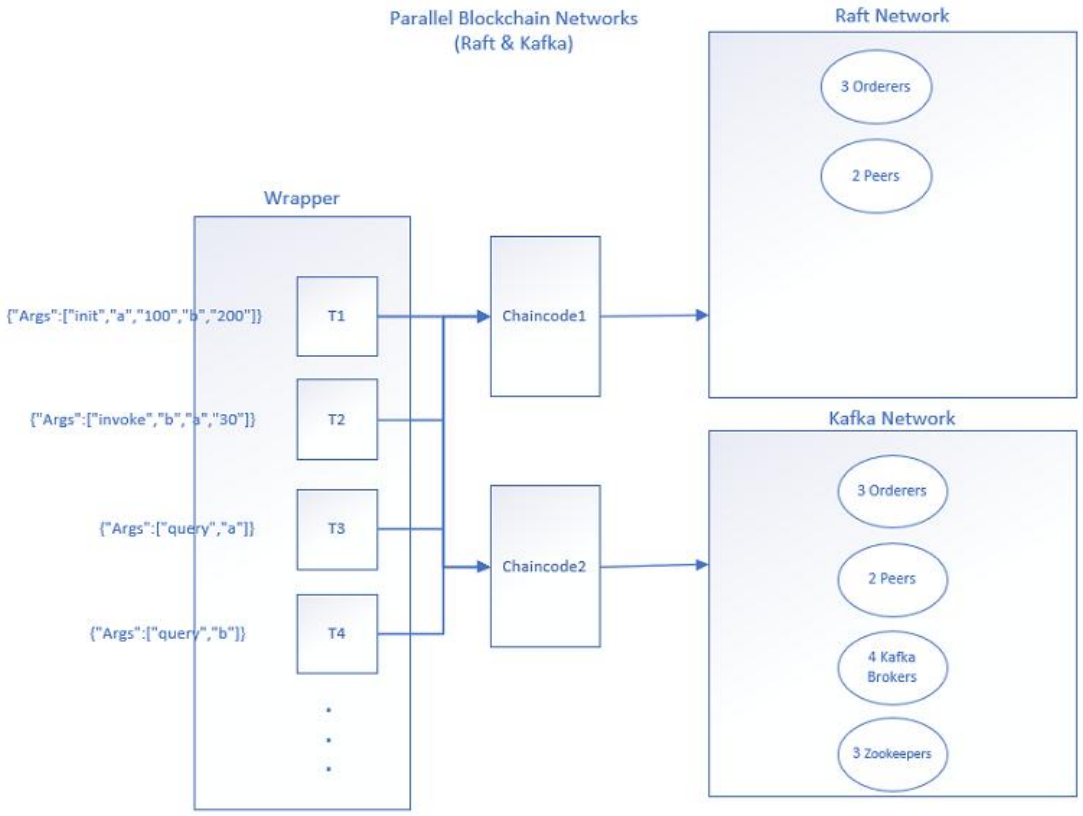

Figure 3. Parallel blockchain networks (Raft & Kafka).

Figure 4 illustrates the performance of this parallel approach, where transaction processing in both networks occurs simultaneously, minimizing overall latency and ensuring continuous operation during the consensus switching process. Performance analysis of these parallel-operating blockchain networks clearly demonstrates that parallelization significantly reduces the latency typically incurred through complete reconfiguration during consensus transitions. Results reflected in experimental measurements indicate a notable reduction in latency and improved system reliability and availability. Building upon this parallel approach, an automated mechanism was implemented to handle active-passive channel switching. The system dynamically selects the active channel based on predefined criteria such as workload or network conditions. This transition is further optimized by implementing a buffer-based approach to manage incoming transactions during the switching process. For instance, if a surge in transactions occurs—such as receiving 1000 transactions at once—the system temporarily stores these transactions in a buffer. Once the new active channel is ready, the transactions are processed from the buffer, ensuring minimal downtime and maintaining optimal transaction consistency. This development addresses the challenge of handling transaction bursts during the active-passive channel switching process, improving both efficiency and transaction handling under varying network conditions.

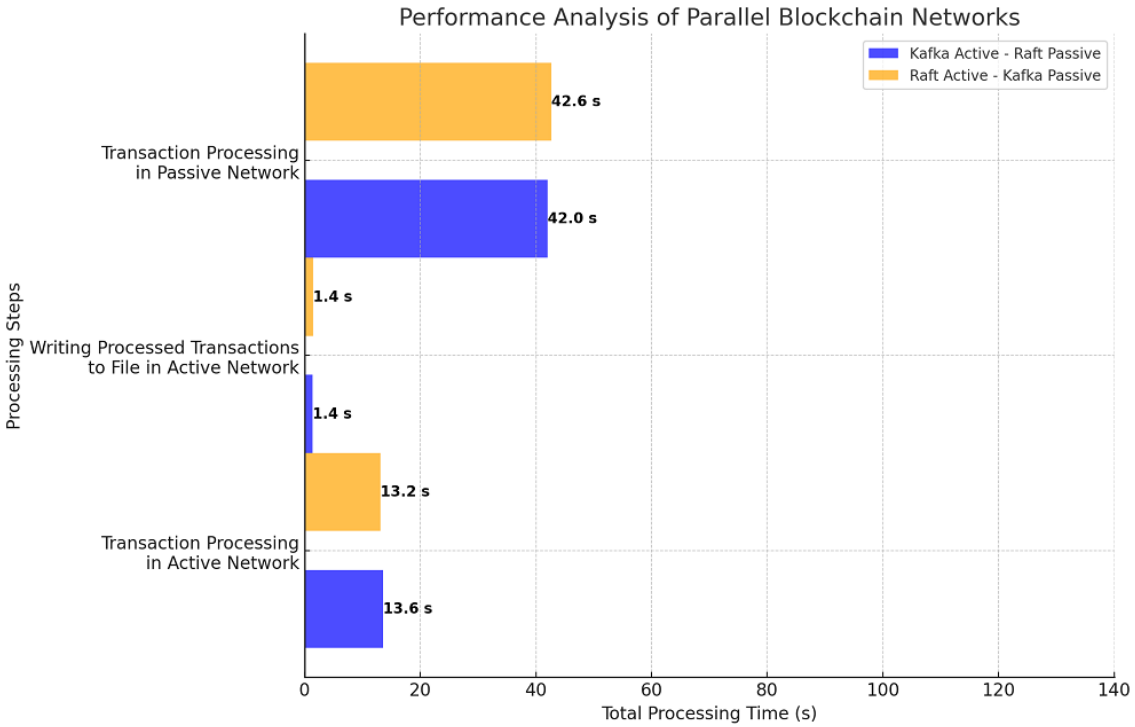

Figure 4. Performance analysis of parallel blockchain networks.

Findings

This research highlights significant drawbacks associated with switching consensus algorithms, such as transitioning from Raft to Kafka, by restarting blockchain networks. Restarting introduces substantial latency, operational complexity, and downtime, severely affecting high- availability and real-time applications. Downtime halts transaction processing, negatively impacting user experience, especially in high- volume scenarios. Moreover, reconfiguring nodes, updating channels, and resynchronizing networks require extensive resources and increase the risk of human error. Raft provides lower latency and simplicity, making it ideal for rapid transaction processing; however, its leader-based structure makes it less effective for high-throughput scenarios. In contrast, Kafka excels in handling massive transaction volumes with high fault tolerance but incurs higher per-transaction latency. Thus, selecting between Raft and Kafka depends on various factors, including the specific performance requirements, scalability considerations, and operational priorities of the application [1,7]. The parallel channel architecture proposed in this research addresses these challenges effectively. By simultaneously operating Raft and Kafka channels, the system dynamically selects the optimal consensus algorithm based on real-time network demands and application-specific priorities, ensuring uninterrupted transaction processing. The network maintains consistency through file-based synchronization, and the automated active-passive channel management mechanism enables seamless switching. This approach significantly enhances performance compared to traditional single-channel approaches, offering superior latency, throughput, and operational flexibility.

Conclusion

In conclusion, this study demonstrates that dynamic consensus switching in Hyperledger Fabric can be achieved through a parallel channel architecture. By running Raft and Kafka channels simultaneously and implementing an automated switching mechanism, the limitations of consensus algorithm switching can be mitigated. The proposed approach reduces latency, ensures transaction consistency, and provides a scalable solution for real-time blockchain applications. The findings highlight the potential of parallel channel architectures to enhance the flexibility and performance of blockchain networks. Future work will focus on optimizing the synchronization process, integrating additional consensus algorithms, and

evaluating the proposed solution in large-scale, real-world deployments. This research opens new avenues for improving the adaptability of blockchain systems in dynamic environments.

Reputation Based Decision Making Consensus Mechanism for UAV Swarms with Ethereum Blockchain

Mustafa Tosun[a], Şerif Bahtiyar[b]

[a] Istanbul Technical University, Department of Cybersecurity Engineering, Türkiye
[b] Istanbul Technical University, Department of Computer Engineering, Türkiye
tosunmu17@itu.edu.tr, bahtiyars@itu.edu.tr

Keywords: Blockchain, Decision, Swarm, UAV, Voting.

Aim

Blockchain technology within drone swarm systems gained a huge impact in recent years for several domains, within military, commercial, and political contexts (Koulianos & Litke, 2023).
Byzantine fault tolerance (BFT) is a critical aspect of UAV systems, especially in networked environments where security and reliability are paramount. In order to reduce the impacts of Byzantine UAVs in the swarm, blockchain based consensus mechanisms are being proposed by researchers (Cheng et al., 2022) (Alsamhi et al., 2023).
This study proposes a blockchain based consensus mechanism for autonomous target selection in military drone swarms. The system integrates reputation weighted voting and Byzantine fault tolerance to enable decentralized decision making. Dynamic thresholds (60% for normal missions, 70% for critical missions) and timeout mechanisms ensure the robustness of the system. This study bridges the gap between decentralized trust and real time operational efficiency in autonomous warfare systems.
The integration of voting based consensus mechanisms into UAV swarms revolutionizes autonomous decision making by addressing critical challenges in military operations, such as Byzantine (faulty/malicious) node resilience, decentralized trust, and real time adaptability.
This study aims to enhance the efficiency, security, and reliability of swarm drone operations with the help of blockchain technology for decentralized decision making. The study will explore how reputation systems can be integrated into swarm Unmanned Aerial Vehicles (UAV) to improve consensus and decision making processes, ultimately leading to more effective and resilient UAV swarms.

Material and Method

The proposed system will utilize Ethereum's blockchain technology to implement a decentralized decision making mechanism for swarm drones. This system will incorporate a reputation based consensus algorithm to ensure efficient and secure operations.
The proposed system contains a smart contract programmed in Solidity language to manage the voting process and dynamically re-evaluate the reputation scores of UAVs. With the help of smart contract, the system creates trust in no trust contracting contexts (Eenmaa-Dimitrieva, H., & Schmidt-Kessen, 2023) (Rouhani, S., & Deters, R., 2019).
The workflow of the proposed system can be seen in Figure 1. Firstly, an administrator user sets the criticality level at the beginning of mission. During mission, highest reputation UAV suggests a target. Other UAVs in the swarm evaluates this suggestion and based on their own sensors and capabilities, they cast votes as yes or no. Smart contract calculates each UAV's vote weight based on their reputation. Calculated votes will be added to blockchain as a transaction. After all UAVs cast their votes, voting will end. Based on the criticality level (60% for normal missions, 70% for critical missions) , if consensus achieved align with the highest reputation UAV's suggestion, the target will be approved for engagement. Otherwise, it will not ensure mission success and safety. After the voting process concludes, each UAV's reputation (including the highest reputation UAV) will be re-evaluated. The re-evaluation system provides a dynamic reputation for each UAV in the swarm based on the accuracy of previous votes.

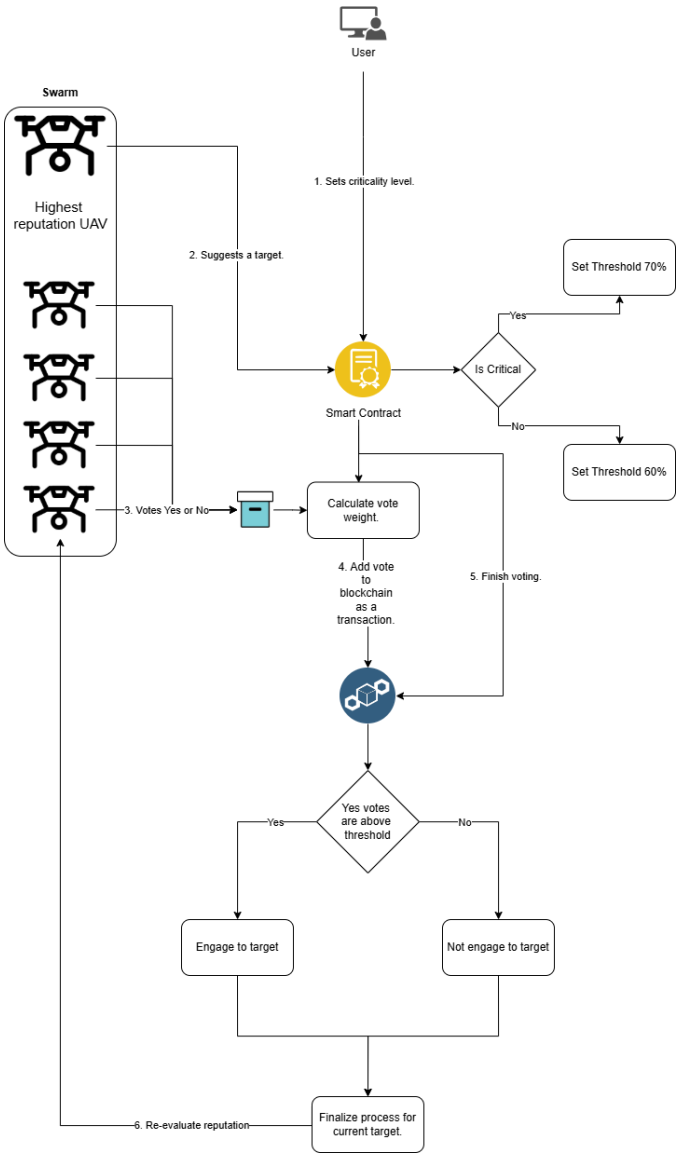

Figure 1. Workflow.

The re-evaluation process will be applied as follows: Reputation of UAVs with accurate votes will be increased by 10 points, Reputation of UAVs with inaccurate votes will be decreased by 5 points. UAVs that did not vote will have their reputations decreased by 2 points. After the re-evaluation process, there is a possibility that the highest reputation UAV may also change due to re-evaluation.

After the process is completed for the current target, the highest reputation UAV may suggest another target. Whenever a new target is suggested, the voting process will be started again.

Some UAVs may cast their vote after a certain amount of time. This may cause the mission to be delayed or result unsuccessfully. The timeout duration will be set as 5 seconds to prevent that problem. In case voting is not completed within 5 seconds, if consensus is not achieved, voting will be restarted. Restarting operation will be applied a maximum of 3 times. If the voting process fails to reach a consensus after 3 attempts, the system will not engage to current target.

Findings

The study is expected to yield several key findings related to the implementation and effectiveness of the proposed system. The use of blockchain technology is anticipated to enhance the security and reliability of the decision making process by providing a decentralized platform.

The reputation based consensus mechanism is expected to improve the efficiency of swarm operations by prioritizing input from drones with higher reputations.

The proposed system aims to enhance the reliability and efficiency of UAV operations by utilizing reputation scores to inform collaborative decision making processes among UAVs, ensuring that actions are taken based on trustworthiness and accuracy of previous votes. By integrating this reputation based approach, the system minimizes the risks associated with unreliable sensors and Byzantine UAVs, ultimately enhancing mission success rates across diverse operational environments.

Conclusion

In this study, we present a new system to carry out decision making process for target engagement in UAV swarms. The integration of Ethereum blockchain technology with a reputation based decision making consensus mechanism offers a promising approach to enhancing the integrity and reliability of swarm UAV operations. With the help of blockchain's decentralized nature, along with a reputation system, the proposed system improves decision making processes and ensures more effective swarm operations. The study's findings will contribute to the growing body of research on blockchain applications in swarm UAV applications, highlighting the potential for innovative solutions in this field.

Keywords: Neuromorphic Computing, Network Security, NSL-KDD Dataset, Zero-Day Attack Detection, Cyber Security.

Aim

The increasing complexity of digital infrastructures has led to the rapid evolution of cyber security threats. Traditional Intrusion Detection Systems (IDS) and Intrusion Prevention Systems (IPS) are becoming inadequate against increasingly sophisticated cyber attacks [1]. This study aims to integrate neuromorphic computing and memristor-based architectures into cyber security solutions to improve attack detection efficiency, reduce false positives, optimize energy consumption, and develop real-time threat mitigation mechanisms [2].

Neuromorphic processors, which mimic the neural structure of the human brain, offer higher computational efficiency and rapid adaptation capabilities to dynamic environments compared to traditional computing systems [3]. Processors such as Intel's Loihi and IBM's TrueNorth simulate biological neural networks, enabling real-time analysis of large datasets with high efficiency and low power consumption [4,5]. Other significant neuromorphic projects like SpiNNaker have also demonstrated the potential of brain-inspired computing architectures [6]. The structure of the neuromorphic processor is shown in Figure 1. Intrusion Detection and Prevention Systems

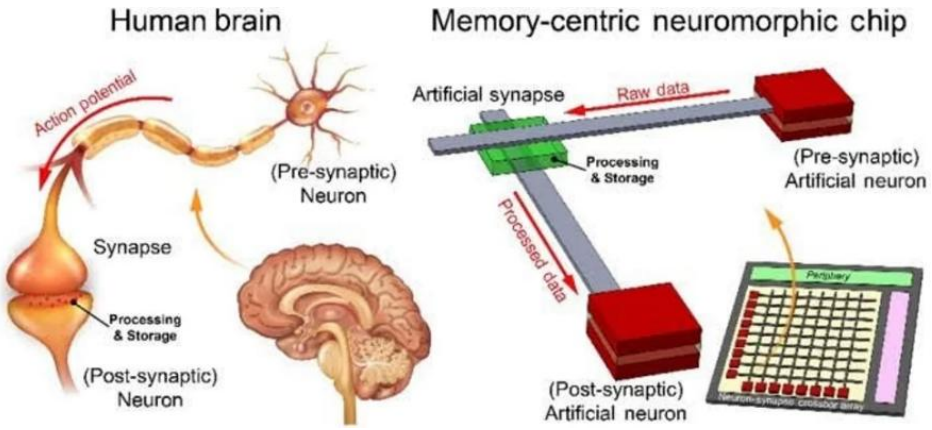

Figure 1. Human brain and memory-centric neuromorphic chip.

Intrusion Detection Systems (IDS) and Intrusion Prevention Systems (IPS) are critical components of modern cyber security infrastructures [7]. These systems continuously analyze network traffic to detect anomalies and enable measures against potential security breaches.

IDS systems are primarily divided into two categories:

- Signature-Based IDS: Detects known threats by searching for predefined attack patterns but is inadequate in identifying new types of attacks.

• Anomaly-Based IDS: Uses machine learning algorithms to detect deviations by creating models of normal network behavior, providing the advantage of detecting previously unseen attacks. Deep belief networks have shown particular promise in this area [8].

The similarities and differences between IPS and IDS are described in detail in Table 1.IPS systems combine the detection capability of IDS with active intervention capacity. These systems conduct comprehensive traffic monitoring, use advanced attack detection mechanisms, and provide automatic intervention when threats are detected.

Table 1. Comparison of IDS and IPS.

Comparison Parameters	IDS	IPS
Full Form	Intrusion Detection Systems	Intrusion Prevention Systems
Release to Market	Released between 1984 and 1986	Released in the mid-2000s
Definition	A system that detects files passing through the gateway for any malware	Software that detects malware according to a defined set of rules and can even block them
Type	A passive software type	An active software
Operation	Involves detecting and reporting malware and errors	Does not require human intervention or participation of other software as it solves the problem on its own
Performance	Does not affect network performance due to offline deployment	Slows down the network due to detection process
Communication	Out-of-band communication	Compatible with data communication
Advantage	Detects malicious traffic	Drops, alerts, and cleans malicious traffic

Materials and Methods

The research methodology evaluates the effectiveness of existing IDS/IPS systems against current cyber threats through comprehensive comparative analysis. Two important datasets were used to objectively measure the performance of neuromorphic IDS models:

1. CIC-IDS2017 Dataset: A comprehensive resource that includes modern attack types such as DoS, ransomware, phishing, and data leakage [9]. This dataset was created by the Canadian Institute for Cybersecurity at the University of New Brunswick in 2017 and contains network traffic data captured over a five-day period. The dataset includes benign traffic and attack scenarios executed in a controlled environment, comprising over 80 network flow features extracted from pcap files. The CIC-IDS2017 features realistic background traffic generated using the B-Profile system, which creates profiles of abstract behaviors for different user groups.

It contains a diverse range of attacks including Brute Force FTP, Brute Force SSH, DoS, Heartbleed, Web Attack, Infiltration, Botnet and DDoS, making it particularly valuable for evaluating modern IDS systems.

2. NSL-KDD Dataset: A standard reference in the classification of network-based attacks, developed to address the inherent problems in the original KDD Cup 99 dataset [10]. The NSL-KDD dataset eliminates redundant records from the original KDD dataset to prevent biased classification towards frequent records and includes a reasonable number of records in both training and testing sets, making performance evaluation more consistent and comparable.

Key characteristics of the NSL-KDD dataset include:

Attack Categories: The dataset classifies attacks into four main categories:

- Denial of Service (DoS): Attempts to make resources unavailable to legitimate users (e.g., SYN flood, Neptune, Smurf)
- Probe: Surveillance and scanning activities to gather information or find vulnerabilities (e.g., portsweep, nmap, satan)
- User to Root (U2R): Unauthorized access attempts to gain superuser privileges (e.g., buffer overflow, rootkit)
- Remote to Local (R2L): Unauthorized access from a remote machine (e.g., password guessing, ftp_write)

Feature Composition: Each record contains 41 features categorized as:

- Basic features (1-9): Derived from TCP/IP connection information
- Content features (10-22): Domain knowledge-related attributes like number of failed login attempts
- Time-based traffic features (23-31): Computed using a two-second time window
- Host-based traffic features (32-41): Historical features examining connections with the same destination host.

Dataset Statistics: The training set contains 125,973 records while the test set has 22,544 records, with different attack distributions between the sets to provide a more challenging and realistic evaluation environment.

Advantages: The NSL-KDD dataset removes redundant and duplicate records, includes a balanced proportion of different attack classes, and has a reasonable number of records that makes it feasible to run experiments on complete datasets without sampling.

The NSL-KDD dataset remains a vital benchmark for evaluating intrusion detection systems despite being somewhat dated, as it allows direct comparison with numerous prior studies and contains attack patterns that remain relevant to contemporary security research.

Data Processing Techniques and Optimization

Data processing techniques applied for optimal performance of neuromorphic systems:

Data Encoding and Normalization Methods

- One-Hot Encoding, Label Encoding
- Min-Max normalization and Z-Score standardization
- Binary Coding, Rate Coding, and Time-to-Spike Coding.

These three methods are comparatively shown in Table 2.

Table 2. Comparison of coding methods.

Criteria	Binary Coding	Rate Coding	Time-to-Spike Coding
Definition	Encodes data in binary format	Encodes signal frequency according to various data characteristics	Encodes based on timing and event sequence of data
Advantages	Simple and understandable- Fast computation	Sensitive to signal strength- Takes time factor into account	Provides time sensitivity- High precision based on event sequence
Disadvantages	Can increase data size- May be inefficient for High-dimensional data	May have noise in High-frequency data- Can create complexity	May be more complex due to time dependency- High computational cost
Usage Areas	Suitable for categorical data and small datasets	Suitable for neural networks and biological signal modeling	Used in neuromorphic systems and biological systems
Coding Type	Binary coding	Frequency-based coding	Time-based coding

Data Balancing strategies are given below. These methods are detailed in Table 3.

- SMOTE (Synthetic Minority Over-sampling Technique): Generates synthetic examples for minority classes [11].
- ADASYN
- Holdout Method
- K-Fold Cross Validation
- Stratified K-Fold
- Random Undersampling

Table 3. Comparison of techniques and practical examples.

Method	Advantages	Disadvantages
Holdout Method	Easy to implement, fast with large datasets	Representation issues in small datasets, distribution variability
K-Fold Cross Validation	Improves generalization ability, provides reliable results	High computational cost in large datasets
Stratified K-Fold	Preserves class distribution, effective in imbalanced datasets	Computation time may increase
SMOTE	Increases minority class, improves model performance	Synthetic data may deviate from real distribution
Random Undersampling	Reduces data size, gives quick results	Minority class examples may be lost
ADASYN & Cost-Sensitive	Dynamically solves imbalance problems	Complex implementation, requires parameter tuning

Common Cyber Attack Types

Understanding different types of attacks is critical when developing modern cyber security systems. Major attack types include:

- Phishing Attacks: Aim to obtain sensitive information through fake emails or web pages that appear to come from trusted sources.
- Distributed Denial of Service (DDoS) Attacks: Aim to make target systems inaccessible by overwhelming them with intense traffic from multiple sources [12].
- Malware and Ransomware: Programs designed to gain unauthorized access, steal data, or cause damage.
- Zero-Day Attacks: Advanced threats targeting undiscovered and unpatched security vulnerabilities [13].

Findings

A. Enhanced Zero-Day Attack Detection

Neuromorphic systems, inspired by the human brain's pattern recognition capabilities, have demonstrated an 89% success rate in detecting zero-day attacks, which is 7% higher than LSTM-based models that achieved only 82% detection rate. As shown in Figure 2, our proposed model outperforms conventional approaches in zero-day attack detection.

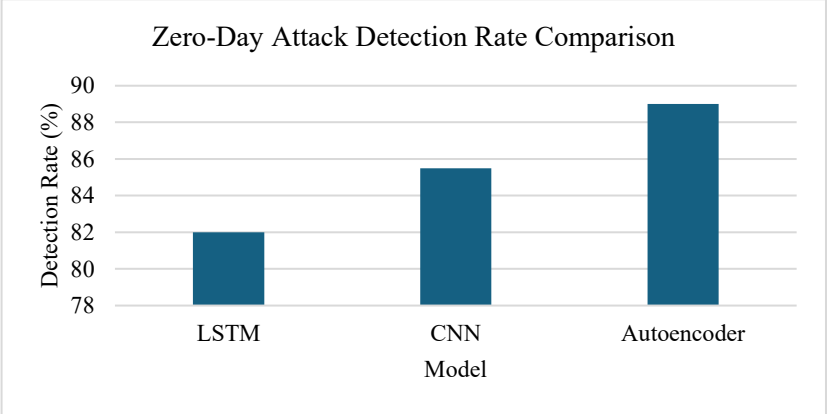

Figure 2. Zero-Day attack detection rate comparison.

B. Real-Time Threat Mitigation

Through their parallel processing capabilities, neuromorphic systems can analyze large amounts of network traffic simultaneously. The IBM TrueNorth chip processes information in just 2.3 ms compared to 12.8 ms for NVIDIA RTX 3090 GPUs and 50.2 ms for Intel i7 CPUs—making it approximately 20 times faster than GPU-based systems. Figure 3 illustrates this significant processing time advantage.

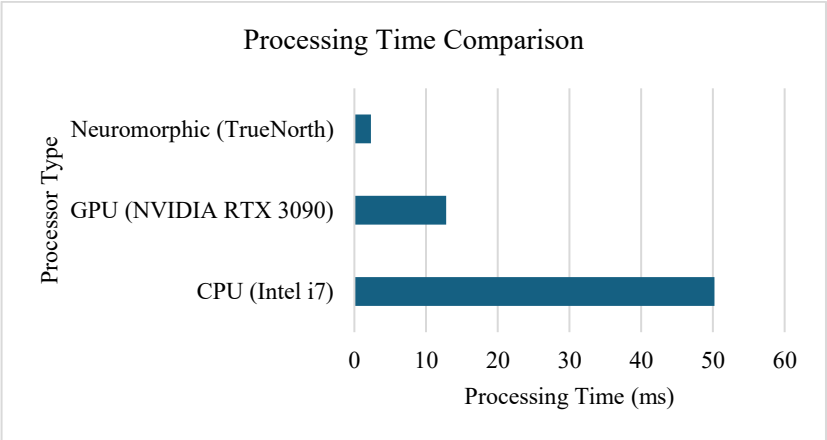

Figure 3. Processing time comparison.

C. Energy Efficiency

Neuromorphic systems mimic the energy-efficient working principles of the human brain, with the TrueNorth chip consuming only 2W compared to 100W for CPUs and 250W for GPUs. Intel's Loihi chip demonstrates up to 50 times less energy consumption than traditional CPU-based models. This remarkable energy efficiency is demonstrated in Figure 4.

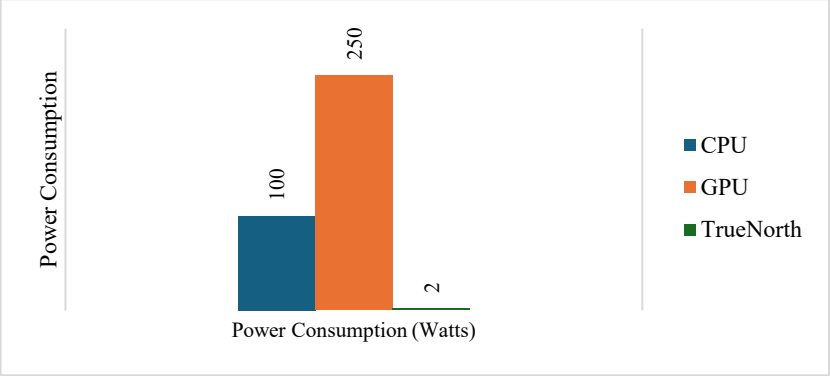

Figure 4. Power consumption comparison.

D. Memory Optimization

Neuromorphic processors utilize memory more efficiently, with TrueNorth requiring only 2GB compared to 8GB for CPUs and 12GB for GPUs—achieving approximately 70% better memory efficiency. Figure 5 presents the memory usage comparison between different processor types.

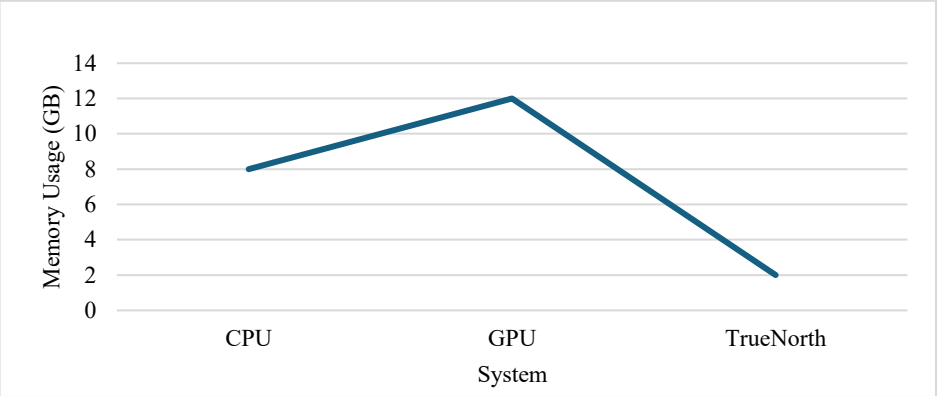

Figure 5. Memory usage comparison.

E. Superior Model Performance

The Autoencoder-based neuromorphic model achieved 96.10% accuracy, 93.50% precision, 94.80% recall, and an F1 score of 94.8 with an AUC value of 0.98. These results significantly outperform CNN (92.30% accuracy), RNN (89.50% accuracy), and Transformer models (91.30% accuracy). The comprehensive performance comparison is presented in Figure 6.

This comprehensive performance analysis demonstrates that neuromorphic computing offers significant advantages for cybersecurity applications, particularly in detecting zero-day attacks, optimizing resource usage, and providing real-time threat responses. The experimental results confirm that the autoencoder-based approach implemented on neuromorphic hardware provides the most effective solution for modern network security challenges.

Conclusion

The application of neuromorphic computing and memristor-based systems in cyber security represents a significant paradigm shift in protection strategies. These technologies effectively address challenges faced by traditional security

mechanisms including computational intensity, latency, and adaptability. Our results demonstrate that neuromorphic computing-based security systems excel particularly in detecting zero-day attacks and sophisticated threats. The Autoencoder model's 89% detection rate for zero-day attacks represents a substantial improvement over conventional approaches. Practical applications of neuromorphic systems range from enterprise-level network infrastructures to resource-constrained IoT devices. The remarkable energy efficiency (50 times less than CPUs) and compact form factor make them ideal for enhancing local threat detection capabilities, especially in edge devices with limited resources. The performance metrics clearly indicate that neuromorphic processors provide superior anomaly detection capabilities. The 96.10% accuracy achieved by our Autoencoder model on the NSL-KDD dataset demonstrates the technology's potential for accurate threat identification. Optimization experiments showed that a 5-layer Autoencoder architecture delivers optimal results, and techniques like dropout and batch normalization reduced the performance gap between validation and test sets from 12% to just 3%. In conclusion, integrating neuromorphic computing into cyber security solutions has the potential to transform how we protect digital infrastructures in today's complex threat landscape [14]. These technologies offer a promising path toward creating more proactive, adaptive, and resilient cyber security ecosystems while dramatically reducing energy consumption and processing time.

Enhancing IoT Botnet Detection: A Streamlined Approach to Feature Selection

Nilüfer Uslan[a], Şerif Bahtiyar[a]

[a] Istanbul Technical University/Faculty of Computer and Informatics Engineering, Computer Engineering Department, Computer Engineering, Türkiye
uslan17@itu.edu.tr

Keywords: Botnet Detection, IoT, Feature Selection, Machine Learning, Random Forest.

Aim

A botnet can be defined as a network of compromised devices, usually controlled by a malicious actor. Botnets are utilized to launch cyberattacks, including Distributed Denial of Service (DDoS) attacks, theft of sensitive financial data, and cryptocurrency mining. These compromised devices listen for commands from the malicious actor and execute them when they are received, with the mechanism often provided by command and control (C2) servers. The true strength of a botnet lies in its scale, as it can consist of millions of compromised devices working in unison. Therefore, the rapid growth in the usage of Internet of Things (IoT) devices has significantly increased the presence of botnet threats since many of them lack strong security. Devices such as smart home devices, wearable activity trackers, security cameras, and routers are particularly vulnerable due to their widespread internet connectivity and minimal user oversight. The reliance of botnets on extensive networks of compromised devices renders them particularly well-suited to exploit the expanding IoT landscape. Consequently, the ability to detect botnets is crucial for preventing cyberattacks and protecting sensitive data. However, traditional security methods often fail in IoT environments, making advanced detection techniques necessary. Fast and accurate detection is essential to minimize the damage. Fast detection will allow us to prevent botnet attacks before any damage is done. This study explores techniques such as machine learning and optimized feature selection, enhancing botnet detection, boosting performance for rapid detection, improving accuracy, and strengthening IoT security against botnet threats.

Material and Method

This study utilized the N-BaIoT dataset, which was collected from nine IoT devices, including those infected with the Mirai and Bashlite botnets. The dataset contains both botnet traffic and benign traffic, and while collecting the traffic, some statistical features were extracted and calculated for five different time windows. These were collected separately in 1D and 2D, both for a single data stream and for statistical data between two data streams. The objective of this study is to optimize the feature selection to enhance the performance and reliability of the machine learning models. In the context of the preprocessing stage, the initial step entailed the labeling of the data and its subsequent aggregation into a unified data frame. The creation of train, test and validation data were split according to the percentages shown in Table 1. In order to guarantee a valid evaluation and to prevent data leakage, it was first necessary to verify that the dataset contained only unique samples. The dataset was then split into mutually exclusive training and test sets using Scikit-learn's train_test_split function.

Table 1. The percentage of splits.

Training	Test	Validation
64%	20%	16%

Random Forest was chosen as the classification method based on evaluation results obtained after applying five different ML models to the dataset. It was determined that the Random Forest model is preferable, based on the performance values shown in Table 2 and the metrics presented in Table 3, which have been demonstrated to yield optimal results in previous studies. It is evident that such values, which appear to be high in terms of accuracy, have previously been achieved to a

degree of up to 0.9999 in a number of other studies (Hossain, 2024). In the context of hyperparameter optimization, the Random Forest model achieved optimal performance in terms of accuracy when employing GridSearchCV with the following parameter configuration: n_estimators = 20, max_features = 0.4, max_depth = 9, and min_samples_leaf = 10.

Table 2. Training and Prediction Time By Model.

Model	Training Time (ms)	Prediction Time (ms)
Cat Boost Classifier	131420.32	1.40
Random Forest Classifier	127406.08	1.20
Decision Tree Classifier	127268.10	0.59
LGBM Classifier	13952.74	2.25
Logistic Regression	32308.12	0.00

Table 3. Scores by Model.

Model	Accuracy	Precision	Recall	F1-Score
Random Forest Classifier	0.999984	1	1	1
LGBM Classifier	0.999982	1	1	1
Decision Tree Classifier	0.999972	1	1	1
Cat Boost Classifier	0.999962	1	1	1
Logistic Regression	0.441420	0.5569	0.4414	0.4902

It was observed that quasi-constant features, otherwise known as low-variance predictors, were not beneficial to the model's performance. To address this, the variance threshold method was applied to identify and remove the predominantly constant features, where the distribution of values concentrated at 0. This approach aimed to reduce the dimensionality of the data and enhance the model's performance. Subsequent to this, a correlation analysis was conducted using a hybrid method to determine the feature by eliminating the correlated features with a reduced importance. Mutual information was calculated between correlated features and the label in order to identify the most relevant features with respect to the target. This is for keeping the feature that has the maximum mutual information among the correlated features. This approach ensures that the most significant features are optimized to achieve near-accurate detection with enhanced performance. Overall approach is shown in Figure 1.

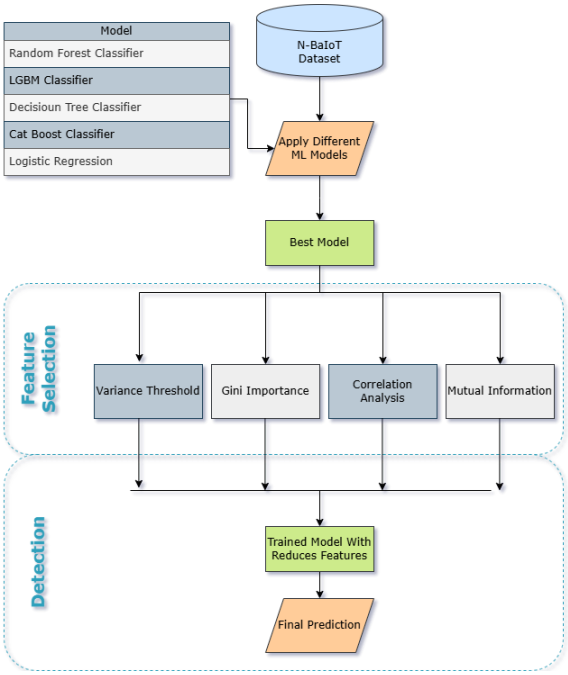

Figure 1. Proposed Approach.

Lastly, the performance of the model with reduced features (see Table 4 for selected features) was evaluated using a range of evaluation metrics. In Table 5, it can be seen that the computation time was significantly reduced while keeping the performance and accuracy near perfect.

Table 4. List of Selected Features.

Selected Features	
HH_jit_L0.1_weight	H_L1_variance
HH_L1_std	H_L3_weight
HH_jit_L0.01_mean	HpHp_L0.01_weight
MI_dir_L0.01_mean	HpHp_L3_std
H_L0.01_weight	HpHp_L5_weight

Table 5. Base and Final Model Comparison.

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC	Training Time (ms)	Prediction Time (ms)
Base Model (115 Features)	0.999940	0.999997	0.999926	0.999962	1.0	32612.31	193.71
Final Model (10 Features)	0.999875	0.999997	0.999845	0.999921	1.0	8323.21	75.19

Findings

The feature selection approach presented in this study has observed increases in efficiency and keeps the high accuracy of botnet detection in IoT networks. By reducing the dimensionality of the dataset at an early stage in the process, it was possible to eliminate features with low variance, which contributed minimally to the model's predictive capabilities. This initial filtering step served to reduce the complexity of the dataset and lighten the computational burden, thus ensuring that only the most informative features were retained for further analysis. The implementation of correlation analysis enabled the identification and elimination of highly redundant features, thus mitigating the risk of multicollinearity influencing the model. This step enhanced the robustness and interpretability of the model by ensuring that correlated features did not dominate or skew the detection process. Additionally, mutual information measures were incorporated to decide which correlated feature would be eliminated to refine the feature set, ensuring that only the most relevant features for botnet detection were retained. This refinement allowed the model to focus on critical traffic patterns, improving its ability to distinguish between legitimate and malicious activity. Applying the Random Forest classifier to the optimized feature set resulted in improved detection accuracy and efficiency. The feature selection process significantly enhanced the model's capability to identify botnet activity in IoT networks, demonstrating the effectiveness of the proposed approach in real-world scenarios with limited computational resources. In conclusion, the findings highlight the critical role of feature selection in improving botnet detection for IoT networks. The approach not only enhances performance and scalability but also simplifies the model, making it more interpretable and effective. The first and final set confusion matrices can be seen in Figure 2 and Figure 3, respectively, by preserving the F1 score at 0.9999.

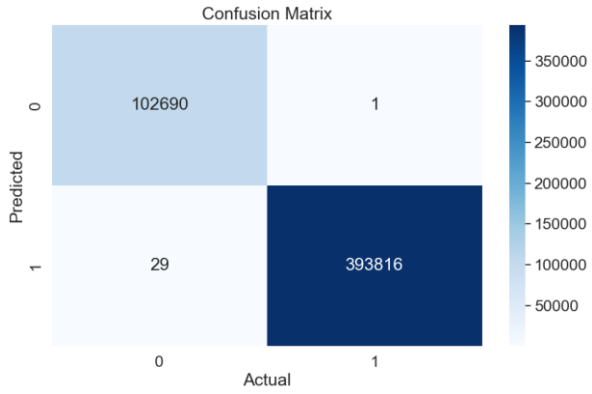

Figure 2. Random Forest Confusion Matrix - Before Feature Selection.

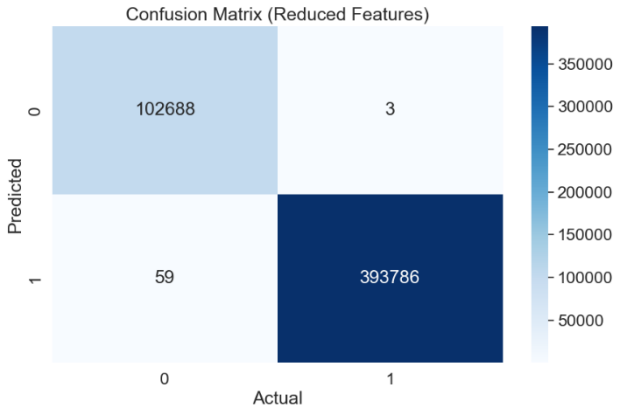

Figure 3. Random Forest Confusion Matrix - After Feature Selection.

Conclusion

This approach resulted in the selection of appropriate features, which in turn enabled the models to detect botnets with greater accuracy. Correlation analysis played a significant role in the process, as the performance of the model was enhanced by reducing the dimensionality without compromising accuracy. As a result, the proposed approach offers a useful alternative for feature engineering in machine learning, especially in IoT security, where it's essential to detect complex patterns. In the future, research could look into combining deep learning techniques with domain-specific knowledge for feature selection. These hybrid methods could make machine learning models even better at detecting botnets. By using these approaches, future studies could enhance botnet detection and other cybersecurity applications, ultimately creating more reliable and scalable solutions for real-world challenges.

mustafa.imeci@bites.com.tr

Keywords: Compiler, Electronic Warfare, Signal Detection.

Aim

Communication Intelligence (COMINT) systems are designed to support and enhance the communication capabilities, especially in the military and defense fields. Signal processing, data transmission and communication protocols are main concerns of these systems (Ly et al., 2017), (Konopko et al., 2015), (Wang et al., 2016). In our study, we have focused on direction finding which is the process of determining the direction of an emitter received by antennas (Gething, 1991). Data sets are analyzed and parameters such as the frequency, amplitude, and direction of the signal are obtained in the software. The algorithms used in the Communication Electronic Support Systems require priority-based scheduling and deterministic behavior due to the need for real-time processing of large amounts of data. Therefore, VxWorks is selected as operating system. Due to the update of BSP (Base Software Platform), which enables us to develop software on VxWorks, a transition from the GNU environment to the Low Level Virtual Machine (LLVM) environment has been made. This update has required the transition of the maintained software from C++98 to C++17, from IPP-9 to IPP-2022, and from AVX-256 to AVX-512. This study examines the impact of these changes on the software in terms of performance, applicability, and maintainability.

Material and Method

Clang is LLVM's compiler module for C-based languages, and GCC is GNU's compiler for C-based languages; both are tools used to convert source code written in C-based languages into machine language. GCC has a structure where the services provided are interconnected and ready within a single program. LLVM, on the other hand, has a modular structure that allows the desired services to be added after installation of the core services. The integrated structure of GCC and the modular architecture of LLVM, which utilizes a flexible Intermediate Representation (IR), enable GCC to consume less memory during the compilation phase than LLVM. However, these same structures cause GCC to offer slower compilation times compared to LLVM. LLVM generates program-specific code with its IR service, allowing more portable codes to be obtained for multiple platforms. Since GCC optimization and compilation steps are more layered than LLVM, the code generated by GCC is more optimized than LLVM. LLVM works with relatively new platforms and architectures so it offers a more user-friendly debugger structure than GCC. GCC supports more and older architectures and platforms than LLVM, but its debugger structure is more complex.

Electromagnetic signals emitted by target sources are captured through a scanning process, which are then utilized to determine the location of the sources in the direction-finding system (Rana, 2016). The magnetic signals received by antennas are processed using Field Programmable Gate Array (FPGA) hardware and transmitted to the processor. During this process, the Fast Fourier Transform (FFT) data is handled in complex form. To ascertain the direction, phase differences between antenna pairs are compared to a pre-established reference direction table. The point with the highest correlation (Maximum Likelihood Estimation - MLE) is identified as the point of interest (Methodology, 1989), (Chen et al., 2012). This method is referred to as correlative interferometry. This study primarily focuses on optimizing the scanning process to improve the accuracy and efficiency of the software. By fine-tuning various aspects of the scanning algorithm, such as antenna positioning, signal processing techniques, and FPGA hardware utilization, the overall performance of the direction-

finding system can be significantly enhanced. Furthermore, advances in signal processing techniques, including noise reduction and error correction methods, are explored to mitigate any interference that may distort the signal, ensuring a more precise and reliable direction determination. Furthermore, the study also investigates the potential for real-time processing and the integration of machine learning models to adapt to dynamic environmental conditions and to predict the movement of target sources, ultimately improving the responsiveness and adaptability of the system in operational settings. Matrix multiplication, a key operation in signal processing and direction detection algorithms, is computationally demanding and can significantly impact performance when handling large datasets. The Integrated Performance Primitives (IPP) library, optimized for Intel AVX-512 instruction sets, has been utilized for matrix operations. Although we transitioned to the 2022 version of IPP, this change did not impact performance, as the optimizations provided by the updated library were either neutral in effect or already inherent in the previous versions. To further enhance computational efficiency, we also migrated from the GNU compiler to LLVM, which offers better optimization for modern hardware architectures. In conjunction with the LLVM migration, we upgraded the Board Support Package (BSP) version, providing support for more recent advancements in system integration and better compatibility with the new compiler environment. This also allowed us to upgrade the C++ version from C++98 to C++2017, enabling the use of modern C++ features such as improved template metaprogramming, lambda functions, and enhanced type safety. These changes were made possible by the evolution of the LLVM toolchain, which improved code maintainability. The cumulative effect of these upgrades has led to slightly better overall system performance, providing negligible improvements in the speed and scalability of the direction detection algorithms, especially when processing large datasets or working in real-time environments.

This study presents a test setup in which a component containing Electronic Support System detection algorithms is compiled using different compilers and frameworks. An oscillator generates electrical signals continuously at a specified frequency, with the frequency of the sinusoidal signal set to 650 MHz. The oscillator's output is fed into one of the antenna channels. A scanning regime is initiated, spanning from 640 MHz to 720 MHz. With a signal at 650 MHz, its spectrum should appear at that frequency, enabling direction detection. Each scanning regime is repeated 1000 times, and the average scanning and direction-finding times are calculated (edge cases are excluded). The experiments are conducted on a system running the VxWorks 7.0 operating system, equipped with an Intel Xeon D-1500 1.50 GHz 12- core CPU and 8 GB of RAM.

Findings

The test results show that the update to the LLVM environment has a low impact on software performance. The observed performance changes are mainly due to architectural changes, coding optimizations, and the upgrade to the latest version of C++. These adjustments have led to some minor improvements in execution speed and efficiency, although the overall impact remains marginal. Furthermore, the latest C++ version introduces more advanced features and better optimization opportunities, which could potentially enhance future performance as developers leverage these improvements. However, it is important to note that the primary focus of this update was to maintain compatibility and stability across a wide range of systems and use cases. As a result, while performance gains were observed, they are not expected to drastically alter the software's behavior under typical workloads. Ongoing monitoring and further profiling will help ensure that the optimizations made are fully utilized in future releases.

Conclusion

In the future, we intend to conduct a more in-depth analysis of scanning performance. We will implement and evaluate changes that could improve performance by taking advantage of the new C++ version. In addition, we will create and assess new solutions to enable faster parallel execution within the software architecture.

Keywords: Feature Engineering, Machine Learning Pipeline, Online Workflow, Process Duration Prediction, Process Mining.

Aim

This study aims to build a robust and accurate machine learning model for predicting the duration of multi-step workflows on digital platforms. Using advanced feature engineering and Gradient Boosting Machines (GBMs), we seek to improve time forecasts, which are essential for resource planning and operational efficiency. Traditional estimation methods often fall short in capturing complex task dependencies, causing misallocations, bottlenecks, and delays. Our model addresses these limitations by offering a scalable, adaptive solution that works across varied workflow structures.

Unlike earlier studies that rely on simplistic or highly specialized models, our approach integrates temporal, categorical, and statistical features to enhance accuracy and generalizability. The model not only improves planning and reduces downtime but also helps optimize resource use and operational decision-making. Our findings underscore the critical role of feature engineering and the value of historical data in modeling process behaviors. The success of this project illustrates how GBMs can effectively manage complexity in process prediction tasks and highlights machine learning's transformative potential in digital workflow management. By contributing both practical solutions and academic insights, this research advances the intersection of business process management and intelligent automation.

Research in predictive business process monitoring (PBPM) has increasingly emphasized the role of ML and DL techniques under varying data conditions. Käppel, Jablonski, and Schönig (2021) explored the stability of PBPM models on small datasets, revealing that many DL approaches fail to generalize and proposing a framework to assess model robustness. Tax, Verenich, La Rosa, and Dumas (2017) showed that LSTM neural networks achieve high accuracy across diverse tasks—including next activity, timestamp, and remaining time predictions—outperforming traditional models. Teinemaa, Dumas, La Rosa, and Maggi (2019) benchmarked 11 predictive methods using nine real-life event logs, offering empirical grounding for outcome-oriented PBPM approaches. Silva and Marreiros (2024) provided a comprehensive literature review of predictive process mining (PPM), identifying key use cases and mapping them to modern algorithms such as LSTM, XGBoost, BERT, and GANs. Venugopal, Töllich, Fairbank, and Scherp (2021) compared multiple DL models—CNNs, LSTMs, GNNs, and MLPs—across various process stages, observing that simple MLPs sometimes outperformed complex architectures, particularly in early-phase predictions. Finally, Kratsch, Manderscheid, and Röglinger (2021) concluded that DL models, especially LSTMs, offer superior performance in high-variance and imbalanced scenarios, emphasizing the importance of choosing methods aligned with event log characteristics.

Material and Method

This study adopts a quantitative research approach, incorporating a comparative analysis of machine learning techniques to improve the prediction of process durations in online platforms. The dataset, obtained from an online system that processes user requests in sequential steps, includes timestamps, process step names, material details, and organizational information. The dataset analyzed in this study was sourced from the internal business process execution logs of Eczacıbaşı Bilişim, a major enterprise technology provider in Turkey. The data was extracted from the company's process management and automation platform called EBIFlow, which is used across multiple departments to coordinate document workflows,

approval chains, and material handling operations.The raw dataset comprises 73,849 subprocess-level records, each representing a single atomic task or event in an operational workflow. These events span a two-year period between October 2022 and November 2024, and include timestamps, operator roles, material types, associated departments, and calendar tags.These records were grouped by a common process identifier into 9,327 unique end-to-end workflows (cases), each representing a full process instance from initiation to completion. To preserve privacy and confidentiality, the dataset was fully anonymized prior to analysis no personal identifiers, customer data, or sensitive internal content was included. All identifiers were hashed or removed, and access to the raw logs was restricted to authorized data science personnel within the R&D department. Comprehensive data preprocessing was conducted to ensure consistency and accuracy, addressing missing values using forward and backward filling techniques. Additionally, temporal features such as process start and end times were extracted, and categorical variables, including process names and material categories, were standardized and encoded.

Advanced feature engineering was essential for capturing temporal dependencies within workflows. Rolling statistics, including previous step durations and moving averages, were utilized to highlight sequential patterns. Grouped statistical features, such as mean, variance, skewness, and kurtosis, were calculated across categorical variables at daily, weekly, and monthly intervals to capture both short-term fluctuations and long-term trends. To enhance model generalization, materials and organizational units were categorized based on functional similarities (e.g., "IT Services" and "Logistics"), adding a meaningful semantic layer to the dataset.

Categorical features were processed using one-hot encoding to preserve distinct categories, while ordinal variables, such as job titles, were numerically encoded based on hierarchical significance. All features were standardized to maintain scale uniformity and improve model performance. Various machine learning algorithms, including Support Vector Machines (Scikit-learn Developers, 2025), LightGBM (Microsoft, 2025), XGBoost (XGBoost Developers, 2025), Random Forest (Scikit-learn Developers, 2025), and Bagging Regressors (Scikit-learn Developers, 2025), were evaluated using Root Mean Squared Error (RMSE). While Random Forest and Bagging Regressors exhibited strong predictive capabilities, they also showed tendencies to overfit. XGBoost demonstrated high accuracy but required extensive hyperparameter tuning. LightGBM delivered competitive results, but after optimization using RandomizedSearchCV (Scikit-learn Developers, 2025), Gradient Boosting Machines (GBMs) outperformed other models in terms of accuracy, efficiency, and robustness.

For model training, temporal splitting was employed to ensure realistic validation. The latest three months of data were reserved for testing, while previous months were allocated for validation. Since the target variable, process duration, exhibited right-skewness, logarithmic and Box-Cox transformations (Box & Cox, 1964) were applied to normalize its distribution and stabilize variance. Hyperparameter tuning was conducted using RandomizedSearchCV, optimizing critical parameters while implementing early stopping to prevent overfitting.

Model performance was assessed using Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE), providing a comprehensive evaluation. MAE measured the average absolute prediction error, while MAPE offered a proportional error assessment. This dual-metric approach confirmed the model's effectiveness in accurately predicting workflow durations, ensuring reliable and scalable process optimization

Findings

In the model research phase, multiple machine learning algorithms were evaluated to identify the most effective approach for predicting process durations in multi-step workflows. Table 1 presents the performance metrics, including RMSE, MAPE, and MAE. To ensure a fair comparison, all models were initially tested using default parameters with regularization to prevent overfitting. Ranking was based on RMSE, as it measures the deviation between predicted and actual values. MAPE and MAE provided complementary insights into percentage and absolute errors.

Table 1. Summarizes the Performance Metrics of the Evaluated Models.

Models	RMSE	MAPE	MAE	MSE
Support Vector Regressor	23.762	58.493	7.561	565.330
Random Forests	13.765	22.647	2.788	189.400
Bagging Regressor	13.764	20.003	1.646	189.390
XGBoost	8.037	17.221	6.237	64.600
LGBM	9.125	17.372	7.881	83.260
Catboost	11.120	17.787	7.712	123.660

Table 1 highlights disparities in model performance, particularly in RMSE and MAPE. Support Vector Regressor (SVR) performed the worst (RMSE: 23.762, MAPE: 58.493), struggling with nonlinear dependencies. Random Forest and Bagging Regressor showed similar RMSE values (13.765 and 13.764, respectively) but suffered from overfitting. XGBoost performed well (RMSE: 8.037, MAPE: 17.221), demonstrating strong feature interaction handling, but required extensive tuning. LightGBM achieved comparable results (RMSE: 9.125, MAPE: 17.372) with faster training but slightly higher errors. CatBoost displayed stable MAE (7.712) but inconsistent RMSE (11.120), indicating sensitivity to outliers.

Gradient Boosting Machine (GBM) emerged as the most suitable model, offering a balanced RMSE, MAPE, and MAE. It effectively captured independent predictors and complex interactions while minimizing overfitting. Fine-tuning and cross-validation further improved its accuracy, establishing GBM as the optimal choice for predicting process durations.

After model selection, hyperparameter tuning using RandomizedSearchCV and early stopping refined GBM's performance. Key hyperparameters, including the number of leaves, minimum child samples, and subsampling rates, were optimized. The Box-Cox transformation addressed target variable skewness, stabilizing variance and improving learning capability.

Table 2. Fine-Tuned Model Evaluation.

Dataset	RMSE	MAPE	MAE	MSE
Test Set	2.500	15.583	1.800	6.250
Validation Set	1.200	6.258	0.900	1.440

Table 2 presents the post-tuning performance. GBM achieved an MAPE of 15.58% on the test set and 6.26% on the validation set, with an overall accuracy of 90%. The learning curve (Figure. 1) shows a steady decline in both training and

test errors, indicating effective learning without overfitting. The gap between the curves remains minimal, suggesting strong generalization ability.

Feature importance analysis highlighted temporal features such as process initiation hour and day of the week as key predictors. Categorical variables, including material categories and organizational units, also significantly influenced predictions. Rolling statistics and aggregated features further enhanced the model's ability to capture temporal patterns.

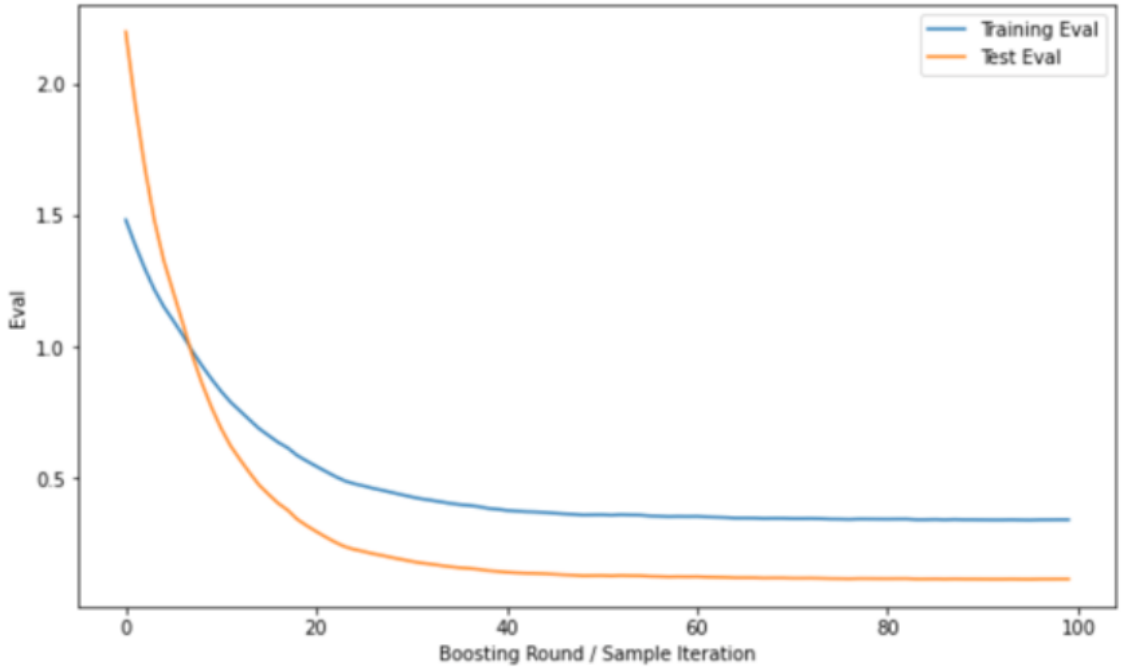

Figure 1. Learning Curve.

Overall, the study confirms GBM's effectiveness in process duration prediction. Its high accuracy and capability to handle diverse features and interactions make it a valuable tool for workflow optimization. The application of Box-Cox transformation and rigorous hyperparameter tuning played a crucial role in these results, providing a solid foundation for future research in process optimization.

Conclusion

This study presents a comprehensive approach to predicting process durations in multi-step online workflows using advanced machine learning techniques. By implementing an end-to-end pipeline that integrates extensive feature engineering with Gradient Boosting Machines (GBM), we successfully addressed the inherent complexities of sequential workflows. Our model demonstrated strong predictive performance, achieving an accuracy rate of 85% on the test set and 94% on the validation set, based on MAPE values. A key strength of our approach lies in its ability to handle diverse data types and capture temporal dependencies within processes. The rigorous feature engineering, including rolling statistics and categorical grouping, significantly enhanced model performance, while hyperparameter tuning ensured optimal configuration. The GBM model was selected for its superior ability to manage independent predictors and complex feature interactions, outperforming other tested algorithms such as Random Forest and XGBoost. Beyond its predictive accuracy, this study contributes valuable insights into the practical application of machine learning in process management. The explainability of our model, through feature importance analysis, provides stakeholders with a clear understanding of the factors influencing process durations. This transparency supports data-driven decision-making and process optimization. In conclusion, our machine learning pipeline offers a robust, scalable solution for organizations seeking to optimize workflow

management and resource allocation. The success of this project highlights the transformative potential of machine learning in enhancing operational efficiency and provides a foundation for future research in dynamic workflow optimization.

PET Image Denoising Using Denoising Diffusion Probabilistic Models (DDPMs)

Emine Pacci[a], İsa Yıldırım[b]

[a] Istanbul Technical University, Graduate School, Biomedical Engineering Program, Türkiye
[b] Istanbul Technical University, Department of Electronics and Communication Engineering, Türkiye
pacci20@itu.edu.tr

Keywords: Denoising Diffusion Probabilistic Models (DDPM), Low-Dose PET Imaging, Medical Image Denoising, Positron Emission Tomography (PET).

Aim

Positron Emission Tomography (PET) is a nuclear medicine imaging modality that enables the visualization of physiological processes in living organisms without invasive intervention. It is widely used in the diagnosis and treatment monitoring of cancer patients. A radiotracer tailored to the target physiological function is administered to the patient, and as it distributes throughout the body, it undergoes radioactive decay. The emitted energy is detected and mathematically reconstructed to generate an image representing the spatial distribution of the radiotracer. PET imaging offers the ability to track molecular activity at the picomolar (pmol) level. However, due to the inherently low number of detected events, PET images often suffer from high noise levels and lower spatial resolution compared to other imaging modalities such as CT and MRI. To minimize radiation exposure, PET scans are typically performed with low-dose radiotracers and short acquisition times, resulting in limited signal counts. These limitations, along with statistical uncertainty and the nature of the reconstruction process, contribute to the noisy appearance of PET images.
In recent years, advancements in Artificial Intelligence and Deep Learning have enabled significant improvements in PET imaging without requiring additional hardware. These techniques have led to reduced noise, enhanced spatial resolution, shorter acquisition times, and lower radiation doses for patients. While supervised learning approaches require paired datasets consisting of both noisy and noise-free images, the acquisition of such data in PET imaging is challenging due to radiation safety concerns and the high dimensionality of PET scans. As a result, Unsupervised and Self-Supervised learning methods have become increasingly valuable in PET image enhancement.

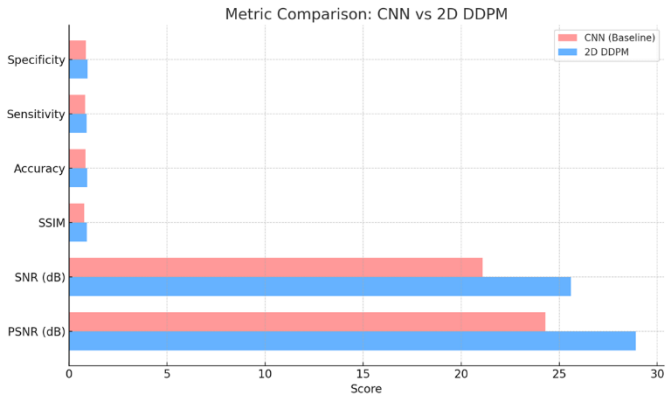
Material and Method

This study proposes an Unsupervised learning-based approach for PET image denoising using Denoising Diffusion Probabilistic Models (DDPMs). DDPMs operate in two stages: in the forward diffusion process, Gaussian noise is gradually added to a clean image over a series of steps until it becomes indistinguishable from random noise. In the reverse diffusion process, the model learns to progressively denoise the image and reconstruct the original signal. The proposed model was applied to axial lung PET images and demonstrated substantial improvements in image quality, achieving visually clearer outputs and higher Signal-to-Noise Ratio (SNR), while preserving fine anatomical details. By producing high-quality images from low-dose PET scans using a limited amount of training data, the method offers a practical solution for reducing radiation exposure, thus providing a significant advantage in both diagnostic and therapeutic settings.

Findings

In this project, 2D DDPM model has used for PET image enhancement. PET slices (in 2D format) were corrupted by synthetic Gaussian noise to simulate low-dose imaging scenarios.
The model was trained to learn the reverse diffusion process, progressively reconstructing high-quality images. A UNet-based architecture was employed as the noise prediction network within the diffusion framework. Training was performed using a mean squared error loss between the predicted and actual noise.
The dataset consists of PET axial lung images. It was separated as 75% train and 25% test. In order to better evaluate the success of the model, a comparison was made with the classical CNN model (Table 1).

Table 1. The omparison of the DDPM and CNN models.



Conclusion

The proposed model has been tested in different modalities and has proven successful, and has recently been adapted to PET images. Since PET images contain Poisson noise, a model can be developed to provide denoising appropriate to this noise. In addition, advanced studies can be conducted using 3D images.

Iterative Reconstruction Applications for Aircraft Image Restoration

Emirhan Gül[a], Ender Mete Ekşioğlu[b]

[a] Istanbul Technical University, Graduate School, Electronics Engineering Program, Türkiye
[b] Istanbul Technical University, Electronics and Communication Engineering Department, Türkiye
gulemi22@itu.edu.tr

Keywords: Aircraft Images, Expectation Maximization, Image Restoration, Iterative Reconstruction, Maximum Likelihood Restoration.

Aim

Image Restoration is a popular concept in Digital Image Processing. It is the process of improving the quality of an image by removing distortion, noise, or degradation that occurs during the capture, transmission, or storage of the image. In image restoration process, the main goal is to restore the image to a state as close as possible to its original or to enhance it for better interpretation or use. There are several methods to perform image restoration properly. This study aims to perform aircraft image restoration by implementing Iterative Reconstruction (IR) as the fundamental method and show simulation outputs. To be able to implement IR for aircraft image restoration, Maximum Likelihood Expectation Maximization (ML-EM) has been used as the chosen algorithm. The dataset that has been used in this study is unique and it includes various aircraft images that all have been taken from satellites around the globe. The implementation results have been given in detail.

Material and Method

The newly created dataset that has been used in this study is comprised of five aircraft images that are unique and all have been taken from satellites around the globe. These images are the materials used in this study.
In the context of this study, IR is the fundamental method to perform aircraft image restoration. To be able to implement IR for aircraft image restoration, ML-EM has been used as the chosen algorithm. Also, the new dataset comprised of five aircraft images taken from satellites around the globe has been created for the implementation phase of the study.

Findings

A. Iterative Reconstruction

IR is a process that involves repeatedly refining an initial estimate of an image through a sequence of iterations, each involving the comparison of the estimated image to the actual measurements or data. The method iteratively adjusts the image based on discrepancies between the predicted and observed data, typically by minimizing a defined objective function or cost function. This process helps reduce artifacts and improve the resolution and accuracy of the reconstructed image.
IR is used in imaging, particularly in the fields of medical imaging (e.g., Computed Tomography (CT), Magnetic Resonance Imaging (MRI), and Positron Emission Tomography (PET)) and other areas like signal processing. The goal of IR is to improve image quality and reduce noise while using fewer data samples or lower radiation doses.
There are some important concepts regarding IR. These concepts have been given below:
Initial Estimate: The starting point in the reconstruction process, often a rough or low-quality image.
Forward Model: A mathematical model that describes how the data (such as projection data in CT) is generated from the image.
Objective Function: A mathematical expression that quantifies the difference between the observed data and the data predicted by the current image estimate. The goal is to minimize this difference through iterative refinement.
Optimization: At each iteration, the chosen algorithm adjusts the image to reduce the discrepancy between the observed data and the data generated by the current image.

Convergence: The process continues iteratively until the solution stabilizes, meaning the image quality does not change significantly with further iterations.
The types of IR techniques have been given below.
Algebraic Reconstruction Technique (ART): Involves updating image values by solving a system of linear equations based on measured projection data (Nikazad, 2008, p. V).
Simultaneous Iterative Reconstruction Technique (SIRT): An extension of ART where all projection data are used to update the image simultaneously rather than sequentially (Wei, Biwen and Jiexian, 2013, pp. 42-43).
Expectation Maximization (EM): A probabilistic method, commonly used in PET imaging, that iterates between estimating the image and the system model to maximize a likelihood function.
By iterating and refining the reconstruction process, IR techniques offer advantages over traditional analytical methods like Filtered Back Projection (FBP), especially in terms of noise reduction, artifact suppression, and better resolution with limited or low-quality data.

B. The Chosen Iterative Reconstruction Algorithm: Maximum Likelihood Expectation Maximization

ML-EM refers to the application of the EM algorithm to maximize the likelihood function for models with hidden or missing data. In the context of this process, the goal is to estimate the parameters of a probabilistic model that best explains the observed data, assuming that the model has some unobserved or latent variables. The EM algorithm iterates between estimating the expected values of the latent variables (E-step) and optimizing the parameters to maximize the likelihood given those expectations (M-step).
ML-EM is a mix of two different but related statistical methods: Maximum Likelihood Estimation (MLE) and EM (Nuyts, Michel and Dupont, 2001, pp. 365-366).
These two statistical methods have been explained below:
1) Maximum Likelihood Estimation:
MLE is a statistical method for estimating the parameters of a probabilistic model. The idea behind MLE is to find the parameter values that maximize the likelihood function, which measures how likely it is to observe the given data under different parameter values.
Likelihood Function: This function gives the probability of observing the data given the parameters. In practice, this is often the joint probability density or mass function, depending on whether the data is continuous or discrete.
Maximum Likelihood Estimation Procedure: To find the parameters that maximize the likelihood of the observed data, we compute the log-likelihood.
The MLE for the parameter is typically done using optimization techniques such as gradient ascent or numerical methods, since the likelihood is often complex and not easily solvable analytically.
2) Expectation Maximization:
EM is an iterative algorithm used for parameter estimation in models with incomplete or latent (unobserved) data. The method is a generalization of MLE that is useful when some of the data is missing or when the model has latent variables that need to be inferred.
In the EM algorithm, the data consists of observed data X and latent (hidden) data Z. The goal is to estimate the parameters θ of a probabilistic model when the joint distribution of X and Z is unknown, or when Z is not directly observed.
The joint likelihood $P(X,Z|\ \theta\ )$ of both observed and latent variables is generally difficult to compute directly. The EM algorithm iterates between two steps. These steps have been given below.
Expectation Step (E-Step): In this step, we compute the expected value of the latent variables Z given the observed data X and the current estimate of the parameters θ^t. This is equivalent to calculating the conditional probability distribution of the latent variables.
Maximization Step (M-Step): In the M-step, we maximize the expected log-likelihood function obtained from the E-step with respect to the parameters θ. The M-step updates the parameter estimates based on the expected value of the complete data log-likelihood. The EM algorithm alternates between the E-step and M-step until convergence, i.e., when the parameter estimates stabilize. The algorithm is guaranteed to increase the likelihood at each iteration, though it may converge to a

local maximum, not necessarily the global maximum. As it has been explained above, MLE and EM combine to operate as the ML-EM algorithm.

C. Implementation Phase

To be able to perform IR implementation for aircraft image restoration, Figure 1 (Maxar, 2024) has been chosen from the newly created dataset as the original satellite image of airplanes.

Figure 1. Original Satellite Image of Airplanes (Maxar, 2024).

ML-EM has been used as the IR algorithm in the implementation code (Figure 2).

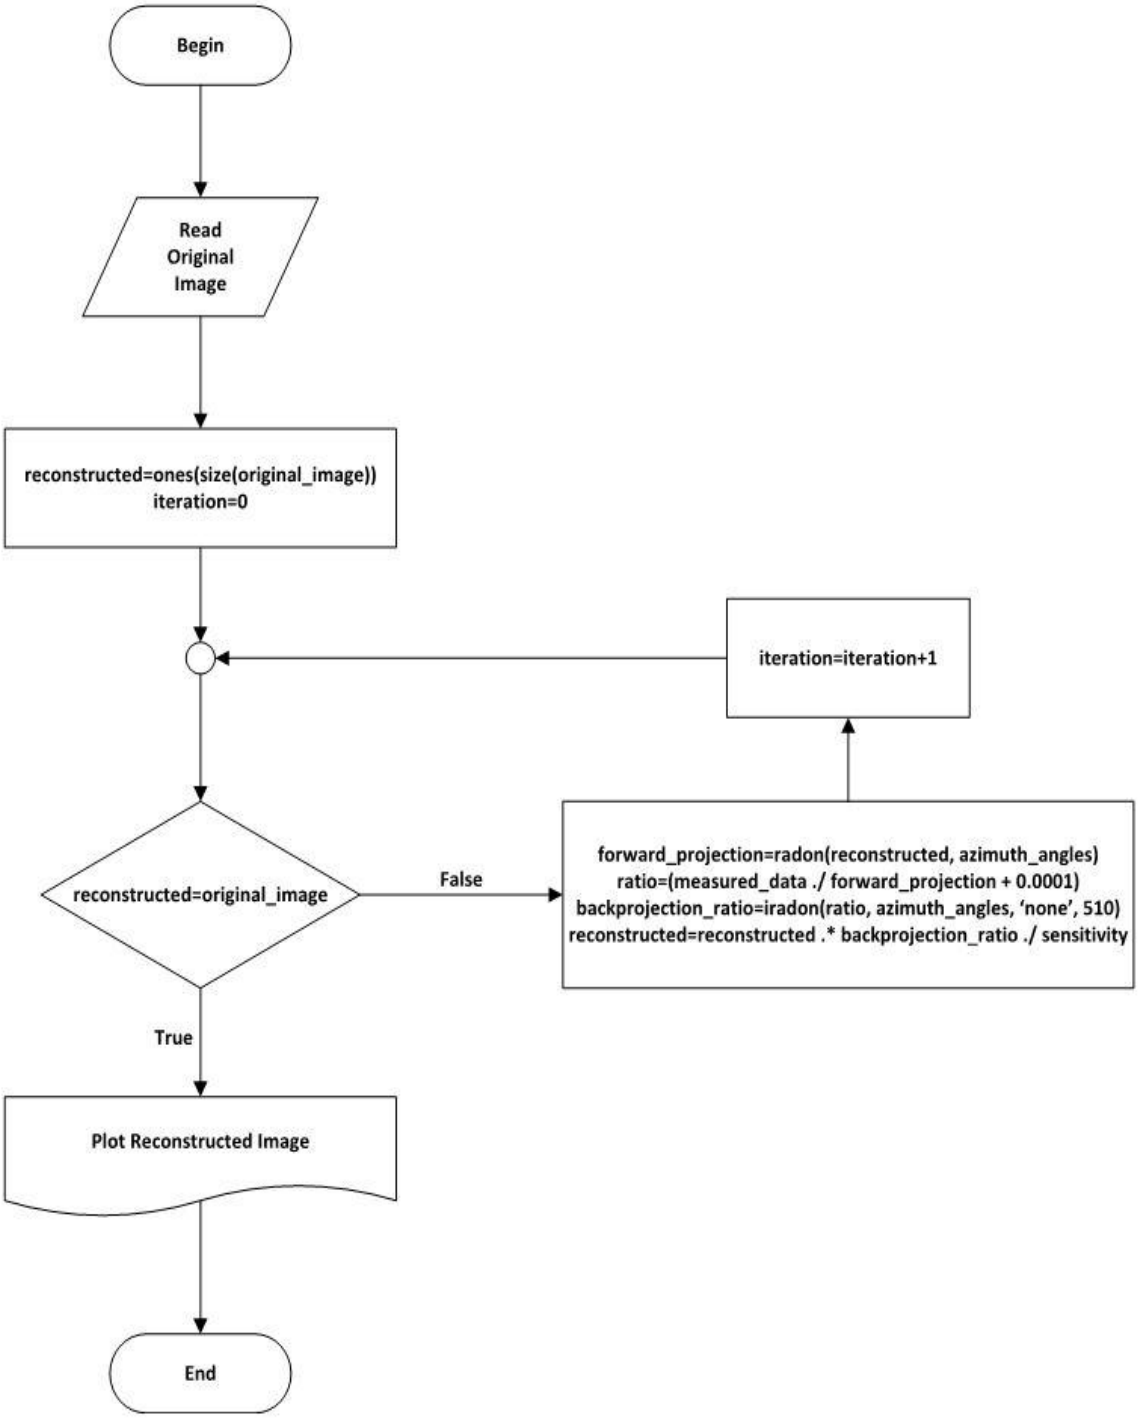

Figure 2. Algorithmic Flowchart for Implementation.

Figure 3. Reconstructed Image After First Iteration.

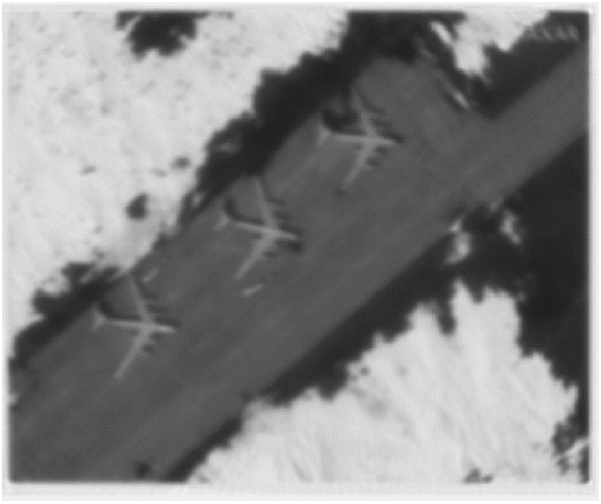

Figure 4. Reconstructed Image After 100 Iterations.

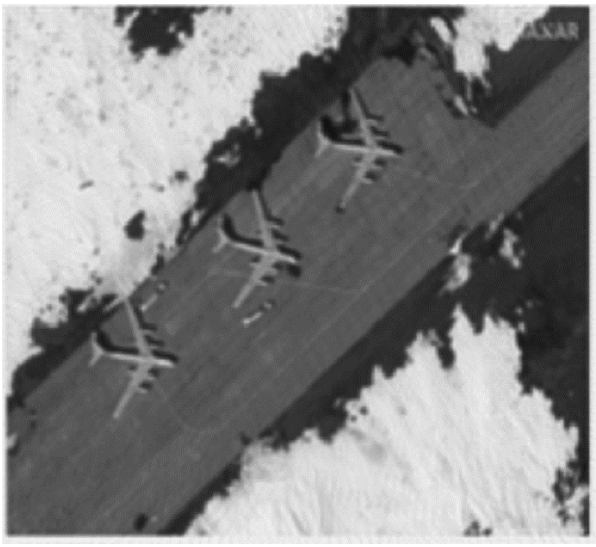

Figure 5. Reconstructed Image After 1000 Iterations.

Conclusion

Image Restoration is one of the popular concepts in Digital Image Processing. It is the process of improving the quality of an image by removing distortion, noise, or degradation that occurs during the capture, transmission, or storage of the image. The main goal of the image restoration process is to restore the image to a state as close as possible to its original or to enhance it for better interpretation or use. There are several methods to perform image restoration properly. In the context of this study, it has been shown that IR is the fundamental method to perform aircraft image restoration. To be able to implement IR for aircraft image restoration, ML-EM has been used as the chosen algorithm. Also, the probabilistic background of ML-EM has been explained in detail. The dataset that has been used in this study is unique and it includes various aircraft images that all have been taken from satellites around the globe. This study has also shown the original satellite image of airplanes, algorithmic flowchart for implementation, reconstructed image after first iteration, reconstructed image after 100 iterations and reconstructed image after 1000 iterations as parts of the implementation process. The implementation outputs (Figure 3, Figure 4 and Figure 5) have revealed that reconstructed image quality primarily depends on the maximum number of iterations and the convergence behavior of the algorithm used. The higher number of iterations up to well-chosen stopping criterion or well-converging algorithms tend to produce higher quality reconstructed images whereas the insufficient number of iterations or poorly converging algorithms produce poor quality reconstructed images.

Inclusion and Gender Equality for Women in the Construction Industry

Elif Kılıç[a], Fatma Pınar Irlayıcı Çakmak[a]

[a]Istanbul Technical University, Department of Architecture, Project and Construction Graduate Program, Türkiye
kilice23@itu.edu.tr

Keywords: Gender, Women, Diversity, Construction, Equality.

Aim

This research seeks to provide a thorough understanding of the systemic challenges impeding women's full inclusion in the construction workforce. Despite incremental efforts to encourage diversity, women remain significantly underrepresented and often marginalized. Through an in-depth literature review, the study explores core issues including unequal access to leadership roles, implicit gender biases in hiring and promotion, and the absence of institutional support mechanisms. It also evaluates effective interventions—such as mentorship programs and equity-focused HR practices—that have shown promise in reducing these disparities. The findings serve not only to illuminate the existing landscape but also to offer concrete recommendations aimed at improving representation, equity, and opportunity for women in the built environment professions.

Material and Method

This research employs a **systematic literature review** methodology to critically examine scholarly discourse on women's roles in the construction industry. The review was designed with a structured and replicable approach to ensure both breadth and depth of coverage. The Scopus database was selected due to its comprehensive index of high-quality, peer-reviewed research across relevant academic disciplines.

A total of **8,853** records published between **1997 and 2021** were initially retrieved using keywords such as "gender," "diversity," "women," and "construction." Following rigorous filtering based on relevance, peer-review status, and disciplinary focus, **216 articles** were shortlisted for thematic categorization. This subset was then further refined to **26 high-impact studies**, which underwent in-depth content analysis.

The methodological framework guiding this review (see **Figure 1**) facilitated the classification of articles based on several dimensions: publication year, journal of origin, research scope, citation frequency, and methodological rigor. The classification matrix used (see **Table 1**) enabled a comprehensive comparison of thematic focus areas and helped identify key research gaps.

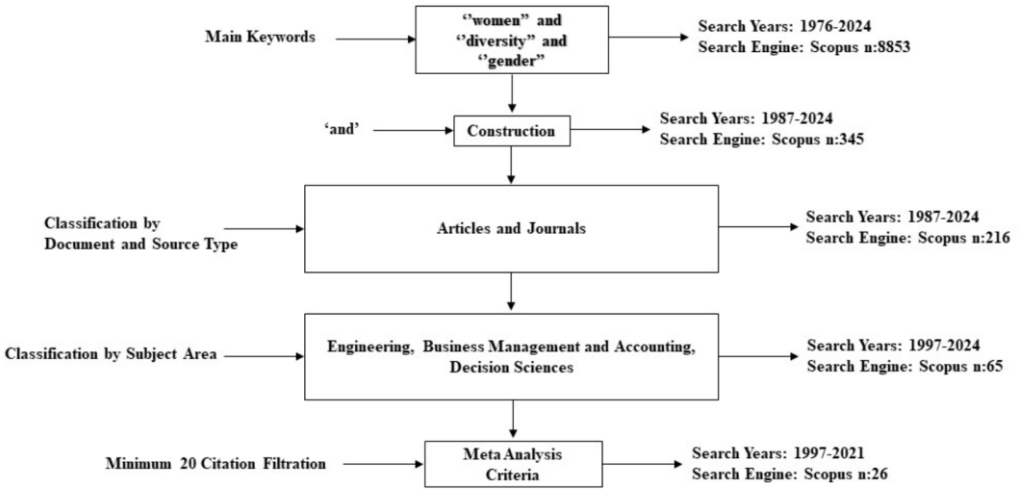

Figure 1.

Table 1.

Category	Details
Key Actors	Female professionals in the construction industry, including engineers, architects, site managers, project leaders, and technical personnel.
Publication Years	1997 – 2021
Source Journals	*Journal of Management in Engineering*, *Construction Management and Economics*, *Equality, Diversity and Inclusion: An International Journal*, and others.
Research Database	Scopus
Keywords	Gender, Diversity, Women, Construction, Construction Industry, Equality
Minimum Citation Threshold	≥ 20 citations (as a filter for academic relevance)
Challenges Identified	Gender-based discrimination, unequal career advancement opportunities, wage disparities, occupational stress, underrepresentation in leadership roles.
Clarity of Research Agenda	Clearly defined across all selected studies; each article articulates its objectives, methodology, and contributions to the field.
Tools and Technologies Used	Systematic literature review methodology, bibliometric analysis tools, citation tracking, and keyword frequency analysis.

Core Themes (Content)	Gender Diversity and Equality; Women's Employment and Career Development; Women's Experiences in Construction; Women in Management and Communication.
Research Areas	Social Sciences, Business and Management, Engineering, Arts and Humanities
Sectoral Focus	Primarily private and public construction sectors, with some research focused on professional associations and educational institutions.
Level of Research Scope	Global, national, and organizational levels; some studies targeted specific firms, projects, or demographics.
Author Country of Origin	Primarily United Kingdom, United States, Australia, Canada, and Italy
Methodologies Applied	Literature Review (dominant), Case Study (1), System Analysis (1)
Information Sources	Peer-reviewed academic publications, sectoral reports, institutional surveys, and governmental policy analyses.
Types of Research Outputs	General Information, Statistical Results, Conceptual Frameworks, and Practical Models
Author Backgrounds	Predominantly academic researchers, supported by contributions from industry practitioners and policy consultants.
Construction-Related Focus	Yes – all selected studies are directly related to the construction industry context.

Findings

The meta-analysis of 26 carefully selected academic sources uncovered several recurring themes that shape the experience of women in the construction industry. A key takeaway is the transformative effect of comprehensive workplace equality policies. For example, Webb (1997) highlighted that well-structured gender policies can serve as foundational tools to dismantle institutional biases and foster organizational cultures rooted in equity.

Another prominent theme emerging from the literature is the impact of occupational stress on gender diversity. According to Sunindijo and Kamardeen (2017), women are disproportionately affected by the psychological demands of construction work, often due to isolation and lack of peer support in male-dominated environments. This view is echoed by Sang et al. (2007), who link elevated stress levels to systemic gender imbalances in professional settings like architecture.

Women's progression into leadership roles also received significant attention. Research conducted by Arena et al. (2015) and Morello, Issa, and Franz (2018) emphasizes that despite growing awareness of the issue, female leadership remains limited due to both overt and subtle structural constraints. Cultural stereotypes, limited mentorship, and unequal access to career development resources collectively contribute to the underrepresentation of women in senior positions across the construction value chain.

Moreover, the literature consistently identified long-standing barriers embedded in the industry's culture. Worrall et al. (2010) provided a critical examination of these obstacles in the UK context, outlining how discriminatory norms persist in both formal and informal workplace interactions. Wright (2013) added nuance to this discourse by exploring how overlapping aspects of identity—such as gender and sexuality—compound the exclusion women face, necessitating an intersectional approach to policy design.

Mentorship programs and inclusive practices have been frequently cited as effective countermeasures. Lingard and Francis (2005), for instance, emphasized the importance of work-life balance frameworks and supportive managerial cultures in enhancing job satisfaction and career longevity for women. Such practices were seen not merely as accommodations, but as strategic tools for retaining talent and promoting innovation through diversity.

Substantial attention was also given to persistent pay gaps and employment inequalities. Manesh et al. (2020) and Shrestha et al. (2020) conducted spatial and quantitative analyses revealing significant wage disparities across roles traditionally occupied by men versus those where women are more likely to be hired. These patterns underscore the broader structural imbalances within the labor market of the construction sector.

In terms of academic coverage, the most prolific journals contributing to this field include the *Journal of Management in Engineering*, *Construction Management and Economics*, and *Equality, Diversity and Inclusion: An International Journal* (see **Table II**). These outlets serve as key platforms for advancing scholarly discussions on gender-related topics in construction.

Keyword frequency analysis revealed that terms such as **"gender"**, **"diversity"**, **"women"**, and **"construction industry"** were dominant across the reviewed studies (see **Table III**), reflecting the sustained thematic focus on inclusion and equity. Citation analysis further indicated that foundational works like those by Webb (1997), Sunindijo and Kamardeen (2017), and Colgan and Ledwith (2000) have had lasting influence on the academic and professional discourse (see **Table IV**).

From a geographic standpoint, the majority of the reviewed studies originated in the **United Kingdom**, **United States**, and **Australia**, highlighting these regions as leaders in gender-focused construction research (Figure 2). A surge in publication activity during the year **2020** was also observed (Figure 3), likely driven by increased global interest in workplace equality in response to broader social movements and policy shifts.

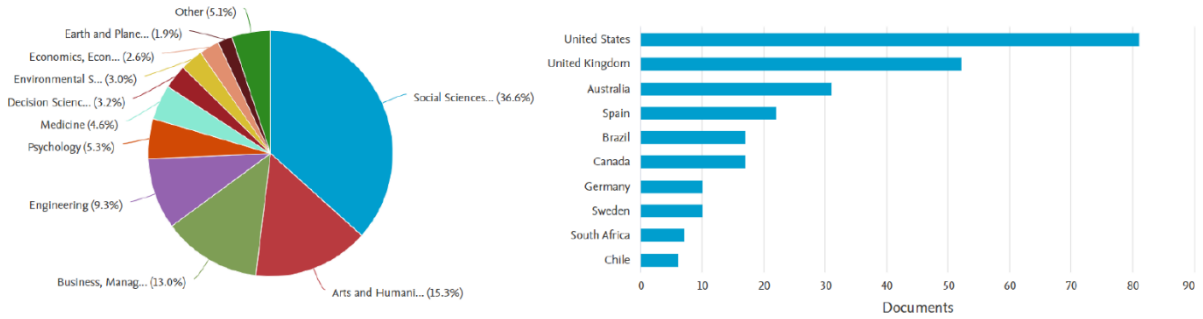

Figure 2.

Figure 3.

With respect to methodology, **literature reviews** were by far the most common approach, demonstrating a scholarly preference for synthesis and meta-analysis in studying systemic issues (Figure 4). The main types of research outputs included **statistical analyses** and **conceptual models**, illustrating a balanced emphasis on both empirical data and theoretical development (Figure 5).

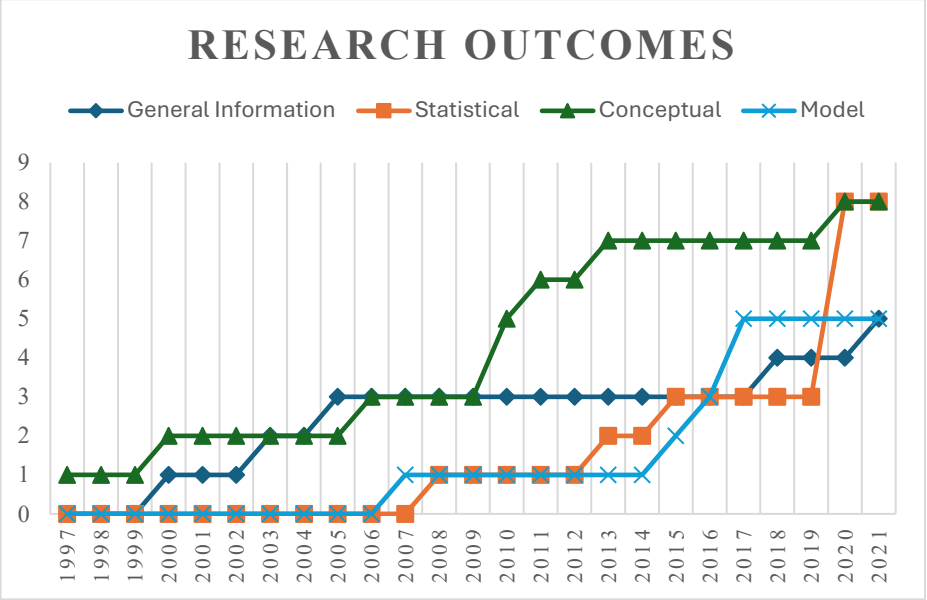

Figure 4.

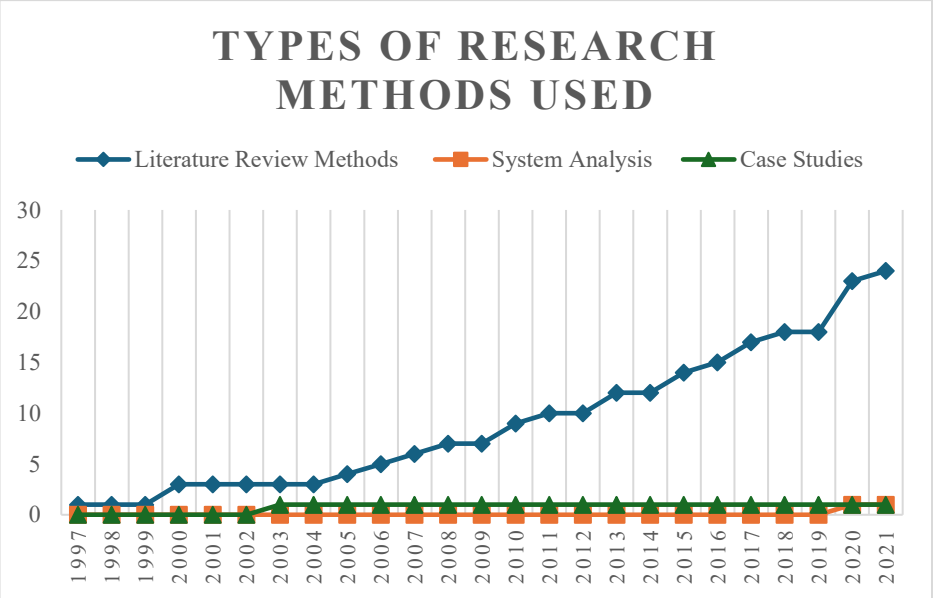

Figure 5.

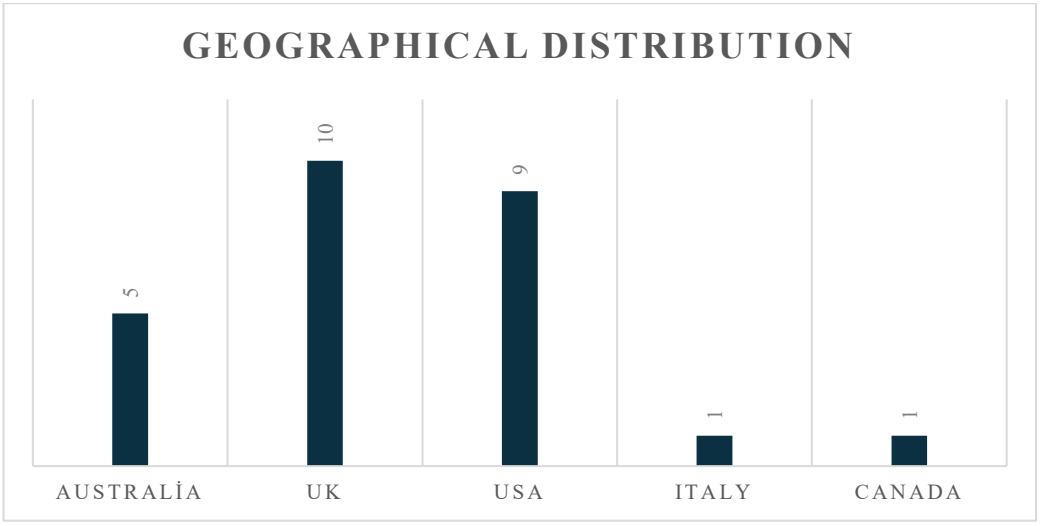

Figure 6.

Conclusion

This systematic review has presented a detailed synthesis of the academic landscape concerning gender dynamics in the construction industry. Despite decades of discussion around inclusion, the findings reaffirm that women remain underrepresented and face a unique set of obstacles, ranging from unequal access to leadership roles and mentorship, to institutionalized wage disparities and psychological stress linked to exclusionary workplace cultures.

By analyzing 26 high-impact studies, this research identified that while initiatives such as gender equality policies, mentorship programs, and inclusive work environments show measurable benefits, their practical implementation often falls short. In particular, the disconnect between policy creation and on-the-ground realities continues to limit women's ability to participate meaningfully and sustainably in construction-related roles.

Importantly, several studies highlighted the necessity of considering intersecting identities—such as race, class, and sexuality—in future inclusion efforts. This intersectional approach is crucial to designing policies that address the full spectrum of discrimination that women may encounter.

The rise in academic interest—particularly visible in the surge of publications around 2020—demonstrates that gender diversity in construction is gaining global attention. Yet, for this awareness to result in tangible change, collaboration between academia, industry leaders, and policymakers must intensify. Initiatives must move beyond symbolic gestures and be grounded in measurable targets and accountability frameworks.

In conclusion, this review offers a foundational reference for future research and policy reform, emphasizing the importance of translating academic insight into actionable strategies. The road to gender equity in construction requires sustained effort, rigorous monitoring, and the commitment of all stakeholders to build not just structures, but fair and inclusive environments within them.

Difficulties Faced by Construction Experts in Construction Sector Cases in the Turkish Justice System

Bekir Haktanır[a], Murat Kuruoğlu[a], Onur Behzat Tokdemir[a]

[a] İstanbul Technical University, Faculty of Civil Engineering, Department of Construction Management, Turkey
haktanirb17@itu.edu.tr

Keywords: Construction Expert, Technical and Legal Classification of Construction Cases, Turkish Justice System.

Aim

The construction-related lawsuits in the Turkish justice system face prolonged litigation processes and significant difficulties in decision making due to differences between the technical classification system used by technical experts and the legal classification system employed by legal professionals. The technical classification system is more detailed and specialized, focusing on the specific sub-disciplines of construction, whereas the legal classification is more general, abstract, and normative. These differences cause issues in clearly defining the types of construction lawsuits, understanding the technical aspects of the disputes, and lead to differences in perception and approach between technical experts and legal professionals. As a result, the case may be misjudged, which extends the litigation process and increases the number of appeals. The thesis aims to explore the relationship between these two classification systems and help create a common understanding, enabling both technical experts and legal professionals to better understand each other's perspectives and improve their collaboration.

The Turkish justice system is founded on the principle of separation of powers, in which the legislative, executive, and judicial branches function independently, within the framework of a democratic state governed by the rule of law (Tanrıver, 2023). The normative foundation of this system is established by the Constitution of the Republic of Turkey, which was adopted through a public referendum on November 7, 1982, and remains in force today. The Constitution guarantees the independence and impartiality of the judiciary while also emphasizing the protection of individual rights and freedoms as one of its core objectives. Structurally, the Turkish legal system adheres to the continental European legal tradition, particularly influenced by the French and German legal systems, and is characterized by the primacy of codified legal norms. Judicial bodies render decisions in accordance with the hierarchy of norms, including the Constitution, laws, bylaws, and regulations (Gözler, 2024). The primary objective of this thesis is to examine the reasons behind the prolonged duration of construction related legal proceedings adjudicated by the judiciary within the Turkish legal system, particularly in courts, and to identify the underlying factors contributing to these delays. In this context, a comparative analysis was conducted between the 'legal classification of construction lawsuits' utilized by legal practitioners and the 'technical classification' employed by expert technical consultants in the field of construction. As a result of this analysis, it was determined that the legal classification comprises 66 distinct types of cases under 27 main categories, whereas the technical classification encompasses 215 distinct types of construction-related disputes under 54 main categories. This numerical disparity highlights not only a methodological divergence in classification approaches but also reveals significant differences in perspective and interpretation between legal professionals and technical experts throughout critical stages of the judicial process, including issue identification, evaluative reasoning, and the rendering of judgments. The findings of this thesis aim to elucidate the nature of the relationship between the technically detailed and expertise-driven classifications used by technical experts and the more generalized legal classifications employed by legal practitioners. Furthermore, the study seeks to contribute meaningfully to the discourse on how this relationship impacts both the duration and effectiveness of judicial proceedings (Arditi & Tokdemir, 1999).

Material and Method

In the process of developing the technical and legal classifications presented in this study, a comprehensive literature review was conducted, drawing on both national and international academic and professional sources relevant to the subject matter. During the technical classification phase, an in-depth examination was carried out of academic studies at the master's and doctoral levels, primarily sourced from university thesis databases, as well as peer-reviewed scientific articles published in scholarly journals and relevant periodicals in the field. For the legal classification, foundational and supplementary legal texts authored by expert jurists were consulted, along with precedent-setting judicial decisions issued by high courts. Additionally, insights were obtained from practitioners with extensive professional experience and sector-specific knowledge. This multidisciplinary and integrative approach has ensured that the classification framework is grounded on a robust foundation, both theoretically and practically.

Findings

The research findings clearly indicate a significant disparity between the number of case types in the legal classification and the technical classification. This quantitative difference holds substantial importance not only in terms of the scope of the classification systems but also due to its direct impact on the functioning of the judicial process. Indeed, the challenges faced by judges in making decisions in construction related cases, along with the increased number of appeals against the decisions and the subsequent prolongation of the trial duration, are concrete manifestations of this disparity. As identified in the study, there is no direct overlap between the 66 case types used by legal professionals and the 215 technical case types defined by technical experts; in fact, in many cases, a single case type in the legal classification corresponds to multiple subtopics with significantly different technical characteristics. This misalignment complicates the accurate understanding of the case content and hinders the full integration of technical details into the judicial process (Arditi, Oksay, & Tokdemir, 1998). A topic that is highly specific from a technical expert's perspective is often placed into a more general legal category in the court, leading to discrepancies in the manner of case adjudication, the criteria for evaluation, and consequently, the rendered decision. As a result, the decisions are often not fully aligned with the technical realities of the case, prompting appeals from the adversely affected parties and thus extending the duration of the trial. The most effective solution to this issue is the inclusion of experts who possess both technical knowledge and legal expertise in the process. However, despite the growing need for such multidisciplinary experts—i.e., technical consultants with legal knowledge and legal professionals with technical expertise—the limited number of specialists with these qualifications presents a significant structural barrier in the resolution of construction-related disputes in Turkey.

Conclusion

Construction-related lawsuits in the Turkish justice system face prolonged litigation processes and significant challenges in decision-making due to structural and conceptual differences between the technical classification system developed by technical experts and the legal classification framework employed by legal professionals. The classification system used by technical experts is more detailed, specialized, and application-oriented, taking into account the sub-disciplines specific to the construction field. In contrast, the legal classification of construction lawsuits is approached in a more general, abstract, and normative manner. This disparity in scope results in the inability to clearly express the meaning of the types of construction lawsuits presented to the court, a lack of comprehensive understanding of the technical aspects of the dispute, and the emergence of perceptual and approach differences between technical experts and legal professionals. Such communication and conceptual misalignments often lead to the incomplete or incorrect evaluation of the case, which in turn prolongs the judicial process and frequently results in appeals against the decisions. This thesis aims to reveal the relationship between the technical classification system used by technical experts and the legal classification framework relied upon by legal professionals, fostering the development of a shared understanding between both parties. The findings aim to contribute to the establishment of a conceptual bridge that will enable technical experts to better assess legal perspectives and allow legal professionals to more effectively engage with technical details.

Procurement Phases in EPC Projects: A Bibliometric Analysis

Hasan Utku Uygun[a], Zeynep Işık[a]

[a] Yıldız Technical University, Departmant of Civil Engineering, Construction Management, Turkey
utku.uygun@std.yildiz.edu.tr

Keywords: EPC, Procurement, Bibliometric Analysis.

Aim

The construction industry plays a significant role in the global economy, with various approaches developed to ensure financial and temporal efficiency in project management. Construction companies aim to select the most suitable construction method and contract type based on project nature, budget, and past experience. Engineering, Procurement, and Construction (EPC) contracts integrate design, procurement, and construction into a streamlined process, widely used in large-scale infrastructure and industrial projects due to their efficiency in risk allocation and cost management (Dissanayake et al., 2022; Yeo & Ning, 2002).

The procurement phase is crucial to EPC projects, ensuring the timely acquisition of materials, equipment, and services. It bridges engineering and construction, supporting the flow between office and site (Jianhua & Yeo, 2000). This study conducts a bibliometric analysis of the procurement phase in EPC projects, identifying research trends and critical areas for further investigation. Using publications from the Scopus database and VosViewer network analysis, the research provides a comprehensive overview of procurement challenges and management strategies in EPC projects.

Material and Method

The methodology adopted in this study follows a systematic bibliometric approach. The research process starts with the identification of relevant publications from the Scopus database using predefined keywords (procurement, EPC, project, construction) related to procurement in EPC projects. The initial dataset was refined by filtering for subject areas (Engineering, Business, Management and Accounting, Decision Sciences), document types (article, conference paper) and language (English). As a result of this search, 417 studies were examined and 115 of them were found to be related to the researched topic and these studies were included in the analysis.

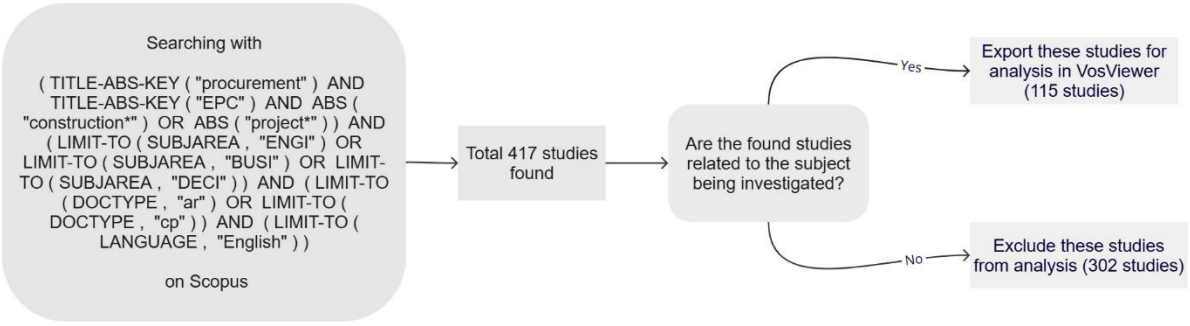

Figure 1. Flow diagram of searching and analyzing progress.

Table 1. Searching criteria.

Title - Abstract - Keyword

Subject Area
Engineering
Business, Management and Accounting
Decision Sciences
Document Type
Article
Conference Paper
Language
English

Subsequently, a detailed bibliometric analysis was conducted using VosViewer software to assess key parameters such as publication trends, keyword co-occurrence patterns, geographical distribution of research outputs, and the most influential journals in this domain.

Findings

A. Research Trends and Key Findings

The analysis of 115 selected articles revealed a steady growth in research activity related to EPC procurement since the early 2000s. Keyword co-occurrence analysis indicated a strong focus on four critical areas: risk management, supply chain management, contract administration, and delay analysis with cost-overrun issues. These thematic areas have significant implications for the efficiency and success of EPC projects.

Figure 2. Mapping of keyword analysis.

Table 2. Keyword analysis result.

Keyword	Occurences	Total Link Strength
project management	12	51
epc	12	43
procurement	8	40
risk management	7	23
epc projects	6	22

cost overrun	2	10
exploratory research	2	9

Financial, technical, logistical, and operational risks are all present in EPC projects, and they must be effectively managed by early detection, in-depth assessments, and proactive response. It is essential to manage a worldwide supply chain, which includes digital tracking systems, logistics, inventory optimization, and supplier selection. Automation and digital transformation developments can improve the transparency and resilience of the supply chain. Future study will concentrate on novel approaches including performance-based incentives and flexible dispute resolution procedures. Clear, flexible contracts are crucial for outlining roles, risk-sharing, and performance criteria. In EPC projects, delays and cost overruns are still frequent problems. By examining these issues using statistical techniques and historical data, the underlying causes can be identified. Key areas for additional research include improved planning, financial monitoring, and early corrective action.

B. Geographical Distribution of Research Output

The bibliometric analysis shows that research on EPC procurement is mostly concentrated in countries with strong construction industries and advanced technology. China stands out as a major contributor, with many publications on procurement risks and cost management in EPC projects. According to the 2024 ENR rankings, six of the top 20 global construction firms are based in China, reflecting its large-scale infrastructure investments and focus on EPC contracting in international markets.

C. Most Cited Study in EPC Procurement Research

Among the analyzed articles, the most frequently cited study is "Integrating Supply Chain and Critical Chain Concepts in Engineer-Procure-Construct (EPC) Projects" which has been referenced 168 times (Yeo & Ning, 2002). Conducted in Singapore, this study explores the integration of supply chain management principles with critical chain project management in EPC projects. It provides a framework for optimizing procurement processes and mitigating risks associated with supply uncertainties, highlighting the importance of aligning procurement strategies with overall project objectives.

D. Discussions

The bibliometric analysis highlights the strengths and weaknesses of procurement in EPC projects. Developed countries, like the United States and China, dominate the publication landscape, aligning with the large-scale cash flow requirements of EPC projects.

Supply chain and procurement are often confused, but supply chain is a broader process that includes procurement (Azambuja et al., 2014). Future research should explore studies combining both terms while recognizing their differences.

Common keywords include risks such as delays and cost overruns, which are significant challenges for EPC projects (An & Shuai, 2010; Hatmoko & Khasani, 2019). Additionally, "risk management," "risk control," and "risk analysis and evaluation" are frequently associated with risk (He & Han, 2022; Wang & Wang, 2022). Given the complexity of risk, there is room for further research in this area.

Although Singapore has fewer publications, it ranks second in citations, mainly due to the 168 citations of the article "Integrating supply chain and critical chain concepts in EPC projects" (Yeo & Ning, 2002). This paper is crucial for future researchers in this field, as it provides valuable insights into integrating supply chain and critical chain concepts in EPC projects.

Conclusion

This study presents a comprehensive bibliometric analysis of procurement research in EPC projects, highlighting key themes, research trends, and knowledge gaps. The analysis reveals the dominance of research contributions from countries with strong construction industries. It also emphasizes the need for further studies to bridge the gap between academic research and industry practices. Future research could focus on developing predictive models for procurement risk assessment, improving contract frameworks, and exploring artificial intelligence in EPC procurement. Strengthening these areas could lead to more efficient procurement strategies and better project outcomes in the global construction industry.

Determining the Factors Causing Rework in the Turkish Construction Industry

Eda Nur Erdem[a], Gülden Gümüşburun Ayalp[b]

[a]Adana Alparslan Türkeş Science and Technology University, Department of Architecture, Building Construction, Türkiye
[b] Hasan Kalyoncu University, Department of Architecture, Architecture, Türkiye
enerdem@atu.edu.tr

Keywords: Construction Rework, Project Performance, Statistical Analyses.

Aim

The construction sector is a critical backbone of economic growth and national development, particularly in developing countries like Turkey. Despite its economic significance, the industry often suffers from inefficiencies such as cost overruns, delays, and quality deviations—issues frequently arising from construction rework (Fayek et al., 2003; Josephson et al., 2002; Love, 2002; Yap et al., 2020). Rework is the unnecessary effort to correct tasks initially performed incorrectly (Love & Edwards, 2004a). It is a persistent and costly problem that can occur at any project stage (Love & Edwards, 2004b). Its late detection, often due to errors, omissions, or last-minute changes, significantly undermines project performance and efficiency (Trach et al., 2019). Although rework is a well-known global issue, its specific impact and underlying causes in the Turkish construction industry have not been thoroughly investigated. This study aims to fill that gap by identifying the primary factors leading to rework, assessing their frequency and significance, and offering data-driven recommendations to mitigate them. By shedding light on the most common and influential causes of rework, the research seeks to enhance project outcomes, minimize waste, and support sustainable improvement in the performance and quality of the Turkish construction sector.

Material and Method

The study employed a systematic literature review to identify potential rework causes, then gathered empirical data via a survey of 209 industry professionals including architects, engineers, and contractors. A total of 43 rework criteria were categorized into six groups: client-related, design team-related, project management-related, implementation team-related, project conditions, and general/external factors (Table 1).

The survey utilized a 5-point Likert scale to assess the impact of each criterion. The SPSS 22.0 program and Monte Carlo simulation were used for data analysis. Since the skewness and kurtosis values of the dataset are between -2 and +2, it has been determined that the entire dataset follows a normal distribution, and therefore, parametric tests have been used. Data analysis included descriptive statistics, reliability analysis, relative importance index (RII) (Equation 1), One-Way ANOVA as hypothesis testing, and explanatory factor analysis (EFA). Specifically, to test the hypothesis that there is a statistically significant difference between the types of projects participants were involved in (residential, public, commercial, and others) and the reasons for rework, a one-way ANOVA was conducted. RII was calculated using the following equation: W is the weighting given to each factor by participants (ranging from 1 to 5); A is the highest weight (i.e., 5 in this case); and N is the total number of participants (Pallant, 2007).

Relative importance index (RII) formula:

$$\mathrm{RII} = \frac{\Sigma W}{(A \times N)} \quad (1)$$

The findings obtained from the analyses were evaluated within a scientific framework by comparing them with existing literature, and the validity of the results and their contributions to the sector were thoroughly discussed.

Table 1. Identification and Classification of the Rework Causes.

Cause Group	Cause Code	Rework Cause Definition
Client Related Factors	C1	Client directed changes
	C2	Poor communication
	C3	Client choice and low-cost contractor
	C4	Lack of client involvement
	C5	Inadequate or weak feasibility study
Design Team Related Factors	D1	Incomplete design
	D2	Errors and omissions in design
	D3	Design changes
	D4	Insufficient coordination
	D5	Lack of constructability review
	D6	Poor communication
	D7	Design management failure
	D8	Drawing not clear
	D9	Lack of using modern technology and tools
Project Management Related Factors	PM1	Lack of experience of project manager
	PM2	Inability to perform adequate document review
	PM3	Poor planning and coordination
	PM4	Poor workload planning
	PM5	Inefficient management
Implementation Team Related Factors	IT1	Lack of worker skills
	IT2	Time pressure
	IT3	Poor workmanship
	IT4	Non-compliance with specifications
	IT5	Shortage of skilled laborers required to complete task
	IT6	Lack of motivation
Project Conditions	PC1	Poor site condition

Related Factors	PC2	Congestion of trades
	PC3	Increase in work due to interferences
	PC4	Increase in project changes or the number of trade subcontracts on site
	PC5	Lack of safety enforcement in the site
General Related Factors	G1	Schedule pressure
	G2	Poor communication
	G3	Poor coordination
	G4	Change in project scope
	G5	Inadequate as-built documentation
	G6	Unavailability of materials
	G7	Delivery of construction materials in short supply
	G8	Wrong initial budget
	G9	Change of economic condition and ineffectiveness of follow-up
	G10	Change of contractors
	G11	Change in construction laws of the country
	G12	Natural disasters
	G13	Change in construction method

.

Findings

The statistical analysis of the collected data revealed the following findings: Among the 43 potential criteria evaluated by participants as causes of construction rework, the most significant factors were identified as changes in project scope, modifications initiated by the employer, late design changes, employer-driven adjustments to project scope or schedule, and communication failures between teams. This highlights the critical role of late-stage changes in projects within the Turkish construction sector, demonstrating that rework-inducing modifications negatively impact project performance and significantly reduce productivity.

The influence of rework-related criteria varies depending on project type, with a statistically significant relationship found between six of the 43 factors and specific project categories through a One-Way ANOVA. In commercial buildings, key issues include poor employer communication, scope or schedule changes imposed by the employer, insufficient employer involvement, inadequate feasibility studies, and weak workload planning, all perceived as more problematic than residential projects. In other project types (industrial buildings, socio-cultural structures, etc.), limited time allocated to design teams for task completion and deficient feasibility studies emerge as more prominent concerns. Consequently, the nature of rework risks requiring managerial intervention differs across project types.

Finally, according to the results of the EFA, critical factors contributing to construction rework in the Turkish construction sector were determined and named based on thematically related causes that led to rework occurrence. The analysis was conducted on a survey dataset consisting of 209 responses, evaluating 36 variables with factor loadings greater than 0.5. The parallel analysis using Monte Carlo simulation statistically supported the extraction of five factors. Considering both the distribution of the items and their conceptual alignment with the literature, the factor structure was limited to five, each with an eigenvalue greater than 1.

Based on the underlying variables they comprise (as per the EFA results), the five critical factors were named, and their order of importance (determined by analyzing the mean RII) is as follows (Table 2.):

1. Factor 3 – Communication gaps and lack of coordination (consisting of 6 variables),
2. Factor 4 – Errors due to personnel expertise and knowledge deficiencies (consisting of 5 variables),
3. Factor 5 – Late changes made by the employer (consisting of 5 variables),
4. Factor 1 – Inadequate design and project management (consisting of 12 variables)
5. Factor 2 – Weaknesses in project documentation and difficulties accessing project requirements (consisting of 8 variables).

Table 2. Factor Groups and Related Values Obtained from Exploratory Factor Analysis.

Definition of Rework Factors and Related Causes		**Loads of Causes**	**Eigenvalue**	**% of Variance**	**Avg. RII**	**Factor Importance Rank Order**

Conclusion

This study systematically identifies and categorizes the factors causing rework in the Turkish construction sector, providing valuable insights. The empirical findings of this study strongly align with those of prior research. These research outcomes revealed that stakeholders in the Turkish construction sector must recognize these critical rework drivers and prioritize preventive measures to mitigate their impact. Proactive strategies addressing these factors are essential to enhancing project efficiency and reducing avoidable costs and delays. The study recommends several strategies to reduce construction rework in Turkey. Key measures include improving communication and coordination through regular team meetings, implementing continuous quality monitoring to catch and correct these issues early, and establishing robust quality control systems. It also advises early contractor involvement to enhance constructability, using BIM for clash detection, and providing training in project management areas such as risk analysis and cost control. Additionally, introducing incentive programs for workers can further minimize errors and rework. By adopting these measures, construction firms can reduce rework, enhance efficiency, and improve project outcomes, ultimately contributing to sustainable growth.

Assessing the Level of Digitalization of the Construction Permit Processes in Türkiye

Gamze Nur İşeri Çetin [a], Esin Ergen Pehlevan [b]

[a] Istanbul Technical University, Faculty of Civil Engineering, Construction Management Division, Türkiye
[b] Istanbul Technical University, Graduate School, Department of Civil Engineering, Türkiye
iserig@itu.edu.tr

Keywords: Automated Permit Approvals, Digital Construction Permit Procedures, Digital Transformation in Construction Industry, e-Permitting Systems.

Aim

Digital transformation has become one of the leading subjects of progress in the construction industry with Building Information Modelling (BIM) at the forefront. Digitalization appears in numerous process-focused areas, such as urban planning and construction permit procedures (Olsson et al., 2018). In this context, one of the significant advancements in the digitalization of the construction sector is electronic permitting (e-Permitting). E-Permitting procedures include document submissions, project controls and the assessments that need to be carried out, from the permit application stage until the issuance of the construction permit. It includes processes such as electronic applications, electronic submission of project documents, submission of BIM projects and IFC files in addition to two-dimensional project submissions, automated compliance controls of architectural, structural, mechanical and other properties of the projects, as well as defining and checking the spatial relations of the buildings with their surroundings through three-dimensional, real-time city models. The primary objectives of e-Permitting are to minimize human error, reduce the reliance on physical documentation, accelerate the permit approval process and overall to increase the efficiency of the construction permitting procedures (CHEK, 2023).

In Türkiye, e-Permitting is not being implemented nationwide and there are limited studies on building permit processes at the national level, as well as studies on the development of e-Permitting systems. Although some municipalities have taken steps towards the digitalization of the construction permitting procedures, there is no national framework that facilitates and guides the transition to the nationwide adoption of e-Permitting systems. In order for institutions to adopt e-Permitting, certain adaptations should be implemented in the existing systems. It is primarily necessary to resolve several legal issues in order to accomplish implementing an automated and model-based e-permitting structure, some of which can present significant challenges (Shahi et al., 2019). Submission of BIM models as part of the construction permit processes are required for different types of projects in countries like Singapore, Norway and the UK (Kim et al., 2020), however it is not a widespread practice worldwide. Studies on the realisation of automatic code compliance controls and the integration of geoinformation usage are currently ongoing. The most extensively researched topic is the automated regulation compliance controls and it has the potential to achieve higher maturity. However, significant gaps remain in the use of geoinformation, particularly in relation to BIM and exchangeable conversions (Noardo et al., 2024). Several governments and municipalities worldwide have adopted different levels of e-Permitting procedures and numerous pilot projects take place which incorporate the submission of BIM models and perform the automated code controls for different aspects of the projects (Srinivasan et al., 2020). Considering the global advancements and ongoing research, it is important to understand and assess Türkiye's position in digital permitting procedures. Therefore, the aim of this study is to identify the current digital transformation applications in the building permit processes of municipalities in Türkiye and to develop a roadmap for transition to e-Permit processes.

Material and Method

To achieve this aim, a systematic review of the literature was carried out in the first step. Initially, studies focusing on worldwide e-Permit applications were reviewed, different levels of digital maturity in e-Permit procedures were defined, and e-Permit applications implemented globally were examined. Within the global practices, the steps that were taken to improve the digitalization of the permitting procedures were analysed. Then, studies on the automatic regulation (code) control used in e-Permit practices were investigated.

In the second step of the study, research which focuses on the 30 metropolitan municipalities in Türkiye was conducted to assess the digitalization levels of construction permitting processes. As part of the research, digitalized services and construction permit issuance procedures of a total of 519 district municipalities were investigated and analysed. The research investigated the municipalities that have implemented digital solutions, the extent of digitalization in construction permit issuance, as well as the degree to which municipalities are integrated with national digital systems related to the construction sector. In line with the local digital developments, national services that serve for the digitalization of the construction sector and their impact on the local construction permit procedures were investigated and their further potentials have been analysed. In the third step of the study, interviews were conducted with main stakeholders of the e-Permitting procedures, including e-Permit software and system developers, construction permitting experts from metropolitan district municipalities and experts from metropolitan city municipalities in Türkiye. These interviews provided an understanding of the building permit processes implemented locally and the level of adoption of e-Permitting procedures.

Findings

By analysing the results obtained, the challenges of the building permit issuance processes in both national and local contexts in Türkiye have been identified. The research on metropolitan district municipalities showed disparities between the adoption of digitalization, and while some regional similarities were observed, no clear coordinated approach could be identified. It has been observed that although more than two-thirds of the district municipalities have adopted the digitalization of the systems for general municipal services, different levels of e-Permitting applications and infrastructures have been identified in fewer than one-fifth of the district municipalities. Based on the results obtained from the stakeholder interviews conducted, key challenges against the nationwide implementation of e-Permitting systems included regulatory gaps and legal barriers, lack of standardization across municipalities, lack of trained personnel and technical infrastructure, and lack of planning and organisational structuring. Despite the identified challenges and certain bureaucratic and technical barriers still affecting the implementation process, no explicit and direct resistance against the adoption of e-Permit systems has been reported. Furthermore, legal regulation attempts and local efforts to include BIM models within construction permitting procedures were defined.

Conclusion

Based on the findings of the global studies in the field of e-Permitting, data collected through the research of metropolitan district municipalities and stakeholder interviews, a roadmap for the development of e-Permitting applications in Türkiye has been proposed. The proposed roadmap consists of key phases including the establishment of national regulatory guidelines, development of technical infrastructure, organizational capacity building, and implementation of pilot e-Permitting projects to establish the adoption of nationwide e-Permitting procedures.

The academic contribution of this study is to determine the levels of digitalization and the development of e-Permitting procedures in 519 metropolitan district municipalities for the evaluation of the national and local e-Permitting efforts within the construction sector and the proposal of an e-Permit roadmap. By using the e-Permit roadmap, nationwide e-Permit implementation could be attained in Türkiye and localised solutions for e-Permit applications can be developed.

Industrialisation of Natural Building Materials for Sustainability in the Built Environment

Merve Guven[a], Deniz Artan[b]

[a] Istanbul Technical University/Institute of Informatics, IT in Construction Management Program, Türkiye
[b] Istanbul Technical University/Faculty of Civil Engineering, Department of Civil Engineering, Türkiye
guvenme23@itu.edu.tr

Keywords: BIM, Industrialisation, Natural Building Materials, Sustainable Construction, Sustainable Development.

Aim

Construction sector has a significant impact on environmental pollution.(Murtagh, Scott, & Fan, 2020). Natural building materials such as earth, wood and straw bale offer sustainable alternatives but face challenges in industrialisation and standardisation(Dams, et al., 2023). Buildings constructed with natural building materials offer an eco-friendly approach that harmonises with ecosystems by reducing their environmental footprint. While traditional construction materials contribute to high carbon emissions and depletion of natural resources, natural building materials are renewable, biodegradable and can be produced with low energy consumption.(Yahia,A.K.M, et al., 2024). For example, bamboo is a sustainable and durable building solution thanks to its fast growth cycle and high strength.(Abera, 2024). Biomaterials like mycelium, a fungal substance, enhance energy efficiency by offering insulation and structural support, making buildings more resilient to extreme weather conditions (Al-Qahtani,S. et al., 2023). ,Furthermore, organic structures, combining traditional ecological knowledge with modern engineering, harmonise with nature.(Balducci, Camilli, 2022). Thus, buildings made with biological materials not only reduce carbon emissions but also become more flexible and resilient in the face of future climate uncertainties. Despite their benefits, research on natural building materials is still limited. Abera (2024) also emphasizes the significance of advancing hybrid materials and conducting innovative research on natural materials to facilitate the incorporation of traditional ecological knowledge.
This study examines the requisite conditions for the industrialization of natural materials through a literature review, industry surveys, and expert interviews. In this context, their resilience and economic feasibility are assessed for their integration into modern structures. The role of Building Information Modelling (BIM) in their adoption and standardization is also considered. Barriers to their widespread adoption were examined, including economic and perceptual challenges and regulations.

Material and Method

A mixed-method strategy was employed to collect qualitative and quantitative data. A structured online survey was administered, collecting responses from 64 industry professionals, including architects, engineers, constructors, and end users. The survey explored awareness and perceptions of natural materials, including commonly used materials and their related applications, as well as barriers to adoption and possible solutions. In-depth interviews were performed with four material producers and two building professionals to obtain perspectives on practical uses, industrialization problems, and potential policy interventions.

Findings

The interview respondents include producers of natural building materials and practitioners who have utilized these materials in construction projects. The interviews aimed to gather qualitative insights into practical work with natural materials, including production challenges, market trends, and experiences of use. The inquiries aimed to elucidate the specific circumstances favoring the use of natural materials, the technical and economic obstacles to industrialization, and the performance of these materials in daily life concerning durability and health effects. Thematic analysis was utilized on

qualitative data obtained from the interviews to delineate prevalent themes and insights that would enhance the quantitative results from the survey.

Seventy percent of the respondents are engaged in the construction sector, with the majority indicating their involvement in residential and commercial projects. 56.5% of this section within the construction sector reported utilizing natural building materials, while the remaining portion indicated either non-use or uncertainty over their use. The predominant materials utilized are wood and stone. Subsequently, earth and clay-based materials are addressed. Natural materials are extensively utilized as facades, structural components, and interior architectural finishes.

The results of the survey show that when evaluating the performance of natural building materials against natural disasters, individuals who know the materials find them more effective. Participants stated that the study provides a general evaluation, but it would be more accurate and necessary to consider each material separately. It was generally agreed that natural materials are more resistant to earthquakes and fire, but less effective for flood and hurricane resistance, although to varying degrees. In addition, there was a common view that these materials have positive effects on life and human health (Figure 1).

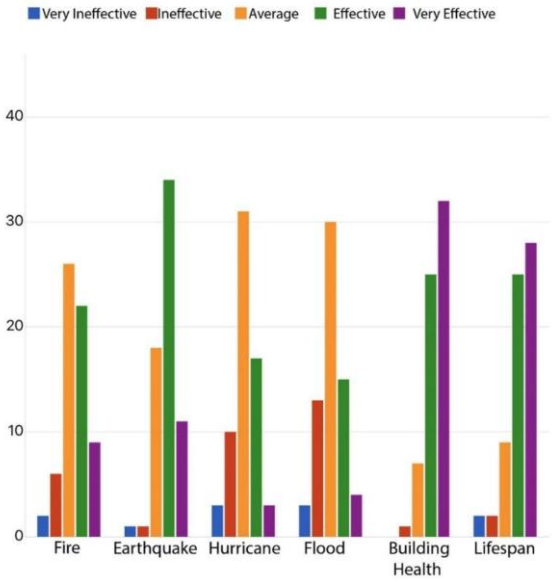

Figure 1. The effects of natural building materials.

Forty-five percent of participants highlighted the lack of standards and high costs as the primary concerns, while forty-one percent cited insufficient training and awareness. The simplicity of usage and the insufficiency of current production capacities were identified as crucial factors.

About 30% of respondents reported using Building Information Modelling (BIM) and about 30% of BIM users reported that they actively incorporate natural building materials as data in BIM and use them in various building analyses. Furthermore, survey results reveal that the majority rely on national material libraries from other countries or modify existing materials, often favoring pre-fabricated library components. Consequently, the establishment of a local natural building material library within the BIM system would be advantageous.

The majority of participants who responded affirmatively or negatively to the preceding questions regarded the prospects of natural building materials as favorable or highly favorable. The research audience is optimistic in this regard. Concerning hybrid building materials, 46.8% of respondents deemed them an optimal choice in terms of durability. 38.7% indicated they could be suitable during the transition phase, while 33.9% expressed concerns over the chemical constituents utilized. Furthermore, 19.4% indicated the risk of greenwashing.

Furthermore, 35.5% indicated that they perceive it as a chance to fulfill the EU Green Deal objectives.

In material-based interviews with manufacturers and practitioners, it has been observed that end-user trends have increased after the pandemic, and materials have proven their durability despite disasters such as floods and earthquakes in applications. For example, the BKM film plateaus, which were manufactured with rammed earth, were exposed to flooding twice; it is observed that there was no deformation on the walls after the disaster and there was no color change(Figure 2). Although it is argued that compacted soil becomes rocky over time, it can be said that there is a need for scientific evidence-based research in this field.

Figure 2. Earth Rammed Techniques & Resillience Interview Alişan,E. (2024).

Conclusion

Despite the overall favorable inclination toward natural construction materials, a notable disparity exists in the methodologies employed by experts who are adept in utilizing these materials and those who lack such expertise. This suggests that resources need to be better recognised and integrated more effectively into training and courses. The pertinent departments inadequately assess building biology and health-related concerns. Conversely, they ought to be incorporated more efficiently by evaluating creative sustainable strategies, including Environmental Social and Governance objectives and the EU Consensus. Considering that one of the main difficulties in the use of natural building materials is that outdoor weather variable factors, such as fluctuations in relative humidity and temperature, create variable results, it can be said that it is a very important factor in front of industrialisation for standardisation and wider application. Anticipating identical functionalities and durability from current chemical materials is impractical and overlooks the health and ecological advantages of natural construction materials. Nonetheless, while it is encouraging to assess durable performance and resilience through appropriate techniques and methodologies, further evidence-based analysis, evaluation, and practical examples are requisite in this domain. This requires appropriate policies and incentives for support. In this regard, while it is anticipated that the non-governmental organization and initiatives of the Natural Building Materials Association will make substantial contributions, additional projects should get support through incentives and research. The study's scope was finalized in two months; it would be advantageous to extend the research with a more exhaustive literature survey, a thorough contextual analysis utilizing BIM, and a more profound investigation of the applications.

Circular Economy Performance Assessment in Construction: A Critical Review of Firm-Level Models

Mohammed Ahallaq[a], Deniz Artan[a]

[a] Istanbul Technical University, Faculty of Civil Engineering, Department of Civil Engineering, Construction Management Program, Turkey
alhallaq21@itu.edu.tr

Keywords: Circular Economy, Performance Assessment, Construction Industry, Firm-Level Performance, CE Indicators.

Circular Economy (CE) concepts have gained increasing attention as industries search for more sustainable ways to use resources. In construction, the urgency is particularly clear: the sector consumes vast amounts of raw materials and generates a high volume of waste (Gasparri et al., 2023). Using CE ideas could make a real difference here by improving how materials are sourced, reused, and managed. Yet, putting CE principles into action in construction settings is often anything but straightforward. This industry tends to work through one-off projects, with various parties involved and site-specific decisions, all of which make systematic changes harder to implement (Kristoffersen et al., 2020).
What makes things more complicated is the lack of common tools to measure how "circular" a construction firm actually is. A lot of the models out there were originally designed for other industries, especially manufacturing, and don't match the day-to-day reality of construction work (Núñez-Cacho et al., 2018). They also rarely account for the shifting conditions across projects or the regulatory landscape construction firms must navigate (Berglund-Brown et al., 2022). Because of this, there's no widely accepted way for construction firms to assess CE performance at the firm level, and that creates a barrier to progress.

Aim

In this work, we reviewed existing models used to evaluate Circular Economy performance, paying close attention to how relevant they are to construction firms. Rather than proposing a new model at this stage, our goal was to better understand how these frameworks were designed, what they measure, and whether they could realistically be adapted for use in construction. This review is also part of a broader PhD project that aims to eventually build a practical, firm-level CE assessment tool specifically for the construction industry.

Material and Method

A systematic literature review was conducted to identify relevant CE performance assessment models. The selection process involved keyword-based searches across academic databases, focusing on circular economy assessment, sustainability metrics, and firm-level indicators in construction and related industries. Databases such as Scopus, Web of Science, and Google Scholar were utilized, with keywords including "Circular Economy Performance Assessment," "Construction Industry," "Firm-Level Circularity," and "Sustainability Metrics." Models lacking a structured assessment methodology or focused solely on macro-level policy analysis were excluded to ensure applicability at the firm level
The selected models were categorized into three structured tables to facilitate comparison:

- **Table 1:** Overview of Circular Economy Performance Assessment Models – Summarizes the year, model type, sector, and key contributions.
- **Table 2:** Theoretical Methodologies of CE Performance Assessment Models – Includes models based on literature reviews and conceptual frameworks.
- **Table 3:** Empirical Methodologies of CE Performance Assessment Models – Covers models that apply case studies, surveys, or industry validation.

Each model was analyzed based on key methodological parameters, including scope, validation approach, and sectoral application. The analysis also considered the strengths and weaknesses of each model, particularly in how well they address construction-specific challenges such as material circularity, lifecycle impacts, and regulatory compliance.

Findings

As we read through the 14 CE performance models, we noticed a recurring trend. Many were designed with manufacturing in mind, where systems tend to repeat and data is easier to track (Baratsas et al., 2022; Kristoffersen et al., 2020). But construction doesn't work that way, it's based on temporary projects, varying sites, and complex stakeholder arrangements. These characteristics make it harder to apply many of the existing CE models directly to construction settings. The workflow and data availability in construction are fundamentally different from manufacturing, which leads to compatibility issues when using standardized performance frameworks.

Out of the four models we found that connect to construction, just two used real-world data from construction companies. The Importance–Adoption Analysis model developed by Lee et al. (2023) focuses on how construction companies perceive and prioritize CE strategies. Similarly, the Circular Information Flow (CIF) model proposed by Shooshtarian et al. (2022) maps how information related to circular practices flows between actors in industrialized construction. These models helped us understand things like awareness levels and communication patterns, but they stopped short of offering practical tools for performance assessment. The other two construction-related models, such as the Circular Business Model review and the Circular Economy Index by Núñez-Cacho et al. (2018), were more conceptual. They provided useful frameworks but lacked clear performance indicators, sector-specific benchmarks, or systematic processes for firm-level tracking.

Something else that became apparent during our review was the limited attention to design-stage planning and lifecycle thinking. Only a handful of models mentioned these aspects, despite their crucial importance in construction. Design decisions, such as material selection, modularity, and adaptability, can directly impact the feasibility of circular practices like reuse and disassembly (Ghisellini et al., 2016; Shooshtarian et al., 2022). Ignoring the early planning phase weakens the overall effectiveness of CE models, especially in a sector where initial design often dictates long-term sustainability outcomes.

Another notable gap was the underuse of digital tools in construction-focused CE models. In other industries, CE frameworks are increasingly integrated with advanced technologies, including the Internet of Things (IoT), artificial intelligence (AI), and big data analytics (Kristoffersen et al., 2020). These tools support real-time tracking of material flows, performance metrics, and environmental impact. However, we found that the construction-specific models largely ignore these technologies, even though the sector generates large volumes of process data. This suggests that the construction industry may be underutilizing available digital tools that could otherwise support circular performance measurement.

While reviewing models designed for general or cross-sectoral use, we also identified certain structural ideas that could potentially be adapted to construction. For example, maturity models like C-METRIC (Holly et al., 2024) and modular indicator frameworks used in MICRON (Baratsas et al., 2022) offer structured approaches that allow firms to assess and compare their progress. However, these models tend to assume controlled environments and consistent data availability. Such assumptions may not hold in the construction sector, where project variability, decentralized data, and regulatory constraints present real challenges.

Taken together, these observations highlight a significant research gap. Despite the diversity of CE models and their growing refinement in various sectors, there is currently no established model that effectively addresses CE performance measurement at the firm level within the construction industry. Most of the models are either too generic or too focused on narrow aspects of circularity, such as material reuse or awareness tracking. For firms operating in the construction sector, this lack of a comprehensive and practical tool limits their ability to benchmark performance, identify areas for improvement, and align with broader sustainability goals. Addressing this gap is a necessary step toward enabling more effective implementation of CE principles in the built environment.

Conclusion

Through this review, we aimed to understand whether current CE performance models are suitable for application in construction firms at the firm level. After analyzing 14 different models, it became evident that while the interest in CE continues to grow, practical tools for performance evaluation in construction are still missing. Existing models are often designed for manufacturing or broader multi-sectoral use. Their structures tend to rely on assumptions such as operational uniformity, centralized data collection, and stable production environments, conditions that are rarely found in construction. Even the four models we identified as relevant to the construction industry had limited value when it came to firm-level performance measurement. Two models were grounded in empirical data, but their scope was confined to perceptions and information flows (Lee et al., 2023; Shooshtarian et al., 2022). The other two offered conceptual insights, but lacked actionable indicators or implementation frameworks (Núñez-Cacho et al., 2018). As a result, construction firms still lack a method to systematically assess and improve their CE performance.

We also noted a significant gap in how existing models deal with early-stage design and digital technologies. These are both critical in construction but are either ignored or only superficially addressed in current CE frameworks. The absence of lifecycle-based thinking and real-time tracking tools limits the effectiveness of existing models when applied to complex, project-based operations.

What this review reveals is more than just a list of what's missing. It clarifies where future efforts should be directed. There is a clear need for a new CE performance assessment model that takes into account how construction firms operate—one that is flexible, measurable, and grounded in real project workflows. Such a model would need to integrate key aspects like firm-level indicators, lifecycle thinking, and the use of digital tools to track performance over time.

This study reinforces the urgency of developing a tailored framework for CE performance measurement in the construction industry. Doing so would not only fill a gap in academic research but also support practitioners and firms aiming to improve their sustainability outcomes. The insights gathered here will directly support the next phase of this PhD research, which focuses on building and validating a sector-specific assessment tool for construction.

Keywords: Control Allocation, Control Surface Failures, Dual-System VTOL UAVs, Fault Tolerant Control, Fault Detection and Isolation.

Aim

The primary objective of this study is to design, develop, and implement a comprehensive fault-tolerant control (FTC) strategy for dual-system Vertical Take-Off and Landing (VTOL) Unmanned Aerial Vehicles (UAVs) that ensures stable flight performance under fault conditions, particularly during the cruise phase. One of the main challenges in dual-system VTOL UAVs is the loss of control authority due to control surface failures, which can lead to instability and loss of mission effectiveness. To address this issue, the proposed FTC strategy leverages vertical motors, which remain inactive during cruise flights, as auxiliary actuators to compensate for these failures and maintain UAB stability.
The study also presents a real-time fault detection system that can immediately identify and categorize surface failures. Moreover, an adaptive control allocation method is designed to distribute control commands between conventional aerodynamic surfaces and vertical motors according to the failure scenario. A nonlinear dual-system VTOL UAV model created in MATLAB/Simulink is used to simulate dual-system VTOL UAV dynamics and evaluate the performance of the proposed control architecture under multiple failure conditions.

Material and Method

The study is conducted using a comprehensive nonlinear dual-system VTOL UAVs model, developed in Simulink, which features a hybrid dual-system architecture integrating both fixed-wing and rotary-wing components. The dual-system VTOL UAV model consists of a single horizontal motor for forward flights, four vertical motors primarily used for takeoff, landing, and hover but repurposed for fault compensation in cruise, and an inverted V-tail and two ailerons as primary control surfaces for fixed-wing flights.
To ensure accurate representation of real-world flight conditions, the nonlinear flight dynamics of the dual-system VTOL UAVs are rigorously modelled, incorporating aerodynamic forces, moments, actuator dynamics, and limitations. A cascade PID control architecture is employed, featuring separate controllers for rotary-wing and fixed-wing configurations, allowing independent tuning for each mode. One key challenge in the control design arises from the difference in response times between the fixed-wing control surfaces and the vertical motors. The control surfaces exhibit faster response times, whereas the vertical motors introduce slower dynamics. This discrepancy necessitates careful tuning of the fixed-wing controller gains to maintain stability, especially when vertical motors are activated as additional actuators in the event of control surface failures.
A model-based fault detection system is integrated into the study to detect faults that may occur in the control surfaces. This system estimates the expected behavior of each control surface using control surface commands and servo feedback. It then analyzes the deviations that occur in the control surfaces, considering the aerodynamic loads. When this deviation exceeds a predefined deviation threshold, the system perceives this as a fault. The severity of the fault is classified and evaluated, and based on this evaluation, it is decided whether to activate the vertical motors.
Control allocation is performed adaptively, distributing commands between aerodynamic surfaces and vertical motors according to the fault's magnitude. This strategy ensures continued stability and performance, even under substantial actuator failures.

Findings

Extensive simulations in MATLAB/Simulink were carried out to assess the performance of the proposed FTC strategy. The results show that the fault detection system accurately identifies and classifies control surface failures in real time, enabling timely corrective actions. Moreover, the system assesses the severity of each fault and activates the vertical motors only when necessary, conserving energy while preserving control authority.

The controller can maintain flight stability in the event of a failure in either one of the ailerons or one of the inverted V-tail control surfaces. However, if both surfaces fail, the remaining control effectors are insufficient to ensure stable flight. In such cases, the control allocation algorithm engages vertical motors to restore controllability and maintain flight stability.

This control allocation strategy guarantees reliable operation even under severe failure conditions. The cascade PID structure, featuring independently tuned controllers for rotary-wing and fixed-wing modes, provides robust and responsive performance across all phases of flight. Simulation results confirm the system's resilience against various fault scenarios, including isolated aileron failures, inverted V-tail malfunctions, and complete loss of aerodynamic control surfaces.

Conclusion

This study introduces a fault-tolerant control (FTC) strategy for dual-system VTOL UAVs that combines vertical lift motors, a model-based fault detection system, and a control allocation method. Simulation results show that the proposed approach enhances the dual-system VTOL UAV's ability to manage control surface failures during cruise, thereby improving overall flight safety and reliability. By employing vertical motors as auxiliary actuators, the system reduces the risk of mission failure and loss of control, ensuring continued operation under fault conditions. If there is a failure in the aileron or inverted V-tail control surfaces, the dual-system VTOL UAV cannot maintain its attitude with the current controller. However, by using a control allocation algorithm, the vertical motors take over the function of the faulty surfaces and allow the dual-system VTOL UAV to continue its mission.

The cascade PID architecture, with independently tuned gains for different flight modes, provides accurate and responsive control throughout the mission. In addition to improving fault resilience, the strategy reduces dependence on primary aerodynamic control surfaces, making it a practical solution for both civilian and military dual-system VTOL UAV applications.

In future work, vertical motor support will be enhanced in fixed-wing modes to improve the dual-system VTOL UAV's ability to maintain hover and stabilize its attitude angles.

4-D Flight Management System Design for the Fighter Jets

Kaan Tellioğlu[a], Fikret Çalışkan[a]

telliogluk19@itu.edu.tr

Keywords: Flight Management, Guidance, Navigation, Route Management

Aim

The new generation of fighter jets, called the 5th generation, began a new era in the military aviation industry. In particular, multirole jets are capable of performing both air-to-air and air-to-ground missions. These complex and expensive aircraft carry huge avionics such as different types of radars and sensor suites. The system supplies vast amounts of information to the pilots. A fighter jet pilot must fly the aircraft through the route, perform tasks in the mission, and return to the base safely. Most of all, they need to evaluate various sensor information on the way to the success of the mission. This sophisticated and stressful environment is a challenge for pilots.

The goal of this study was to describe the design and simulation of a four-dimensional flight management system (FMS) for fighter jets. Current fighter jets have a basic flight management system (FMS) that is just capable of navigating an aircraft between waypoints in the lateral direction. Our FMS manages the flight route of an aircraft in four dimensions: longitudinal, lateral, vertical, and time. The algorithm performs distance, fuel, time, and speed calculations by means of a performance database of the aircraft in considering mission tasks. Besides this, it generates optimization of the current route to overcome undesired situations, such as meteorological conditions, geographical height, and threats, when necessary.

The idea behind the new-generation FMS is to reduce the workload of the pilot in terms of navigation, support for the decisions, and allow the pilot to focus on subtasks more to increase the success of the mission and return to the base safely.

Material and Method

A six-DOF nonlinear F-16 fighter jet model was developed using parameters obtained from previous studies (Stevens & Lewis, 2003; Russell, 2003), such as aerodynamic parameters, size, mass, and inertia. The aerodynamic database has validity between 0.3 Mach and 0.6 Mach.

Table 1. Aircraft States.

States	Description	Type	Unit
δ_a	Aileron Command	input	deg
δ_e	Elevator Command	input	deg
δ_r	Rudder Command	input	ft
δ_t	Thrust	input	ft
ϕ	Latitude	output	deg
λ	Longitude	output	deg
Npos	North Position	output	ft
Epos	East Position	output	ft
h	Altitude	output	ft
ϕ	Roll Angle	output	rad
θ	Pitch Angle	output	rad
ψ	Yaw Angle	output	rad
Vt	Total Velocity	output	ft/s
α	Angle of Attack	output	rad
γ	Flight Path Angle	output	rad
β	Sideslip Angle	output	rad
P	Roll Rate	output	rad/s
Q	Pitch Rate	output	rad/s
R	Yaw Rate	output	rad/s
CM	AC Weight	output	kg
FCR	Fuel Consumption Rate	output	kg/s
RF	Remaining Fuel Amount	output	kg

The Cascade controller strategies are required for navigation purposes. Our F-16 model is unstable. Therefore, in the inner loop, the stability augmentation system (SAS) is designed for the roll, pitch, and yaw axes of the aircraft to enhance stability (Cook, 2015; McLean, 1990). SAS is a PID-based state feedback controller that damps unstable aircraft rate dynamics. In the middle loop, various cascade autopilots are designed for the roll, pitch, and yaw axes of the aircraft to control attitudes. In the lateral axis, the P controller was used for the Roll Attitude hold autopilot. In the outer loop, the P controller is designed to control the aircraft cross-track (XTK), which is the deviation of the aircraft from the defined route. P-based track angle controller is designed to maintain the aircraft's track angle through the desired route. The XTK and track angle controllers operate in parallel as the outer loop of the roll autopilot (Stevens & Lewis, 2003).

In the longitudinal axis, in the pitch axis, a PI controller is used for the gamma hold autopilot. P controller altitude hold autopilot is used as the outer loop of the gamma hold controller. The P controller is designed for the speed autopilot of the aircraft to keep the air speed constant. VNAV (vertical navigator) is a P-based controller that supplies altitude deviation to the altitude hold autopilot and target speed to the speed hold autopilot.

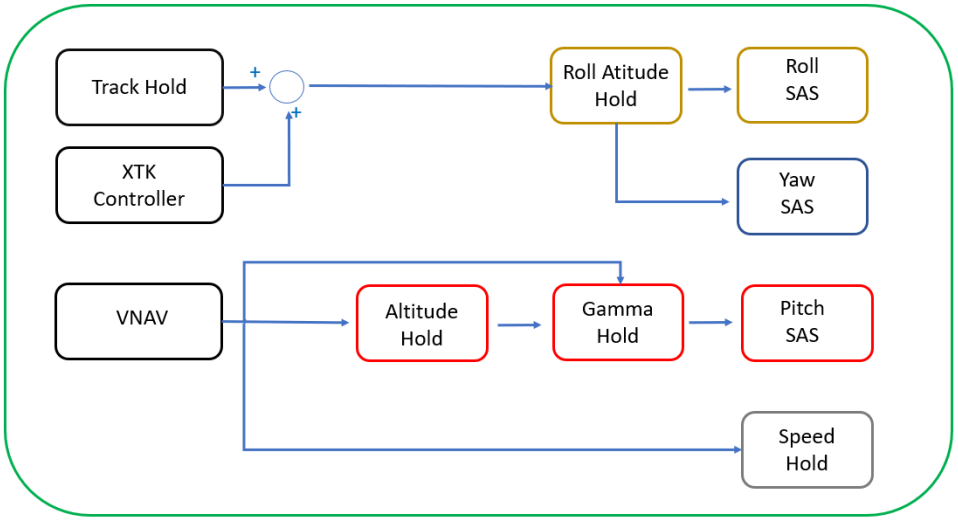

Figure 1. Cascade Controller Loop.

Our FMS consists of four parts, which are planning, execution, editing, and evaluation, respectively. In the planning stage, the distance between waypoints and the desired track of the leg calculations related to the selected route is generated. For this purpose, flat calculations and great circle calculations are used. The proposed FMS uses planning procedures (Slattery & Zhao, 1995). Time calculations were performed using the reference cruise speed information. The estimated time of arrival, estimated leg time, and total route time were the main time variables meaningful to the pilot. An offline performance database was used to calculate the approximate climb, cruise, and descent performance of the aircraft for fuel calculations (Kaminer et al., 1998). The required fuel, estimated on-board fuel, and consumed fuel calculations are crucial for pilots. In the execution part, the XTK and the desired track parameters are generated to navigate autopilots to follow the desired route. In addition, speed and fuel calculations were performed repeatedly in the case of deviation from the planned route and planned speed. In editing mode, the pilot may change the route completely between the active and standby routes. He is also able to add, change, and delete any waypoints on the current route. Planning was necessary after each editing. After automatic planning, the pilot was informed about the changes in the time and fuel of the new route. In the evaluation section, meteorology, geography, and thread in the route information were evaluated. An optimization algorithm offers route updates to overcome unsafe situations during flight, considering the fuel consumption and flight time. For the alternative route generation graph method is used. In this method, the connection between the corners of the restricted area is connected to each other for the purpose of generating a leg. If the corner points are able to reach each other without touching the restricted area, they are accepted as a leg. From the initial point to the final point corner legs are connected to each other to construct alternate routes. The shortest route is offered to the pilot as an alternate route.

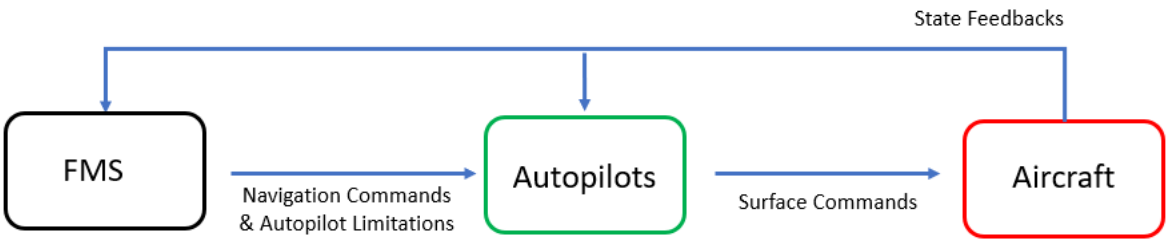

Figure 2. Modelling Scheme.

Findings

The six-DOF F-16 aircraft nonlinear model is trimmable between 0.3 – 0.6 Mach. A three-axis SAS was developed to control the aircraft's attitude in the roll, pitch, and yaw axes. The designed altitude autopilot allows controlling the altitude of the aircraft to reach the selected value without any overshoot and undershoot, and holds the value within less than 100 ft of steady-state error. The designed heading-hold autopilot allows the control heading of the aircraft to reach a selected value without any overshoot or undershoot and hold the value within less than 0.2 degrees of steady-state error. The designed speed-hold autopilot allows the speed of the aircraft to reach a selected value without any overshoot or undershoot and holds the value within less than 5 knots of steady-state error.

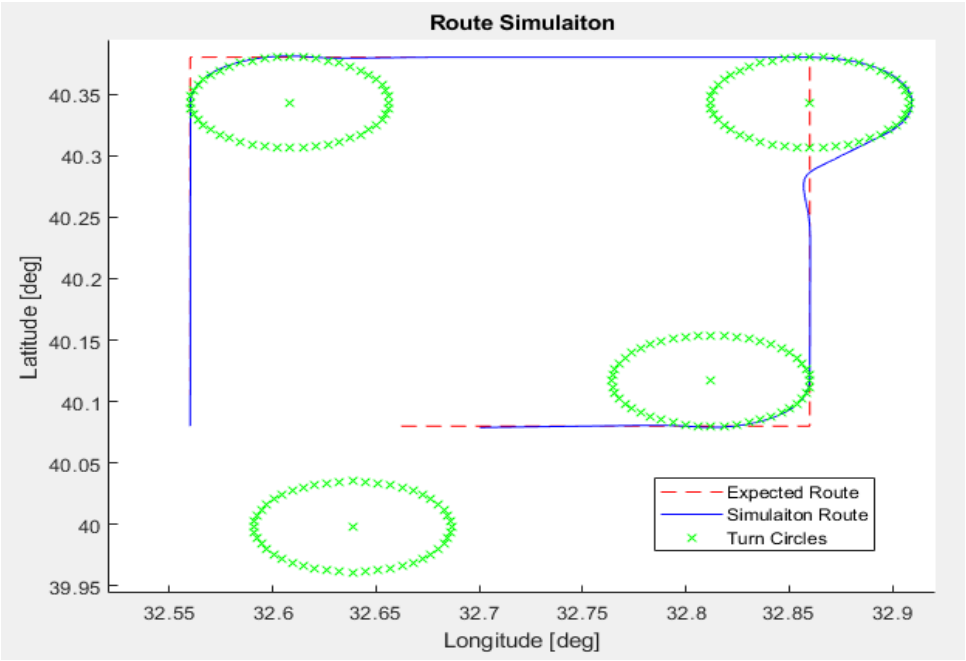

Figure 3. Route Simulation.

The FMS plans the route distance under one-foot error using the great circle algorithm. Fly-by and fly-over transitions were successfully achieved for wide and narrow turn angles. The time calculation deviations between planning and replanning were less than 2 minutes for 2 hours of flight simulations for each waypoint. Fuel calculation deviations are a maximum %3 for 2 hours of flight simulations for each waypoint. The XTK controller holds an XTK of less than 50 feet in the lateral direction. The desired Track controller holds the track less than 0.4 degrees. Route optimization works successfully and offers non-dangerous route waypoints by considering fuel and time. When the return-to-home function is enabled, an automatic path is generated to the emergency airfield.

If the aircraft route passes through any restricted area, the optimization algorithm generates an optimum route and offers it to the pilot (Figure 4).

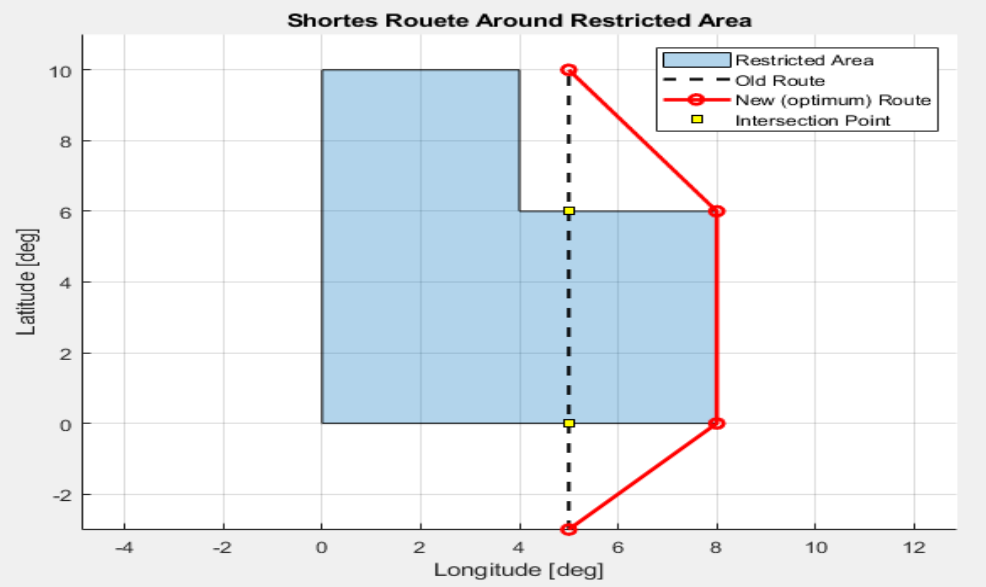

Figure 4. Optimized Route Around Restricted Area.

Conclusion

In conclusion, this study offers a new four-dimensional flight management design approach that involves planning, execution, editing, and evaluation to reduce pilot workload on critical missions to manage aircraft navigation through the performance database. The automatic planning and optimization feature of the FMS increases pilot awareness and consolidates the safety of the flight and the success of the mission. In future works,

Lane Change Decision Making For Autonomous Vehicles By Using Adversarial Learning Methods

Aytuğ Onurhan Efil[1], Mustafa Doğan[1]

[1] Istanbul Technical University, Control and Automation Engineering Program, Türkiye
efil21@itu.edu.tr

Keywords: AIRL, Autonomous Driving, CARLA, GAIL, GAN.

Aim

The primary purpose of this thesis is to analyze the effectiveness of generative adversarial imitation learning and adversarial inverse reinforcement learning in typical highway driving scenarios. The current consensus within the literature indicates that data-based techniques such as IL and IRL, when combined with adversarial approaches, can produce satisfactory results for autonomous driving on highways. Hence, the central hypothesis is: Can data-driven reinforcement learning through adversarial inverse reinforcement learning or generative adversarial imitation learning produce reasonable behavior in a highway driving environment? This research adds to the knowledge base by combining inverse reinforcement learning and imitation learning using a generative adversarial network for autonomous driving in highway driving.

Material and Method

Initially, a highway driving simulation environment was created using CARLA (Dosovitskiy et al., 2017) and Highway-env (MathWorks, n.d.) to generate the datasets required to train the imitation learning and inverse reinforcement learning models. A human driver performed multiple driving maneuvers. Highway-Env environment was initially trained and validated for simple tasks and to generate various driving scenarios. This environment basically mimics highway conditions and helps in the analysis of vehicle dynamics and interactions. The capability of the developed models to generalize and their performance were evaluated by testing under different traffic conditions and driving scenarios. As a next step, CARLA's detailed scenario modeling, autonomous driving validation capabilities were combined with Highway-env's policy testing and driving maneuver generating capability to create a thorough validation of autonomous driving algorithms. The recorded data suitable for offline learning (Hourigan, n.d.) was stored in a dataset after filtering outliers. Then, the imitation learning and inverse reinforcement learning models were trained of ne using these datasets. To further improve the vehicle's performance, a generative adversarial network (GAN) (Goodfellow et al., 2014) deep neural architecture was used. Within the combination of the methods, Generative Adversarial Imitation Learning (GAIL) (Ho & Ermon, 2016) and Adversarial Inverse Reinforcement Learning (AIRL) (Fu et al., 2017) models were achieved. The trained models were then transferred to an ego vehicle in a highway driving environment using a policy-based approach. Proximal policy optimization (PPO) (Schulman et al., 2017) was utilized to perform this task and to improve the learning performance. At each step, the agent receives the distance to the nearest vehicle in each lane, along with the lane number of the ego vehicle, and decides whether to change lanes or stay in its current lane. Each state-action pair represents the expected future reward. After simulating a finite number of steps, the rewards converge to constant values. In the test phase, the model selects the maneuver with the highest expected reward to achieve its goal, which is closely aligned with human-controlled driving behavior. The complexity of highway driving tasks in the context of autonomous vehicles was analyzed, and evidence was provided in the form of state-action rewards and collision measurements to validate the analysis. Moving to a realistic simulation environment that includes modules that provide a mathematical representation of the ego vehicle's environment validated the practical benefits of the research conducted in the study.

Findings

One of the most significant parts of autonomous driving is autonomous lane change during highway driving, with decision-making. Almost all car makers and suppliers develop autonomous driving strategies to come up with reasonable decision-making based on the context of the traffic. Over the last few years, Reinforcement Learning algorithms have been able to produce discrete actions in both discrete and continuous environments. The Highway-Env environment was used initially to train and validate for simple tasks and to generate various driving scenarios. Later on, we trained our model in CARLA and performed our test in the CARLA environment since it is capable of simulating critical safety scenarios that are necessary for assessing collision risks and for improving the performance of autonomous driving systems (Gu et al., 2024). We applied the mentioned GAIL and AIRL algorithms together with PPO in this thesis for the decision-making planning of highway controls in autonomous vehicles. Finally, we compare the results of two different offline learning approaches and assess the appropriateness of their use.

Conclusion

The primary contribution of this thesis to the research literature is the approach to evaluate two different but similar reinforcement learning paradigms in an autonomous driving environment. Instead of applying the methods used in this study to tasks unrelated to autonomous driving, this research contributes to the existing knowledge by integrating inverse reinforcement learning and imitation learning through adversarial learning networks. The results of the performance measurements and the rewards (Figure 1) obtained during training, together with the crash assessments in the highway environment and the generalization assessments, support the hypothesis that data-driven learning methods (inverse reinforcement learning and imitation learning) can be used as effective learning approaches in advanced applications. With this approach, it was observed that the vehicle can learn a policy similar to a human driver's policy to avoid collision with other vehicles (Figure 2). However, challenges may arise due to driving maneuvers that were not sufficiently represented in the training dataset.

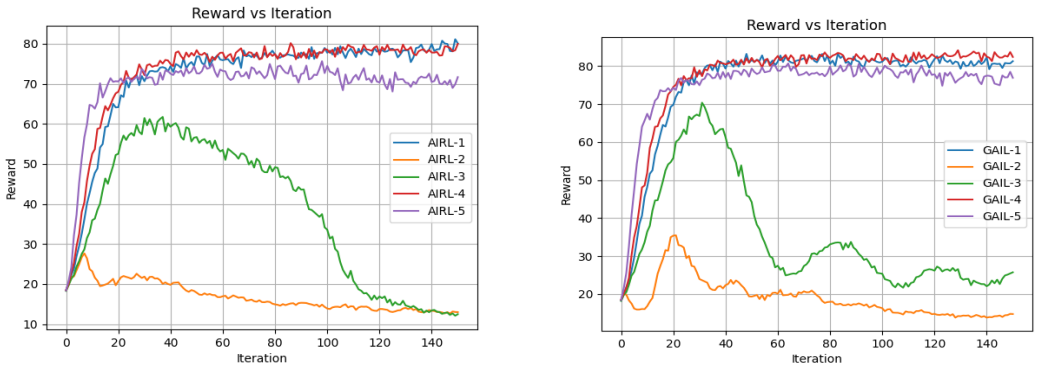

Figure 1. Reward Rate versus Iteration for AIRL and GAIL.

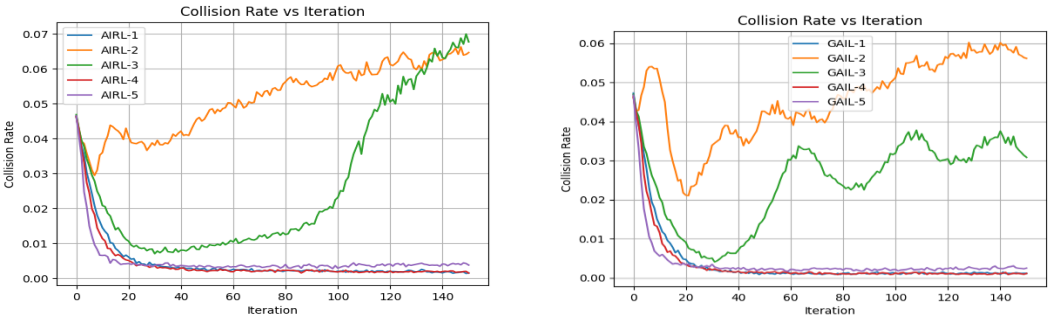

Figure 2. Collision Rate versus Iteration for AIRL and GAIL.

The study focuses on a specific driving task, enabling a meaningful and domain-specific application of reinforcement learning. Additionally, we demonstrate the feasibility and benefits of comparing driving tasks in a minimalist environment.

Applications of Control Engineering

An Optimization-Based Flight Control Law Design for Fighter Aircraft

Bora Akaryıldız[a], Yaprak Yalçın[a]

[a] Istanbul Technical University, Faculty of Electrical and Electronics Engineering, Control and Automation Engineering, Turkey
akaryildiz17@itu.edu.tr

Keywords: Flight Control Law, Flying and Handling Qualities, Stability and Performance Robustness.

Aim

Flight control law design for modern fighter aircraft must meet strict FHQ requirements while ensuring robustness against aerodynamic and inertial uncertainties. The challenge arises due to large flight envelopes where airframe dynamics change with dynamic pressure, Mach number, and mass-inertia properties, necessitating a multi-stage gradient-based optimization scheme to achieve Level 1 handling qualities with stability robustness in a cost-effective manner.
This paper applies a three-stage optimization scheme inspired by industrial applications for designing a lateral-directional flight control law of a fighter aircraft. The control law architecture includes stability axis roll rate, sideslip angle rate, and lateral acceleration feedback, commonly used in flight control applications. Actuators, noise filters, and time delays are modelled to better represent phase lag effects in the flight control system. The objective is to achieve predicted Level 1 handling qualities and ensure stability robustness using a linear control law.

Material and Method

The optimization follows CONDUIT's strategy (Tischler et al., 2017), structured into three sequential stages as given in Table 1. The requirements are mapped into the optimization functions such that, a "good" value corresponds to predicted Level 1 handling qualities, while a "bad" value represents Level 2 or inadequate stability robustness as depicted in Eq. 1. Various algorithms are used for this problem, for example in (Tischler et al., 2017) FSQP is used for control law design applications for both fixed and rotary wing platforms. In (Moritz & Osterhuber, 2006), the SLLSQP algorithm is utilized for the control law design activities of EF 2000. In (Joos & Finsterwalder, 1999), SQP is used for LQR-based control law design of a transport aircraft by optimizing the Q and R matrices based on design specifications. And in (Park & Tahk, 1998), CEALM is utilized for control law design of a fighter-type aircraft. In this study, MATLAB's interior-point algorithm is used as the solver for its compatibility with nonlinear constraint optimization, fast convergence, and good feasibility properties.

$$f_{h,s_i}(K) = f_{map}\left(f_{req.i}(K)\right) \tag{1}$$

Stage 1	$solve\ f_{hard}(K) \leq 0$
Stage 2	$solve\ f_{soft}(K) \leq 0, \quad while\ f_{hard}(K) \leq 0$
Stage 3	$minimize\ f_{sum}(K), \quad while\ f_{cons}(K) \leq 0$

In the first stage, the objective function is defined as the maximum of hard objectives that consist of stability requirements as given in Eq. 2. By decreasing the maximum value to the "good" value, all of the requirements are satisfied. This min-max strategy has the advantage of reducing time and computational cost by decreasing the size of the Jacobian matrix,

making it a time-effective strategy for control law design. As soon as the objective function recedes to a "good" value second stage of the optimization scheme starts.

$$f_{hard}(K) = \left(f_{h_1}, f_{h_2}, \dots f_{h_n}\right) \quad (2)$$

In the second stage, soft objectives that consist of FHQ or generic requirements are defined as the objective function given in Eq. 3, and the same min-max strategy is utilized. The maximum value of hard objectives is taken as the constraint function, and the maximum value of soft objectives is minimized until it recedes to a "good" value. Again, as soon as the "good" value is reached, the third stage starts.

$$f_{soft}(K) = max\ (f_{s_1}, f_{s_2}, \dots, f_{s_n}) \quad (3)$$

In the third stage, the maximum of all the soft and hard objectives that are satisfied in prior stages is taken as the constraint function as depicted in Eq. 4, and a designer-defined objective function f_{sum} is minimized. In (Berger & Tischler, 2013), this stage consists of functions that are related to control surface usage and the optimization scheme aims to satisfy all requirements with minimum control effort, whereas in (Moritz & Osterhuber, 2006), this stage consists weighted sum of several functions.

$$f_{cons}(K) = \left(f_{soft}, f_{hard}\right) \quad (4)$$

Flight Control Law Architecture

Flight control law consists of stability axis roll rate feedback to aileron, with aileron to rudder interconnect, washed out sideslip angle rate to rudder, and lateral acceleration feedback to rudder loops. The commanded control variable in the lateral axis is stability axis roll rate, for which a proportional control with K_p gain is used in the forward path. And an interconnect gain K_{ARI} is used for turn coordination. In the directional axis, lateral acceleration is used to minimize the sideslip angle. The hard, soft, and summed objectives used for the design are explained as follows.

Hard Objectives

The minimum gain and phase margin requirement from (U.S. Department of Defense, 2006) is taken as one of the hard objectives with a minimum phase and gain margin of 45°, 6dB, respectively. However, in order to address simultaneous gain and phase variations in loop transfer functions a more generic measure for stability is used by defining the maximum sensitivity peak value to be less than 6dB, which corresponds to guaranteed phase margin of 30° and gain margin of 6dB (Blight et al., 1983). A time to double requirement is added with a maximum value of 20s.

Soft Objectives

Minimum Dutch-roll damping of 0.4 is taken as recommended from (U.S. Department of Defense, 1997). Northrop criterion in (Innocenti & Bava, 1991), which is a measure of Dutch-roll pole-zero cancellation in the roll response, is chosen as one of the objectives. This ensures that the Dutch-roll contamination in the roll response is not objectionable to the pilot and helps achieve a first-order-like response in the roll axis.

Sideslip angle excursion criteria is added to minimize sideslip angle for stick input and its boundaries are taken from the recommended values of (U.S. Department of Defense, 1997). Disturbance rejection criteria is added for the roll rate loop to minimize the aircraft's response to gusts with a maximum gain of -8dB for around 1rad/s of sensitivity function. In order to address linear PIO tendency, Gibson's average phase rate criteria (Gibson, 1999) and attitude quickness criteria (Klyde et al., 1995) are added to the soft objectives with their recommended values.

Summed Objectives

For the last stage, sideslip angle excursion for stick input is added in order to minimize sideslip angle, and sideslip angle build-up for pedal input is added to increase the disturbance rejection performance of lateral acceleration feedback. Crossover frequency for the aileron loop is added in order to minimize aileron control surface activity.

Findings

Lateral-directional flight control law for a fighter aircraft is designed using the three-stage optimization scheme with MATLAB's interior-point algorithm with the linear state-space models of a fighter aircraft that are obtained by linearizing the nonlinear 6-DOF model of the subject aircraft with aerodynamic data acquired from (Nguyen et al., 1979). The design process involved equivalent airspeeds (EAS) 150 to 400 knots and altitudes 0 to 20kft, where gains are scheduled with respect to EAS and altitude.

Designed gains as an output of the optimization process are given in Figure 1, where it can be seen that all the gains form a smooth trend with respect to EAS and altitude. Here, K_{DC} is the gain that is used to achieve a unit response and K_{ARI} is the interconnect gain that is designed prior to the optimization.

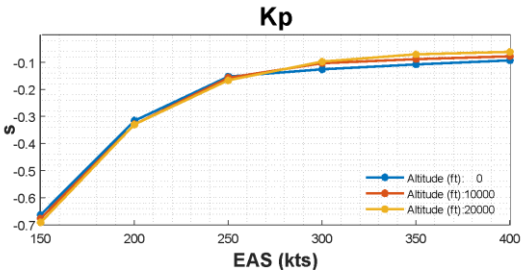

Figure 1.1 Stability axis roll rate gain schedule.

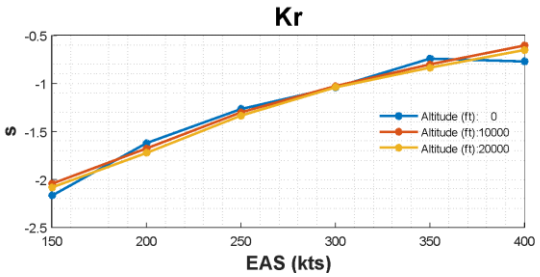

Figure 1.2 Sideslip rate gain schedule.

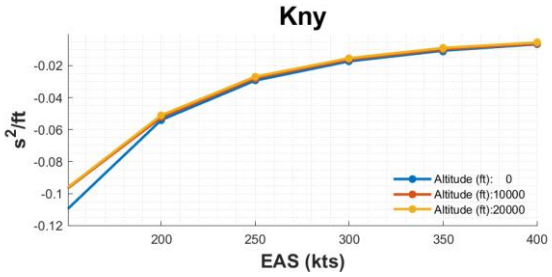

Figure 1.3 Lateral acceleration gain schedule.

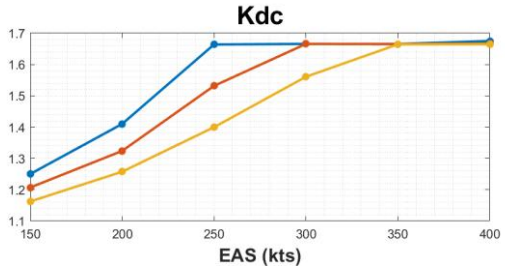

Figure 1.4 "DC" gain schedule.

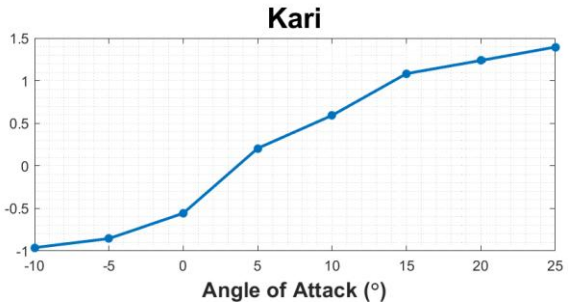

Figure 1.5 Aileron to rudder gain schedule.

As can be seen in Figure 2, all of the hard objective functions are below 0, indicating that all of the stability requirements are satisfied.

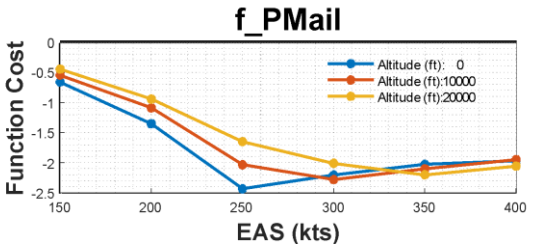

Figure 2.1 Aileron loop phase margin cost value.

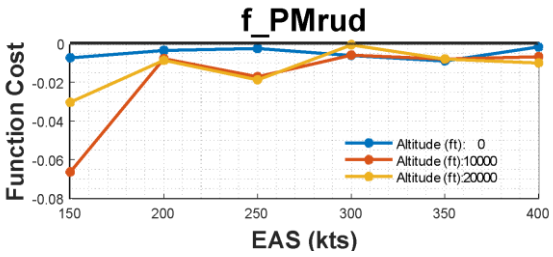

Figure 2.2 Rudder loop phase margin cost value.

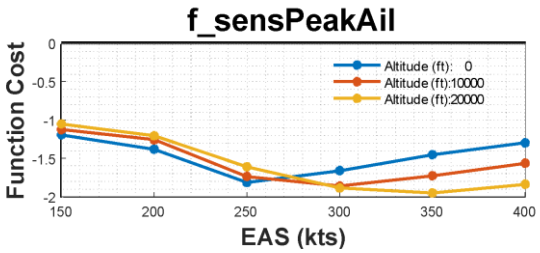

Figure 2.3 Aileron loop sensitivity function peak cost value.

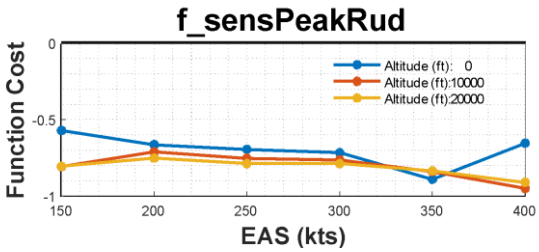

Figure 2.4 Rudder loop sensitivity function peak cost value.

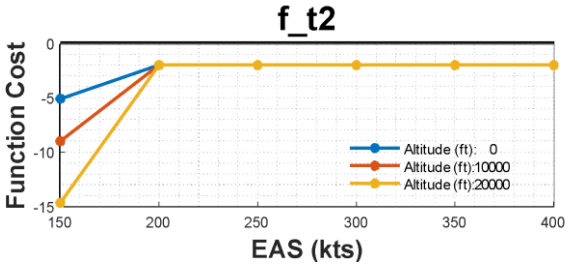

Figure 2.5 Time to double the cost function.

Also, as can be seen from Figure 3, all of the soft objectives are satisfied, indicating a predicted Level 1 FHQ. It can be seen that the disturbance rejection function is around zero for EAS higher than 250kts. Since crossover frequency is minimized in the last stage, the algorithm decreases the roll rate gain K_p which degrades the disturbance rejection performance until it reaches its good value.

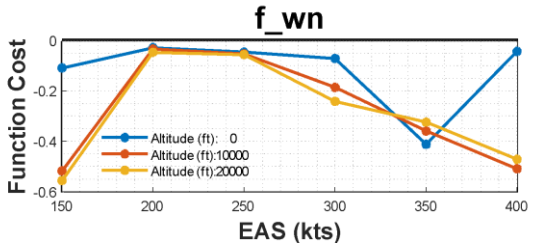

Figure 3.3 Dutch roll frequency cost value.

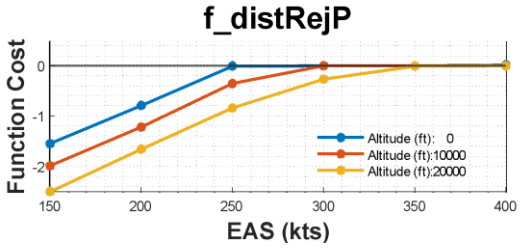

Figure 3.4 Roll rate output sensitivity gain cost value.

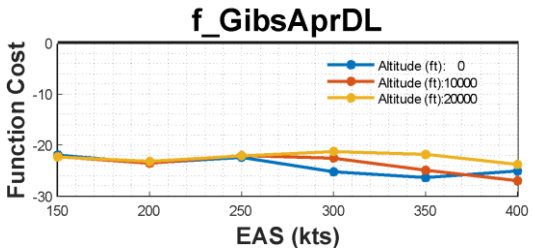

Figure 3.5 Gibson average phase rate cost value.

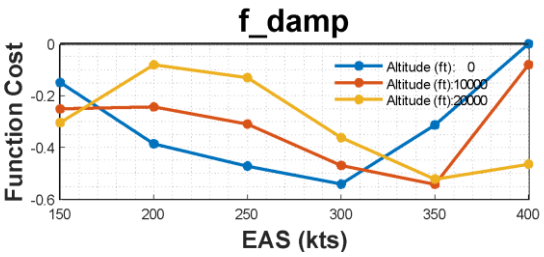

Figure 3.6 Dutch roll damping ratio cost value.

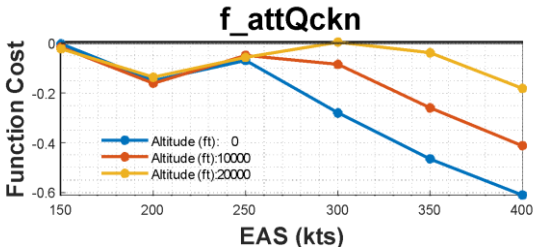

Figure 3.7 Attitude quickness cost value.

In addition, loop transfer functions obtained from actuator inputs and sensor outputs indicate stability robustness against uncertainties as none of them violate the Nichols boundary and satisfy at least 50° of phase margin as depicted in Figure 4.

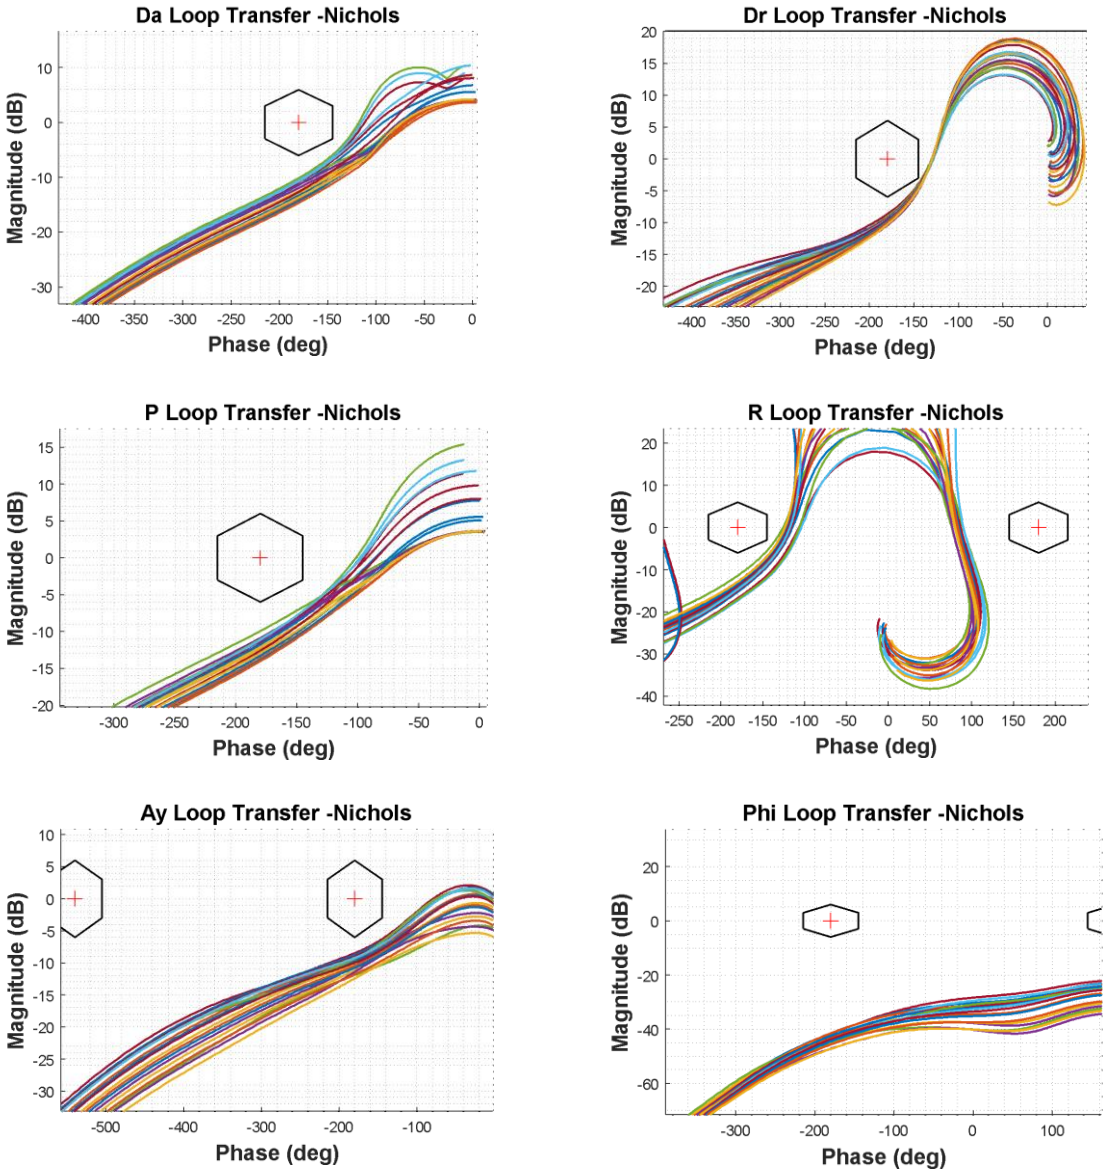

Figure 4. Nichols Exclusion Zone results for actuator input and sensor output loop transfer functions.

As can be seen from the frequency response of the sensitivity function for roll rate output in Figure 5, maximum magnitude around 1 rad/s is -8dB, which is a good value chosen for this criterion. Both frequency responses of loop transfer and sensitivity functions show satisfactory disturbance rejection characteristics around frequencies of interest with good stability robustness.

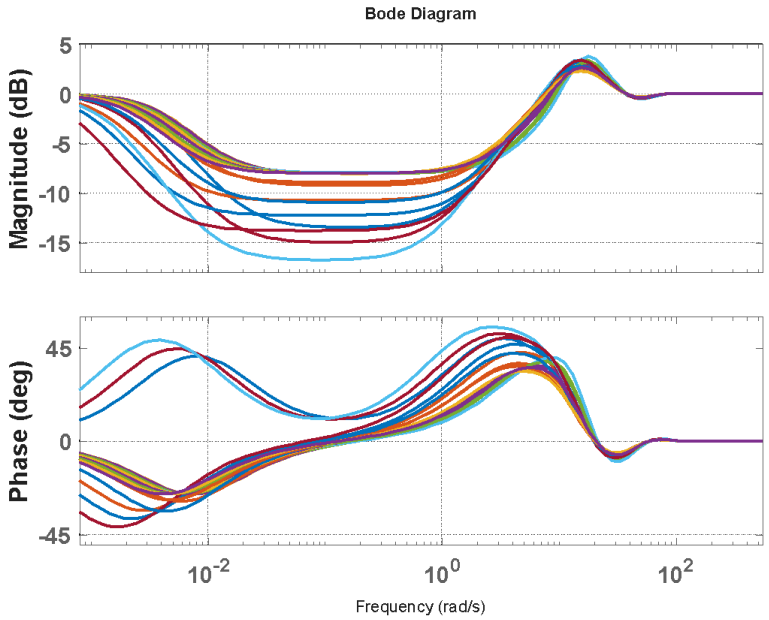

Figure 5. Sensitivity function frequency response of stability axis roll rate output.

It can be seen in FHQ analyses plots, as depicted in Figure 6, that bandwidth and average phase rate criteria indicate a PIO-I free solution as all of the points in the design envelope lie within the Level-I boundaries. There is near-perfect Dutch-roll pole-zero cancellation as solutions lie within the optimal region in the Northrop criterion, and the LOES cost for the roll rate response is well below the Level-I boundary, showing an almost identical response to that of a first-order system that can also be seen in Figure 7. In attitude quickness criteria, some points lie right at the boundary for small stick inputs; however, they move into the Level-I region as the amount of stick input increases. Lastly, for the sideslip excursion criteria,

all of the solutions lie well within the Level-I boundary.

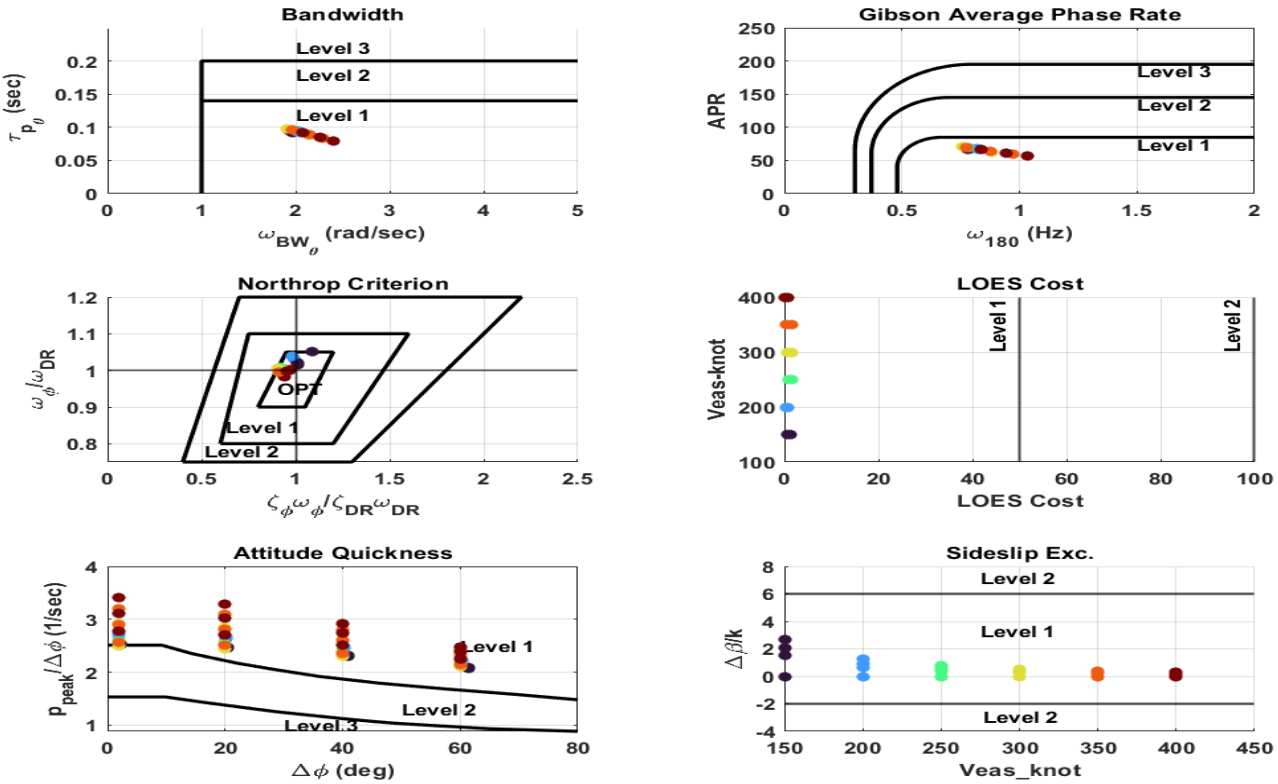

Figure 6. FHQ analysis results.

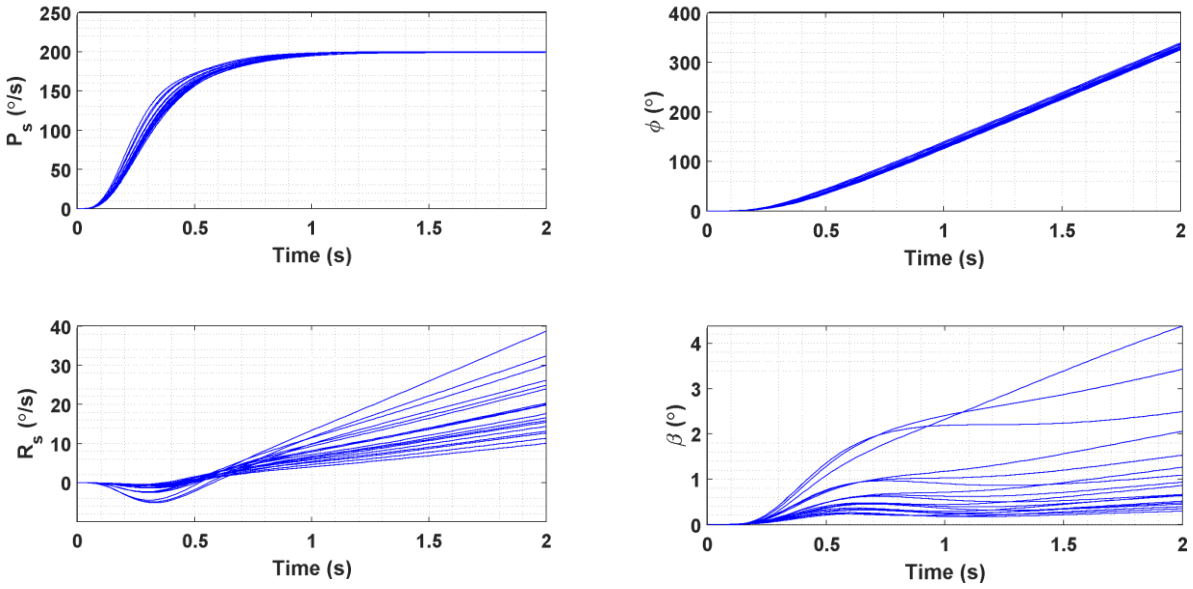

Figure 7. Closed-loop time responses for step input.

Conclusion

An optimization-based flight control law design process is applied to a fighter aircraft by utilizing a min-max strategy with MATLAB's interior-point solver. The design process produced consistent controller gains with respect to EAS and altitude and a smooth gain schedule. The cost functions indicate satisfaction of all of the criteria, although there are several points at the good value limit due to the last stage minimization. Loop transfer functions and sensitivity functions for roll rate output indicate both stability, robustness, and satisfactory disturbance rejection performance. Also, FHQ analyses indicate a PIO-I free, first-order-like roll response with minimal sideslip angle build-up, showing a predicted Level-I FHQ.

Enhancing Aircraft Avionics Safety: Integrating STPA With ARP4761

Şükrü Can Sulak[a], Mehmet Turan Söylemez[a]

Keywords: ARP 4761, Flight Management System, Vertical Navigation (VNAV), System-Theoretic Process Analysis (STPA), Functional Hazard Assessment.

Aim

Safety engineering has repeatedly proven its importance through unfortunate events throughout history and across various fields. For instance, in 2018 and 2019, due to the malfunction of the Maneuvering Characteristics Augmentation System (MCAS) on Boeing 737 Max aircraft, the crashes of Lion Air Flight 610 and Ethiopian Airlines Flight 302 resulted in the loss of 346 lives (Barshi et al., 2023). Another example is the crash of American Airlines Flight 965 in December 1995, which was caused by a malfunction of the Flight Management System (FMS) that misdirected the pilots, resulting in 163 fatalities (National Transportation Safety Board [NTSB], 1996).

The Federal Aviation Administration (FAA) and the European Aviation Safety Agency (EASA) do not mandate specific practices for certification; rather, they issue advisory circulars that identify acceptable methods for aircraft development and certification. SAE Aerospace Recommended Practice (ARP) 4754A is an accepted development assurance process as endorsed by Advisory Circular, AC 20-174. SAE ARP 4761A, on the other hand, is an important document that supports ARP 4754A by outlining the safety assessment processes that should be followed (Leveson et al., 2014a). Although ARP 4761A is not explicitly referenced by any advisory circular, it is widely used in the industry.

With the increasing prevalence of software-containing equipment in modern systems and the growing complexity of tasks performed by intercommunicating algorithms, the comprehensiveness of the safety analyses described in ARP 4761A is being questioned. Indeed, the traditional safety analysis methods mentioned in ARP 4761A—such as Fault Tree Analysis (FTA), Failure Mode and Effects Analysis (FMEA)—were developed long ago to identify failure-related losses in electromechanical systems and are based on reliability theory. However, to identify the hazardous scenarios that have not occurred due to a failure of a component involved in the system of today's complex, software-intensive systems, newer analysis methods are needed (Ishimatsu et al., 2014).

This study aims to show that a new hazard analysis method called System-Theoretic Process Analysis (STPA) can be used as a complementary method to traditional ones suggested in SAE ARP 4761A to uncover additional hazardous scenarios and prevent them by developing safety requirements.

Material and Method

Aircraft safety assessment is a process that occurs in tandem with design and other processes. ARP 4754 employs the V-Model, a well-known systems engineering approach, to frame the development process.

The V-Model can be decomposed into three primary stages, regardless of the area under consideration. The following phases were identified: Concept Phase, Design Phase, and Verification Phase. The outcomes of the safety analysis are transmitted to system engineers, who incorporate these requirements into their designs. Finally, after the hardware and software designs are finished, the integration and verification process begins. Integration starts with low-level products (e.g., components) while verifying them, and finishes when all systems are integrated to create an aircraft.

Functional Hazard Assessment (FHA) is the initial analysis to determine failure conditions that may result in hazards and classify them according to their severity values. Fault Tree Analysis and Failure Mode and Effects Analysis are two recommended safety analysis methods that focus on reliability and probability theory to assess the causes of failure

conditions identified in FHA. However, an aircraft consists not only of elements that may have a failure rate or availability rate, such as software-intensive components. In these cases, Development Assurance Level (DAL) requirements are derived from FHA severity classifications and allocated to software items and their host component hardware. After DAL allocations, item development can be carried out under the guidance of DO-254 (for hardware) and DO-178 (for software). However, DO-178 states that a safety assessment process is not required for software items if the system-level safety requirements are complete. This makes ARP 4761 and its assessment method, FHA, inadequate for evaluating modern software-intensive systems (Rong & Dong, 2019).
According to STPA, safety is primarily a control issue rather than a matter of reliability (Leveson & Thomas, 2018). Fundamentally, STPA consists of two main steps: Identification of Unsafe Control Actions (UCAs) and Development of Loss Scenarios. Below, the main steps are given with brief descriptions:

1. Identification of UCAs: Potential unsafe control actions can be considered as triggering reasons for accidents. UCAs shall be identified and need to be eliminated or controlled to prevent accidents. These UCAs can be analyzed in four main categories:

    a. A control action required for safety is not provided.
    b. An unsafe control action is provided that leads to a hazard.
    c. A potentially safe control action is provided too late, too early, or out of sequence.
    d. A safe control action is stopped too soon or applied too long (Fleming & Leveson, 2014).
2. Development of Loss Scenarios: For each UCA identified in Step 1, there should be causal scenarios explaining how these unsafe conditions might arise (Leveson, 2011).

As a result of STPA, the following can be provided as input requirements to the design phase, along with high-level safety requirements and DAL requirements defined by FHA, and to the verification phase to enhance verification performance: generated safety constraints from UCA and their corresponding loss scenarios, and their corresponding test requirements.

Although STPA is an analysis that can be performed in the concept phase, its outputs can contribute to the design and verification phases.

Findings

In this study, STPA was chosen to reveal additional hazardous scenarios of the Vertical Navigation (VNAV) Function of the Flight Management System (FMS), as the FMS is one of the highly software-integrated systems of a commercial aircraft. The FMS is a complex system that relies heavily on software and has a critical impact on flight safety. VNAV's main duty is to control an aircraft's vertical trajectory from the climb phase until the landing phase by generating a vertical flight plan according to airspace constraints (such as speed and altitude) and generating thrust and pitch control signals for the auto throttle computer and autopilot computers. It is an excellent system to show how STPA can contribute to FHA. Its critical role during a flight, especially during critical phases such as climb and approach, means that even minor anomalies can lead to accidents.
To apply FHA, VNAV functions are defined as follows:

1. Profile Generation
2. Constraint Handling
3. Climb Management
4. Auto throttle / Flight Director Coupling
5. Cruise Management
6. Descent Planning
7. Reversion and Degraded Modes

Each VNAV function is assessed in FHA with the following guidewords: Total Loss, Partial Loss, Erroneous, and Inadvertent. As a result of the FHA, 80 failure conditions are generated from 7 different functions in different flight phases. An example from FHA is given below.

Total Loss Reversion and Degraded Modes

Flight Phase: All flight phases

Effect: Due to total loss of Reversion and Degraded Modes, VNAV will stay active even if a failure occurs in a different function of VNAV. Total loss of Reversion and Degraded Modes means loss of detection and degraded mode capability of both FMCs. Depending on the failure, total loss of Reversion and Degraded Modes may lead to stall, CFIT, or violation of altitude and speed constraints. Repercussion is considered CAT.

Possible Crew Action: The Crew needs to disengage VNAV and manage the related flight phase manually

Severity: Catastrophic
Example Functional DAL requirement and other generated requirements for "Total Loss Reversion and Degraded Modes in Flight" with respect to ARP 4754 and ARP 4761 are given below.

1. Reversion and Degraded Mode function shall be developed with DAL-A.
2. Total loss of Reversion and Degraded Modes in flight shall be less than 10^{-8} per flight.
3. No single event shall lead to total loss of the Reversion and Degraded Mode function.

In parallel, STPA is applied to "Inhibit Command – Profile Generation" Control Action that goes from the Reversion and Degraded Modes function to the Profile Generation function. "Inhibit Command – Profile Generation" signal is used to disable a VNAV function when a critical fault is detected, and it is provided to Profile Generation. It includes the VNAV Disable command, the target module, severity flag. Unsafe Control Actions and their corresponding Loss Scenarios are given below.

1. Not Providing Causes Hazards: Reversion & Degraded Modes function does not provide " Inhibit Command – Profile Generation " to Profile Generation function during approach with detected failure. A/C continues erroneous descent profile.
2. Providing Causes Hazard: Reversion & Degraded Modes function provides " Inhibit Command – Profile Generation " to Profile Generation function during nominal operation. A/C unexpectedly exits VNAV, and the crew is confused.
3. Too Soon: Reversion & Degraded Modes function provides " Inhibit Command – Profile Generation " too soon to Profile Generation during descent. A/C disables VNAV before profile failure is confirmed for TBD ms.
4. Too Late: Reversion & Degraded Modes function provides " Inhibit Command – Profile Generation " too late for Profile Generation during climb. A/C applies incorrect pitch/thrust before inhibition takes effect.
5. Stopped Too Soon: UCA-146: Reversion & Degraded Modes function continues providing " Inhibit Command – Profile Generation" to Profile Generation after failure is resolved. A/C remains in degraded mode.
6. Too Late: Reversion & Degraded Modes function stops providing " Inhibit Command – Profile Generation " too soon to Profile Generation during approach. A/C changes back to faulty vertical path generation.

The following safety constraints are generated regarding UCAs given in the 3rd, 4th, 5th, and 6th sections above, since FHA misses timing-related failures because it does not individually consider timing issues.

1. Reversion and Degraded Modes shall not issue an Inhibit Command to Profile Generation until a profile-generation failure has been positively detected and held for ≥ TBD ms.
2. Until the inhibitor takes effect, the flight-control computers shall limit commanded pitch and thrust to values that preserve positive energy margins.

3. If inhibition persists longer than the scheduled maximum dwell time after Profile Generation recovery, the system shall generate a Level B crew alert.
4. Below 1,000 ft AGL, automatic removal of the inhibit shall be disallowed unless explicitly commanded by the crew.

Conclusion

This study analyses the VNAV of a commercial aircraft using FHA in SAE ARP 4761 and STPA. STPA can identify additional hazardous scenarios related to timing interaction and complex software behaviour that FHA cannot capture. STPA was able to find 4 new causal paths that FHA was overlooking. These new causal paths lead to new requirements that are different than FHA-generated requirements. STPA treats safety as a control problem, so an existing design is not required to perform the analysis. This means the analysis and design can proceed in parallel, each supporting the other [4]. This advantage of STPA should also be considered when considering the implementation of safety analysis for systems with complex software behaviours.

Keywords: Dual Layer Disturbance Observers, Autopilot, Robust Control

Aim

In control design, a frequent discrepancy exists between the mathematical model and the actual system. This distinction between them arises from several factors. Such as including the inherent uncertainties in the system's behavior, the neglect of higher-order dynamics, and the linearization of nonlinear dynamics. Furthermore, when aerodynamic and atmospheric disturbances are factored in, the level of uncertainty in the system increases significantly, which must be considered in the system. All these factors negatively affect the stability and performance of control systems, generating an urgent necessity to lessen the effect of these uncertainties to enhance system stability and performance. PID control is one of the conventional control methods which widely used in the industry due to its simple structure and ease of implementation. However, the PID control approach might lack adequate robustness in the face of external disturbances and uncertainties within the system. Therefore, enhancing the robustness of the PID controller by integrating it with various advanced control strategies can provide significant improvements in terms of performance and stability.

In this study, observer design is considered to enhance the effectiveness of the PID controller against disturbances and achieve a more robust control. Observers estimate unknown and unobservable state variables or external disturbances in a system, allowing the control system to compensate for these disturbances and allow the system to operate more precisely. If control algorithms rely solely on directly observable data, they may overlook such variables, which can weaken control performance. Therefore, by estimating unknown or unmeasurable states affecting the system, observers enable control algorithms to function more accurately. In this study, a Disturbance Observer (DOB) structure is employed as the observer. This observer estimates both internal and external disturbances occurring in the system and adds an appropriate compensation signal to the control input, making the system more resilient to internal and external disturbances. The integration of the Disturbance Observer with the PID controller enhances the dynamic performance of the system and provides a more stable structure against unexpected disturbances. This approach offers a significant advantage, particularly in applications requiring precise control, such as aerospace, by effectively suppressing disturbance effects.

This study aims to evaluate the sensitivity of autopilot systems based on DOB-supported PID controllers against uncertainties and disturbances and to demonstrate how they can enhance stability in flight control systems. In this way, the potential and advantages of the DOB structure in modern aircraft autopilot systems will be revealed.

Material and Method

In this study, a PID controller was implemented as the controller, and the Disturbance Observer method was used as the observer for the scaled model of the delta-winged B2-Spirit bomber aircraft. All design and analysis steps were carried out in the MATLAB and Simulink environments.

PID control is one of the most widely used feedback control strategies in engineering applications and has been preferred for many years due to its simplicity, ease of implementation, and reliable performance. The PID controller produces a control signal using three different components by analyzing the system's current error. The first component is the Proportional (P) component. It provides an immediate response based on the magnitude of the error. The second one is the Integral (I) component. It considers past error values to improve the system's long-term accuracy. The last one is the

Derivative (D) component, and it predicts the system's future behavior and reacts to sudden changes. However, one of the major disadvantages of PID controllers is their sensitivity to modeling uncertainties and external disturbances. Especially in rapidly changing systems and nonlinear dynamics, traditional PID controllers may exhibit insufficient performance. Therefore, enhancing PID controllers with an additional method, such as the Disturbance Observer, to improve their robustness is proposed within the scope of this study.

The Disturbance Observer method is a significant technique used in control systems to estimate and compensate for the effects of external disturbances and modeling uncertainties. The difference between the actual system model $\left(P(s)\right)$ and the nominal model $\left(P_n(s)\right)$ is considered an internal disturbance. When calculating this difference, the inverse transfer function of the nominal model $\left({P_n}^{-1}(s)\right)$ is typically used in conjunction with a low-pass filter $\left(Q(s)\right)$ to ensure system stability and prevent algebraic loops (Schrijver & van Dijk, 2002). The total disturbance effect is obtained by summing this difference with the effects of external disturbances, and this calculation is fed back as a cancellation signal to suppress the disturbance effects.

Thus, DOB is regarded as a method for achieving robust control. In other words, DOB transforms a basic, non-robust feedback controller into a robust one. The fundamental controller is designed for a nominal plant model without external disturbances, noise, or uncertainties. When DOB is added to the inner feedback loop, the nominal stability and performance achieved by the basic controller and the nominal plant can be approximately recovered even in the presence of disturbances and uncertainties.

A general DOB structure for a Single Input Single Output (SISO) plant is illustrated in the upper part of Figure 1. Here, r represents the reference command input, u_r is the control input, d is the external disturbance input, y is the model output, and n represents the sensor noise. $P(s)$ represents the physical plant to be controlled, $P_n(s)$ is the nominal plant model, and $C(s)$ is the feedback controller. Finally, $Q(s)$ is a transfer function that is designed as a low-pass filter to prevent algebraic loops.

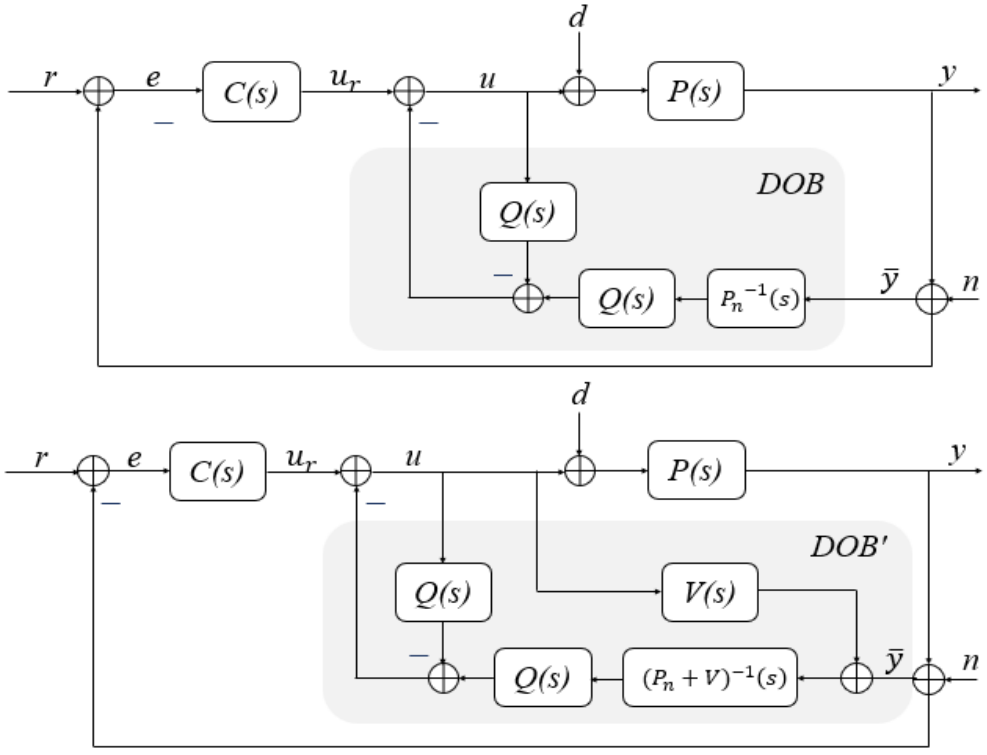

Figure 1. Minimum phase and non-minimum phase DOB structure.

In the Disturbance Observer, disturbance rejection is achieved by directly feeding back the difference between u_r and u, assuming that this difference represents an estimate of the total disturbance. However, the direct feedback of the estimated disturbance signal ($\hat{d}$) cannot be implemented because using the inverse plant model is not an appropriate approach. Additionally, direct feedback leads to an algebraic loop. Therefore, the Q-Filter is used. With this approach, the DOB design can be reduced to the design of the Q-Filter. However, since the selection of Q-Filter requires a trade-off between disturbance rejection and noise rejection, the design must be carried out carefully. In Figure 2, it can be seen that as the cutoff frequency of the low-pass filter increases, the disturbance estimation capability improves, but the noise sensitivity also increases.

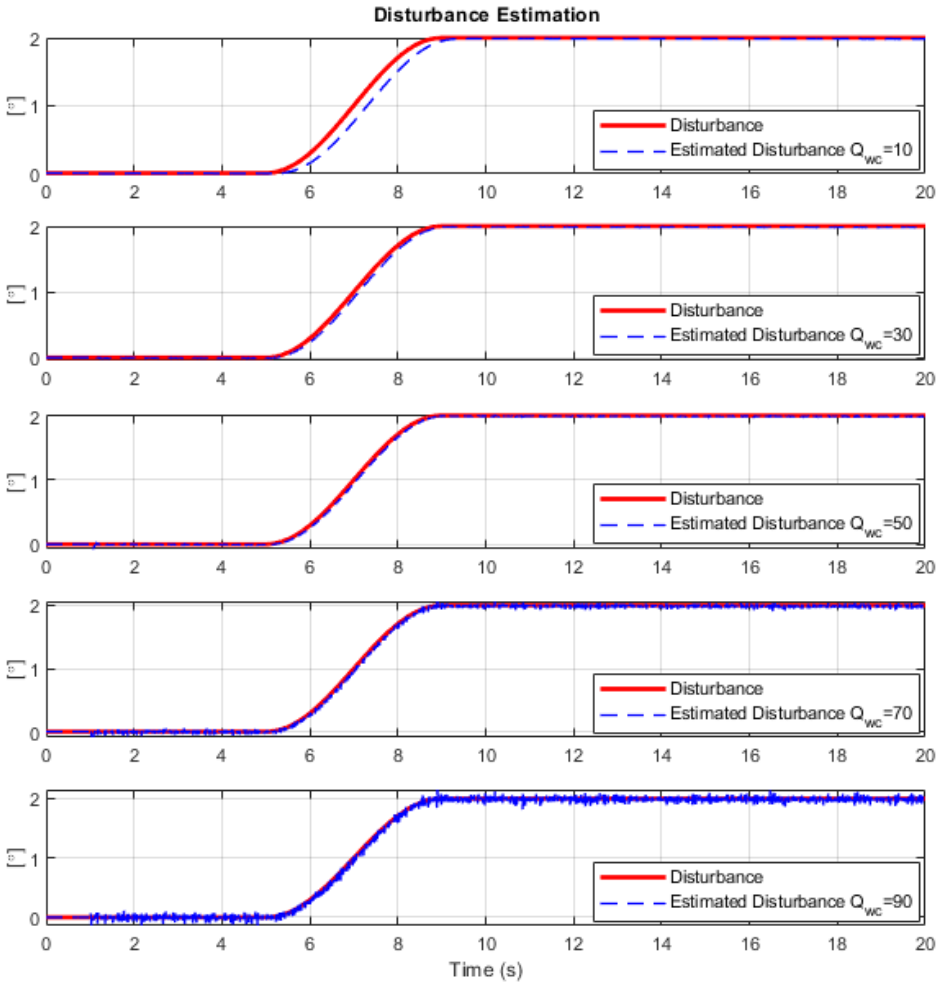

Figure 2. Disturbance estimation performance at different cutoff frequencies under noise.

Although the Disturbance Observer method is effective in suppressing disturbances, some challenges arise when applying it to a non-minimum phase system. If the nominal model $P_n(s)$ has unstable right-half-plane (RHP) zeros, the inverse transfer function ${P_n}^{-1}(s)$ used in the inner feedback loop of the DOB will cause these unstable zeros to transform into unstable poles. As a result, the system response may diverge to infinity. To eliminate this issue and apply the DOB method to such systems, a new parallel filter is added to the given system, modifying the classic DOB method (Shim et al., 2007). Non-minimum phase DOB structure can be seen in the lower part of Figure 1.

This additional filter, called the V-Filter, is designed to ensure that the inverse of the nominal model used in the inner feedback loop of the DOB becomes minimum-phase. With the inclusion of the V-Filter, the classical DOB method becomes applicable to non-minimum phase systems. The key feature of this new structure is the design of a V-Filter that transforms the parallel connection in the DOB feedback loop $(P_n(s) + V(s))$ into a minimum-phase system.

The control design for longitudinal axes consists of two separate controllers, namely the inner loop and outer loop controllers. Inner loop controllers are typically responsible for controlling faster-changing variables that require a higher bandwidth. In this loop, variables such as attitude, angular rate, or velocity are monitored, and quicker responses are generated for the control surfaces. The outer loop, on the other hand, is responsible for controlling slower-changing variables that define the overall flight profile. Variables such as altitude, position, or heading are addressed in the outer loop. This loop provides reference values to the inner loop and ensures that overall flight objectives are achieved. In this study, the disturbance observer design is employed in the inner loop for pitch angle control and in the outer loop for altitude control. In the inner loop, due to the structure of the disturbance observer method, the disturbance affecting the system includes servo errors or errors arising from the control surface interface. With the design of the outer loop controller, atmospheric disturbances affecting the aircraft are directly introduced to influence the attitude angles.

During the PID controller design phase, the inner loop controller was initially designed using a linearized model. While designing the controller, care was taken to ensure that the percent overshoot did not exceed 20%, and the settling time did not exceed 3 seconds. Control surface commands were also examined, and it was confirmed that they remained within the actuator limits. The PID controller gains were obtained using an optimization method based on the Integral of Squared Error criterion, which also considered percent overshoot, phase margin, and gain margin. These initially obtained gains were then manually fine-tuned based on the system's response. After the controller design, a Classical Disturbance Observer was designed and integrated into the inner loop. In the outer loop, a PI controller was first designed similarly, and then a Non-Minimum Phase Disturbance Observer was designed and integrated into the system.

By designing a disturbance observer for both the inner and outer loops, it is aimed to suppress all types of disturbances affecting the aircraft. The longitudinal autopilot architecture incorporating the disturbance observer method is presented in Figure 3.

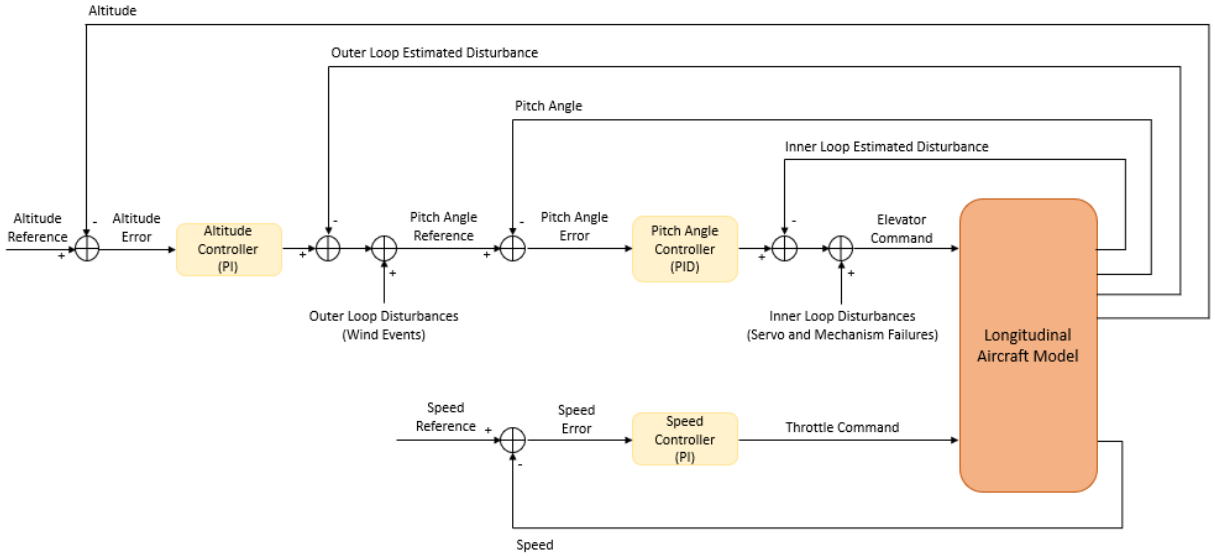

Figure 3. Longitudinal autopilot architecture.

Findings

All design and analysis processes were carried out in the MATLAB and Simulink environments. In the inner loop, a PID controller was initially designed for pitch angle control, and later, the classical disturbance observer structure was added. To evaluate the system's performance, the $P_n(s)$ model was modified by changing the coefficients C_l, C_m and C_n by 25% to obtain a new linear model, which was then incorporated into the system as $P(s)$. Additionally, 0.2° white noise was introduced into the pitch angle feedback signal, and an internal disturbance was simulated by assuming a servo jam that begins at 5 seconds and gradually leads to a 2° blockage over time. The inner loop performance evaluation is shown in Figure 4.

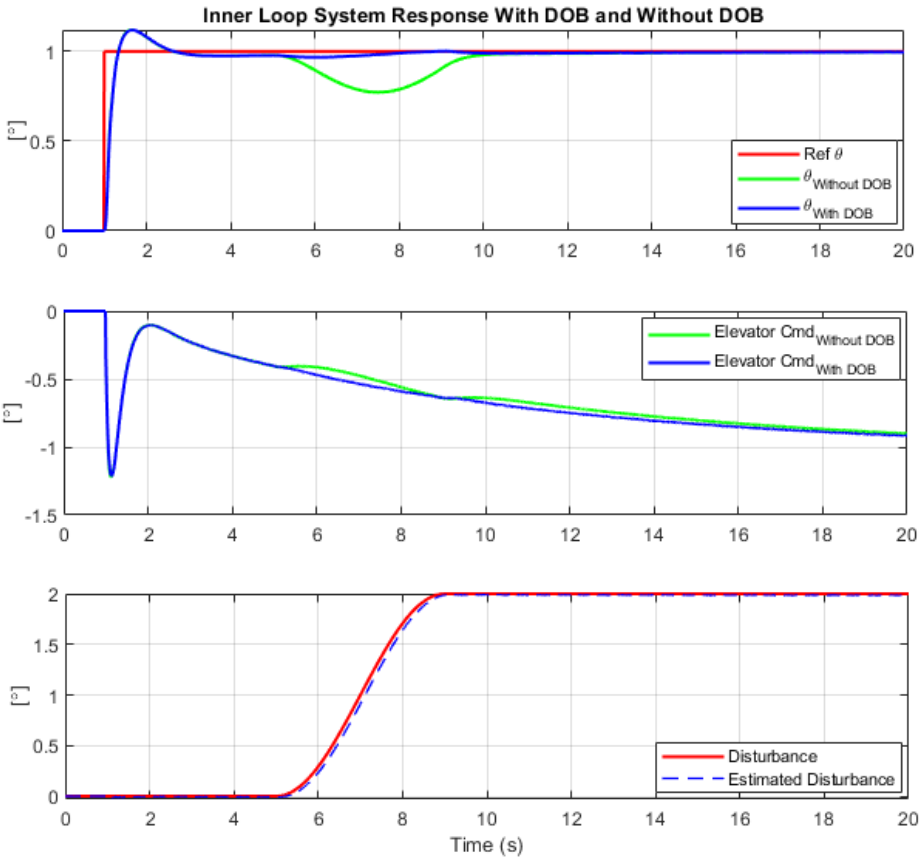

Figure 4. Inner loop performance.

In the outer loop, the pitch angle reference signal is generated. In this loop, altitude is controlled, thereby enabling the investigation of the effects of wind disturbances on altitude and the compensatory effect of the DOB structure during the desired phase of flight. For this purpose, a PI controller was designed. When designing the DOB, it was noted that the $P_n(s)$ model obtained for the outer loop is a non-minimum phase system. Therefore, a V-Filter was added to the DOB structure to ensure proper design for such systems.

To assess system performance, 0.2 m white noise was introduced into the altitude feedback signal. Additionally, as an external disturbance, a wind gust of 13 m/s was applied at 30 seconds, causing a 5° pitch angle deviation, and its effect diminished at 40 seconds. The performance results of the PI controller supported by the outer loop DOB are presented in Figure 5.

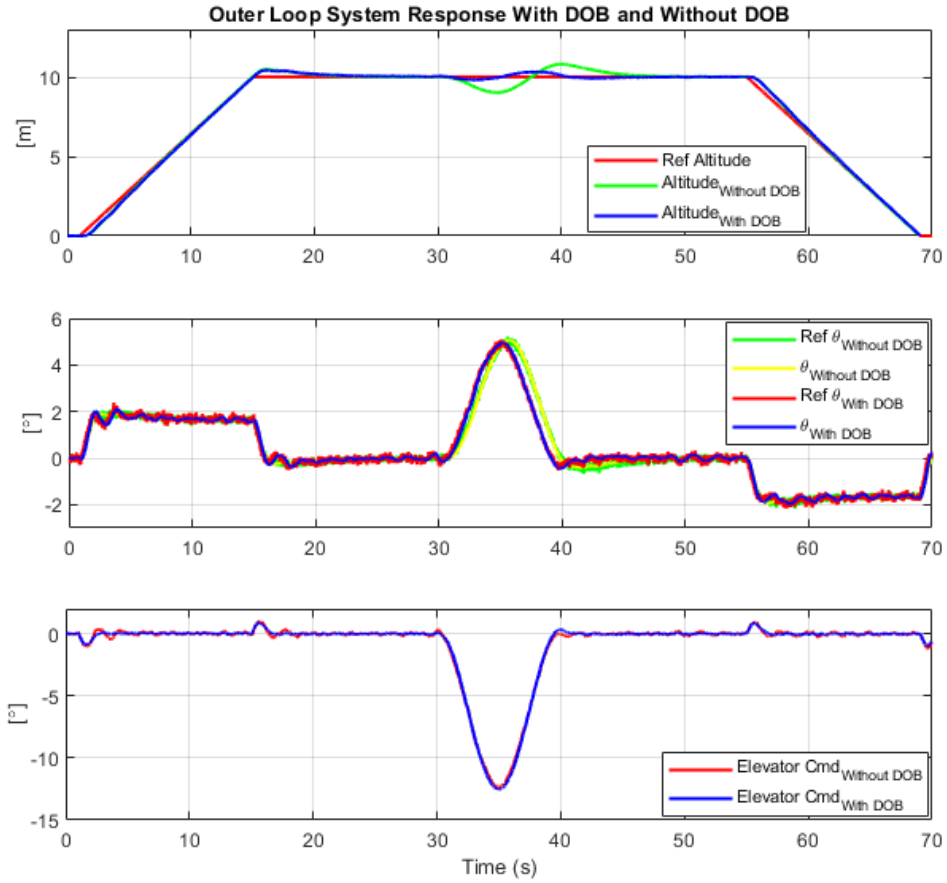

Figure 5. Outer loop performance.

Conclusion

It has been shown that the Disturbance Observer-supported PID controller makes the fixed-wing aircraft less affected by disturbances in the longitudinal axis compared to the PID controller without an observer. Thanks to the Dual-Layer Disturbance Observer structure, all disturbances, including modeling-sourced disturbances, internally sourced disturbances such as servo errors, and externally sourced disturbances such as wind gusts, are simultaneously estimated and eliminated from the system. As a result, a more robust and stable controller resistant to all disturbance effects has been achieved.

Fuzzy Gain Decision for Different Types of Aircraft with Dynamic Pitch Control Envelope Cue

Ali Karaduman[a], İlker Üstoğlu[a]

[a]Istanbul Technical University, Control and Automation Engineering Program, Turkey

karaduman23@itu.edu.tr

Keywords: Aviation; Pilot-İnduced-Oscillations; Flight Envelope; Fuzzy Logic.

Aim

Loss of control in flight is one of the most critical safety problems in aviation. The main objective of this study is to design and validate an envelope cueing strategy that improves flight safety by dynamically adjusting controller gain parameters in response to pilot behavior and system feedback. Dynamic-pitch-control envelope cueing method was developed to evaluate the oscillations caused by the pilot to minimize PIO risk. Fuzzy modeling was used to include the fuzziness of human behavior, and pilot responses within the control envelope were also modeled using fuzzy logic to assess cueing method performance with a human pilot model. The proposed cueing method can help reduce control loss incidents resulting from pilot-aircraft system oscillations.

Material and Method

I. Dynamic Pitch Control Envelope Cue

The pitch axis is the axis on which the aircraft can maneuver nose down or nose up. Figure 1 shows the axes of the aircraft. A dynamic pitch control envelope is created depending on elevator deflection and dynamic pitch attitude. Dynamic pitch attitude is obtained by adding the pitch angle and its derivative. The dynamic pitch attitude equation is given in Eq. (1).

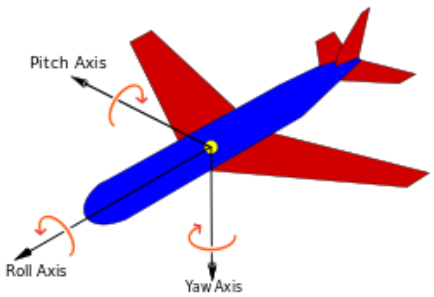

Figure 1. Aircraft principal axes [2].

$$\theta' = \theta + \dot{\theta} \tag{1}$$

This flight envelope, which is created depending on the dynamic pitch attitude and the control authority of the pitch axis, is given in Figure 2. The dynamic pitch control envelope can also be presented in 3D in a membership value manner. This representation is given in Figure 2.

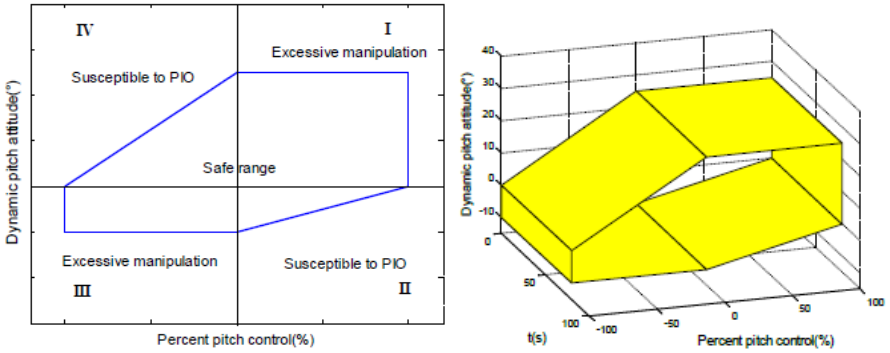

Figure 2. Dynamic pitch control envelope and with envelope with membership function [6].

II. Modelling

The pilot-aircraft model is formed by the combination of several systems. These are the human-pilot model, interceptor, and aircraft system. The block diagram of the pilot-aircraft system with dynamic pitch control envelope cue is given in Figure 3.

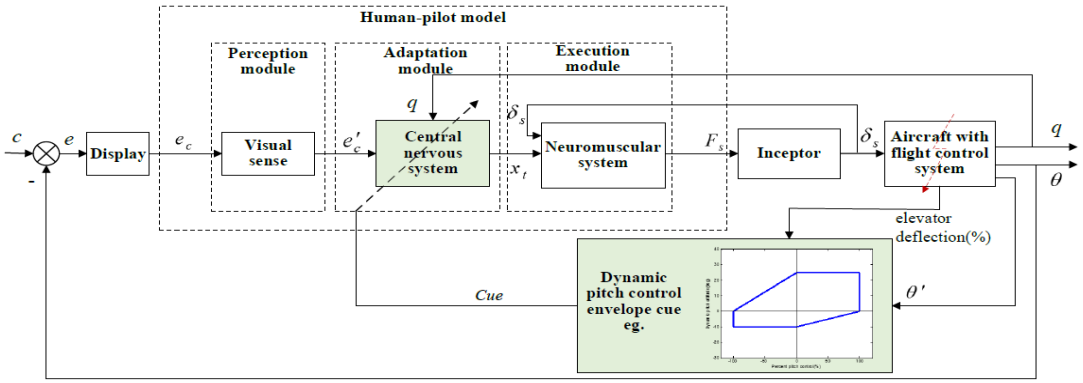

Figure 3. The block diagram of the pilot-aircraft system with dynamic pitch control envelope cue [3].

As seen in Figure 3, the input of the system is pitch angle θ (it is given as c in the figure), and the system output is pitch angle θ and pitch rate q. Error (e) is calculated by taking feedback from the output to the input, and this error signal enters the display. The e_c signal coming from the display is transmitted to the human-pilot model.

The aircraft system with the inceptor model consists of two parts. The first one is the inceptor module, and the other one is the aircraft system module.

1) Inceptor Model

The transfer function of the feel system is obtained with the parameters that are given in Table 1. The transfer function can be found as Eq. (2).

Table 1. Feel System Dynamics Parameters [5].

Parameter	Value
Spring gradient (N/m)	400
Damping ($N \cdot s \cdot m^{-1}$)	28.28
Mass (kg)	1
Control system gearing	1

$$\frac{400}{s^2+28s+400} \tag{2}$$

2) Aircraft System

Two different types of aircraft dynamics were used for testing in this paper. The first one is the configuration dynamics, which is used in the simulation tests, and its transfer function is shown in Eq. (3). The second one is the linear configuration dynamics of the Boeing-747 aircraft.

$$\frac{\theta}{\delta_e} = \frac{31520(s+0.02379)(s+1.246)}{(s^2+2\times0.2389\times0.05637s+0.05637^2)(s^2+2\times0.702\times4.571s+4.571^2)(s^2+2\times0.7\times75s+75^2)} e^{-0.10s} \tag{3}$$

This transfer function is obtained with the input elevator and the output pitch angle. Therefore, the parameters of the flight control system are given in Table 2.

Table 2. Parameters of Flight Control System [5].

Flight control system	Form	Parameter value
Rate limit ((°)/s)		$V_L = \begin{cases} 10\ (°)/s \text{ failure} \\ 100\ (°)/s \text{ baseline} \end{cases}$
Surface actuator	$\frac{\omega_n^2}{s^2+2\xi\omega_n s+\omega_n^2}$	$\omega_n = 44$ rad/s, $\xi = 0.707$
Surface position limit	$\delta_{e_{max}}$	30°

The linear configuration dynamics of the Boeing 747 are also calculated. Firstly, it is linearized by trimming at a selected point. Subsequently, the state-space representation of longitudinal motion is obtained. This representation is given in Eq. (4).

$$[\Delta\dot{u}\ \Delta\dot{w}\ \Delta\dot{q}\ \Delta\dot{\theta}\ ] = \begin{bmatrix} X_u & X_w & 0 & -g \\ Z_u & Z_w & u_0 & 0 \\ M_u + M_{\dot{w}}Z_u & M_w + M_{\dot{w}}Z_w & M_q + M_{\dot{w}}u_0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} [\Delta u\ \Delta w\ \Delta q\ \Delta\theta\ ] + \begin{bmatrix} X_\delta \\ Z_\delta \\ M_\delta + M_{\dot{w}}Z_\delta \\ 0 \end{bmatrix} [\Delta\delta_e\ ] \tag{4}$$

Then the characteristic parameters of the short mode were determined. In this direction, the transfer function between the pitch rate and the elevator for the short period was found. This transfer function is given in Eq. (5).

$$\frac{\Delta q(s)}{\Delta\delta e(s)} = \frac{-0.553s-0.3886}{s^2+1.639s+0.82} \tag{5}$$

3) Simulink Models

The entire structure can be seen in Figure 4. The sum-of-sines function was created so that the model receives an input test signal. It can be seen in Eq. (6).

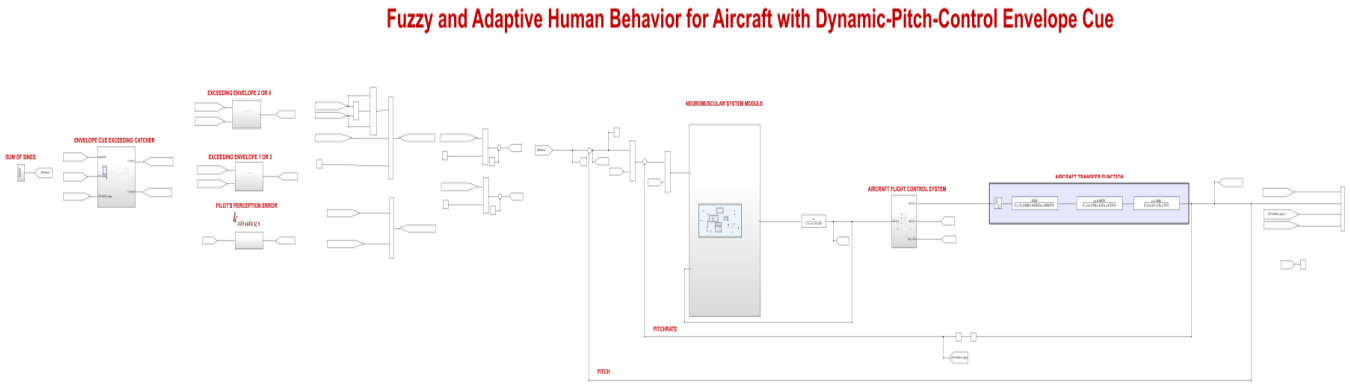

Figure 4. The entire structure in SIMULINK.

$$\sum \quad A\,sin(2\pi f + \phi) = Sum\ of\ sines \tag{6}$$

The envelope cue membership value was obtained in Figure 5. The structure that determines whether the envelope is in zone 2 or 4, or zone 1 or 3, is set up as shown in Figure 6. The freezing process is carried out in the same way for both regions. The structure of the freezing process is shown in Figure 6.

By inserting the error signal into the system's fuzzy logic, the $k_{strategy}$ parameter, which is the strategy variation coefficient of the pilot, is obtained. This structure is given in Figure 6.

The Fuzzy Logic app is used to create a file to evaluate fuzzy decisions. The smallest of the maximum was chosen as the defuzzification method. The app settings and the obtained $k_{strategy}$ output are shown in Figure 7. Then, ΔK_r and ΔK_p parameters were calculated as shown with Eq (7) and Eq (8).

$$\Delta K_r = k_{tuning_1} * k_{strategy} \tag{7}$$

$$\Delta K_p = 0.35 * k_{strategy} * (k_{tuning_1} + k_{tuning_2}) \tag{8}$$

Finally, these parameters were integrated into the system by giving initial values.

The neuromuscular system, with its components, is modeled as seen in Figure 8. The feel system, with its input and output, and the aircraft flight control system are seen in Figure 9. The transfer function given in Eq. 4 has been added to the model. The pitch angle, which is the output of the aircraft transfer function, is fed back into the model. In addition, the transfer function of the Boeing 747 aircraft has been added to the model.

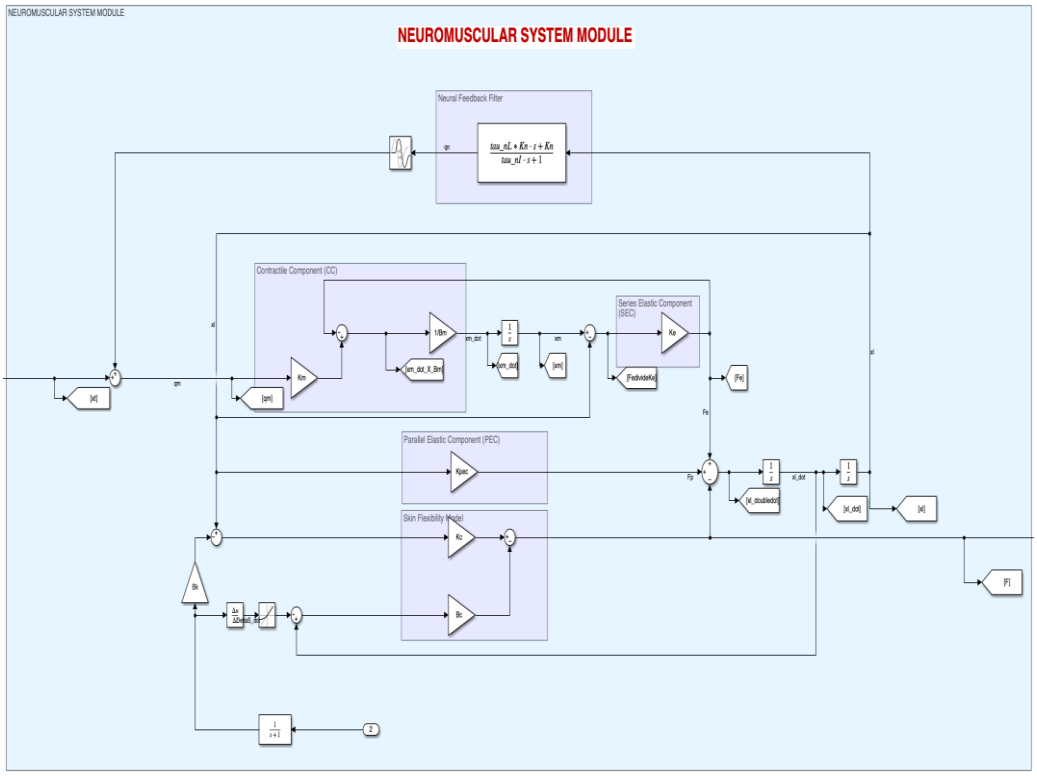

Figure 8. Neuromuscular System Model.

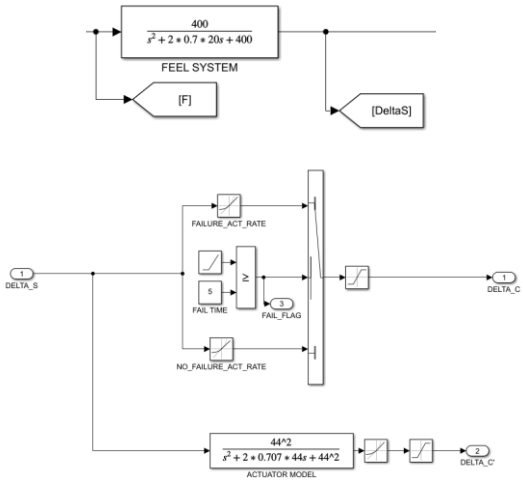

Figure 9. Feel the system and aircraft flight control system model in SIMULINK.

Findings

I. Simulation Results

In these simulations, the system's response to Pilot Induced Oscillation (PIO) is analyzed, and methods for its recovery are explored. The system was designed to enter PIO at the fifth second of the simulation through a switch in the model. Initially, the rate limit of the control surfaces of the system, which enters the PIO, was reduced from ±100 degrees to ±10 degrees. Once the system entered the PIO, the K_p and K_r values were adjusted to ensure the recovery of the system.

By adjusting the $K_p$and K_r coefficients, the system was able to recover from PIO effectively. The system was evaluated using three different test cases. In the first test case, the gap in the envelope cue is narrow, in the second test case, it is wider, and in the third test case, the system behavior of Boeing-747 aircraft is examined.

The 2-D and 3-D envelope cues of the first test case, the impact of K_p and K_r coefficients on system performance, and the variations in the K_p and K_r parameters are illustrated in Figure 10.

In addition, the envelope cues obtained with fixed gain and gain adjustment were compared. The corresponding envelope graphs are presented in Figure 11.

As seen in the figures, the system successfully adjusted the gains and enabled recovery. It was also observed that narrowing the envelope cue reduced the gains faster; however, this adjustment occurred prematurely.

Subsequently, the 2-D and 3-D envelope cues of the second test case, the impact of K_p and K_r coefficients on the system, and the variations in the K_p and K_r parameters are seen in Figure 12. The envelope graphs of the second test case, obtained with fixed gain and with gain adjustment, are presented in Figure 13. In Test 2, K_r value decreases only when the stick and dynamic pitch have opposite signs, while K_p decreases whenever the signal goes out of range.

Finally, simulation results of the tests conducted with Boeing-747, including gain variation and envelope cues with and without gain adjustment, are presented in Figure 14. If Boeing-747 had not implemented dynamic pitch control, the aircraft would have experienced oscillations, but it remained stable when the system used the gain regulator.

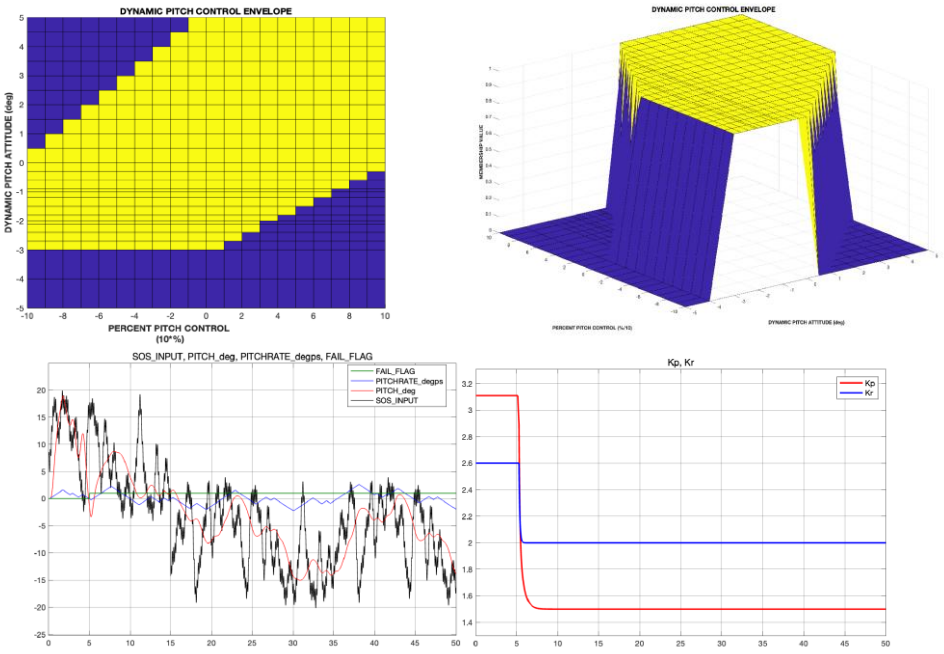

Figure 10. The 2-D, 3-D envelope cues and simulation results of the first test case.

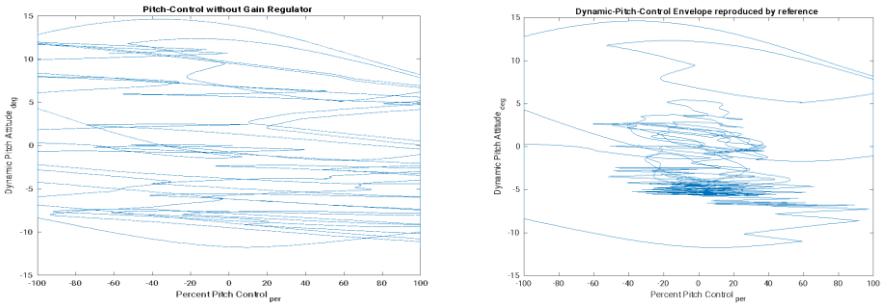

Figure 11. Envelope with and without Gain Regulator for the first test case.

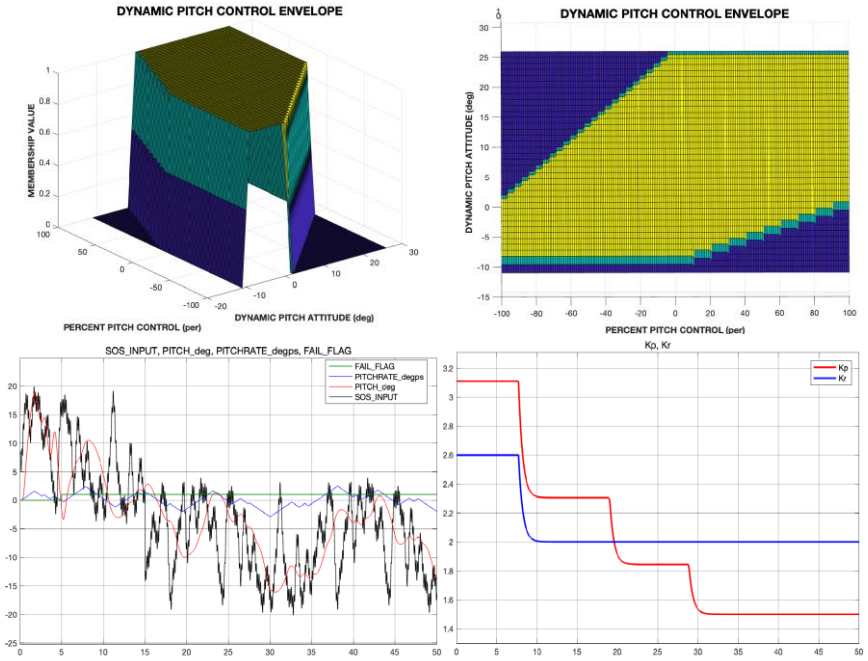

Figure 12. The 2-D envelope cue of the second test case.

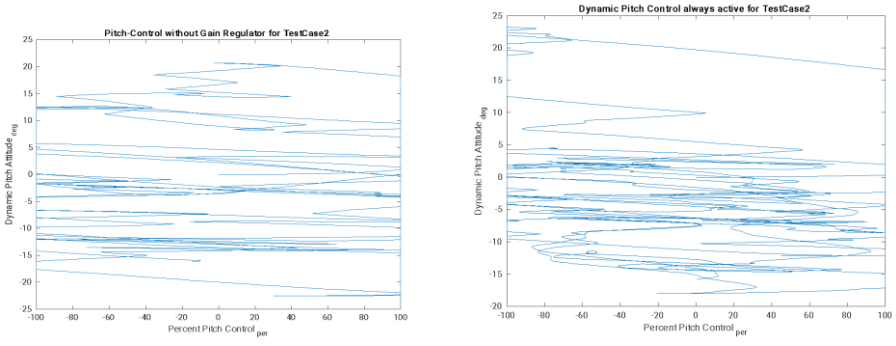

Figure 13. Envelope with and without Gain Regulator for the second test case.

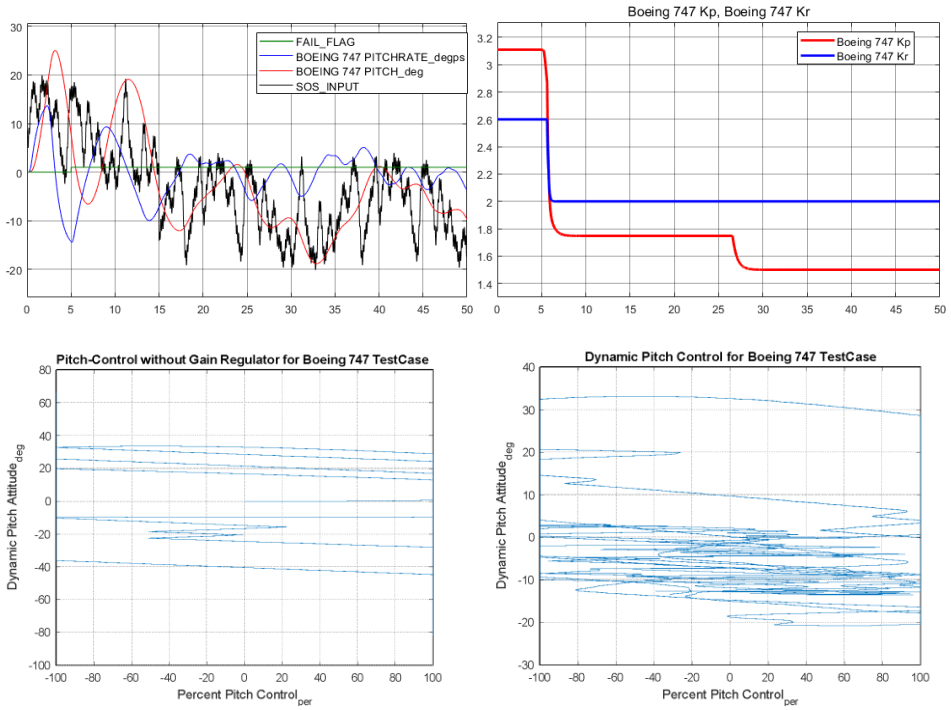

Figure 14. Simulation Results of the Third Test Case.

Conclusion

As a result, the human pilot model was implemented in the SIMULINK environment, and the relevant tests were conducted. By inserting the system into a PIO condition, the corresponding gain values were adjusted in a fuzzy and adaptive manner, enabling the system to recover. All tests demonstrate how significantly our system contributes to preventing oscillation conditions.

However, designing this system to rely only on pitch would require generating different envelope cues, as each altitude, weight, angle of attack, pitching moment coefficient C_m, lift coefficient C_l, dynamic pressure ,and velocity would correspond to different trim points. This would make it difficult to apply the method across all trim conditions. As a suggestion, an envelope cue based on $\frac{N_z}{\alpha}$ could be developed. In this way, a single envelope cue could potentially cover the entire flight envelope.

Enhanced Aircraft Control Throughout Total Energy Control Systems: A Comparative Study with Conventional Autopilots

Rumeysa Kökoğlu[a], Müjde Güzelkaya[a]

[a] Istanbul Technical University, Faculty of Electrics and Electronics Engineering, Department of Control and Automation Engineering, Türkiye
kokoglu16@itu.edu.tr

Keywords: Energy Control, Longitudinal Autopilots, Small UAV Control.

Aim

Longitudinal control of aircraft involves regulating altitude and airspeed. Conventionally, longitudinal control has been achieved using separate autopilot systems. These systems typically use the elevator to maintain altitude and engine thrust to control airspeed. This Single Input, Single Output (SISO) approach simplifies control design and is widely preferred in aviation because it is easy to implement. However, this approach ignores the coupled effects between altitude and airspeed dynamics (Brockhaus, Alles, & Luckner, 2011; Stevens, Lewis, & Johnson, 2016). When an aircraft is set to a certain altitude by elevator input, the airspeed is inevitably affected by the aircraft's total energy distribution and the coupled effects between altitude and airspeed. For example, when an aircraft maneuvers to gain altitude, some of its kinetic energy is converted to potential energy, causing a short-term speed decrease. Conversely, when the aircraft performs a maneuver that will decrease its altitude, potential energy is converted into kinetic energy, causing the airspeed to increase. Ignoring this energy exchange can lead to slower responses, excessive deviations, and the system performing more control actions to correct unwanted deviations. Conventional autopilots rely on separate control loops that do not take into account energy distribution/transfer, coupled effects, and therefore, adjusting one parameter, such as airspeed or altitude, can cause unintended changes to the other, resulting in efficiency and performance losses. In order to overcome these problems, the Total Energy Control System (TECS) has been proposed in the literature. TECS has been proposed as an advanced control architecture that integrates the coupled effects between altitude and airspeed by considering the total energy of the aircraft and the energy distribution rates (Lambregts, 1983, 1984). The purpose of this study is to compare the results of the TECS with conventional autopilots and to highlight the advantages of TECS.

Material and Method

Total Energy Control System (TECS) is a Multi-Input Multi-Output (MIMO) control architecture that can simultaneously control the airspeed and altitude of an aircraft. This system works by considering the kinetic and potential energy of the aircraft. The basic principle of TECS is to control the total energy rate with the engine thrust (throttle) and manage the energy distribution rate with the elevator. Unlike conventional autopilots, TECS optimizes control inputs more efficiently by considering the interaction and coupled effects between kinetic and potential energy. While the total energy rate is controlled using the throttle, the energy distribution is rearranged between kinetic and potential energy via the elevator. This method minimizes cross-coupling effects and increases tracking performance, robustness against disturbances, and control efficiency. This principle, introduced by Lambregts in the 1980s, was developed to improve flight path and speed control.

For an aircraft modeled as a point mass, the total energy (ET) is the sum of the kinetic and potential energy, and the rate of change is affected by both altitude and speed.

$$E_T = \frac{1}{2}mv^2 + mgh$$

$$\dot{E}_t = mv\dot{v} + mg\dot{h}$$

where m is mass, g is gravitational acceleration, h is altitude, and v is speed. Dividing $\dot{E}$ by mgv yields the non-dimensional specific energy rate $\dot{E}_s$, which is controlled by the throttle.

$$\dot{E}_s = \frac{\dot{v}}{g} + \frac{\dot{h}}{v} = \frac{\dot{v}}{g} + \gamma$$

To manage the energy distribution between kinetic and potential forms, TECS uses the Lagrangian L , defined as the difference between kinetic and potential energy.

$$L = \frac{1}{2}mv^2 - mgh$$

$$\dot{L} = mv\dot{v} - mg\dot{h}$$

Dividing by mgv gives the specific energy distribution rate $\dot{L}_s$, is controlled by the elevator.

$$\dot{L}_s = \frac{\dot{v}}{g} - \frac{\dot{h}}{v} = \frac{\dot{v}}{g} - \gamma$$

Where γ is the flight path angle. TECS employs proportional-integral (PI) control loops to minimize the errors in both $\dot{E}_s$ and $\dot{L}_s$. The throttle command δ_{T_c} and pitch command θ_c are determined as follows.

$$\delta_{T_c} = K_{TI}\int\left(\dot{E}_{s_{cmd}} - \dot{E}_s\right)dt + K_{TP}\dot{E}_s$$

$$\theta_c = K_{EI}\int\left(\dot{L}_{s_{cmd}} - \dot{L}_s\right)dt + K_{EP}\dot{L}_s$$

where K_{TI} and K_{EI} are integral gains, and K_{TP} and K_{EP} are proportional gains. This dual-loop architecture ensures that the aircraft's total energy is adjusted primarily through throttle modulation, while the elevator redistributes energy between kinetic and potential forms, reducing cross-coupling effects.

The unmanned aerial vehicle DEHA (Experimental Aircraft) is a high-performance experimental platform for evaluating advanced flight control systems. The aircraft has a fuselage length of 2.14 meters and a wingspan of 2.21 meters. It is equipped with a jet engine capable of providing 12 kilograms of thrust and is capable of performing high-speed flight operations. Primary control surfaces include ailerons for roll, elevators for pitch, and rudders for yaw. In addition, DEHA has retractable landing gear that improves performance by minimizing aerodynamic drag during flight. DEHA has extensive flight experience, having conducted over 200 sorties under various flight conditions. This extensive flight history has allowed for detailed system identification tests, which have enabled the development of a high-fidelity, six-degree-of-freedom (6DOF) nonlinear simulation model of DEHA. This model, created in a MATLAB/Simulink environment, provides a reliable virtual testbed for evaluating control algorithms by accurately simulating the aerodynamic and dynamic properties of DEHA. The simulation model includes realistic aerodynamic forces, engine dynamics, and deflections of control surfaces to reflect actual flight behavior closely. In this study, conventional longitudinal autopilots and Total Energy Control System (TECS) architecture were implemented within this simulation framework. The accuracy and reliability of the model allowed detailed performance comparisons to be made in various flight scenarios such as altitude step changes, speed adjustments, and combined maneuvers.

Findings

To evaluate the performance of the TECS architecture with conventional longitudinal autopilots, a series of flight maneuvers were simulated using the DEHA's 6-degree-of-freedom (6DOF) model. In the tested maneuver, the aircraft aimed for a 10-meter climb while performing a coordinating turn with 60 degrees of bank angle and simultaneously reducing its airspeed by 5 m/s. As shown in Figure 1, the results show that the TECS architecture performed better in tracking performance than conventional autopilots. In particular, the results of TECS reached the target altitude faster and showed less overshoot while adjusting to the reference airspeed. In addition, the throttle input generated by TECS is significantly less than that of the conventional autopilot, making energy management more efficient. These results show that the TECS architecture takes into account the coupled effects between altitude and airspeed, resulting in better performance.

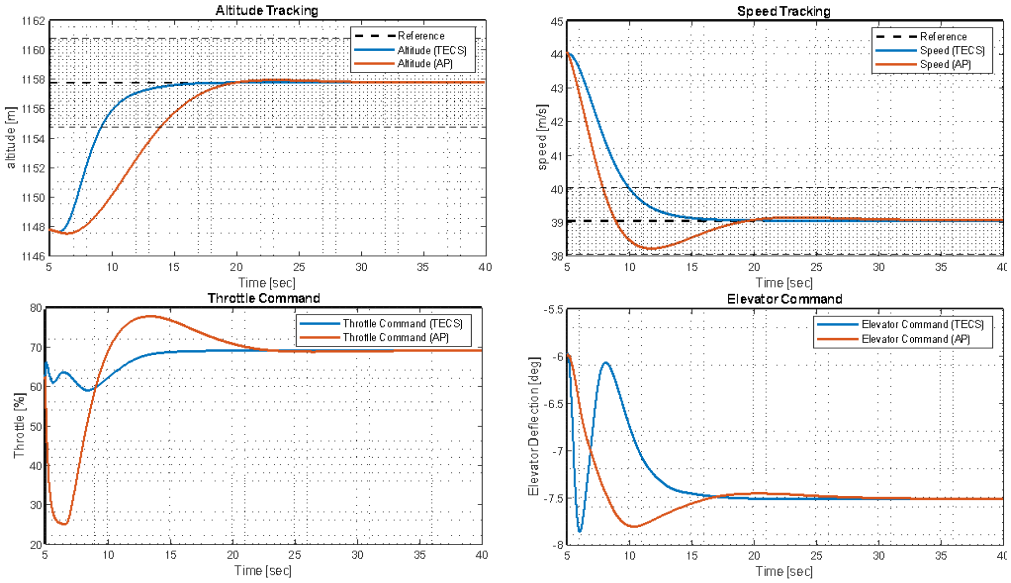

Figure 1. 10m Climb & 5m/s Deceleration ~ 60-degree Bank.

Conclusion

In conclusion, the comparative analysis of TECS with conventional longitudinal autopilots shows that TECS provides higher performance thanks to its energy-based approach. Unlike conventional autopilot systems, TECS takes into account the coupled effects between altitude and airspeed, providing faster response times, less overshoot, and smoother control inputs. Including the effects of both control inputs on airspeed and altitude allows TECS to maintain precise altitude and airspeed tracking even during sudden maneuvers and external disturbances. In addition, TECS produces fewer control inputs and exhibits less activity during engine thrust and elevator deflections compared to conventional autopilots. These advantages make TECS particularly suitable for applications where energy efficiency, performance, and reliability are critical.

Performance Comparison of Guidance Algorithms for Aerial Vehicles: A Software-In-The-Loop Based Approach

Alper Makaraç[a], Mustafa Doğan[a]

[a] Istanbul Technical University, Control and Automation Engineering, Türkiye
makarac22@itu.edu.tr

Keywords: Guidance, PNG, TPNG, APNG, MPNG.

Aim

The main aim of this research is to evaluate the performance of different guidance algorithms for aircraft, which are designed to reach specific target coordinates. The main algorithms explored include Proportional Navigation Guidance (PNG), Augmented Proportional Navigation Guidance (APNG), Modified Proportional Navigation Guidance (MPNG), True Proportional Navigation Guidance (TPNG), and similar algorithms. These are studied together under different conditions to evaluate their responsiveness and reliability. A software-in-the-loop (SITL) simulation was established by incorporating aerodynamic coefficients—derived via DATCOM—into JSBSim, thus creating an accurate mathematical model of the missile. This model was linked with Ardupilot via UDP communication, enabling real-time interplay between flight simulation and guidance commands. Additionally, the simulation experience was improved by integrating Unreal Engine 5.0, which offers high-quality, real-time visualization of the missile's flight dynamics and target interception movements. The main goal is to understand the strengths and weaknesses of these guidance methods, especially in situations with stationary, constant-speed, and accelerating targets, as well as under aerodynamic disturbances. Figure 1 illustrates the data flow between different software components. Using this data flow, guidance algorithms can be tested by implementing aerodynamic effects and control surface commands.

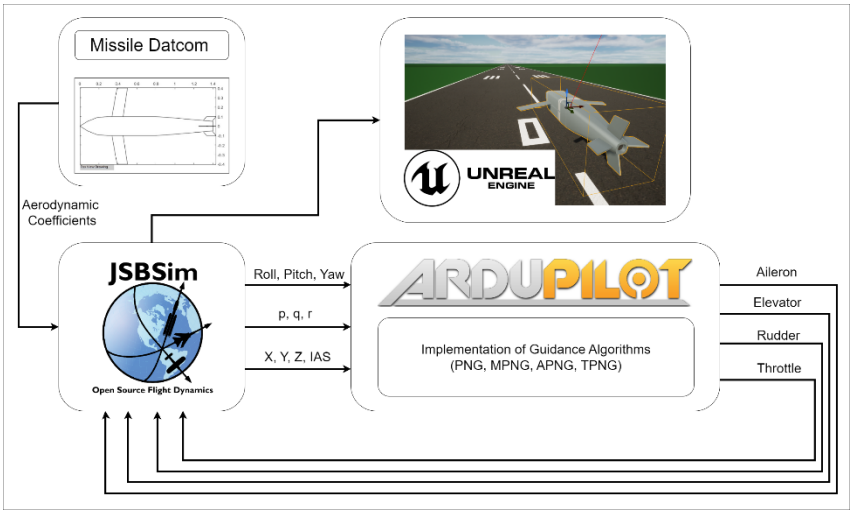

Figure 1. Simulation System Architecture.

Material and Method

The study was initiated by generating aerodynamic coefficients for the cruise missile using the DATCOM tool. *Figure 2* visualizes the physical properties of the aircraft transferred to the DATCOM model. Aerodynamic moments and derivatives of the aircraft shown in this figure were obtained and utilized in the simulation. These coefficients were carefully

implemented into JSBSim software, forming the foundational mathematical model. This step ensured that the simulation environment accurately reflected real-world aerodynamic forces and moments acting on the missile. Once the JSBSim model was established, the development advanced toward integrating Ardupilot via a UDP-based data exchange. Within this SITL configuration, JSBSim delivers updated state variables such as position, velocity, orientation, and angular rates to Ardupilot. Concurrently, Ardupilot produces guidance and control commands (for example, control surface deflections and thrust commands), which are then streamed back into JSBSim. This continuous transfer of data allows the simulation loop to approximate real-flight conditions while giving researchers the flexibility to test, refine, and analyze various guidance algorithms.

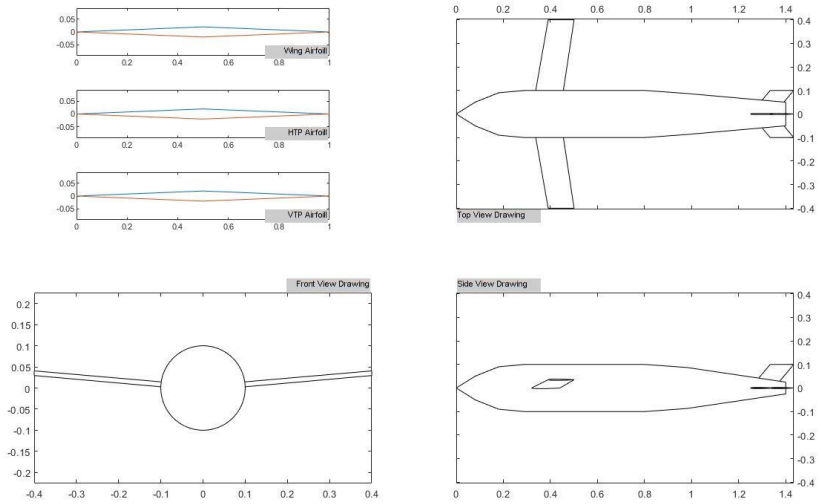

Figure 2. Appearance of the Datcom Model.

In parallel, Unreal Engine 5.0 was employed to provide an immersive, high-resolution visualization layer. By rendering 3D scenarios that reflect real-time flight states, Unreal Engine aids in better interpreting the missile's trajectory and how it responds to algorithmic instructions. As seen in *Figure 3*, the situation between the aircraft and the target can be easily observed in the 3-dimensional simulation environment.

Figure 3. Unreal Engine Implementation.

Using this comprehensive framework, the following guidance algorithms were examined:

1. Proportional Navigation Guidance (PNG): PNG is a classical missile guidance technique where missile acceleration commands are proportional to the rate of change of the line-of-sight (LOS) angle to the target. This method is known for its effectiveness in intercepting relatively predictable targets due to its straightforward and efficient nature (Siouris, 2004). However, PNG can show significant limitations when targets undertake high acceleration maneuvers, as its assumptions of target predictability and constant velocity may lead to larger miss distances (Yanushevsky,2007).
2. Augmented Proportional Navigation Guidance (APNG): APNG is an advanced guidance law that builds upon the standard PNG by incorporating additional feedback channels or corrective terms. These augmentations are designed to enhance the system's ability to compensate for target maneuverability and environmental disturbances, such as wind or sensor noise, making APNG more robust and adaptable in complex engagement scenarios. For instance, APNG often includes acceleration feedback or predictive terms to account for the target's future motion, which improves interception accuracy against highly maneuverable targets (Zarchan, 2012). Additionally, APNG can integrate adaptive control techniques to dynamically adjust its parameters in real-time, further improving performance in uncertain or rapidly changing environments (Lin, 1991). This adaptability makes APNG particularly suitable for modern missile systems and autonomous vehicles operating in challenging conditions.
3. Modified Proportional Navigation Guidance (MPNG): MPNG enhances traditional PNG to effectively address real-world combat scenarios involving highly maneuverable or high-speed targets. Unlike PNG, which assumes constant velocities and ideal dynamics, MPNG employs adaptive gain adjustments, additional correction terms, cross-range compensators for improved observability, and sophisticated filtering techniques to enhance robustness and accuracy (Lin et al., 2010). Additionally, it includes advanced techniques such as lead-bias commands, improving missile interception accuracy by targeting specific interception points (Moharampour et al., 2010). Moreover, MPNG dynamically accounts for missile velocity variations, particularly useful during significant speed changes like boost phases (Dohi et al., 2004).
4. True Proportional Navigation Guidance (TPNG): TPNG is an advanced form of the PNG, characterized by generating acceleration commands perpendicular to the instantaneous missile-target line-of-sight (LOS), proportional to the LOS rate and closing velocity. TPNG provides distinct advantages over standard PNG, especially in scenarios demanding high accuracy and minimized overshoot, as it can be analytically easier to

handle and offers improved predictability in missile-target engagements (Ghose, 1994). Additionally, in three-dimensional engagements, TPNG is effectively implemented by decomposing the guidance problem into three orthogonal planes (xy, yz, and xz), independently solving pursuit scenarios within these planes, and then integrating the computed acceleration commands back into three-dimensional space. This method enhances missile performance significantly in terms of interception accuracy and effectiveness against high-g maneuvering targets (Moran, 2005).

All four guidance approaches were tested under three distinct target profiles:

- Stationary Target: The target remains at a fixed coordinate, allowing initial validation of the algorithms and baseline performance measurements.
- Constant Velocity Moving Target: The target moves linearly at a steady speed, evaluating each algorithm's ability to track and intercept a uniformly moving object.
- Accelerating Target: The target undertakes varying acceleration profiles, creating highly dynamic and unpredictable engagement conditions that stress-test each guidance method's adaptability.

To further challenge the algorithms' resilience, aerodynamic disturbances, including wind gusts, turbulence, and control surface defects, were introduced in JSBSim. Monitoring how quickly and effectively the missile guidance re-acquired accurate interception trajectories revealed the comparative robustness of each algorithm. Unreal Engine 5.0's rich visualization played a key role here, facilitating real-time observation of subtle trajectory deviations and flight path corrections.

Findings

In analyzing extensive simulation datasets, notable distinctions emerged in how each guidance method addressed varying target and environmental complexities:

- **Performance of PNG:** PNG successfully intercepted stationary and constantly moving targets. It works well by following the LOS rate, creating a direct path when the target moves steadily. However, its performance dropped significantly with accelerating targets, causing the missile to react more slowly. This led to longer flight times and larger miss distances, especially when the target moved sideways with high acceleration.
- **Strengths of APNG:** APNG outperformed standard PNG in most scenarios involving maneuvering targets. By integrating additional feedback loops or calibration factors, APNG compensated more effectively for abrupt target trajectory changes and aerodynamic disturbances, maintaining tighter control over the intercept path.
- **Advantages of PNG:** MPNG demonstrated improved tracking performance compared to standard PNG, particularly against maneuvering targets. By incorporating adaptive gain adjustments or correction factors, it responded more effectively to rapid target accelerations. This resulted in shorter reaction times and reduced miss distances. However, its effectiveness depended on proper parameter tuning, and in highly dynamic environments, it still faced challenges in maintaining optimal intercept trajectories.
- **Effectiveness of TPNG:** TPNG demonstrated a balanced performance profile that bridged some of the gaps found in basic PNG. By adjusting specific gain factors and introducing refined handling of abrupt target maneuvers, TPNG exhibited quicker response times in intercept calculations. Although not as robust as APNG in every scenario, TPNG significantly mitigated issues encountered by standard PNG, particularly under moderate target accelerations.
- **Influence of Environmental Disturbances:** Wind gusts, variable atmospheric conditions, and minor control surface anomalies introduced additional challenges. PNG and LOS guidance were generally more susceptible to

becoming unstable, requiring longer to reorient intercept solutions. APNG and TPNG held up better, with APNG showing the smallest average miss distance under high-disturbance simulations.

Conclusion

In summary, the comparative study highlights that the optimal choice of guidance algorithm depends on the anticipated target motion and existing environmental conditions. PNG stands out for simpler engagements but encounters perceptible limitations against agile or unpredictable targets. TPNG modifies the classical PNG framework with more flexible gain parameters, delivering improved results over pure PNG in moderately dynamic conditions. MPNG, while an improvement over standard PNG, can still be insufficient when dealing with highly unpredictable or aggressively maneuvering targets. APNG shows the highest adaptability and resilience, a feature that is particularly advantageous against high-acceleration targets or significant aerodynamic disturbances.

The integration of Unreal Engine 5.0 within the SITL environment was a practical solution, allowing for a detailed visual inspection of missile flight behaviors under diverse conditions. This approach improved the interpretability of algorithmic performance and highlighted pathways for further refinement. Prospective research directions may focus on incorporating real sensor feedback, thereby reducing reliance on ideal seeker or tracker assumptions. Additionally, advanced machine learning models can be explored to dynamically tailor guidance laws to evolving scenarios, potentially unlocking further performance gains. Ongoing improvements in aerodynamic modeling, weather simulation fidelity, and real-time disturbance injection can also enhance the fidelity of SITL setups.

Robust Attitude Control of the F-16 Aircraft Using Incremental Nonlinear Dynamic Inversion

Yasin Şahin[1], İlker Üstoğlu[1]

sahinyas18@itu.edu.tr

Keywords: F-16 , Modelling , NDI , INDI.

Aim

It is necessary for modern fighter planes, such as the F-16 Fighting Falcon, to have flight control systems that are exceptionally responsive and resilient in order to ensure that the aircraft maintains its stability and mobility in challenging flight conditions. Additionally, the F-16 is dependent on a technology known as fly-by-wire (FBW), which involves digital flight controllers continuously modifying control surfaces. This technology is inherently unstable. Traditional Proportional-Integral-Derivative (PID) controllers find challenges due to the nonlinear and time-varying features of such aircraft, requiring the adoption of more complicated control algorithms.
This research contrasts two prevalent nonlinear control methodologies, Nonlinear Dynamic Inversion (NDI) and Incremental Nonlinear Dynamic Inversion (INDI), for the attitude control of an F-16 aircraft. NDI depends on a precise model of aircraft dynamics, whereas INDI reduces model dependency through real-time incremental updates. The primary objectives of this research are to construct a comprehensive model of the F-16 aircraft by incorporating its aerodynamic characteristics, actuator mechanisms, and control system dynamics; to devise and execute both NDI and INDI controllers specifically for attitude stabilization; to assess and compare the robustness of these controllers with respect to the effects of external disturbances such as wind gusts and sensor noise; and ultimately, to deliver a quantitative evaluation of control performance based on essential criteria including attitude tracking accuracy, control effort, and system stability. Through the utilization of simulations and a comprehensive comparison examination, this study contributes to the enhancement of the optimization of existing flight control methods, specifically for future high-performance aircraft.

Material and Method

A complex nonlinear model of the aircraft is developed to evaluate the attitude control effectiveness of the F-16. This model incorporates aerodynamic forces and moments based on traditional F-16 flight dynamics equations, actuator dynamics considering control surface deflections and physical limitations, and external disturbances like wind gusts and sensor noise to enable a thorough assessment of the system's robustness. The overall closed-loop structure implemented for both NDI and INDI controllers is illustrated in Figure 1, emphasizing the integration of the F-16 aircraft dynamics, control laws, and feedback paths.

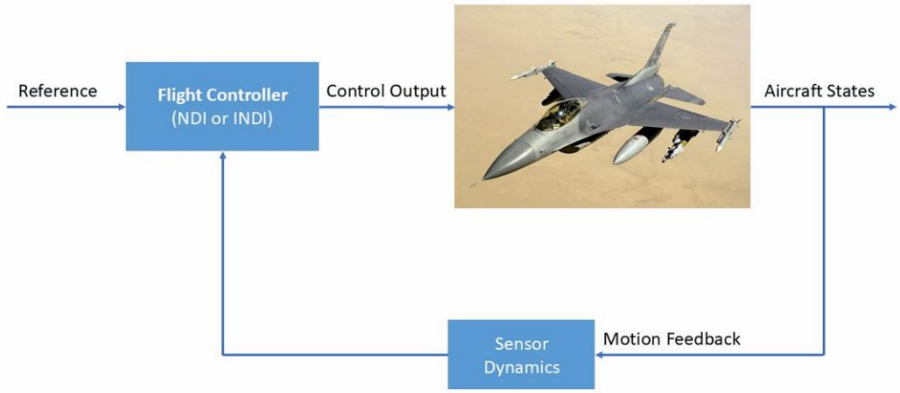

Figure 1. Closed-loop control architecture of the F-16 fighter utilizing NDI or INDI flight controllers.

a. Nonlinear Dynamic Inversion (NDI) Approach

NDI is a prevalent nonlinear control methodology that depends on the precise cancellation of nonlinear components in an aircraft's dynamic model to attain a linearized system response. The primary control law for NDI is articulated as follows:

$$u = A^{-1}(v - f(x))$$

where u is the control input, A denotes the control effectiveness matrix, v represents the virtual control input, and $f(x)$ encompasses the system's nonlinear dynamics.

A significant constraint of NDI is its pronounced reliance on a precise model of airplane dynamics. Modelling inaccuracies or external perturbations might lead to substantial performance deterioration. Moreover, actuator limitations and sensor noise generate uncertainties that diminish the robustness of pure NDI systems. NDI necessitates a precise understanding of the aircraft's dynamics, rendering it extremely sensitive to fluctuations in aerodynamic coefficients, control surface efficacy, and actuator latencies. Furthermore, it presupposes the existence of the inverse of the control effectiveness matrix, which may not be applicable in instances of actuator failures or saturation. The resilience of NDI has been thoroughly examined, and several improvements, including adaptive NDI and disturbance observer-based NDI, have been proposed to address its shortcomings. NDI is typically efficient when precise aerodynamic models are accessible; nevertheless, its efficacy diminishes considerably in real-world scenarios where aerodynamic factors fluctuate. This has resulted in the creation of incremental control approaches that depend on sensor-based feedback instead of the explicit inversion of the aircraft's dynamic model.

b. Incremental Nonlinear Dynamic Inversion (INDI) Approach

Incremental Nonlinear Dynamic Inversion (INDI) is a control strategy that improves robustness by minimizing dependence on an accurate aircraft model. In contrast to Nonlinear Dynamic Inversion (NDI), which relies on precise model inversion, INDI utilizes real-time sensor data to estimate unmodeled dynamics and emphasizes incremental modifications in control inputs.

The rotational dynamics of an aircraft are governed by:

$$J\dot{\omega} = M_{tot}$$

where J is the moment of inertia, ω is the angular velocity, and M_{tot} is the total moment acting on the aircraft. The total moment consists of aerodynamic, control, and external moments: $M_{tot} = M_{aero} + M_{prop} + M_{ext}$ where M_{aero} represents aerodynamic moments, M_{prop} accounts for propulsion effects, and M_{ext} includes external disturbances.

Rather than calculating the complete control input u, INDI emphasizes incremental control updates Δu, resulting in the control formulation:

$$\Delta u = J^{-1}(M_{cmd} - M_{prev})$$

where M_{cmd} is the commanded moment from the controller and is M_{prev} the previously estimated moment.
To enhance resilience, inbuilt gyroscopes and accelerometers quantify angular acceleration, facilitating real-time estimation of the unknown moments: $\omega_{meas} = J^{-1}M_{meas}$ where M_{meas} is the measured moment based on sensor feedback. The ultimate INDI control law, which includes real-time adaptation, is articulated as:

$$u = u_{prev} + J^{-1}(M_{cmd} - M_{meas})$$

This guarantees that INDI consistently adjusts for unmodeled dynamics and disturbances, providing enhanced adaptability compared to conventional NDI. In contrast to NDI, which necessitates predetermined aerodynamic characteristics, INDI adaptively modifies control inputs according to real-time aircraft performance, rendering it far more robust against uncertainties, actuator latencies, and environmental perturbations. The internal structure and signal flow of the Incremental Nonlinear Dynamic Inversion (INDI) controller are depicted in Figure 2, outlining the real-time computation of incremental control inputs.

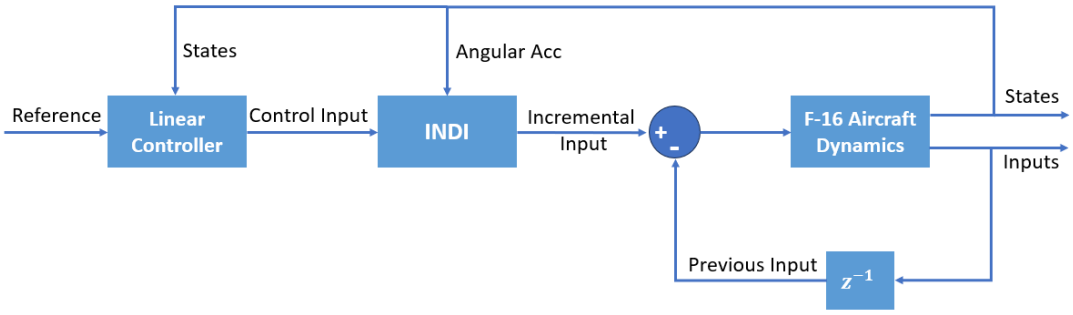

Figure 2. General block diagram of an INDI controller.

Findings

The simulation findings of this work demonstrate that the Incremental Nonlinear Dynamic Inversion (INDI) controller has superior performance compared to the Nonlinear Dynamic Inversion (NDI) method, especially for disturbance rejection. The disparity in performance is apparent across multiple essential aspects. The INDI controller constantly demonstrates superior precision and enhanced stability in sustaining the correct pitch and roll angles in terms of attitude tracking performance. Both Figure 3 and Figure 4 provide evidence that INDI ensures greater stability and accuracy in angular response, particularly when model fidelity is compromised. Conversely, the NDI-based system demonstrates more significant divergences from reference trajectories, particularly during dynamic flight conditions. Secondly, regarding control effort, INDI necessitates less actuator burden and produces smoother, more continuous control surface inputs, hence enhancing overall system efficiency and prolonging actuator lifespan. Ultimately, the INDI controller exhibits enhanced adaptability to fluctuating aerodynamic circumstances and unmodeled dynamics, rendering it a more feasible and pragmatic option for real-time flying applications characterized by uncertainty and environmental unpredictability.

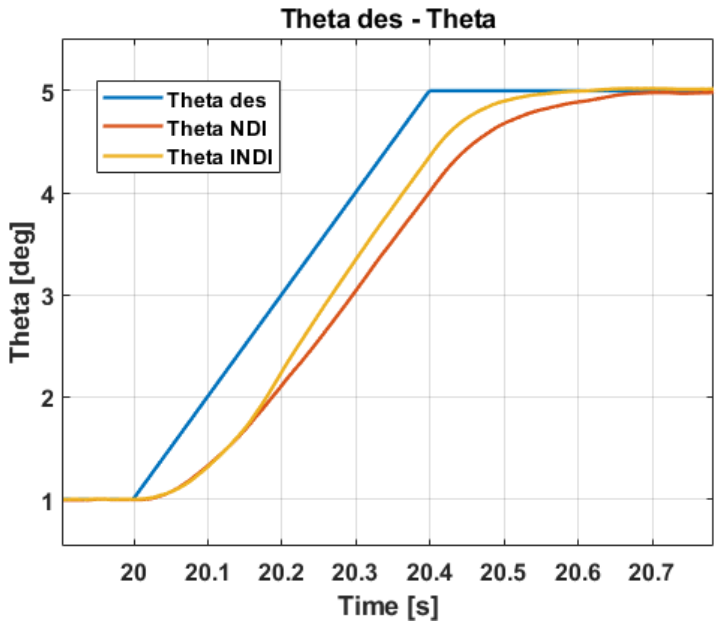

Figure 3. Pitch angle (θ) tracking response under model uncertainty using NDI and INDI controllers.

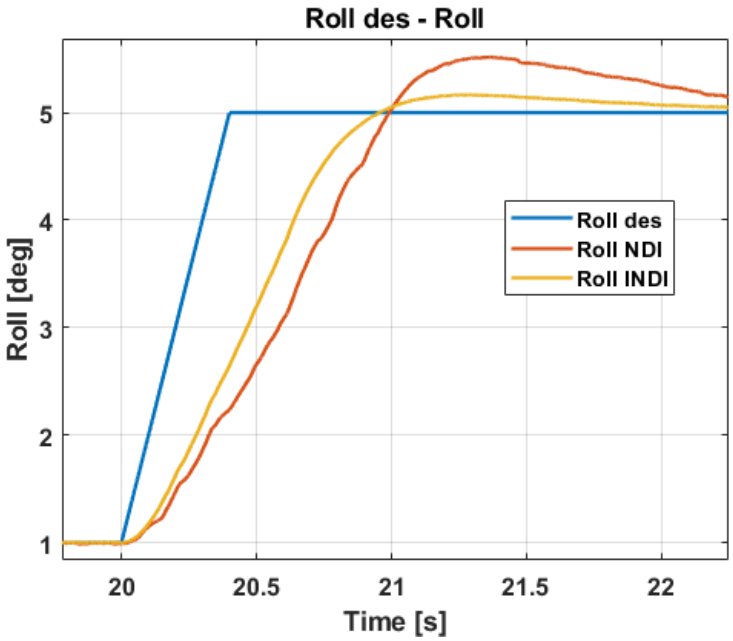

Figure 4. Roll angle (φ) tracking response under model uncertainty with NDI and INDI controllers.

Conclusion

This paper provides a comprehensive comparison of NDI and INDI controllers for F-16 attitude regulation, illustrating that INDI achieves superior tracking accuracy and demonstrates effective mitigation of external disturbances. In contrast, NDI is highly dependent on precise modelling, which limits its effectiveness in uncertain or unpredictable flight environments. Moreover, while INDI demands higher computational resources, this requirement is compensated by improved flight stability and robustness.

These findings highlight the potential of INDI-based control architectures as a promising approach for next-generation fighter aircraft. Future studies are planned to investigate the real-time implementation of such methods within embedded flight control systems.

Adaptive Kalman Filter-Based Gyroscope Error Compensation for IMU Sensors

Mehmet Eren Savaştürk [a], Mustafa Doğan [b]

[a] Istanbul Technical University, Department of Electronics Engineering, Master of Science Program, Turkiye

Keywords: Adaptive Kalman Filter, Gyro Bias, IMU, Prefilter.

Aim

This research aims to compensate gyro errors of an inertial measurement unit (IMU) by using magnetometer and accelerometer measurements of the same IMU sensor. IMU devices usually have three types of sensors, which are accelerometers, gyroscopes, and magnetometers. So, IMU's can measure the movement of the object that the IMU has been integrated into. However, these sensors are noisy and have fixed or time-varying biases. All these sensors have different types of noise or biases that can be eliminated by different methods. So, a cross-check between these sensors has become possible, and error compensation can be applied to sensor data.

This research focuses on gyro data, which has a major impact on navigation solutions. Gyroscope data can cause divergence in the navigation solution easily because even accelerometer data is integrated by using attitudes (Groves, 2013). So, a correction on Gyroscope's data can lead to a significant enhancement in the navigation solution. This error correction is based on magnetometer and accelerometer data that have been collected from the same IMU device. Thus, an inertial navigation solution is still possible with one device.

This research aims that correct gyro errors by using accelerometer and magnetometer measurements and makes IMU which have low-performance gyroscopes usable for inertial navigation solutions. So, size, weight, power, and cost advantages of IMU devices like MEMS IMU's can be used for reliable navigation solutions, and cheap navigation can become more common.

Material and Method

Simulated IMU measurements were used for this research. Matlab's IMU model is selected as a simulation tool (MathWorks, n.d.). This model includes magnetometer, accelerometer, and gyroscope data. The type and magnitude of error are determined for each sensor type separately. Constant bias, bias instability, random walk error, and axis misalignment were taken into account during the data generation process for the accelerometer and gyroscope. On the other hand, constant bias error and noise density parameters were determined for the magnetometer and added to the simulated data. The IMU data rate was selected as 100 Hz. Simulation was run for 100 seconds, and the generated data were used in algorithms.

Simulated data was chosen in this study because in studies using real-world data, it is difficult to determine an accurate ground truth, which makes performance evaluation challenging.

After simulated data were created, different methods were tested. There were 3 different types sensor measurements, and some data that were derived from measurements were used as the state vector for the Kalman Filter. Different combinations of parameters generate different state vectors, and the succession of different methods is examined. Methods requiring low computational power are preferred in this study, as navigation applications are real-time systems and low-cost IMU devices are often paired with simple processing units. Therefore, an Adaptive Kalman Filter approaches were examined (Hashlamon & Erbatur, 2013). The adaptive Kalman filter was combined with basic low-pass filters. While methods such as the Extended Kalman Filter (EKF) could also be used, they demand significantly more processing power. Moreover, EKF is highly dependent on the system model, meaning that system and measurement noises must be modeled with high precision (Simon, 2006). In contrast, this study focuses on adaptive methods that operate based on real-time data, aiming to reduce dependency on precise modeling.

1. Adaptive Kalman Filter by using gyroscope measurements and attitude change is examined. In this method, the IMU device's attitude has been calculated by using magnetometer and accelerometer measurements. A new parameter, which has been named attitude change, is derived. The system state vector has been chosen as gyroscope measurements and gyro biases. The measurement noise covariance matrix has been updated by using the difference between gyro measurements and the rotation rate derived from magnetometer measurements. An adaptive Kalman filter has been implemented for the updated measurement noise covariance matrix. Gyro measurements and gyro biases have been estimated as the output of the filter. The algorithm is illustrated with a flowchart in Figure 1.

2. Adaptive Kalman Filter by using gyroscope measurements and prefiltered attitude is examined. A low-pass prefilter process has been applied for both accelerometer and magnetometer data (Toroslu & Doğan, 2018). The moving average method was used as a prefilter because navigation applications are generally used in real time. So, a method that does not require too much processing power but is still effective against white noise is needed. The moving average method matched these requirements. IMU device attitude has been calculated by using filtered magnetometer and accelerometer measurements. As a result, more accurate and less noisy attitude data is calculated. The system state vector has been chosen as gyroscope measurements and sensor attitude. The difference between prefiltered IMU sensor attitude data and estimated IMU sensor orientation was used to update the measurement noise covariance matrix of the Adaptive Kalman Filter. So, a cross-check between sensors is possible. Then, adaptive Kalman filtering is applied to the generated IMU device attitude data and gyroscope measurements. The algorithm is illustrated with a flowchart in Figure 2

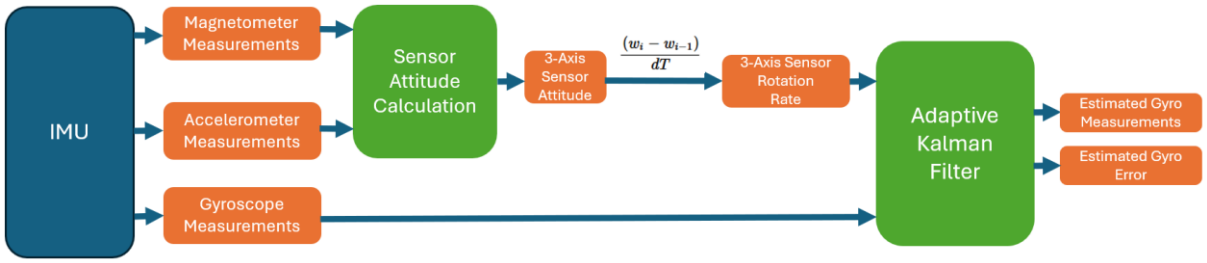

Figure 1. Adaptive Kalman Filter by Using Gyroscope Measurements and Rotation Rate Data.

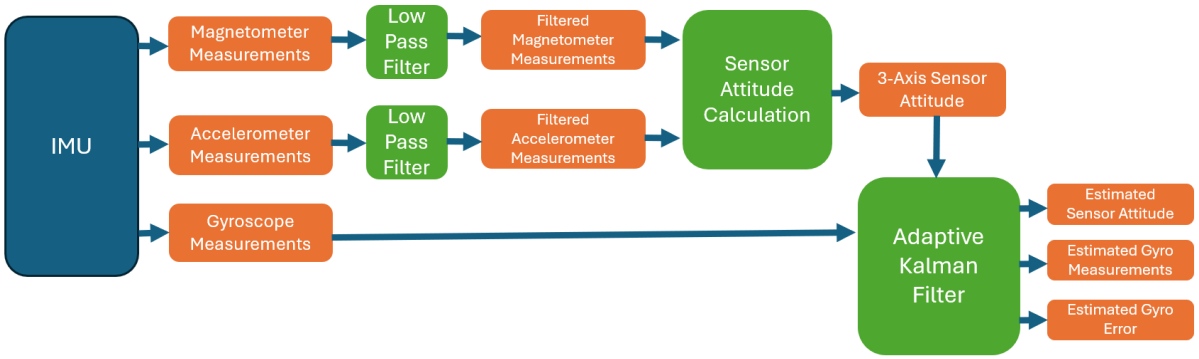

Figure 2. Adaptive Kalman Filter by Using Gyroscope Measurements and Prefiltered Attitude Data.

Findings

In the first method, accelerometer and magnetometer measurements have been used without prefiltering. Accelerometer and magnetometer data are noisy, and the random walk error has a dominant effect for both these sensors. When this data is used without prefiltering to calculate attitude, a very noisy attitude data is generated. On the other hand, the difference between attitude data is used to update the measurement noise covariance matrix, but the random walk on the data hinders

an appropriate update for the matrix. There is a random difference that cannot reflect real attitude change because of the random walk error.

In the second method, a low-pass filter is implemented for magnetometer and accelerometer data. A moving average filter has been used as a low-pass filter. So, the random walk error was removed from measurements. IMU sensor attitude is calculated by using filtered magnetometer and accelerometer measurements. On the other hand, the state vector consisted of three-axis IMU sensor orientations and three-axis gyroscope measurements. Using sensor orientations instead of orientation changes proved to be a more advantageous choice in terms of gyro error compensation. This way, it became possible to estimate gyro errors more accurately. The difference between prefiltered IMU sensor attitude data and estimated IMU sensor orientation was used to update the measurement noise covariance matrix of the Adaptive Kalman Filter. This method seems more usable for estimating gyro biases and attitude change for IMU devices.

Conclusion

This study demonstrates that if you have an IMU device capable of producing accelerometer, gyroscope, and magnetometer data along all three axes, it becomes possible to compensate for IMU gyro errors. By feeding an adaptive Kalman filter with sensor orientation information, along with gyro measurements, a better solution with error compensation for gyro data is possible. There are two steps to improve gyro error estimation. The first of them is prefiltering the accelerometer and magnetometer data. When a low-pass filter is applied to sensor data, the random walk effect is mostly removed from measurements. So, more accurate attitude data can be available for the sensor. At this point, this study focused on the rotation rate instead of absolute attitude accuracy. So, the rotation rate can be compared with gyro measurement, and gyro biases or gyro errors can be estimated. Of course, gyro errors can be time-varying errors. At this point, the adaptive Kalman filter is implemented, and the measurement covariance matrix is updated according to measurement differences. Measurement differences have been calculated between generated sensor attitude data and gyroscope measurements, so a cross-check between sensors becomes possible. According to the simulation, gyroscope errors were estimated with an average error of less than 4% across all three axes, and estimated gyro measurements provide more accurate data for inertial navigation.

By using these two steps, derivative gyro measurements have been generated, and this data can be replaced with raw gyro measurements. For inertial navigation solutions, gyroscope errors are the most critical error type. Gyroscope measurements affect not only attitude, but also acceleration, velocity, and position calculations. Because acceleration, velocity, and position updates are based on sensor attitude. According to this study, using compensated gyro data instead of raw gyro measurements can provide a better navigation solution. All data for the method that is described in this research can be provided by only one IMU sensor, so this method guarantees simplicity in hardware and better gyro data. So, better navigation data is possible with a low-performance gyro sensor.

As a direction for future work, gyro bias estimation can also be performed using the Extended Kalman Filter, and the strengths and weaknesses of EKF compared to the methods proposed in this study can be investigated.

Immersion and Invariance Disturbance Observer-Based Discrete Time Vector Control of BLDC Machines

Ziya Cem Salış[a], Yaprak Yalçın[a]

[a] Istanbul Technical University, Department of Control & Automation Engineering, Turkey
salis21@itu.edu.tr

Keywords: BLDC Machine, Discrete Time Control, Disturbance Observer, Immersion and Invariance, Vector Control.

Aim

The performance of BLDC machines can be adversely affected by disturbances, parameter uncertainties, and inherent system nonlinearities. To mitigate these challenges, Nonlinear Disturbance Observers (NDOs) have been developed, offering the capability to estimate and compensate for unknown disturbances in real time.
Many control approaches based on NDO exhibit significant complexity and sensitivity to modeling assumptions. In contrast, Immersion and Invariance (I&I) observers ensure asymptotic convergence of the estimation error to zero and can be flexibly adapted to accommodate a wide range of nonlinear dynamic models, while preserving a straightforward structure and ease of implementation. Consequently, in this paper, we propose an I&I Observer-Based Vector Control strategy specifically tailored for BLDC Machines. This proposed strategy is intended to enhance the system's robustness against external disturbances and model uncertainties. The primary focus of our approach lies in its structural simplicity, real-time applicability, and, critically, the formulation of a systematic method for applying the I&I framework to BLDC machines—an area that has not yet been addressed within the existing academic literature.
The key contributions of this work are as follows:

1. Design of a Reduced-Order I&I Disturbance Observer: The proposed observer is specifically tailored to accommodate the dynamic characteristics of BLDC machines, ensuring accurate disturbance estimation.
2. The I&I disturbance observer is integrated into a vector control strategy.
3. The effectiveness of the proposed approach is demonstrated through simulation results.

Material and Method

The BLDC machine model is first established, and disturbances are systematically formulated. A modified state-space equation is derived to facilitate the design of an I&I observer. The proposed observer is then integrated into a Vector control framework to mitigate the effects of disturbances through the incorporation of a feedforward term. The performance of the proposed control structure is evaluated through simulation studies.

1. BLDC Machine Model

To implement the I&I framework, it is essential to utilize an accurate BLDC machine model, as outlined in (Rashid, 2013; Krause et al., 2013). The parameters employed in this study are presented in Table 1.

Table 1. Used parameters.

Parameter	**Description**	**Unit**
V_x	Phase Voltage	V
R	Phase Resistance	Ohm
i_x	Phase Current	A
is_{max}	Maximum Stator Phase Current	A
Ls	Phase Inductance	Henry
e_x	Back Electromotive Force (EMF)	V
K_e	Back EMF Constant	Vs/rad
W_{elec}	Electrical Angular Speed	rad/s
Q_{elec}	Electrical Angular Position	rad
J	Inertia	Kg m^2
T_e	Electromagnetic Torque	Nm
T_l	Load Torque	Nm
B	Fluid Friction Coefficient	Nm s/rad
W_{mech}	Mechanical Angular Speed	rad/s
Q_{mech}	Mechanical Angular Position	rad
pp	Pole Pair	-
K_t	Torque Constant	Nm/A
T	Sampling Time	s

1.1. Electrical model

In the electrical model, electromagnetic field generation is achieved by passing current through the phase conductors of the machine. The equations governing these circuitries are presented below.

$$V_a = Ri_a + L\frac{di_a}{dt} + e_a \quad (1)$$

$$V_b = Ri_b + L\frac{di_b}{dt} + e_b \quad (2)$$

$$V_c = Ri_c + L\frac{di_c}{dt} + e_c \quad (3)$$

Back EMF is the voltage potential generated because of rotational motion, which acts to oppose the current flowing within the circuitry. The corresponding equations are provided below.

$$e_a = K_e W_{elec} sin(Q_{elec}) \tag{4}$$

$$e_b = K_e W_{elec} sin(Q_{elec} + \frac{2\Pi}{3}) \tag{5}$$

$$e_c = K_e W_{elec} sin(Q_{elec} - \frac{2\Pi}{3}) \tag{6}$$

1.2. Mechanical Model with Disturbance

Disturbances can be categorized into two types: measurable disturbances and non-measurable disturbances. Non-measurable disturbances include factors such as friction in bearings, variations in phase resistance or inductance due to manufacturing imperfections, and temperature differences. These disturbances are incorporated into the mechanical equations with the parameter du.

$$J \frac{dW_{mech}}{dt} = T_e - T_l - BW_{mech} - du \tag{7}$$

In the Equation (8), T_e denotes the generated torque by machine.

$$T_e = pp\ K_t\ (i_a\ sin(Q_{elec}) + i_b\ sin(Q_{elec} + \frac{2\Pi}{3}) + i_c\ sin(Q_{elec} - \frac{2\Pi}{3})) \tag{8}$$

1.3. State Space Model

The state-space representation of the given system can be expressed as follows.

$$\frac{d}{dt}\ [i_a\ i_b\ i_c\ W_{mech}\ Q_{elec}\ ] = \left[-\frac{R}{L}\ 0\ 0\ 0\ 0\ 0\ -\frac{R}{L}\ 0\ 0\ 0\ 0\ 0\ -\frac{R}{L}\ 0\ 0\ 0\ 0\ 0\ -\frac{B}{J}\ 0\ 0\ 0\ 0\ pp\ 0\right][i_a\ i_b\ i_c\ W_{mech}\ Q_{elec}\ ] +$$
$$\left[\frac{1}{L}\ 0\ 0\ 0\ 0\ 0\ \frac{1}{L}\ 0\ 0\ 0\ 0\ 0\ \frac{1}{L}\ 0\ 0\ 0\ 0\ 0\ -\frac{1}{J}\ \frac{1}{J}\ 0\ 0\ 0\ 0\ 0\right][V_a\ V_b\ V_c\ T_l\ du\ ] + \left[-\frac{1}{L}\ 0\ 0\ 0\ -\frac{1}{L}\ 0\ 0\ 0\ -\frac{1}{L}\right][e_a\ e_b\ e_c\ ] \tag{9}$$

The primary challenge in applying the I&I framework arises from the treatment of back EMF. Specifically, the back EMF is inherently dependent on rotational speed and position, leading to non-constant matrix coefficients. This variability hinders the direct application of the I&I framework. To address this issue, we propose a novel approach involving the utilization of update functions external to the state-space representation. These updated equations are formulated as presented in Equations (10) to (11).

$$U_x = V_x - e_x = R\ i_x + L \frac{di_x}{dt} \tag{10}$$

$$T = T_e - T_l \tag{11}$$

The update functions will be computed externally from the state-space equations, and their outputs will be supplied to the state-space representation. This approach yields Equation (12).

$$\frac{d}{dt}\ [i_a\ i_b\ i_c\ W_{mech}\ Q_{elec}\ ] = \left[-\frac{R}{L}\ 0\ 0\ 0\ 0\ 0\ -\frac{R}{L}\ 0\ 0\ 0\ 0\ 0\ -\frac{R}{L}\ 0\ 0\ 0\ 0\ 0\ -\frac{B}{J}\ 0\ 0\ 0\ 0\ pp\ 0\right][i_a\ i_b\ i_c\ W_{mech}\ Q_{elec}\ ] +$$
$$\left[\frac{1}{L}\ 0\ 0\ 0\ 0\ 0\ \frac{1}{L}\ 0\ 0\ 0\ 0\ 0\ \frac{1}{L}\ 0\ 0\ 0\ 0\ 0\ -\frac{1}{J}\ 0\ 0\ 0\ 0\ 0\ \frac{1}{J}\right][U_a\ U_b\ U_c\ T_l\ du\ ] \tag{12}$$

2. I&I Disturbance Observer Design

This method has been described in (Adıgüzel & Yalçın, 2021, 2022; Astolfi & Ortega, 2003; Astolfi et al., 2010; Yalçın, 2015; Yalçın & Astolfi, 2012) and is summarized below. It is important to note that this method operates under the assumption that unknown constant or time-varying disturbances vary at a significantly slower rate compared to the system dynamics. The disturbance estimation error can be defined as follows.

$$z(k) = \hat{\theta}(k) - \theta + \beta(x(k-1))\, x(k) \tag{13}$$

The variable θ(k) represents the estimated disturbance, which will be updated according to a specified update rule. The parameter β is a free design variable that allows for controlling the behavior of the observer. The time difference of the error dynamics, considering the system equations, can be expressed as follows.

$$z(k+1) - z(k) = \hat{\theta}(k+1) - \hat{\theta}(k) + \beta(k)\left(x(k) + T\left(Ax(k) + Bu(k)\right)\right) - \beta(k-1)x(k) + \beta(k)\, T\,(\hat{\theta}(k) + \beta(k-1)x(k) - z(k)) \tag{14}$$

The update rule for the disturbance estimation is selected as follows,

$$\hat{\theta}(k+1) = \hat{\theta}(k) - \beta(k)\,(x(k) + T(Ax(k) + Bu(k)) + \beta(k-1)\, x(k) - \beta(k)\, T\,(\hat{\theta}(k) + \beta(k-1)x(k)) \tag{15}$$

yields to following error dynamics,

$$z(k+1) = (1 - \beta(k)\, T)\, z(k) \tag{15}$$

Selecting β(k)= diag(α) I_5, where I_5 is the identity matrix with dimension 5, and selecting $0 < \alpha < 2$ makes these dynamics asymptotically stable.

3. Vector Controller and I&I Disturbance Observer Control Structure

Vector control, also referred to as Field Oriented Control (FOC), is a technique employed to achieve effective control over the entire torque and speed range. The most utilized control modes within FOC are speed control and torque control (Blaschke, 1972; Bose, 2002; Vas, 1990). However, due to the presence of disturbances within the system, it becomes challenging to achieve the desired reference value. To address this issue, we incorporate the previously developed I&I disturbance observer into the control loop in a feedforward configuration (as indicated by the red-marked section) as illustrated in Figure 1.

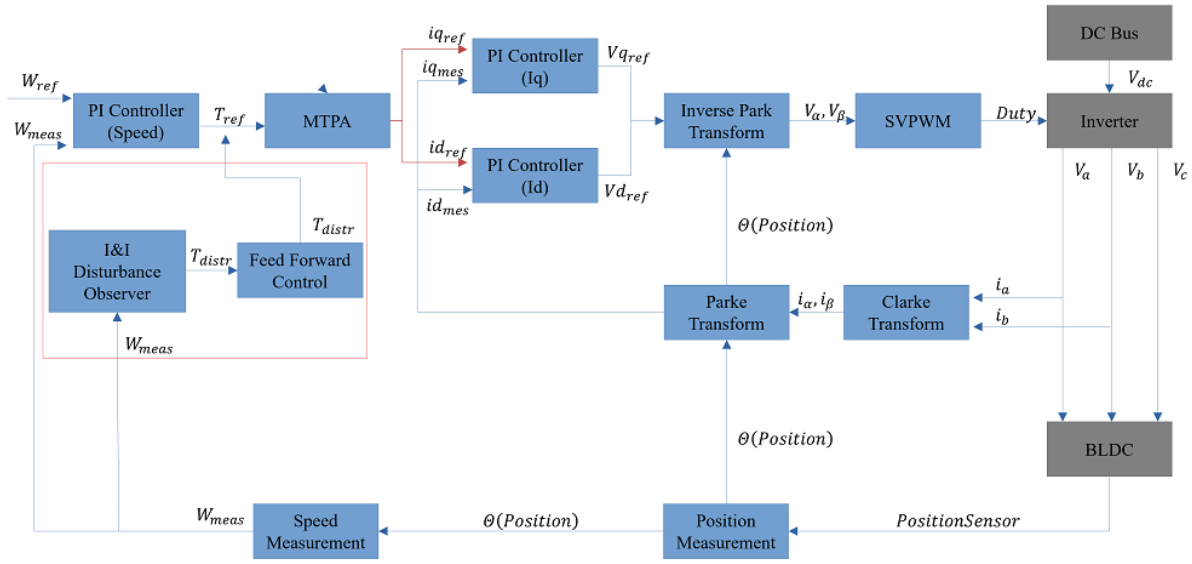

Figure 1. Proposed control loop.

Findings

To evaluate the performance of the proposed method, a simulation environment was developed using the Simulink platform. A BLDC machine characterized by the parameters listed in Table 2 is utilized.

Table 2. BLDC machine parameters.

Parameter	is_{max}	pp	R	L	K_e	K_t	J	T
Value	30	2	0.416	1.365e-3	0.0957	0.0957	2e-3	0.0001

The simulation environment adopts a control structure like that depicted in Figure 1. The performance of the system is evaluated under the following scenarios:

1. Performance under different β, constant disturbance, and speed

In the simulations, the constant parameters du=1.5 and W_{ref}=1000 are employed, while different values of β (0.1, 0.25, 0.5, 1) are selected. The objective of this test is to assess system performance and determine the optimal value of β for use in subsequent simulations.

The simulation results, illustrating the tracking of disturbance values, are presented in Figure 2. The parameter β influences both the estimation speed and the overshoot of the system. It is observed that selecting a larger β results in improved disturbance attenuation and reduced overshoot during estimation.

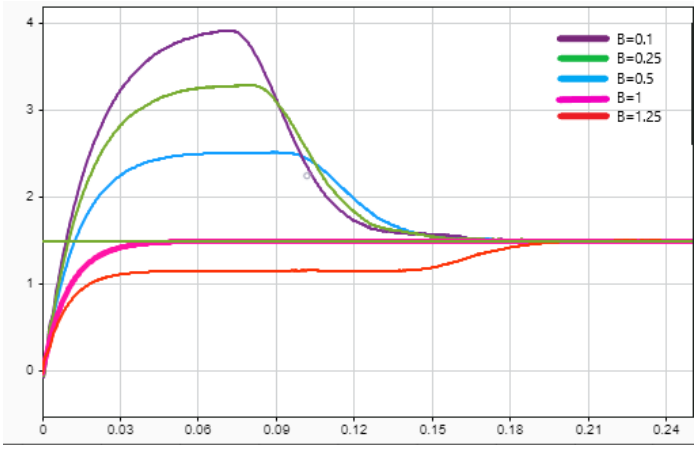

Figure 2. Observer performance for different β.

It can be claimed that parameter tuning of the proposed method is easy with the β parameter; with this free design parameter, settling time and overshoot characteristics can be directly influenced. This means that in practical implementations, this free design parameter can be adjusted on the side to meet the desired output characteristics.

2. Performance under different β, constant disturbance, and speed

The constant parameters β=1 and W_{ref}=1000 is utilized. Various disturbance profiles, including ramp and sinusoidal functions, are introduced to the system to evaluate its performance under time-varying disturbances. Ramp function disturbance and the system's tracking performance are illustrated in Figure 3.

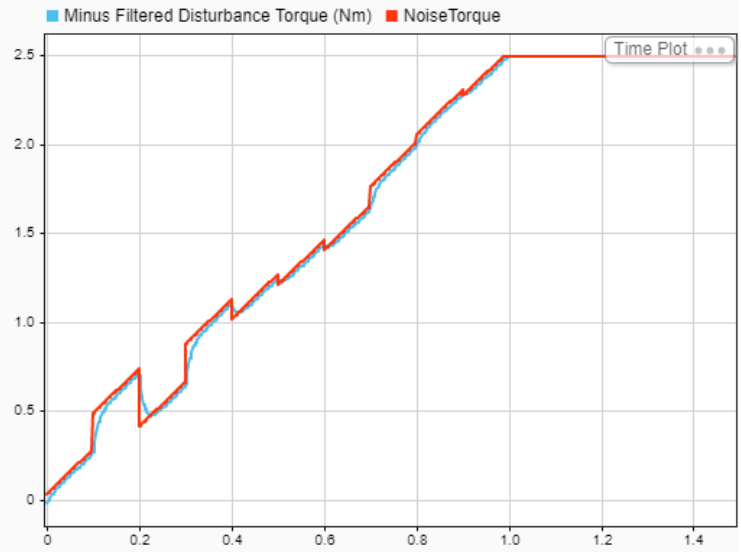

Figure 3. Disturbance tracking with ramp disturbance.

The sinusoidal disturbance and tracking performance for this case are depicted in Figure 4.

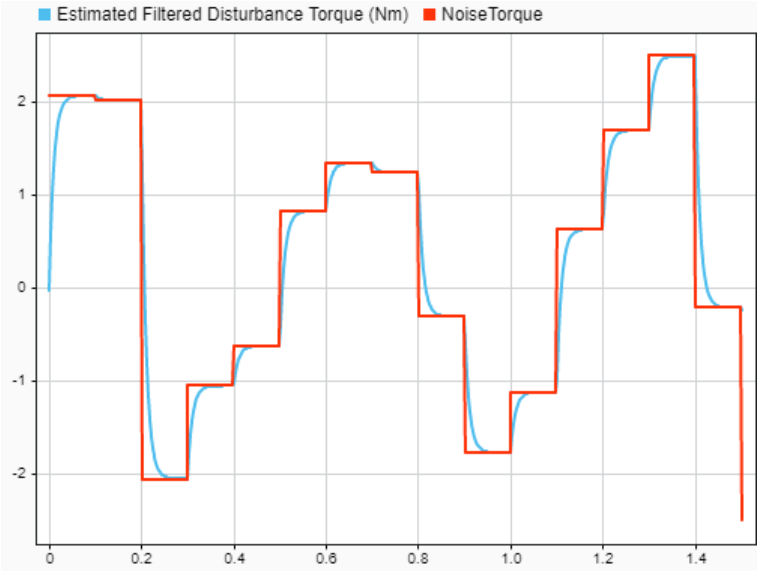

Figure 4. Disturbance tracking with sinusoidal disturbance.

The ramp disturbance profile emulates the most dominant disturbance source of friction-based disturbances to the system; thus, it increases as the speed increases and settles at a constant disturbance torque once the machine settles down to a constant speed. In traction applications motor experiences acceleration and deceleration also experiences sudden changes in disturbances because of the ever-changing conditions of the road. A sinusoidal disturbance emulates this behavior. The proposed I&I disturbance observer effectively tracks the time-varying injected disturbances, exhibiting minimal delay and negligible overshoot.

3. Comparison with or without feed forward I&I Disturbance Observer control present in the system

The constant parameters β=1 and W_{ref}=1000 are utilized, and a sinusoidal disturbance profile is introduced. The primary objective of this test is to assess the impact of feedforward I&I Disturbance Observer control on the system. The tracking performance is presented in Figure 5.

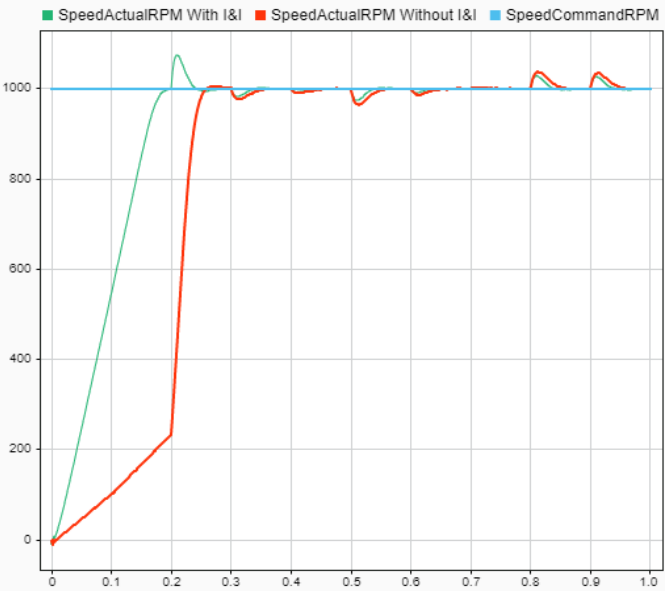

Figure 5. Tracking performance with sinusoidal disturbance.

In a detailed analysis, performance evaluation can be divided into:

1. Transient Part: A System without feedforward control exhibits a significantly slower response in achieving the desired speed compared to the system with feedforward control. At the instance of 0.2 seconds machine shows an unwanted acceleration which is not desirable in a practical application. Feedforward experiences the same sudden drop in disturbance torque, but the acceleration is less critical and less severe, and lasts for a considerably smaller time.

2. Steady-State Part: In the absence of feedforward control, the system experiences a reduction in the magnitude of disturbance, leading to improvement in control quality. This highlights the effectiveness of the feedforward I&I Disturbance Observer in maintaining steady-state performance despite the presence of disturbances.

In practical applications, the proposed observer and the feedforward control structure improve and enable quicker settling time, and reduce disturbance effects on the system.

Conclusion

In this paper, a dynamic model of a BLDC machine subjected to disturbances is developed. To address unmeasured disturbances, a disturbance estimator design based on the I&I observer approach is proposed. The FOC method for BLDC machines is integrated into the control strategy. This approach leverages estimated disturbance information to mitigate the impact of disturbances through a feedforward control mechanism and is formulated within a discrete-time framework.

The proposed method is implemented in a Simulink environment to evaluate its applicability. Performance tests are conducted through simulations under various scenarios, demonstrating that the proposed I&I disturbance observer, combined with feedforward control, effectively attenuates unmeasured disturbances.

In future work, the proposed control structure will be implemented in hardware and tested on a physical BLDC motor to further validate its effectiveness.

Keywords: Waste Detection, UAV, YOLO, Real-Time Monitoring, Convolutional Neural Network.

Aim

Plastic pollution is a major threat to coastal ecosystems, wildlife, and human health. Beaches, as dynamic interfaces between land and sea, are particularly vulnerable to plastic litter. Traditional methods of plastic waste clean-up face significant limitations due to being slow and labor-intensive. However, advancements in drone technology and deep learning offer promising alternatives [1]. This project aims to develop an automated system for detecting, identifying, and classifying plastic waste on beaches using drone images and deep learning models like YOLO [2]. By leveraging this approach, we aim to enhance clean-up prioritization, reduce human labor reliance, and support environmental conservation efforts.[3]
Plastic pollution poses significant threats to biodiversity, ecosystem functionality, and public health. Beaches are particularly susceptible to plastic litter due to their dynamic nature as interfaces between land and sea [4]. Traditional methods of addressing plastic waste, while effective on a small scale, are limited by labor intensity and inefficiency when scaled to large coastlines. Advances in drone technology and deep learning have paved the way for more efficient monitoring and detection systems.
Drones provide large-scale surveillance with high-resolution imagery, enabling precise identification of plastic waste [5][6]. Coupled with models like YOLO (You Only Look Once) [2], these technologies facilitate real-time detection and classification, supporting cleanup and conservation initiatives [7]. Various studies have explored AI-driven waste detection systems, including the development of specialized datasets such as the FloW [8] Dataset for floating waste detection and UAV-BD for drone-based plastic bottle recognition. These studies highlight the importance of multimodal data fusion and orientation-aware detection but also expose challenges related to scalability and computational demands.
A UAV-based real-time marine trash monitoring system integrating YOLO detection and data management frameworks has demonstrated the feasibility of autonomous waste monitoring. However, issues such as false positives in complex environments and the need for improved standardization persist. This paper builds upon these advancements by integrating multiple deep learning models to enhance plastic waste detection on beaches. [9][10]

Material and Method

Dataset

The dataset for this project includes drone-captured images of waste materials on beaches [11]. It is organized into three subsets: test, train, and validation, with categories such as plastic bottles, takeaway cups, retort pouches, tin and aluminum cans, glass, and takeaway containers. The original dataset, sourced from Roboflow [12], contains 1,151 labeled images, while the created dataset expands this to 2,072 labeled images using augmentation techniques as shown in Figure 1. These techniques include: Saturation adjustments (±50%), Brightness adjustments (±25%), Exposure adjustments (±10%), Blur (up to 5.7px), Noise (up to 2% of pixels).

Figure 1. A sample image that represent the dataset [11]

Method

Deep learning-based object detection methods are mainly divided into:

- One-Stage Detectors: Predict object locations and classes in a single step, offering high speed for real-time use.
  - YOLO: Processes the entire image in one pass for fast detection, though it may struggle with small objects [2].
- Two-Stage Detectors: First generate region proposals, then classify them more accurate but slower.
  - Faster R-CNN: Uses a Region Proposal Network (RPN) for precise detection at the cost of speed [13].

Comparison of Methods

Table 1. Comparison of YOLO and Faster R-CNN [14].

Model	Type	Speed	Accuracy	Pros	Cons
YOLO	One-Stage	Fast	Moderate	Real-time performance, low latency	Struggles with small objects
Faster R-CNN	Two-Stage	Slow	Very High	High detection accuracy	Not suitable for real-time use

Table 1 shows a comparison between YOLO and Faster R-CNN models in terms of type, speed, accuracy, advantages, and limitations.

Workflow

Overall workflow of the proposed waste detection system using drone imagery, from data collection to model deployment and cleanup guidance as shown in Figure 2.

1. Image Preprocessing: Images are evaluated for quality parameters like resolution, brightness, and noise. Low-quality images undergo preprocessing, including denoising, brightness adjustment, and color enhancement.
2. Exploratory Data Analysis (EDA): Insights such as class distributions, object dimensions, and heatmaps are analyzed to optimize the dataset.
3. Model Training: The YOLOv8 pre-trained model is employed. Training occurs over 25 epochs using GPU computation, and the best-performing model is selected for predictions. Other methods also trained in same way.
4. Validation: Ground truth labels are compared against predictions to evaluate model accuracy and prioritize cleaning efforts.

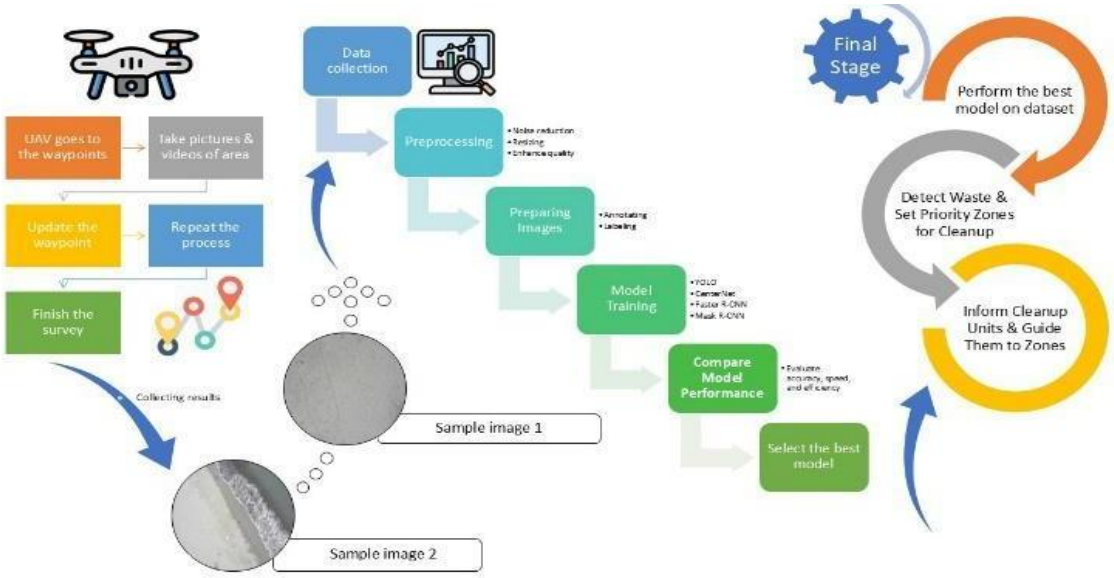

Figure 2. Workflow.

Findings

A. Dataset Metrics

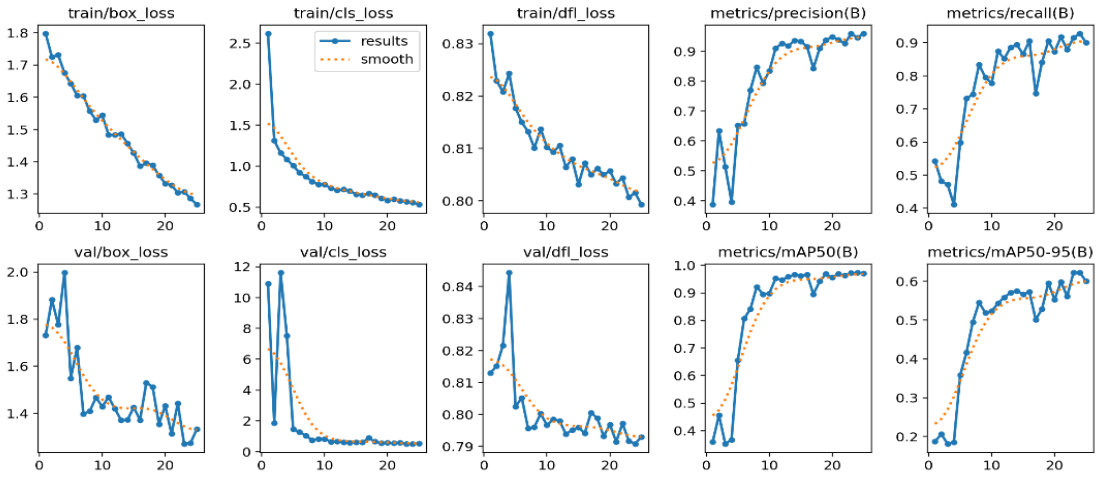

Figure 3. Dataset metrics for train and validation session.

Figure 3 presents the training and validation loss curves and performance metrics over the training epochs. Loss Metrics (a–f):

(a) train/box_loss: Measures training loss for object localization. A steady decline indicates improved bounding box accuracy.

(b) val/box_loss: Same as (a) for validation data; fluctuations suggest varying generalization.

(c) train/cls_loss: Tracks training classification loss; decreasing values show better class differentiation.

(d) val/cls_loss: Validation classification loss; divergence from training loss may signal overfitting.

(e) train/dfl_loss & (f) val/dfl_loss: Distribution focal loss for refining box predictions in training and validation, respectively.

Performance Metrics (g–j):

(g) Precision: Proportion of correct predictions; higher values mean fewer false positives.
(h) mAP@50: Mean Average Precision at 50% IoU; a key detection performance metric.
(i) Recall: Rate of correctly identified objects; higher recall means fewer misses.
(j) mAP@50–95: mAP across IoU thresholds (0.50–0.95); a broader performance indicator.

Interpretation: Training losses (a, c, e) decrease consistently, while validation losses (b, d, f) fluctuate but trend downward—suggesting good generalization. Metrics (g–j) improve, reflecting enhanced detection accuracy.

B. Model Performance:

Table 2. Comparison of YOLOv8 detection performance on different dataset configurations.

Dataset\Metrics	Precision	Recall	F1	mAP-50
Raw dataset Without pre-processing	0.9669	0.8916	0.9277	0.974
Enlarged dataset Without pre-processing	0.9629	0.9047	0.9329	0.985
Enlarged dataset with pre-processing	0.9682	0.9057	0.9359	0.988

Interpretation of Results (Table 2):

1. Raw Dataset Without Pre-processing:
   - High precision (0.9669) indicates the model is good at avoiding false positives.
   - Recall is slightly lower (0.8916), meaning some objects were missed.
   - mAP-50 is already strong at 0.974, showing good detection capability even without modifications.
2. Enlarged Dataset Without Pre-processing:
   - Slightly lower precision (0.9629) but improved recall (0.9047), meaning the model detects more objects but at the cost of slightly more false positives.
   - The F1-score improves slightly, showing a better balance between precision and recall.
   - mAP-50 jumps to 0.985, indicating the model benefits from having more training data.
3. Enlarged Dataset with Pre-processing:
   - The best overall performance.
   - Precision (0.9682) increases slightly, meaning fewer false positives compared to the enlarged dataset without pre-processing.
   - Recall (0.9057) remains strong, showing the model still detects a high percentage of objects.
   - The highest F1-score (0.9359), indicating the best balance between precision and recall.
   - mAP-50 reaches 0.988, the highest value, meaning pre-processing further improves detection accuracy.

Table 3. YOLOv8 model configuration and execution time breakdown.

Model specs	Ultralytics 8.3.58 Python-3.11.7 torch-2.5.1+cu118 CUDA:0 (NVIDIA GeForce RTX 3080 Laptop GPU, 16384MiB)
Model summary	365 layers, 43,634,466 parameters, 43,634,450 gradients, 165.4 GFLOPs
Pre-Processing execution time	176.85 seconds
Train execution time	1659.04 seconds
Val execution time	27.36 seconds
Test execution time	11.42 seconds

Table 3 provides detailed specifications of the YOLOv8 model, including the computing environment, model architecture, and the execution times for preprocessing, training, validation, and testing phases.

Figure 4. Detected objects in pictures with their corresponding confidence score.

Figure 4 shows the detection results of the trained model, where objects such as takeaway cups, containers, and glass are accurately identified across various beach images, each labeled with their confidence scores. The consistent detection with high confidence (mostly ≥0.7) indicates reliable model performance in real-world scenarios.

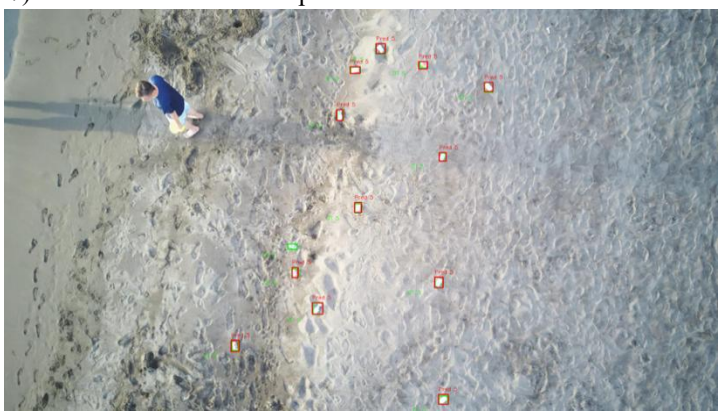

Figure 5. Predicted objects(Red labels) and ground truth(Green labels) comparison.

Many predictions match the ground truth, indicating good performance as shown in Figure 5. However, some false positives and missed detections are present, suggesting room for improvement.

Conclusion

Enlarging the dataset through augmentation resulted in a more robust and richer dataset, which also led to increased mean average precision, accuracy, and recall. On the other hand, while pre-processing slightly improved performance, it is more time-consuming compared to other methods. Therefore, for faster, real-time detection, we may need to sacrifice some accuracy for speed.

This study demonstrates the potential of integrating drone technology and deep learning for effective monitoring and detection of plastic waste on beaches. The system's high accuracy and efficiency in identifying and classifying waste types can significantly enhance cleanup prioritization and resource allocation. However, challenges such as improving algorithms for aerial imagery interpretation, expanding datasets, and incorporating additional data like thermal imaging remain areas for future research.

Future work will focus on:

- Enhancing real-time detection: Optimizing deep learning models to balance speed and accuracy for practical deployment.
- Improving dataset diversity: Incorporating additional environmental conditions and image types (e.g., thermal imaging) for robust model generalization.
- Developing an improved model: Exploring hybrid architectures that combine the strengths of one-stage and two-stage models.
- Implementing real-time applications: Deploying the system on edge devices for autonomous waste detection and classification.

By addressing these areas, we aim to develop a more efficient and scalable solution for environmental monitoring and beach cleanup prioritization.

Agentic Workflows for Self-Service Analytics Applications in E-Commerce

Taylan Yurtsever[a]

[a] Istanbul Technical University, Graduate School, Big Data and Business Analytics, Türkiye
yurtsever15@itu.edu.tr

Keywords: Large Language Models, LLM Agent, Model Context Protocol, Self-Service Business Intelligence and Analytics.

Aim

Recent years have seen widespread adoption of large language models for a variety of business tasks (Singla, 2025), including use cases in the analytics space (Zhang, 2024). Efforts on enhancing the capabilities of these models led to reasoning models (Huang, 2023) and more recently tool development frameworks for use by large language models. On the business side e-commerce has been one of the sectors that require fast decision making it an ideal candidate for self-service analytics due to its promise of faster turnaround times (Bani-Hani, 2017). The aim of this study is to provide a framework for agentic workflow use in e-commerce leveraging recent developments from in reasoning models and tool development frameworks to address shortcomings of prior research on LLM use for self service analytics. First one being the lack of context for ad-hoc tasks with basic chat applications such as ChatGPT, and second one being the lack of structured integration of execution solution for generated artifacts. Viability of this approach is tested through a set of analytics tasks.

Material and Method

Analysis of data gathered from different operational and analytical sources is a challenging problem for non-technical users with little to no experience beyond basic business intelligence tools such as spreadsheet software (Bani-Hani, 2019). As such any solution to self-service business analytics requires a careful balance between flexibility and complexity.

Recent advances in large language models allow for creation of code for use with analytical systems such as basic analysis code and SQL queries, achieving this through a chat-only interface brings two major limitations. First limitation in usage of chat-only LLM applications for analytics use cases arise from the lack of context. With no context available the model makes assumptions about the organization of data, including where it is stored, how it is stored and what information is kept within. Providing this manually while possible, is a tedious process and might result in non-repeatable analyses with erroneous results (Ouyang, 2025). Furthermore this approach requires business user to have a deep understanding of the data infrastructure. Second limitation comes from the open ended execution of any suggested steps. Besides risking correctness, any output of a chat-only large language model requires execution by the user leading to problems in security, system performance and usability.

The solution proposed for above given problems is to integrate tool use capabilities combined with self-prompting models to achieve low-level autonomy on the technical side, guided by high level user requests. This can be achieved through use of a recent tool development framework open-sourced by AI services company Anthropic called Model Context Protocol (MCP). Model Context Protocol allows developers to predefine prompts to guide, resources the model can access to and tools that can perform various operations, providing flexibility beyond static prompting while reducing the degree of freedom for structured execution and safe use. Model Context Protocol is based on a client-server architecture, where users interact with MCP compatible client that can make calls to MCP servers, that contain various tools, resources and prompts. Resources can be operational, analytical databases as well as log streams as presented in Figure 1. for an example case from an e-commerce platform.

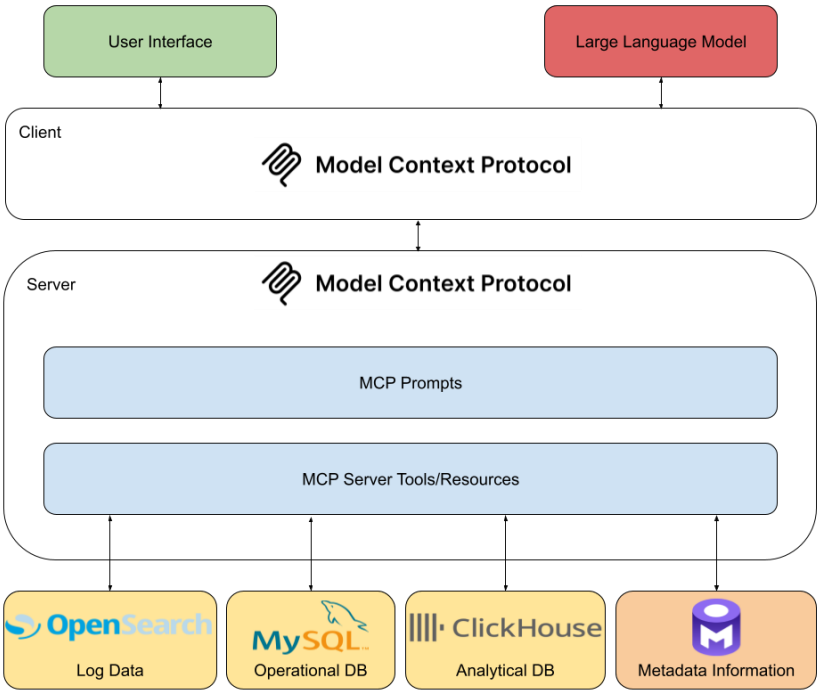

Figure 1. E-commerce data architecture incorporating MCP.

Starting from the bottom up, the first and one of the most important components of the proposed architecture is the metadata information source such as Openmetadata as shown in the diagram. Metadata and data quality management is one of the key areas of data management (Retwisch, 2017). Openmetadata with its functionality for managing metadata and ensuring data quality is one of the platforms of choice for data management (Boukraa, 2024). This component allows for detailed annotation of data sources and organization, providing needed context to LLM for further task planning and execution. With initial analysis request from user relayed via MCP client and server to the LLM, metadata server provides detailed information and notes about different data sources inside the data infrastructure. This step allows LLM model to decide which sources to use and how to use them effectively instead of manual descriptions provided by user.

The second group of components are the actual data sources which the LLM gets its data for analysis. For the case of an e-commerce platform these include operational OLTP (online transaction processing) databases, online analytical processing (OLAP) databases as well as log storage solutions such as OpenSearch for log and event processing on the platform. OLTP databases form the backbone of the data operations for non-analytical tasks for the majority of E-Commerce systems (Yang, 2024). These databases hold normalized data on inventory, pricing, transactions and other information related to daily operations of the business. OLAP databases provide specialized data structures for efficient execution of queries regularly encountered during data analysis tasks (Ansari, 2001). And finally, a search engine such as OpenSearch compliments other databases with its document storage and query capabilities allowing a detailed look into user behavior and experience across the platform via logs and events collected (Poggi, 2013). The combination of these data sources allows for tracking of customer experience from landing page to payment and also provides capabilities of historical analysis of their behavior.

The third component of focus is the MCP Server with its three primitives: prompts, resources, and tools. Prompts provide efficient interaction workflow to the resources and tools by use of predefined message templates. Resources provide the data from the systems in a predefined structured way such as execution of a SQL query with a filter accepting a parameter from the model. Tools can provide both a more flexible way to access the data and also perform operations beyond data fetching, such as creating a view or an index on a database.

The final component of the architecture is the MCP Client that orchestrates user input, MCP server connection and communication with the LLM. Client is the first point of entry for both the user and the model to the MCP context.

Findings

Across 15 tasks in a simulated e-commerce environment, agentic workflows provide correct analyses by utilizing metadata and tools integrated with MCP. Requiring only natural language queries with no information on data organization or steps to take, the system autonomously utilizes its tools to retrieve and process data from multiple data sources.

The integration of MCP with LLMs significantly enhances analytics capabilities for non-technical business users by providing a structured and accessible interface for interacting with complex data systems. Structured contextual information improves the accuracy and relevance of query results, while predefined tooling facilitates ease of access, reliability, and repeatability of analytics processes. The structured approach offered by MCPs also significantly reduces complexity and enhances user confidence in leveraging analytics tools, driving faster, more informed decisions.

In the context of e-commerce, rapid decision-making is essential to maintaining competitive advantage. Efficient self-service business intelligence, enhanced by MCP-driven structured data interactions, accelerates decision-making processes as shown in Figure 2., enabling organizations to swiftly respond to market changes, optimize marketing strategies, manage inventory efficiently, and enhance customer experiences.

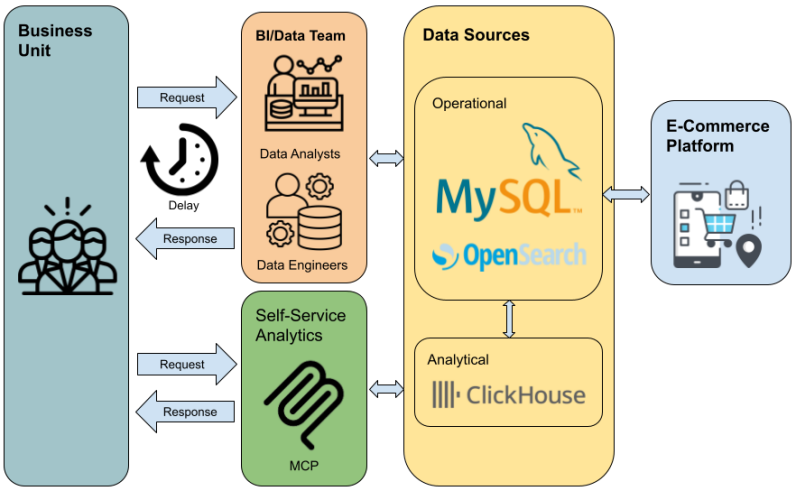

Figure 2. Agentic workflows remove organizational bottlenecks.

Conclusion

Combining advanced LLMs with Model Context Protocols significantly elevates the capability of self-serve analytics, particularly in dynamic and rapidly evolving e-commerce contexts. MCPs specifically address limitations inherent to plain LLMs by providing structured context and standardized data access mechanisms, thus empowering business users with improved accuracy, operational efficiency, and decision-making agility.

Further research should explore scalability, real-time analytical capabilities, and deeper integration with enterprise-wide governance and analytics infrastructures. Additionally, future studies should investigate critical areas such as data governance, privacy, and security implications of MCP-enhanced analytics workflows, ensuring responsible and compliant use of AI-driven analytics solutions.

Keywords: Brokerage Firms, Stock Market, Supervised Learning, Technical Indicators.

Stock transactions in financial markets and the dynamics behind these transactions have always been an interesting research topic for academics and investors. The complexity of financial markets arises from the interplay of multiple factors, including investor sentiment, macroeconomic conditions, and institutional trading strategies [1]. Among these factors, the behavior of brokerage firms plays a crucial role in shaping market trends and influencing price movements. Brokerage firm behavior is believed to have significant effects on price discovery, market liquidity, and overall market stability [2]. Understanding the mechanisms through which brokerage firms execute trades, manage risks, and respond to market signals is essential for both regulators and investors aiming to navigate financial markets effectively.

Therefore, it is believed that understanding the trading strategies and behavioral patterns of brokerage firms can provide valuable information and insights for both market participants and regulators. In particular, analyzing the relationship between brokerage firms' trading decisions and technical indicators may offer predictive power in forecasting future market movements [3]. In light of this information and insights, it is of great importance to understand the buying and selling behavior of brokerage firms in order to carry out an effective decision-making process in financial markets. By integrating machine learning methodologies with traditional financial analysis, it is possible to develop more sophisticated models that can capture hidden patterns in brokerage firm trading behavior [4]. This study represents a pioneering effort in the specific context of the Turkish stock market, being the first to systematically model the trading behavior of specific, major Turkish brokerage firms using a comprehensive set of technical indicators and advanced supervised learning techniques.

Aim

The main objective of this study is to model the trading behavior of two different brokerage firms, Merrill Lynch Yatırım Bank A.Ş. (MLB) and Yapı Kredi Yatırım Menkul Değerler A.Ş. (YKR), on 10 different stocks with the codes AKBNK, BIMAS, EREGL, ISCTR, KCHOL, SAHOL, SISE, TCELL, THYAO and TUPRS. By focusing on these specific brokerage firms and stocks, the study aims to capture firm-specific and stock-specific trading patterns that may not be evident in broader market analyses. This modeling is performed using buy and sell signals generated from 7 different technical indicators and 9 different supervised learning methods. The selection of technical indicators is based on their widespread use in financial analysis and their ability to capture momentum, trend, and volatility-based signals [5].

The study aims to reveal the relationship between the decision-making mechanisms of brokerage firms and technical indicators and to determine the most effective forecasting models. By identifying the most influential technical indicators for each brokerage firm, this research can contribute to the development of more precise trading strategies. As a result of the analysis, it is aimed to learn how the technical indicators used in the study affect the trading strategies of brokerage firms. This knowledge can help investors refine their strategies by aligning their decisions with those of institutional players.

Material and Method

The study was conducted using a historical data set of 587 trading days between January 2022 and June 2024. This period was chosen to ensure that the data set captures a variety of market conditions, including both bullish and bearish trends. By incorporating a sufficiently long-time span, the study aims to mitigate the effects of short-term anomalies and provide a more generalized model of brokerage firm behavior. The data set used in the study includes brokerage firms' trading volumes, net positions and buy and sell signals generated by 7 different technical indicators with RSI, MACD, BBANDS, SMA, STOCH, WILLR and ROC codes. Each of these indicators captures different aspects of market behavior, ranging from momentum oscillations to mean reversion tendencies [6]. For each technical indicator, buy and sell signals are generated using individually optimized thresholds.

In the data preprocessing stage, missing data were checked and completed and features were standardized to be suitable for classification. The target variable for classification is the daily net trading decision for each specific brokerage firm on each specific stock, derived from their daily net trading volume (positive net volume: buy, negative net volume: sell, near-zero net volume: hold). This provides a clear, three-class categorical variable representing the firm's directional bias on a given day for a specific asset. The process of cleaning and normalizing the data is critical to improve the accuracy of the modeling phase. A robust preprocessing pipeline was implemented to ensure data integrity and consistency across different stocks and time periods.

In the modeling phase, 9 different supervised learning algorithms such as Logistic Regression, Decision Tree, Random Forest, Support Vector Machines, XGBoost, K-Nearest Neighbor, Multilayer Perceptron, Gaussian Naive Bayes and Gradient Boosting were used [7]. These models were selected based on their ability to handle classification problems with structured financial data. The performance of the models was evaluated using the F_1-score metric, which balances precision and recall. By prioritizing F_1-score over accuracy, the study ensures that both false positives and false negatives are minimized, leading to more reliable predictions.

Findings

The experimental results show that different supervised learning models perform optimally for different stocks. This finding highlights the importance of model selection in financial prediction tasks, as no single model consistently outperforms others across all scenarios. It is observed that the most appropriate model for the brokerage firm with MLB code is Logistic Regression. This suggests that MLB's trading behavior aligns well with linear decision boundaries, making Logistic Regression a suitable choice. Similarly, the most appropriate model for predicting the trades of the brokerage firm with the code YKR is the Decision Tree. Decision Trees' ability to capture nonlinear relationships may explain their superior performance in modeling YKR's trading patterns.

The stocks and models with the highest F_1-score for the MLB coded brokerage firm are EREGL (Logistic Regression: 0.5424), AKBNK (Logistic Regression: 0.5169), TCELL (XGBoost: 0.5085). The stocks and models with the highest F_1-score for the brokerage firm with YKR code are AKBNK (Logistic Regression: 0.5254), KCHOL (Support Vector Machines: 0.5254), BIMAS (Decision Tree: 0.5085). These results suggest that while some stocks are better modeled using linear techniques, others require more complex decision boundaries to capture the underlying patterns effectively. When these findings are analyzed, it can be concluded that different modeling techniques are more appropriate for different stocks. Crucially, these performance levels significantly exceed the 0.33 baseline expected from random chance in a three-class problem. Given the inherent complexity, noise, and stochastic nature of financial markets, especially when modeling the behavior of individual institutional players, these F_1-scores indicate substantial predictive power and demonstrate the model's effectiveness in capturing meaningful patterns beyond random guessing.

The study concludes that supervised learning methods are an effective tool for modeling the behavior of brokerage firms. In addition, another result of the study is that the decision-making processes of brokerage firms can be explained by using technical indicators. In particular, the Logistic Regression method was found to be more successful in capturing market dynamics compared to other models. The findings may help investors to interpret market signals more effectively and may also contribute to the development of early warning systems by regulators to ensure market stability. The combination of technical indicators and supervised learning models provides deeper insights into the analysis of broker trades.

Practical Implications

The practical implications of this study are direct and actionable. Firstly, it provides investors with valuable insights into the potential drivers behind the trading decisions of two major market participants, MLB and YKR. By understanding which technical indicators are statistically linked to the buy/sell behavior of these firms on specific stocks, investors can potentially anticipate directional pressure or liquidity changes, thereby making more informed trading decisions. Secondly, for regulators, the developed models offer a concrete quantitative framework for monitoring the trading activities of significant brokerage firms. Deviations from the modeled 'expected' behavior, based on prevailing technical signals, could potentially serve as flags for further investigation, aiding in the detection of anomalous trading patterns or contributing to oversight mechanisms designed to prevent market manipulation and ensure market stability. Increased use of supervised learning algorithms in market analysis, as demonstrated here, is expected to increase transparency and predictability in financial markets.

Future Studies

Future studies that will aim to predict the behavior of brokerage firms with higher accuracy can achieve their goals by using time series analysis, deep learning and reinforcement learning models. Time series analysis allows for a better understanding of trends and cycles in market data [9]. Deep learning models can be used to identify more complex relationships, especially when analyzing dynamics in large data sets [10]. Reinforcement learning models, on the other hand, dynamically adapt to market conditions, enabling the development of more effective forecasting models [11]. In future studies, the accuracy of the models is expected to increase by including more stocks and brokerage firms in the analysis.

In addition, the inclusion of macroeconomic variables in the model in order to analyze the impact of economic and political factors on market movements in more detail is thought to increase the accuracy of the results to be obtained. The predictive power of the models can be increased by determining the impact of factors such as interest rates, inflation, exchange rate changes and global economic developments on the decision-making processes of brokerage firms. By integrating such variables into supervised learning and other learning models, a more comprehensive market analysis will be possible.

Conclusion

As a result, as the first study of its kind focusing on modeling the behavior of specific major Turkish brokerage firms (MLB and YKR) on key stocks using technical indicators and machine learning, this study takes an important step forward in understanding the impact of brokerage firms on the market. In particular, the combination of technical indicators and supervised learning algorithms provides a powerful framework for modeling the behavior of brokerage firms trading in financial markets. The achieved F_1-scores, while reflecting the challenging nature of the prediction task in noisy financial markets, demonstrate the feasibility and practical utility of this approach, significantly outperforming random chance. The findings are expected to help market participants make more informed decisions and help regulators supervise markets more effectively. Future research aims to further improve the models used and increase their effectiveness in financial markets. In addition, the scope of the models can be expanded by including macroeconomic factors affecting market dynamics in the analysis, which will enable a more comprehensive modeling strategy to be developed and a deeper understanding of the trading patterns in financial markets will be possible. Ultimately, this line of research holds significant potential to increase market transparency, reduce risks and create a more efficient trading environment.

Keywords: Sentiment Analysis, Financial News, Asset Price Prediction, ChatGPT, Trading Strategy.

The integration of sentiment analysis within financial forecasting has attracted considerable scholarly interest in contemporary research. For example, Halder (Halder, 2022) introduced the FinBERT-LSTM model, which synergizes the sentiment derived from financial news with stock price data to augment predictive accuracy. In a similar vein, Zhu and Yen (Zhu & Yen, 2024) employed BERTopic to conduct an in-depth examination of stock market discourse, consequently integrating sentiment analysis with advanced deep learning architectures to improve the efficacy of stock price forecasting results. Furthermore, a study conducted by Srinivas (Srinivas et al., 2023) developed a theoretical model that analyzes a comprehensive collection of news articles, demonstrating that the incorporation of sentiment analyses derived from financial journalism can significantly affect the predictions regarding stock price movements. Collectively, these studies highlight the potential of employing sophisticated natural language processing techniques and sentiment analysis to more effectively anticipate asset price fluctuations. Recent advancements in large language models (LLMs) have further augmented the capacity to interpret sentiment within financial news articles, yielding enhanced accuracy and contextual comprehension. While traditional sentiment analysis methodologies typically depend on pre-established lexicons or machine learning classifiers, LLMs present a more dynamic and adaptable approach to deriving sentiment scores from intricate financial texts. The application of sentiment analysis in the context of financial markets holds significant relevance for traders and investors who seek to enhance their trading methodologies by leveraging real-time market sentiment. This scholarly investigation aims to assess the effectiveness of sentiment analysis in predicting fluctuations in asset prices triggered by financial news. Specifically, it investigates how sentiment scores, extracted from financial articles and macroeconomic reports, may be utilized to predict both short-term and medium-term market fluctuations. By employing LLM models to generate sentiment assessments, this study explores the correlation between sentiment polarity and actual asset price movements. Additionally, it scrutinizes whether aggregated sentiment scores enhance predictive accuracy and investment performance across diverse time intervals. Through the examination of news data associated with high-volume trading assets in the S&P 100 index, along with macroeconomic reports relevant to the United States economy, this study provides valuable insights into the practical implementation of sentiment-driven trading strategies. The research seeks to address crucial questions about the forecasting effectiveness of sentiment-based models and the potential benefits of time-based aggregation of sentiment information.

Aim

The primary objective of this study is to assess the efficacy of sentiment analysis in predicting asset price variations that are influenced by financial news. By employing large language models to evaluate sentiment assessments derived from news articles, this research aims to enhance trading methodologies for short-term investment horizons, including daily and weekly price direction predictions. The methodology encompasses both asset-specific and macroeconomic news to formulate predictions predicated on sentiment analysis. Furthermore, this study investigates the impact of cumulative sentiment ratings on the precision of predictions and the performance of investments over extended periods.

Material and Method

The dataset encompasses essential financial news acquired from Eikon, which includes ten high-volume trading assets spanning diverse sectors within the S&P100 index over a temporal horizon of approximately 15 months. Additionally, macroeconomic news relevant to the United States is also incorporated. For the purpose of daily forecasts, news articles are aggregated up to 30 minutes prior to the market's opening time (09:30 AM). A Cosine Similarity filter (threshold: 0.98) is employed to exclude redundant news entries. The refined news articles, alongside macroeconomic and sector-specific data, are subsequently processed through ChatGPT to yield a sentiment score that ranges from -1 (indicative of negativity) to 1 (indicative of positivity). The accuracy of the forecasts is confirmed by comparing the sentiment score's direction with the real market path, determined by the difference between opening and closing prices. If the anticipated trajectory corresponds with the actual motion, the degree of accuracy is documented as 1; conversely, in the event that it does not correspond, it is recorded as 0. The calculation of return on investment is derived from the absolute differential in price, whereby inaccurate forecasts lead to adverse returns. The methodology for weekly forecasting utilizes a similar framework, synthesizing information from the initial business day of the prior week to the initial business day of the present week. The same cosine similarity threshold and sentiment scoring methodology are applied. Weekly accuracy and returns are determined in an identical manner to that of daily predictions. Furthermore, cumulative sentiment scores are calculated by summing over designated rolling periods for both daily and weekly frequencies to evaluate their impact on prediction accuracy and return performance.

Findings

The results indicate that forecasts driven by sentiment exhibit superior accuracy for weekly transactions in comparison to daily transactions. Specifically, differentiated sentiment assessments provided more reliable indicators for weekly price variations. The computation of cumulative sentiment scores appeared to have minimal influence on the precision of daily forecasts, yet demonstrated improvements under specific market circumstances. Nevertheless, in the context of weekly predictions, cumulative sentiment scores significantly enhanced the effectiveness of the model during particular temporal intervals. This suggests that the aggregation of sentiment data over time can augment the reliability of predictions, particularly for trades with an extended time frame (see Figure 1).

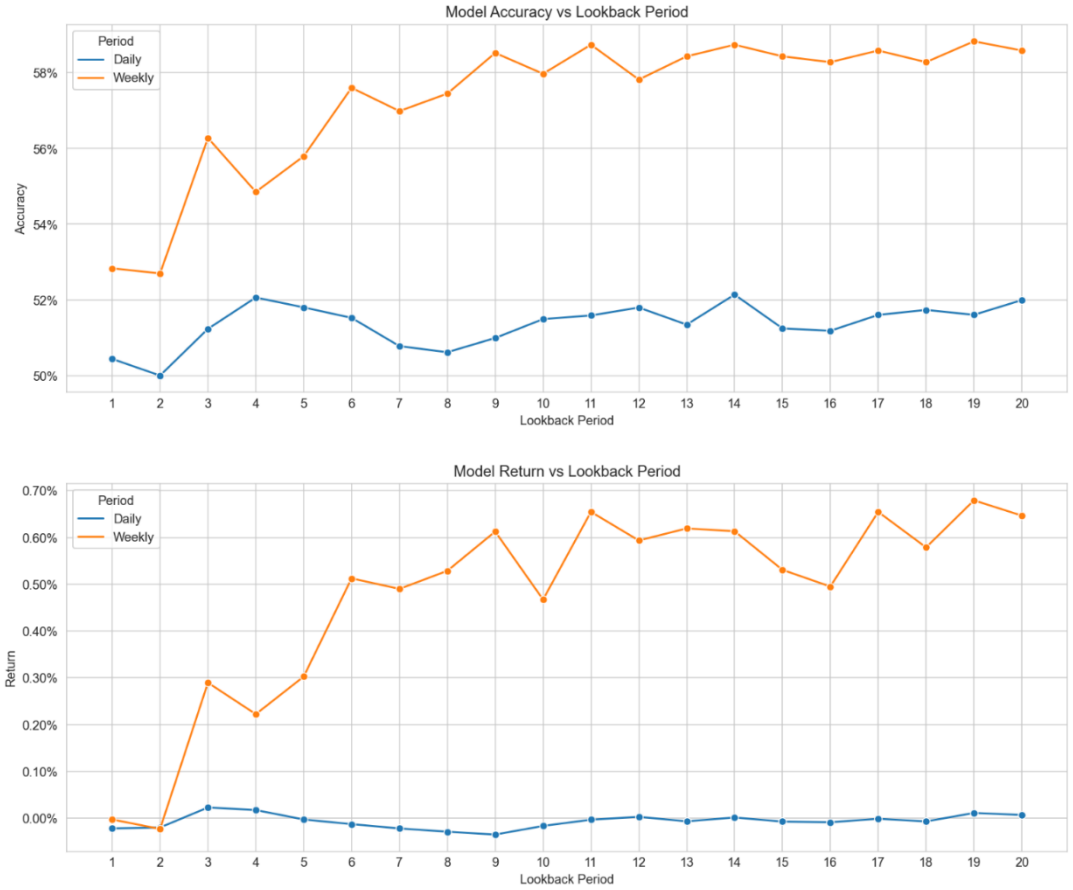

Figure 1. Model Performances.

Conclusion

This research investigates the capabilities of sentiment analysis through the application of large language models (LLMs) to anticipate variations in asset valuations as impacted by financial news. Although daily sentiment assessments exhibited a limited capacity for prediction, weekly sentiment forecasts were determined to be more effective, with aggregated sentiment evaluations considerably improving accuracy within designated temporal spans. These findings underscore the importance of incorporating historical sentiment trends to optimize trading strategies. Subsequent scholarly investigations may delve into sophisticated sentiment aggregation methodologies and alternative machine learning paradigms to further enhance predictive efficacy.

[a]Istanbul Technical University, Department of Defence Technologies, Türkiye
[b] Istanbul Technical University, Faculty of Electrical and Electronics Engineering, Department of Electronics and Communication Engineering, Türkiye
bagcacier19@itu.edu.tr

Keywords: GPRMax, Ground Penetrating Radar, CNN Pre-processing, Background Subtraction, Hyperbola Detection.

Introduction

Ground Penetrating Radar (GPR) is a powerful technology. It images the subsurface using electromagnetic waves, with applications in construction, geophysics, and other fields. It is vital in defense for detecting objects like buried landmines. However, GPR data interpretation is challenging. Complex data arise from ground conditions, noise, and varied subsurface structures. Usually, interpretation of this data is performed by people, but this can be slow and person-dependent. Machine Learning (ML) can address these issues.

This study aims to systematically compare and analyze the effect of different preprocessing techniques on GPR data, to gain an in-depth understanding of their impact, and to determine how the most suitable input data for Machine Learning models can be prepared.

Applied preprocessing steps are evaluated via comparative visualizations and histogram analyses of the processed data, and an optimized preprocessing process for GPRMax simulation data is presented. Results indicate the proposed methods significantly improve signal clarity, making data more suitable for CNN-based analysis.

Aim

Due to difficulties in collecting and labelling real GPR data, GPR simulations are crucial for the investigation of subsurface structures. For this reason, GPRMax simulation data was used in this study. GPRMax models electromagnetic wave propagation, enabling analysis of signal behavior under various ambient conditions. However, simulation outputs are often unsuitable for direct analysis due to:

- May contain high amplitude reflections arising from the air-soil interface,
- Hyperbolas can be blurred due to noise and low signal-to-noise ratio (SNR),
- Since the amplitude distribution is not standard, it needs to be normalized for machine learning algorithms.

The role of pre-processing is to refine this raw data, in particular to clarify reflections from embedded targets and to provide a "cleaned" input to the Machine Learning model. In this study, a comprehensive pre-processing process is developed for optimizing the GPRMax data prior to a CNN-based analysis. Specifically, background removal methods are compared for their effect on preserving hyperbola structures. It is also evaluated how different preprocessing combinations can affect the discriminative properties of radargram images in convolutional neural network (CNN) algorithms.

Material and Method

Raw GPRMax simulation data often contains high noise, artefacts due to air-soil transfer, and variable amplitude distributions. This hinders meaningful data inferences. For deep learning models to work correctly, high-quality input data is required.

This study is distinguished by its use of complex, diversified test scenarios. While single-layer homogeneous environments are commonly preferred in the literature, in this study, scenarios involving multi-layer (up to 4 layers) and heterogeneous

materials, such as PEC-plastic mixtures, were investigated. These more realistic, complex environments demonstrate that the proposed hybrid preprocessing method is effective even in challenging conditions. Beyond the results obtained in single-layer homogeneous media, satisfactory results are obtained even in multilayer media, proving the reliability of the method. The proposed preprocessing process aims to optimize the *.out files generated by GPRMax prior to analysis. Key pre-processing categories include Background Subtraction, Filtering, Time Gain application, Noise Reduction, and feature-emphasizing techniques. In this context, the following steps have been implemented:

1. Background Subtraction

Many background subtraction methods in the literature are based on ideal laboratory conditions. Unlike conventional methods, the hybrid preprocessing approach proposed in this study has the potential to be used in real-time applications. The air-ground transition can mask deep structures as it contains high-amplitude reflections. Different background removal methods are tested and compared to reduce this effect:

a. **Average-based background subtraction:** Pixel averages were calculated on the horizontal axis, and these average values were subtracted from each row. Used alone, this method may produce false artefacts by creating black shadows around the hyperbola.
b. **Gaussian Filter:** Reduces high-frequency random noise while preserving low-frequency components. Used alone, this approach may cause hyperbola details to be blurred because high-frequency components are not preserved.
c. **Grey Opening:** With the morphological opening process, large structures are preserved while small noise structures are removed. This method is effective in suppressing non-structural random noise.
d. **SVD Filter (Singular Value Decomposition):** By performing singular value decomposition of the radargram matrix, components with a low significance level are eliminated, and only the most dominant structural features are preserved.
e. **High-pass Filter:** High-pass filtering, especially in the horizontal axis, was used to suppress broad, low-frequency background fluctuations and emphasize fine, sharp structures.
f. **Curvature Enhanced Filter (CEF):** It uses the second derivative information of the signal to suggest low-amplitude structures in the data. By emphasizing the geometric features of weak signals, the target is made more prominent.

2. Whitening

Whitening normalizes amplitude and equalizes the frequency spectrum by reducing low-frequency signal components. This makes target structures more distinct.

3. Time Gain

Time Gain increases signal amplitude to compensate for its attenuation with depth.

- The underlying structures should become more prominent,
- Since exponential gain is applied, different contrast levels should be seen.

4. Normalization

For consistent CNN results, the entire data set should be processed with the same scaling. Two normalization methods are compared:

- **Min-Max Normalization:** Compresses the data in the range [0,1]. It provides better visualization by preserving hyperbola edges.
- **Z-Score Normalization:** Normalizes data by mean and standard deviation. It increases sensitivity in dense signal regions but may cause loss of detail in low-amplitude regions.

5. Noise Filtering

Only the Non-Local Means (NLM) filter is used in this study. This aims to prevent detail loss during noise reduction.

Findings

The proposed preprocessing method's effectiveness was analyzed via visual comparisons of raw and processed data.
Figure 1 illustrates how pre-processing yields varying results for targets at different depths. For deeper targets (top image, target depth 30mm, even below the second layer), noise is reduced, background subtraction is successful, and the signal is clean.
However, for shallower targets (lower image), it was noticed that unwanted residuals persisted after background subtraction. This indicates that preprocessing performance varies with technique, target depth, and position.

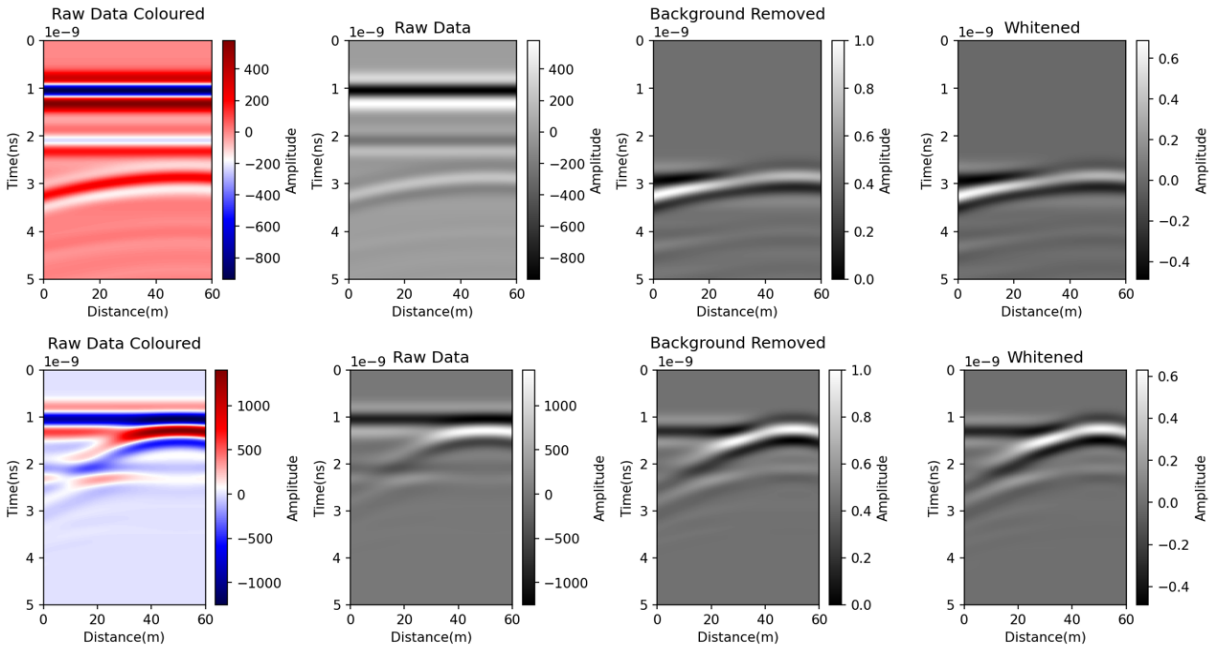

Figure 1. Target depth 30mm and 150mm /Depths of two layers:100mm and 170mm.

In the B-scan of both figures, the curved event that appears at a later time (lower on the vertical axis) below the main hyperbola is a repeated reflection from the target (multiple reflection). These common multiple reflections are considered data-cluttering 'noise'.
A second comparison involves results from different Background Removal techniques. Background removal is a fundamental step in GPR to remove strong, horizontal reflections, such as air-surface.
Figure 2 shows the final images obtained when four different background subtraction techniques (Mean, Grey Opening, SVD, and Gaussian Filter) are applied to the same raw data (keeping the other pre-processing steps the same). Image differences are striking. The techniques yielded significantly different results in background removal and target (hyperbola) highlighting.

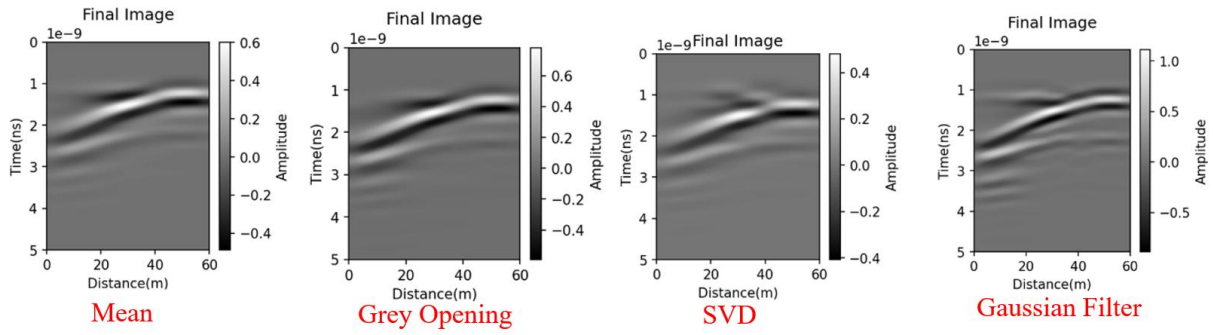

Figure 2. Asphalt and dry sand (two-layer) media, Plastic and PEC mix material.

The effect of the preprocessing step order is also compared. In Figure 3, the results obtained when the location of two specific processing steps, Whitening and Background Removal, is changed are seen.

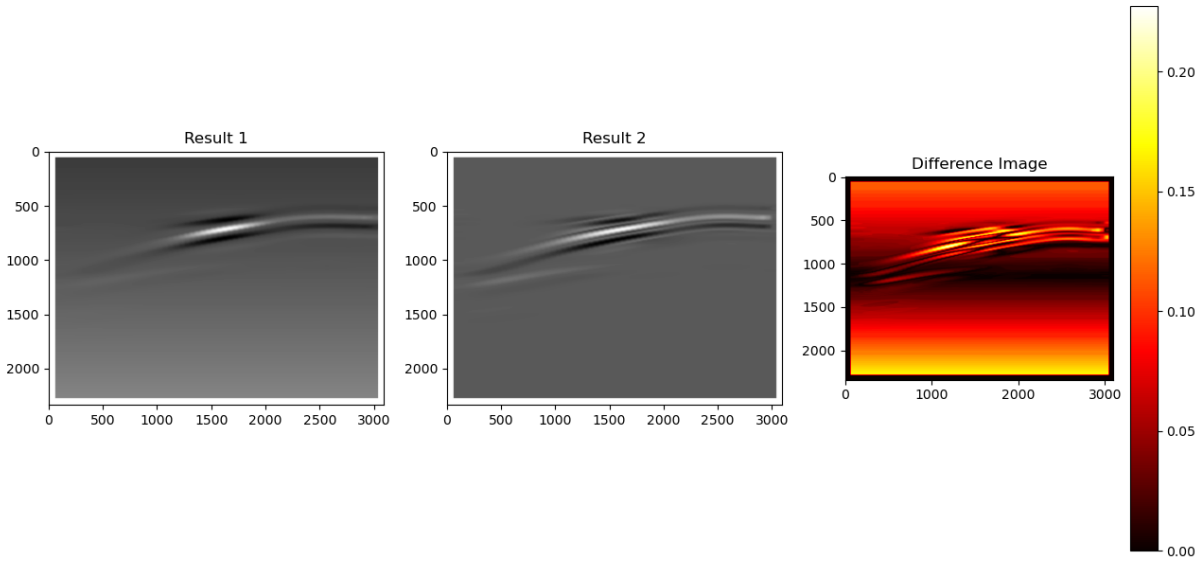

Figure 3. Difference Image.

a. **Whitening first (Result 1):** Whitening normalizes the data and reduces low-value noise. In this case, when the background is removed from the whitened data, the results may be clearer because the targets are already more distinct. However, since whitening changes the data dynamics, background modelling may be affected. Result 1 shows that the reflection around the hyperbola is much smaller. However, when compared to Result-2, it clearly shows that the hyperbola structure is distorted at the peak, where the reflection is the strongest.
b. **Performing background subtraction first (Result 2):** The effectiveness of the whitening process may be reduced because the effect of the background removed during the whitening process may reappear. However, in this approach, the background is first removed from the raw signal, thus improving the dynamic range and target clarity. This allows the hyperbola to be better optimized for CNN analysis.

A key finding was the significant visual differences in the final radargram images produced by the different preprocessing methods. Figure 3 shows the difference between the two approaches: the amount of variation in background components and hyperbola structure is represented by a color intensity diagram. In particular, the shape, amplitude, and contrast of the target reflections with the background vary significantly between the methods.

The difference image and color bar show pixel amplitude differences up to 0.20.
In the histogram analysis in Figure 4, the classical method is shown as Result-1, while the hybrid model is shown as Result-2. This compares pixel intensity distributions of the two methods. There are some differences between the two histograms:

- "Result 2" (orange) has a higher peak and a slightly narrower distribution.
- "Result 1" (blue) has a wider distribution.

This indicates the method makes off-target background regions numerically more homogeneous and stable.

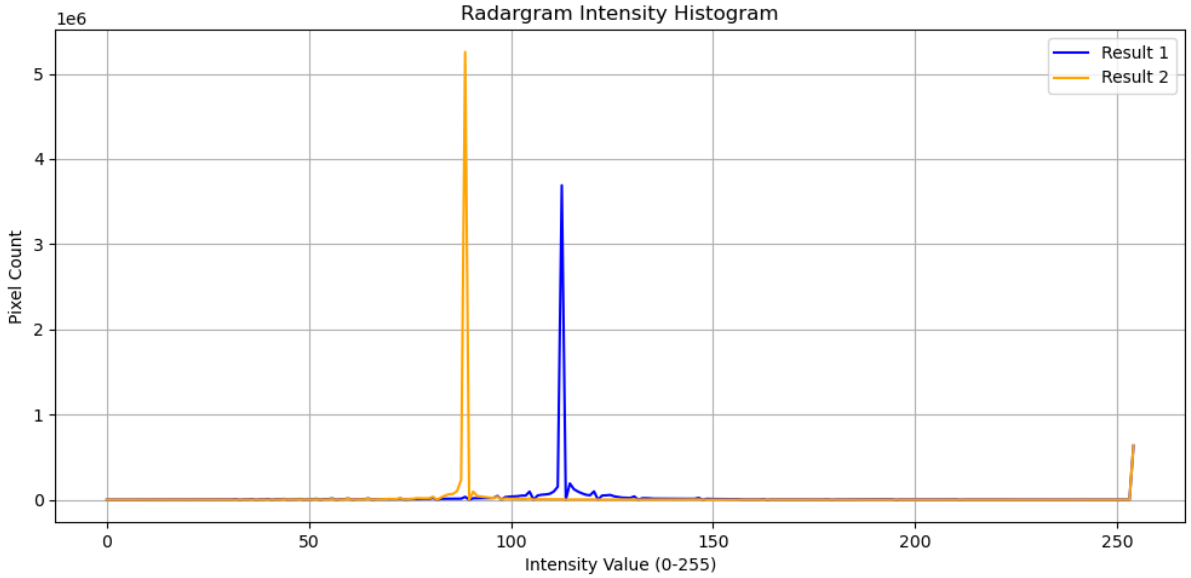

Figure 4. Histogram Analysis.

This is important for CNN models. For the CNN algorithm:

- 'Result 2' appears to have sharper contrasts and more pronounced features.
  If background pixels have very stable and predictable values, the CNN can more easily learn this standard background pattern and focus on target signals (deviations from background). Thus, background stabilization efficacy can be as crucial for Machine Learning performance as signal region brightness.
- 'Result 1' has a wider dynamic range and could potentially have more detail. This could enable finer features to be preserved.

These visual and statistical comparisons demonstrate that different preprocessing steps, sequences, and parameters significantly affect the result. Furthermore:

- The best preprocessing is not a single step or a fixed chain, but may vary depending on the target and the ground.
- High-pass methods for high-contrast applications, SVD-based methods for preserving structural information, and Gaussian filtering for noise robustness have been emphasized.
- As deep learning models readily learn sharp edges and intensity differences, a hybrid preprocessing approach was developed to enhance deep structure visibility.

Based on these observations, an optimized GPRMax preprocessing process combining the most promising steps is presented. This method includes Background subtraction, high-pass filter, Time Gain, Curvature Enhancement, Whitening, and Noise reduction steps.

Figure 5 shows that processing steps significantly improved signal clarity when this hybrid method is applied step by step to a single raw dataset. The raw GPRMax data shows high amplitude reflections and low contrast hyperbolas due to the air-soil transition. In the final image, horizontal components are reduced, and hyperbola structures are emphasized.

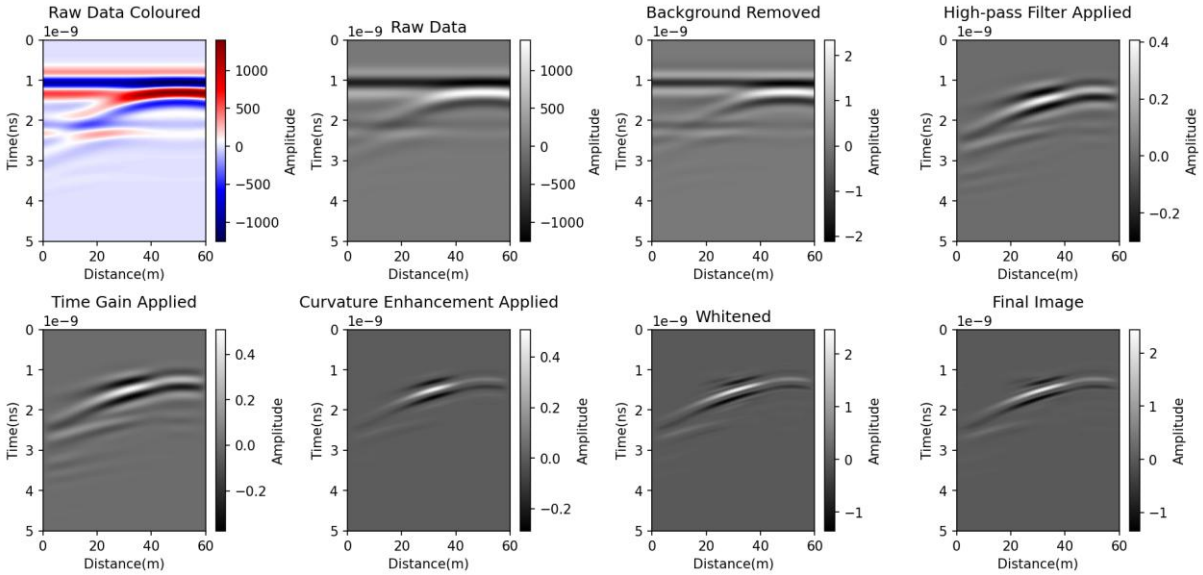

Figure 5. Hybrid Preprocessing Approach.

Conclusion

The key contribution is that Preprocessing methods applied to GPR data radically alter final data representation, and their choice directly impacts ML model success.

This shows that for CNN-based GPRMax data optimization, the correct preprocessing order is crucial for target detection, as incorrect ordering can cause significant information loss.

Different methods or implementations uniquely emphasize or suppress signal features, noise, and target reflections. The sequence of preprocessing steps, the parameters used, and even the target position/depth can significantly change the results. A major challenge is preprocessing sensitivity to different geometries.

The main consequence of this is the following: To achieve the best Machine Learning performance, carefully selecting and optimizing the preprocessing chain that best suits the nature of the data set is the key to success.

Keywords: CubeSat, Helical Antenna, Deployment, Satellite Communication.

CubeSats are small satellite systems to access and benefit opportunities in space in a cost-effective and accessible way for universities, companies, and student groups, which are assigned various missions such as ground observation, telemetry, data transfer, and payload access. These capabilities are only possible when reliable communication between ground systems and the spacecraft is provided. The key elements to enable efficient communication are antennas, which convert electromagnetic waves into electrical signals, making data transmission possible.
The mission of a CubeSat determines the required characteristics of its antenna. For instance, omnidirectional antennas provide wide-area coverage, while directional antennas concentrate energy into a specific region for stronger signals. So, in the process of an antenna, the type of antenna is crucial since each type of antenna has its own specific characteristics. High-gain antennas improve communication quality and speed. Helical antennas promise high gain, wide bandwidth, which is needed for CubeSat communication, which has a structure that requires a deployment system. Deployable antennas are particularly challenging to design; however, successfully implemented versions significantly enhance communication capabilities and overall CubeSat performance, which are the key considerations. Since antennas are initially stowed inside the spacecraft and deploy once in space, ensuring a reliable deployment mechanism is crucial.

Aim

This project aims to design, prototype, fabricate, simulate and test a high-gain, circularly polarized, deployable helical antenna with a large front-to-back ratio, wide bandwidth, and optimized radiation pattern, to prepare the antenna space communication mission and to achieve a gain of 10 dB with an operational frequency range of 2 - 4 G Hz which contains S Band which is a very common band for CubeSat communication. Helical antennas have the advantage of inherently exhibiting circular polarization due to their curved form and helical structure. This project aims Designated frequency, defines most of the antenna's structural and electrical characteristics such as wavelength of antenna, diameter of antenna and ground plane of antenna which is a necessity for helical antennas to provide directivity and target the satellite to ground station and other characteristics are determined as requirements of communication like gain, directivity and spacing limitations such are antenna measures and placement in the CubeSat structure since CubeSats have limited space, which makes balancing antenna size, gain, and directivity particularly challenging and essential approach.
The antenna system consists of multiple materials, which are divided into the helix antenna and the deployment system. Candidate materials for the antenna wire include aluminum, gold-coated titanium, copper, spring steel, phosphor bronze, and beryllium copper, and structural Teflon, PTFE, and carbon fiber composites can be assigned for the mechanical system. The selected materials should not negatively interfere with signal transmission. Material selection is critical for space applications, as components must withstand harsh environmental conditions in space. Beryllium copper is widely used due to its favorable electrical properties, while Teflon is preferred as it does not affect electromagnetic waves. Accessibility and manufacturability are also key factors in material selection.

Material and Method

The primary method used for antenna selection is comparison between several types of antennas, such as patch, helical, conical, log-periodic, quadrifilar helix (QHA), and other deployable configurations. Patch antennas are simpler and more cost-effective, making them a practical choice for many applications. However, helical antennas offer inherent circular

polarization, higher gain, and wider bandwidth, making them more suitable for high-performance communication missions. Helical antennas can provide superior performance with a well-designed and optimized deployment mechanism. Theoretical calculations with fundamental antenna equations help determine the initial results and optimize dimensions and performance characteristics. To refine the geometry to enhance structural stability and to maximize deployment reliability and efficiency CATIA modelling program is used. Catia Kinematics digital mockups have been made to design the mechanism and define the relationship with the CubeSat components, structure, and constraints, also to simulate the deployment mechanism and movements. Deployment of the antenna is also physically evaluated by prototyping with 3D Printing to see the weak points of the design and improve. Besides, testing the antenna in an anechoic chamber to assess real-world performance and validate by comparing with analysis results will contribute helical antenna validation process. Also, the TVAC vacuum chamber is used to test to examine the antennas and deployment mechanisms' space performance with vacuum cycling, outgassing testing, and functional testing.

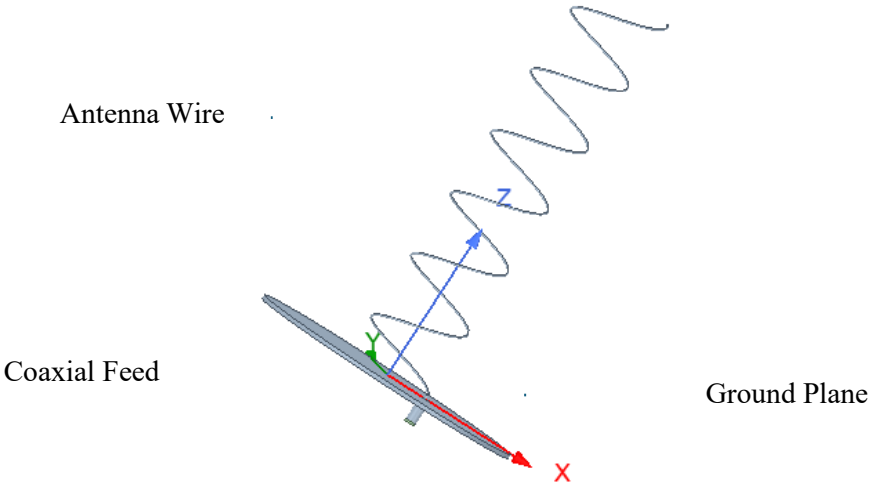

Figure 1. Initial Helical Antenna Model in HFSS.

Table 1. Physical Properties (mm).

Wavelength	132.3
Diameter of ground plane	132.3
Spacing between each turn	33.2
Total length of antenna	231.3
Number of turns	7
Helix Diameter	42.1
Circumference of helix	132.3
Length of coaxial feed	10

Thickness of ground plane	2
Total Length of Wire	954.1
Distance between feed and helix	2

Findings

For radiation performance stability directly impacts communication, analysis is conducted in ANSYS HFSS to analyze radiation characteristics, generate radiation patterns, and evaluate key parameters such as return loss (S11) to ensure that the antenna meets the mission requirements and attempts to achieve the smallest antenna while maintaining performance. Some initial S11 plots are obtained with the defined design parameters.

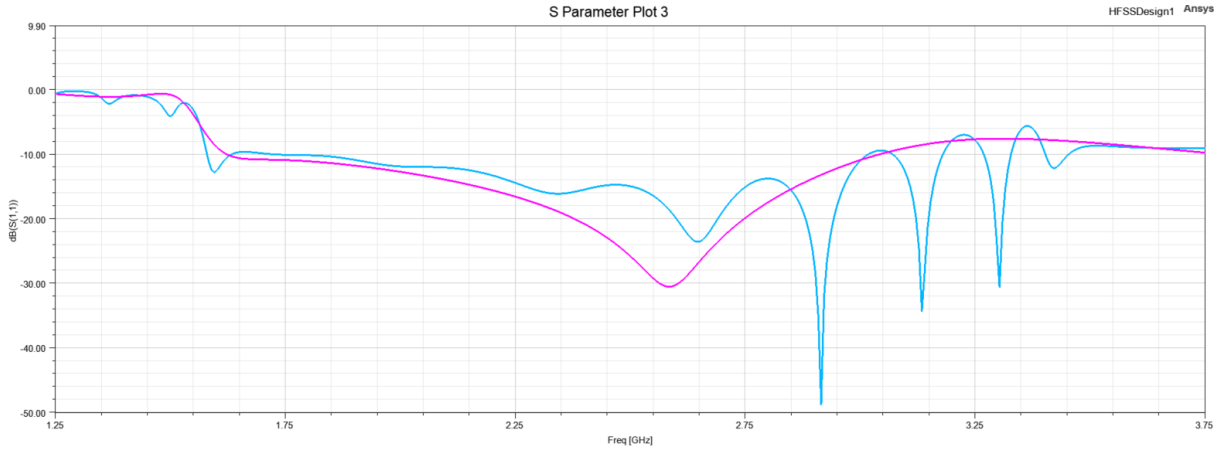

Figure 2. S Parameter of the antenna.

This configuration exhibits a clear resonance at a particular frequency, marked by a significant dip in S11, indicating efficient impedance matching and minimal power reflection. The impedance matching is optimized within a moderate bandwidth, allowing the antenna to operate effectively over a defined frequency range.

The antenna is initially stowed within the satellite and deployed once in orbit. The deployment mechanism is based on a coaxial system that utilizes the strain energy stored in the helical wire since the helix naturally is a spring. When the restraining wire is cut, this stored elastic potential energy is converted into kinetic energy, allowing the antenna to deploy. The initial design for the deployment mechanism is a telescopic structure, where nested parts extend using an internal spring for actuation. Additionally, the structure is enclosed with origami-inspired clothing, an ancient Japanese art of folding, that offers superior deployment capabilities. Origami-based deployment systems are already widely used in space applications, for example, the James Webb Space Telescope, as the clothing helps support telescopic structures and maintain spacing between sections, and antenna wire will be integrated with the origami structure, which is executed with space-qualified polyamide (Kapton) material.

Conclusion

To conclude, this study discusses the design considerations for a deployable helical S Band antenna for CubeSats. It has been found that helical antennas offer circular polarization, high gain, and impressive performance for space communication. However, QHA, log-periodic, and egg-beater antennas remain strong candidates in terms of directivity and gain. Simplicity, cost, and accessibility are major factors in antenna selection. Additionally, the choice of deployment mechanism plays a crucial role in ensuring a reliable and efficient operation in space. Finding the right balance between radiation characteristics and antenna size is key to designing an optimal CubeSat antenna.

Optimization and Finite Element Analysis of Metastructures for Vibration Mitigation

Elif Nur Yaşar[a], Kaan Yıldız[b]

[a] Istanbul Technical University, Defense Technologies Master of Science, Turkey
[b] Istanbul Technical University, Aviation Institute & Aerospace Research Center, Turkey
yasare17@itu.edu.tr

Keywords: Metastructure, Vibration Mitigation, Optimization, Absorbers, Design.

Aim

Metastructures are designed to include distributed absorbers, a tunable approach to vibration damping in advanced engineering systems. Metastructures are exhibiting significant engineering advantages over traditional structures. Metastuctures are made possible by shifting the natural frequency to the desired range and directing vibrations without changing the total mass. A comparison between a baseline structure without vibration absorbers and a Metastructure with integrated absorbers is the typical method to measure the effectiveness of Metastructures. Optimization of structural parameters allows higher efficiency in vibration reduction to be achieved. The structural efficiency of Metastructures to enhance system performance while maintaining mass efficiency is considered a significant advantage in the aerospace, automotive, and defense industries. The development of new systems incorporating smart materials, adaptive Metastructures, and data-driven optimization approaches is anticipated to make significant contributions to engineering applications (Kovacic et al., 2024). The main aim of the study is to achieve maximum damping performance while preserving the total mass of the structure, through the optimization of Metastructure design parameters using the PSO algorithm.

Material and Method

Metastructures' dynamic characteristics are evaluated and validated via finite element analysis (FEA) (He et al., 2016). The validation process ensures the consistency of theoretical models with practical applications while demonstrating the effectiveness of Metastructure designs under real-world conditions. By integrating optimization techniques into vibration engineering, more innovative solutions are provided compared to traditional methods. Metastructures are designed for customization in specific applications and are applied across various fields. In this study, a discrete system model under uniaxial vibrations was developed in MATLAB to enable fast simulations due to its simplicity. In the modeling process, the parameters that were varied include the mass ratio (μ) in equation 1, defined as the ratio of the total absorber mass to the total system mass, the number of absorbers (n), and the natural frequencies assigned to the absorbers. These parameters were utilized as optimization variables in the study. Upon completion of the optimization, the obtained results have been utilized as design inputs for the MATLAB finite element model. In the baseline structure, the mass of each element is defined as m_0. These elements are referred to as the main structure within the Metastructure, and their mass is updated to m_i shown in Equation 1. The m_i value depends on the mass ratio. The total mass of both structures was kept constant. In the initial stage, the host structure without any absorbers was modeled as a system that is free to move only in the axial direction using discrete mass, spring, and damper elements, and this configuration was defined as the baseline structure. In the second stage, a finite element model of the Metastructure was developed as an absorber system with multiple degrees of freedom, consisting of multiple resonators modeled as spring-mass oscillators, as illustrated in Figure 1. The Metastructure was constructed for a model with two absorbers and another configuration with ten absorbers. In both configurations, the natural frequencies of all absorbers were tuned to the natural frequency of the baseline structure. The mass ratio was set to μ=0.3. To analyze the dynamic response of the structure, the mass (M), stiffness (K), and damping (D) matrices were constructed. Based on these matrices, the frequency response function (FRF), H(s), was calculated as shown in Equation 2. The matrix A represents the system, and the axial displacement is denoted by q.

$$\mu = \frac{n * m_{absorber}}{m_{total}}$$

$$H(j\omega) = [-\omega^2 M + j\omega D + K]^{-1} \rightarrow \omega = 2\pi f$$

Findings

To optimize structural parameters, PSO algorithms were applied. The structural design is improved through the use of the PSO algorithm. PSO has been extensively utilized in a wide range of engineering problems, including structural optimization, control systems, and signal processing (Alam, 2016), and has been effectively implemented in Metastructure designs to enhance vibration attenuation, stability, and overall performance (Reichl & Inman, 2017a). The H_2 norm, as defined in Equation 3, was selected as the performance criterion, representing the total area under the FRF curve (Reichl & Inman, 2017b). The objective was to determine the configuration that maximizes the reduction in the H_2 value compared to the baseline structure. In the first configuration, the natural frequency of the baseline structure was calculated to be 613.884 Hz. All absorbers were tuned to match this fundamental frequency, 613.884 Hz. The results showed that the resonance peak in the baseline structure was split into two, effectively reducing its magnitude, as illustrated in Figure 1. It is also observed that the change in the H_2 performance value is relatively small between the cases with 2 absorbers and 10 absorbers. The H_2 reduction values obtained from the two configurations are presented in Table 1. To achieve maximum reduction in the H_2 performance index (Zhu et al., 2014), the natural frequencies of the absorbers were defined as variable values. This was implemented by linearly distributing the natural frequencies of 10 absorbers within an optimized frequency range determined through the optimization process shown in Table 2. An optimization was conducted to determine the minimum and maximum tuning frequencies of the absorbers. The mass ratio was also included as a design variable in the optimization process. The FRF graph of the Metastructure with linearly varying absorber frequencies reveals improvement in the system's dynamic response, as illustrated in Figure 3.

$$H_2 = \| H(s) \|_2^2 = \left(\frac{1}{2\pi}\right) \int_{-\infty}^{+\infty} tr\left(H^*(j\omega) H(j\omega) \right) d\omega$$

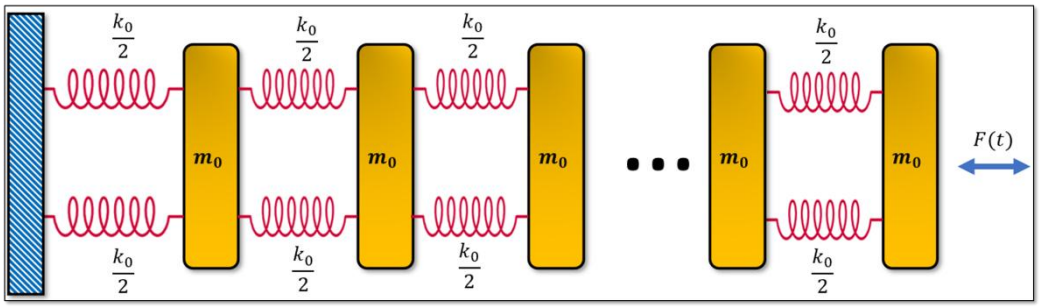

Figure 1.1: Baseline Structure.

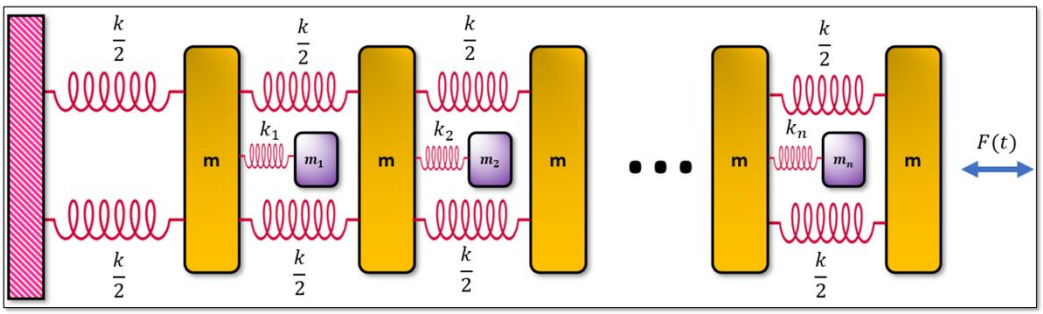

Figure 1.2: Metastructure.

Figure 1. Schematic representations of two structural configurations used in the study: the baseline structure (top), consisting of repeated mass-spring units with identical parameters, and the Metastructure (bottom), which incorporates internal resonators to enhance vibration attenuation performance.

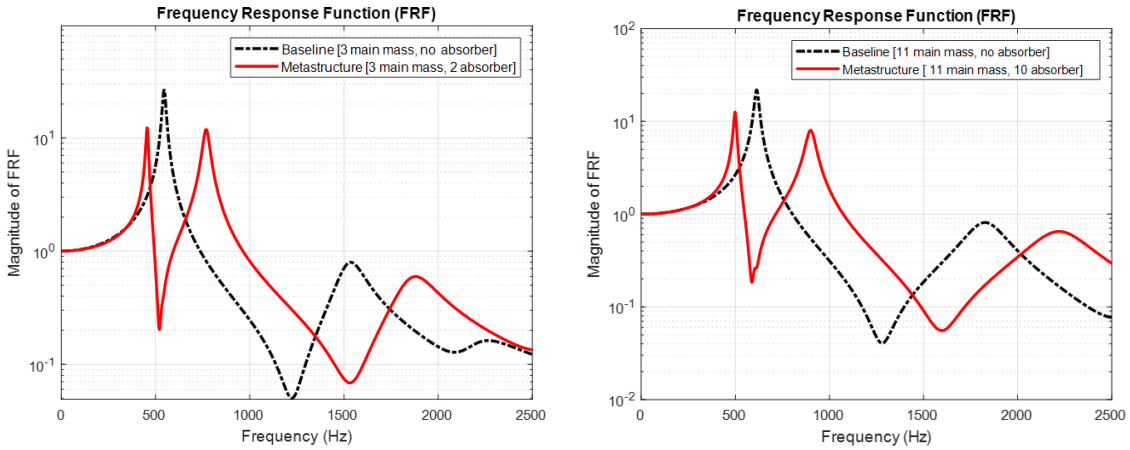

Figure 2. FRF graphs of two configurations are presented: the system with 2 absorbers is shown on the left, and the system with 10 absorbers, tuned to the same frequency, is shown on the right. All absorbers are tuned to the natural frequency of the baseline structure at 613.844 Hz, within the frequency range of 0-2500 Hz.

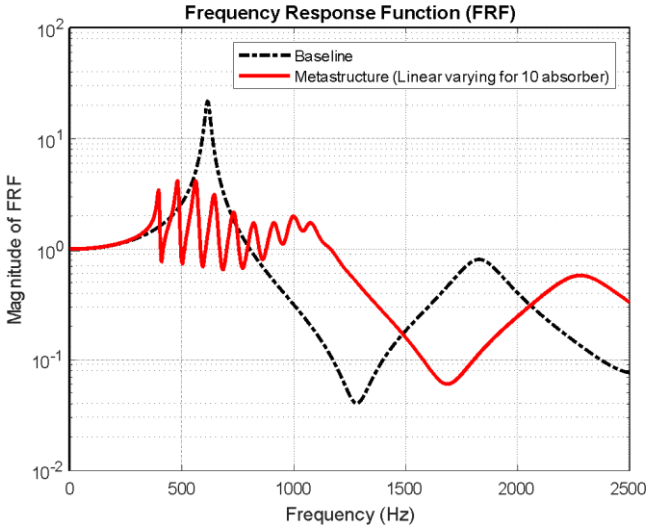

Figure 3. FRF graph of a structure with absorbers having linearly varying frequencies within 0-2500 Hz. The absorber frequencies range between 407-1254 Hz. The total mass of both structures is equal.

Table 1. Different absorber configurations are compared based on their frequency range and effectiveness in reducing the H_2 norm. three configurations are presented: absorbers tuned to the baseline fundamental frequency (with 2 and 10 absorbers) and absorbers optimized with respect to the H_2 norm, where stiffness varies linearly. The results show that the reduction in the H_2 norm increases as the number of absorbers increases and the frequency range is optimized, with the highest reduction (58.74%) achieved when stiffness varies linearly.

Configuration	Number of Absorbers, n			Absorber Frequency (Hz)	H_2 Reduction
Set to Baseline Fundamental Frequency	2			545.887	25.74 %
Set to Baseline Fundamental Frequency	10			613.844	27.50 %
Optimized with Respect to H_2 Norm (Stiffness Varies Linearly)	10			407-1254	58.74 %

Table 2. Optimization results obtained using the PSO algorithm for different iteration numbers and population sizes for 10 absorbers. The table presents the iteration number, population size, mass ratio, minimum and maximum frequency values, H_2 performance metric for each case. The results illustrate the impact of population size and iteration count on solution quality and computational efficiency.

	Iteration Number	Population Size	Mass Ratio	Min. Frequency [Hz]	Max. Frequency [Hz]	H_2 Reduction
Run 1	20	50	0.301	406	1254	59.291
Run 2	40	50	0.302	407	1254	59.293
Run 3	20	100	0.299	404	1256	59.292
Run 4	20	100	0.336	374	1316	59.170

Conclusion

At the final stage, an analysis of H_2 reduction amount showed that the optimized absorber system achieved a 50-60% improvement in vibration mitigation compared to the baseline structure. A certain level of improvement is achieved by tuning the absorbers to the fundamental frequency of the main structure; however, significantly greater enhancement is obtained when varying natural frequencies are assigned to the absorbers, as illustrated in Table 1. The final parameters have been incorporated into the design, enabling the modification of resonance regions without increasing the total mass. Evaluation of the dynamic performance of metastructures under varying conditions demonstrates superior vibration attenuation compared to the baseline structure. In the additional optimization studies, it has been identified that maintaining an adequate population size and a sufficient number of iterations is essential to ensure convergence. The Particle Swarm Optimization (PSO) algorithm has demonstrated the capability to simultaneously optimize more than one parameter.

Parametric Optimization of Semi-Octagon Re-entrant Auxetic Structures for Energy Absorption

Şenay Yener[a], Kaan Yıldız[b]

[a]Istanbul Technical University, Faculty of Aeronautics and Astronautics, Türkiye
[b] Istanbul Technical University Aviation Institute & Aerospace Research Center, Türkiye
yeners21@itu.edu.tr

Keywords: Auxetic Structures, Re-Entrant Unit Cells, Sandwich Panels, Finite Element Analysis, Energy Absorption.

Aim

In recent years, with the advancements in the defense and aerospace industries, the development of new material designs has gained significant importance to meet the needs of these sectors. One of the most innovative designs in these fields is sandwich structures, which stand out due to their high impact resistance and lightweight properties (Reis & Rizkalla, 2008). Traditional sandwich structures, widely used in defense and aerospace applications, consist of a cellular core placed between two thin, rigid, and durable outer layers. These outer layers are generally made of high-strength materials such as aluminum alloys or fiber-reinforced composites, while the core is composed of cellular structures (Schaedler & Carter, 2016).
The deformation behaviors of unit cell structures under mechanical loading can be systematically classified based on their Poisson's ratio into three main categories: Positive Poisson's Ratio (PPR) structures, Zero Poisson's Ratio (ZPR) structures, and Negative Poisson's Ratio (NPR) structures. The majority of conventional engineering materials and structural configurations typically exhibit a positive Poisson's ratio, indicating a tendency to contract laterally when subjected to uniaxial tensile forces. However, in 1987, a novel class of materials characterized by a negative Poisson's ratio was discovered (Lakes, 1987). These materials, known as "auxetic," exhibit the counterintuitive behavior of lateral expansion under tensile loading. Auxetic materials possess several remarkable mechanical properties, including enhanced energy absorption capacity, superior impact resistance, and improved structural stability (Lakes & Elms, 1993; Imbalzano et al., 2018; Liu et al., 2016).

Material and Method

This study focuses on optimizing the mechanical performance of Semi-Octagon Re-entrant (SOR) auxetic core structures designed based on the geometric motifs of the Isfahan Jameh Mosque (Etemadi, Bashtani, & Hu, 2024). The SOR structures consist of modified re-entrant unit cells with a semi-octagonal geometry, providing advantages such as more homogeneous load distribution and enhanced impact resistance. The findings are expected to contribute to the development of next-generation lightweight and high-performance materials for applications in ballistic protection, blast-resistant panels, aerospace armor, and other advanced engineering fields.
Figure 1(a) presents a detailed design of the unit cell structure used in this study. This design encompasses the geometric features and fundamental structural elements of the unit cells. Additionally, Figure 1(b) illustrates the configuration of the lattice structure in which the unit cells are laterally connected through node points (Etemadi et al., 2024). The lattice structure comprises a total of 35 unit cells.

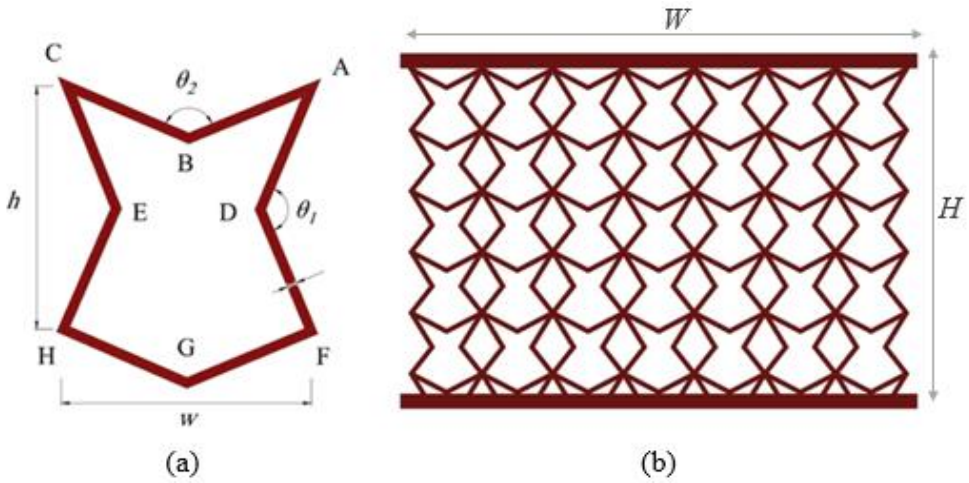

Figure 1. The design parameters (a) unit cell and design parameters of the SOR unit cell (b) auxetic structure with SOR unit cell arrangement (Etemadi et al., 2024).

The dimensions of all design parameters, along with the θ_1 and θ_2 angles presented in Figure 1, are provided in Table 1. In Figure 1(b), the width (W), height (H), and depth (b) of the arranged SOR lattice structure are illustrated. All dimensions are given in millimeters.

Table 1. Design parameters of the SOR structure.

Parameters	t	w	θ_1	θ_2	t	H	W	b
SOR	12	12	110°	125°	1	70.07	102.38	7

In this study, Finite Element Analysis (FEA) was performed using the Abaqus software, with PLA+ selected as the core material. The stress–strain curve of the PLA+ material used in the simulations is presented in Figure 2, while its mechanical properties are listed in Table 2. To analyze the mechanical behavior under compressive loading, a dynamic-explicit solver was employed. The general contact algorithm was applied to model the interactions between structural components, and the coefficient of friction between contact surfaces was set to 0.1. The bottom surface was fixed, while axial displacement loading was applied to the top surface.

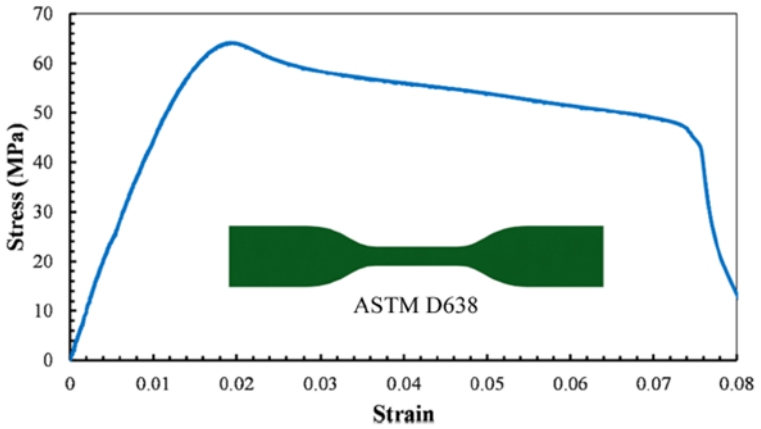

Figure 2. The stress–strain diagram of PLA+ material (Etemadi et al., 2024).

Table 2. Mechanical properties of PLA+ material (Etemadi et al., 2024).

Density (ρ)	1.21 g/cm³
Young's Modulus (E)	3.65 GPa
Poisson's Ratio (ν)	0.35
Yield Strength (σ_y)	64 MPa

To ensure numerical accuracy and computational stability, a mesh size of 0.5 mm was adopted, as shown in Figure 3. For meshing the structures, the C3D8R (solid, reduced integration) element type was used to achieve a balance between computational efficiency and result accuracy.

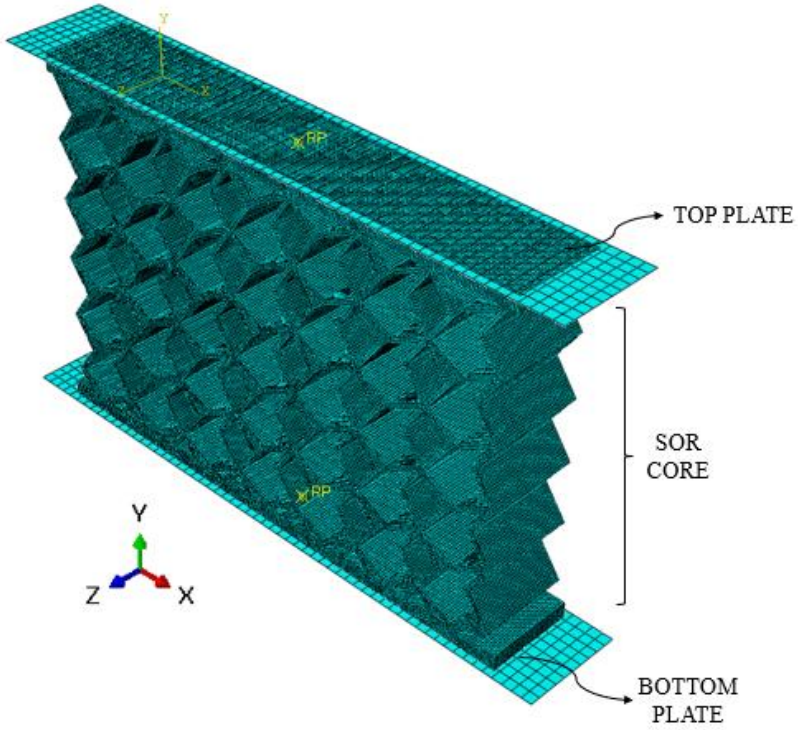

Figure 3. Finite element mesh of the SOR auxetic structure.

Energy Absorption Calculations: The total energy absorption (U) of the auxetic sandwich structures under compressive loading was calculated by integrating the area under the stress-strain curve up to the end of the second region, known as the plateau stage. Energy absorption is considered a critical parameter for evaluating the durability and performance of the structure against mechanical loads such as impact and compression. In this study, the total energy absorption was determined using the method specified in Equation 1 (Li, Liao, Dai, & Xie,2019). $U = \int_0^{\varepsilon} \sigma d\varepsilon \quad \#(SEQ\ Denklem \setminus * ARABIC\ 1)$

Additionally, the Specific Energy Absorption (SEA) was calculated using Equation 2. This parameter represents the amount of energy absorbed per unit mass of the structure and serves as an important measure for evaluating the lightweight and energy absorption performance of materials. In the equation, Δρ denotes the relative density of the structure, which is defined as the ratio of the material density to the total volume of the structure. SEA is widely used to compare the energy absorption capacity of lightweight materials and structural designs (Li et al., 2019). $SEA = \frac{U}{\rho \Delta \rho} \quad \#(2)$

Findings

The stress-strain curve obtained in this study has been compared with reference studies available in the literature (Etemadi et al., 2024). The graph presented in Figure 4 illustrates the mechanical behavior of the SOR auxetic structure under compressive loading examined in this study. Within the scope of the study, numerical analyses will be conducted to thoroughly investigate the mechanical performance of auxetic core sandwich structures. Through simulations, the effects of variations in unit cell angle and cell width on the stiffness and energy absorption capacity of the structure will be comprehensively examined. Additionally, the impact of cell size on structural densification and overall integrity will be evaluated in detail.

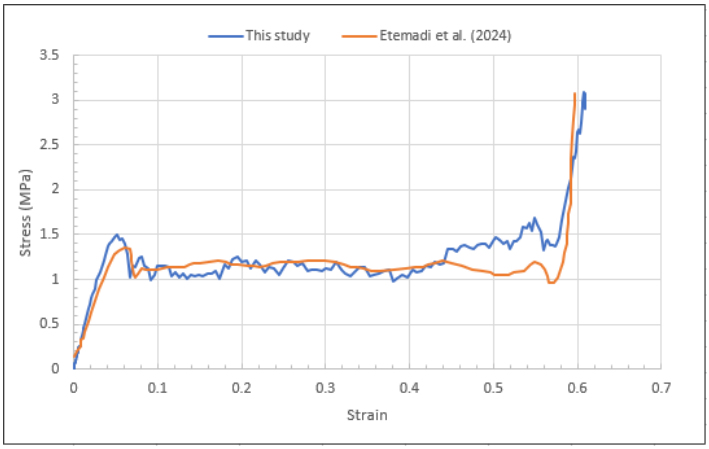

Figure 4. Comparison of the stress-strain curves of the Etemadi et al. (2024) and this study.

Conclusion

At this stage, experimental validation has not been conducted; however, the numerical analyses are expected to provide a solid basis for future physical testing. Based on literature data, Semi-Octagon Re-entrant (SOR) auxetic structures demonstrate significant potential for engineering applications, with geometric parameters playing a decisive role in mechanical performance.

The mechanical behavior of sandwich structures incorporating SOR cores has been shown to offer advantages over conventional re-entrant auxetic designs due to the unique semi-octagonal geometry. Increased energy absorption capacity provides notable benefits for high-performance fields such as defense and aerospace. The prominence of SOR structures stems from their distinctive geometric configuration, which enables a more balanced and efficient mechanical response compared to traditional auxetic structures. These characteristics contribute to enhanced structural stability under high-energy loads and optimized material utilization. Unlike conventional auxetic structures, the SOR configuration absorbs energy more effectively while maintaining structural integrity.

Finite Element Analysis Of Crack Growth Behavior In The Presence Of Crack-Arresting Holes

Buse Yasin Aydin[a], Ibrahim Ozkol[b], Mustafa Tolga Yavuz[b]

[a] Istanbul Technical University, Defense Technologies, Turkiye
[b] Istanbul Technical University, Faculty of Aeronautics and Astronautics, Turkiye
yasin21@itu.edu.tr

Keywords: Crack Arrest, Crack Propagation, Fracture Mechanics, Wing Structures, XFEM.

Aim

In materials science, crack propagation refers to the process in which a void forms within a material and gradually expands over time (Anderson, 2017). This phenomenon is particularly significant in industries such as aerospace, defense, the automotive sector, and machinery production. The reason is that cracks can critically impact the structural integrity and safety of vehicles and machines.

In the aviation industry, crack propagation significantly compromises the structural integrity of aircraft, particularly in the wings, wing components, and where the wings meet the fuselage. This reduces the load-carrying capacity and increases safety risks (Reymer et al., 2023). During flight, wings are subjected to vibrations, aerodynamic forces, and repeated mechanical and thermal loading, which generate high-stress concentrations. These stresses cause material fatigue, facilitating the initiation and progression of micro-cracks that ultimately compromise material performance and strength (Reymer et al., 2023; Shah et al., 2014; Zeng et al., 2018). This issue is critical in aircraft structures, especially fighter aircraft, in which high maneuverability and sudden load changes require early crack detection to prevent structural failure. Improper management and monitoring of crack propagation can lead to catastrophic failures. Both civil and military aviation have experienced severe consequences from unchecked crack propagation. For example, in 1988, an Aloha Airlines Boeing 737-200 had cracks on the upper side of the fuselage near the cockpit on riveted joints, which had gone unnoticed during maintenance. The high-stress environment of the aircraft led to these cracks expanding and caused a structural failure. An 18-foot-long section of the upper fuselage was torn away from the airplane, critically compromising its integrity and endangering lives. This incident highlights the need for proper crack detection procedures (National Transportation Safety Board, 1988). Similarly, a U.S. Air Force F-111A fighter jet experienced fatigue cracks caused by micro defects in the wing pivot joint during production, which eventually led to a sudden fracture of its wing in-flight. Similar cases throughout history have resulted in damage to both civilian and military aircraft due to crack formation and propagation (Molent, 2010). For these reasons, various academic and industrial research efforts are conducted to better understand the mechanisms of crack propagation, perform risk analyses, develop new monitoring technologies, and investigate methods to arrest cracks.

This study aims to investigate how incorporating holes and other geometric shapes into structures might affect crack propagation and also, possibly, how these new designs can delay crack growth. The research explores how such design modifications can enhance structural durability and reduce the risks associated with crack propagation. Specifically, the study focuses more on controlling and analyzing crack propagation in the wings of all types of aircraft, particularly in fighter jets, and investigates the key parameters that govern the crack behavior.

Within this research, the effects of various parameters in aircraft wing components are examined for crack propagation. The study evaluates the crack-arresting potential of incorporating holes and other geometric modifications while also analyzing the influence of material properties and structural thickness. It further investigates how variations in hole diameter, the use of multiple holes, different hole configurations, and the incorporation of various geometric shapes affect crack propagation. Additionally, the research considers diverse boundary conditions to provide a comprehensive understanding of how these factors interact with crack growth.

After conducting a literature review of similar studies, the initial phase of this research involved developing a basic model characterized by standard circular holes and an initial crack (Fageehi & Alshoaibi, 2024). This model served as a foundation for investigating how holes influence stress intensity distribution and also how they affect the crack propagation path. In later cases, various scenarios were created; an increased number of holes, optimizing the placements of these holes. This allows for a better understanding of how these factors affect crack behavior. Additionally, the study examines different types of high-performance alloys such as Ti-6Al-4V, Al 7050, and Al 2050 to determine their effects on crack progression. These materials are commonly used in aircraft wing components and fuselage (Yavuz & Ozkol, 2024; Dursun & Soutis, 2014). Samples with different plate thicknesses were also tested to assess the influence of thickness on crack development.

Material and Method

To accurately capture crack initiation and propagation, analyses were conducted using the Extended Finite Element Method (XFEM). Analyses for the study were done using a software program, ABAQUS. With the help of XFEM, detailed analyses were performed to monitor crack initiation, track crack growth, and evaluate changes in crack orientation under varying conditions.

Findings

Preliminary study results showed that, in samples with holes, cracks were attracted toward the holes, whereas in samples without holes, cracks propagated without deflection, ultimately leading to fracture. Furthermore, higher Von Mises stresses were observed in samples without holes compared to those with holes, indicating that the holes help redistribute stress and lower stress concentrations. These findings lay the groundwork for investigating the effect of circular holes on crack propagation behavior and their potential as crack stoppers.

Conclusion

The expected contributions of this study are comprehensive, offering insights from various perspectives. First, the research provides a detailed investigation for future literature on how different material types, structural thickness, geometric shapes and their dimensions, different boundary conditions, and various configurations of integrated shapes affect crack propagation. Additionally, in the aviation industry, cut-outs are incorporated in aircraft wings for weight reduction, to facilitate maintenance and inspection access, and for fuel cable and pipe passages (De, 2017). This shows that our study can be further included in both the aviation and defense industries. The findings contribute to improved monitoring and management of crack propagation, offering guidelines that could help maintain the structural integrity of wing components and extend their fatigue life. This, in turn, aids in preventing large, unexpected structural failures and minimizes mission risks. Finally, the development of a robust analytical framework to explain the effects of various design modifications on crack propagation not only provides a perspective for future studies but also serves as a roadmap for subsequent research.

Design and Modeling of a Nonlinear Bi-Axial Dynamic Vibration Absorber for Helicopter Applications

Resmiye Ağan[a], Vedat Ziya Doğan[a], Halit Süleyman Türkmen[a], Ali Tatar[a]

[a] Istanbul Technical University, Faculty of Aeronautics and Astronautics, Defense Technologies, Türkiye
doganre@itu.edu.tr

Keywords: Cubic Nonlinear Stiffness Approach, Helicopter Vibration Control, Nonlinear Dynamic Vibration Absorber.

Aim

Helicopter structures are inherently exposed to complex and multi-directional vibration sources, stemming primarily from main rotor dynamics, tail rotor interactions, fuselage resonance, gearbox transmission, and engine-induced oscillations. These vibrational forces vary in direction, amplitude, and frequency over time, leading to considerable challenges in maintaining flight stability, structural durability, and overall system performance. In particular, fuselage vibrations may adversely affect the precision of avionics, increase pilot fatigue, and amplify internal cabin noise levels, compromising both safety and comfort.

Historically, linear dynamic vibration absorbers have been deployed in aerospace and rotorcraft structures to alleviate such oscillations. However, these devices are inherently limited by their narrow operational frequency bands, requiring exact tuning to match the dominant excitation frequency. When the system experiences variable operational conditions such as changes in rotor speed, mass distribution, or maneuvering-induced loads, the excitation frequencies may drift, causing linear absorbers to lose effectiveness. In practical rotorcraft missions, such variations are common, leading to the need for vibration suppression solutions that are more adaptive and capable of functioning across a wide frequency spectrum.

To address these challenges, this study explores the design and modeling of a nonlinear dynamic vibration absorber (NDVA) equipped with a polynomial stiffness component—specifically, a cubic nonlinear spring connecting the primary and absorber masses. The nonlinear element allows for amplitude-dependent stiffness behavior, making the absorber effective over broader frequency ranges and under diverse loading conditions. This characteristic makes it suitable for rotorcraft environments, where multi-axial and time-varying vibrations are expected. The research begins with a single-axis NDVA configuration and transitions into a more advanced bi-axial setup capable of mitigating vibrations in both vertical and lateral directions. This progression allows a comparative understanding of absorber performance and sets the stage for further integration into helicopter fuselage structures.

Material and Method

To understand the dynamic response of the NDVA, both analytical modeling and numerical simulations were performed. A base dynamic system was constructed using MATLAB, incorporating a mass-spring-damper configuration with a cubic nonlinearity introduced into the restoring force. This setup consists of a primary mass representing the helicopter component and a secondary mass acting as the vibration absorber. The governing equation includes linear and nonlinear stiffness terms, damping, and an external harmonic excitation force. Time-domain simulations were conducted using numerical solvers to observe the system's transient and steady-state responses under different excitation frequencies and amplitudes. The Fast Fourier Transform (FFT) was employed to evaluate frequency-domain behavior, enabling the identification of resonance, sub-harmonic, and super-harmonic components.

In parallel with analytical modeling, a finite element (FE) model of a cantilever plate resembling a simplified helicopter fuselage panel was created in ANSYS. This beam-like structure was designed using shell elements, and the appropriate material properties were assigned to reflect aerospace-grade components. A comprehensive modal analysis was performed first to identify the structure's natural frequencies and mode shapes. Subsequently, harmonic response analyses were conducted both with and without the absorber to quantify the effectiveness of the NDVA.

To explore the impact of placement and force direction on absorber efficiency, the NDVA was attached at multiple points along the cantilever plate. Simulations were repeated for various attachment locations under harmonic excitations applied in different directions, mimicking different loading conditions. This allowed assessment of how absorber placement relative to mode shape nodes and antinodes affects energy dissipation performance. Both single-axis and bi-axial absorber configurations were simulated to evaluate improvements in performance and directional effectiveness.

Findings

The simulation results clearly demonstrated the enhanced performance of the nonlinear absorber compared to its linear counterpart. In the single-axis setup, the NDVA was able to reduce vibration amplitudes significantly, with reductions exceeding 90% under resonant excitation. In the bi-axial configuration, the absorber maintained similar levels of suppression in both vertical and lateral directions, confirming the benefit of extending the model to account for multi-directional vibrations typical of helicopter fuselage dynamics.

In MATLAB simulations, the cubic stiffness coefficient was varied to observe its effect on system response. It was found that while a properly tuned nonlinear stiffness greatly improved performance, an incorrectly selected coefficient could result in minimal gains or even amplification at certain frequencies. This highlights the importance of parameter sensitivity and the need for optimization algorithms in future stages of this research. The FFT results confirmed the presence of sub- and super-harmonic peaks in nonlinear cases, suggesting complex energy transfer mechanisms that contribute to improved damping. In ANSYS simulations, the cantilever plate exhibited six primary modes within the frequency range of 1.56 Hz to 53.72 Hz. When the absorber was positioned at locations aligned with peak modal displacements (antinodes), the vibration mitigation effect was significantly enhanced. Conversely, placement near modal nodes showed reduced effectiveness. Changing the direction of excitation also affected absorber performance, with lateral excitations being better suppressed in the bi-axial setup. These results offer valuable design insights for future implementations of NDVAs in full-scale helicopter fuselages.

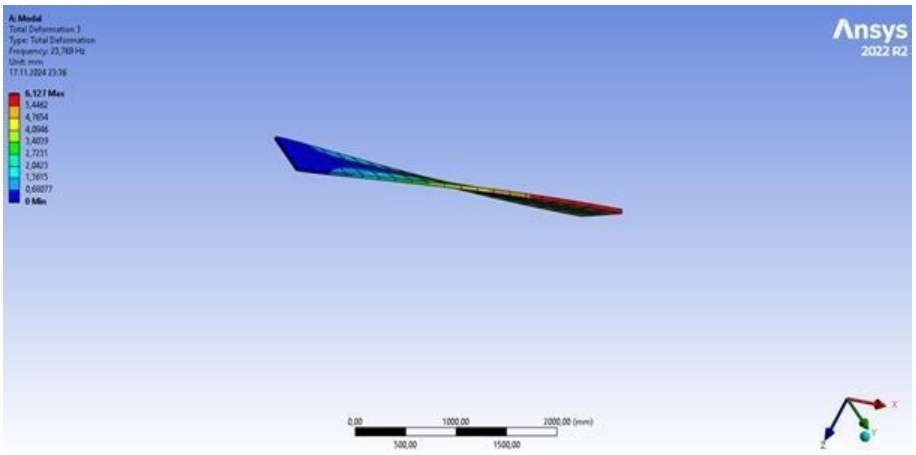

Figure 4. Torsion System Behavior Analysis of a Beam Model Using Finite Element Method in ANSYS (Mode Shape 3).

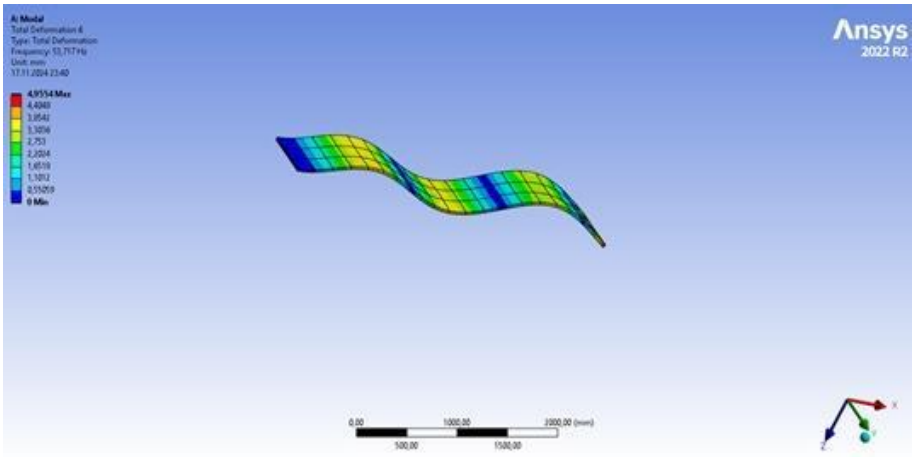

Figure 5. Out-of-Plane Bending System Behavior Analysis of a Beam Model Using Finite Element Method in ANSYS (Mode Shape 6).

Conclusion

This study reinforces the potential of nonlinear dynamic vibration absorbers as a superior alternative to conventional linear systems for rotorcraft vibration control. By transitioning from a single-axis to a bi-axial configuration, the absorber gains the ability to respond to complex, multi-directional excitation environments typically experienced in helicopter operations. The inclusion of a cubic stiffness element extends the effective operational bandwidth, allowing the device to maintain performance even as excitation frequencies drift due to flight maneuvers, payload changes, or other in-flight variations.

The combination of analytical modeling in MATLAB and detailed finite element analysis in ANSYS provides a holistic understanding of system dynamics. The effects of absorber positioning, nonlinear parameter tuning, and loading direction were systematically studied, revealing critical insights that will inform future design and optimization strategies. This research lays the foundation for enhancing structural safety, passenger comfort, and component longevity in rotorcraft systems.

Keywords: Metals, Impact, LS-Dyna.

Aim

There is a wide variety of materials utilized by engineers in the construction of structures, machine components, and various other applications. Among these materials, metals are particularly significant due to their versatile range of uses. In many situations, metals are subjected to loads, which can result in deformation. This deformation may be either elastic or plastic, depending on the nature of the applied force. This study aims to examine material models that are used to investigate the behavior of metals under high-strain-rate deformations, such as those occurring in impact, shock waves, and explosions. Using LS-Dyna.

Material and Method

This study investigates analytical and parametric material models that define the plastic properties of materials. Among the material models found in the literature, particular attention has been given to the Johnson-Cook material and damage model. Based on the obtained information, the material properties of Ti-6Al-4V, a titanium alloy according to the Johnson-Cook approach, have been sourced from the literature, and a material model has been created using the LS-DYNA MAT_015 (LS-DYNA, 2024) material card. The developed material model was defined as a plate with dimensions 250mm × 250mm × 3mm, and the scenario where a sphere with a diameter of 20mm strikes this plate perpendicularly at a velocity of 10 m/s was simulated.

Table 1. Mechanical Properties of Ti-6Al-4V.

Symbol	Description	Value	Unit	Ref.
σ_{uts}	Ultimate stress	1062 +/-11	MPa	(Prakash et al., 2023)
σ_y	Yield stress	972 +/-10	MPa	(Prakash et al., 2023)
ε_{break}	Elongation at break	25	%	(Prakash et al., 2023)
E	Young modulus	114	GPa	(Hu et al., 2020)
ν	Poisson ratio	0,33		(Hu et al., 2020)
G	Shear modulus	44	GPa	(ASM, 2024)
τ_u	Shear stress	550	MPa	(ASM, 2024)

Findings

Material Models

In the literature, there is a variety of mathematical models that describe the plastic behavior of materials. These models can be classified into five categories, which are (Banerjee, 2005):

1. Specific heat model
2. Equation of State Models
3. Melting Temperature Models
4. Shear Modulus Models
5. Flow Stress Models

Studies focusing on Flow stress models are frequently found in the literature. Additionally, "Flow Stress Models" are based on five distinct approaches, which include:

a. Johnson-Cook Model (JC)
b. Steinberg-Cochran-Guinan-Lund Model (SCGL)
c. Zerilli-Armstrong Model
d. Mechanical Threshold Stress (MTS) Model
e. Preston-Tonks-Wallace (PTW) Mode

Johnson-Cook Model (JC)

This study focuses on the Johnson-Cook model, as it is the most widely used model in the literature for metals.
The Johnson-Cook model consists of a Material Model equation (Fig. 1) and a Damage Model equation (Fig. 3). It is a parametric model that utilizes experimental results to construct the equations. (Banerjee, 2005; Johnson, 1983)
JC Material Model (Banerjee et al., 2015; Johnson, 1983):

$$\sigma_{eq} = \left(A + B\left(\varepsilon_{eq}^{pl}\right)^{n}\right)\left(1 + C\, ln\left(\frac{\dot{\varepsilon}}{\dot{\varepsilon_o}}\right)\right)\left(1 - \left(\frac{T - T_o}{T_{melt} - T_o}\right)^{m}\right)$$

Fig. 1 JC Material Model.

JC Material model, in which A, B, n, C, and m represent the reference yield strength, the effect of work hardening, the exponent for thermal softening, the effect of the deformation rate, and the effect of thermal softening, respectively.

The Johnson-Cook material model considers stress as a function of three terms. These terms are strain hardening effect, Strain rate effect, and thermal softening effect.

First term of equation is representing the strain hardening effect:

$$\left(A + B\left(\varepsilon_{eq}^{pl}\right)^{n}\right)$$

Second term of equation represents the Strain rate effect:

$$\left(1 + C\ ln\ ln\ \left(\frac{\dot{\varepsilon}}{\dot{\varepsilon}_0}\right)\right)$$

And third term of equation represents the Thermal softening effect:

$$\left(1-\left(\frac{T-T_0}{T_{melt}-T_0}\right)^m\right)$$

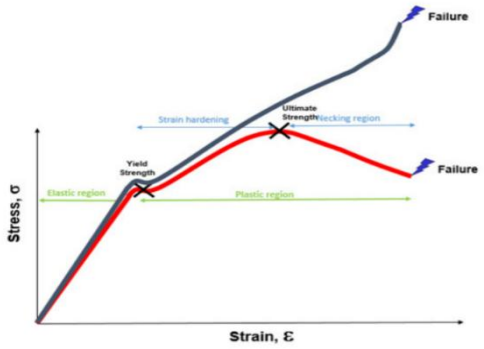

Fig. SEQ Fig. * ARABIC 2: The Presentation of Flow Curve

The coefficients of the Johnson-Cook material model are calculated using engineering stress-strain curves obtained from tensile tests. Since the aim is to examine the material's plastic behavior, the area between the yield strength and the maximum tensile strength points on the curve, referred to as the "flow curve," is considered. (Fig. 2)

JC Damage Model (Banerjee et al., 2015; Johnson, 1983)

The Johnson-Cook damage model (Fig. 3) links the damage phenomenon in the material to the triaxial stress ratio, temperature, and deformation rate. As can be seen from the equation, the first term is related to the triaxial stress, the second term is related to the deformation rate, and the third term is dependent on temperature change/thermal softening.

$$\varepsilon_f = [D_1 + D_2 \exp D_3\sigma^*][1 + D_4 \ln \dot{\varepsilon}^*][1 + D_5 T^*]$$

Fig. 3 JC Damage Model.

JC Damage Model, in which ε_f represents the fracture strain, D_1 is the initial fracture strain, D_2 is the exponential factor, D_3 is the triaxiality factor, D_4 is the strain rate parameter, and D_5 is the temperature parameter. σ_m is the mean stress, and σ_{eq} is the equivalent stress ($\sigma^* = (\sigma_m/\sigma_{eq})$) is known as the stress triaxiality, and $T^* = \frac{T-T_{ref}}{T_m-T_{ref}}$

All constants and coefficients described in the damage model can be calculated from experimental results. These experiments should involve different samples with varying triaxiality properties.

LS- Dyna Material card for JC model

Ansys LS-DYNA is the explicit simulation software used for applications like drop test, impact and penetration, smashes and crashes, occupant safety, and more. Within LS-DYNA, there are 10 material models based on the Johnson-Cook equations. These are shown in Table 2

Table 2 LS-Dyna JC based Material Models (LS-DYNA, 2024).

No	MAT Code	Description
1	MAT_015	JOHNSON_COOK
2	MAT_110	JOHNSON_HOLMQUIST_CERAMICS
3	MAT_111	JOHNSON_HOLMQUIST_CONCRETE
4	MAT_241	JOHNSON_HOLMQUIST_JH1
5	MAT_107	MODIFIED_JOHNSON_COOK
6	MAT_098	SIMPLIFIED_JOHNSON_COOK
7	MAT_099	SIMPLIFIED_JOHNSON_COOK_ORTHOTROPIC_DAMAGE
8	MAT_224	TABULATED_JOHNSON_COOK
9	MAT_224_GYS	TABULATED_JOHNSON_COOK_GYS
10	MAT_264	TABULATED_JOHNSON_COOK_ORTHO_PLASTICITY

In this study, MAT_015 has been studied. MAT_015 can be applied in cases where the deformation rate varies significantly, and softening mechanisms are activated due to the increase in adiabatic temperature. It is suitable for high deformation rates for many metals. The MAT_015 card is shown in Fig. *4*.

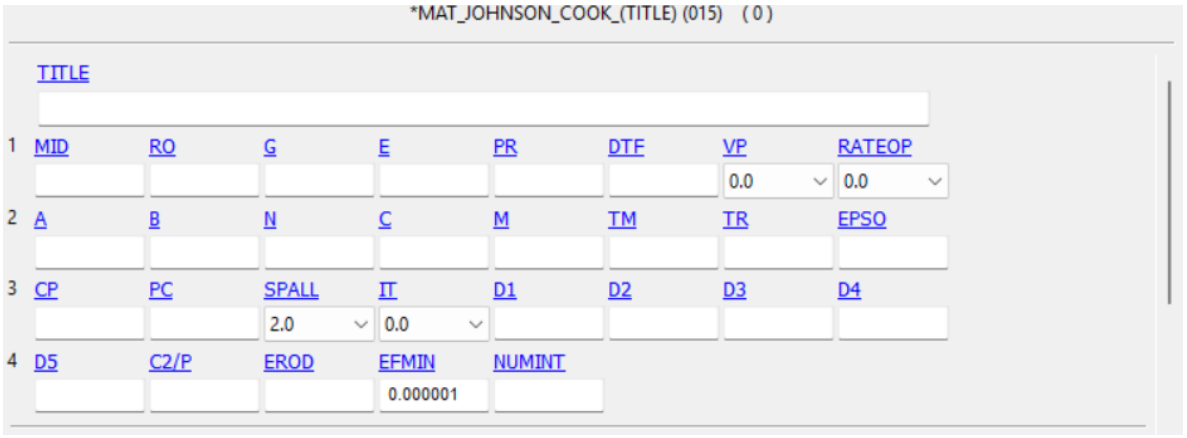

Fig. 4 MAT_015 Material Card. The description of codes can be found on (LS-DYNA, 2024).

Results

Using the information obtained from the literature, the MAT_015 material card was defined (Fig. 6), and an impact analysis was conducted using the LS-DYNA program. The developed material model was defined as a plate with dimensions 250mm × 250mm × 3mm, and the scenario where a sphere with a diameter of 20mm strikes this plate perpendicularly at a velocity of 10 m/s was simulated (Fig. 7). The ball is described as a steel and elastic material. (Fig. 7).
Time duration is 0.1 seconds, and the interval between steps is 0.001. The maximum stress follows at step 5 (t=0,005) and the value is 123.4 MPa at the impact zone (Fig. 8).

Additionally, we can track the history of the kinetic energy of the ball before and after impact. Initially, as per the initial conditions, the ball has 1.6 Joules of kinetic energy (which can be calculated analytically). After the impact, the ball has 0.107 Joules of kinetic energy (Fig. 9).

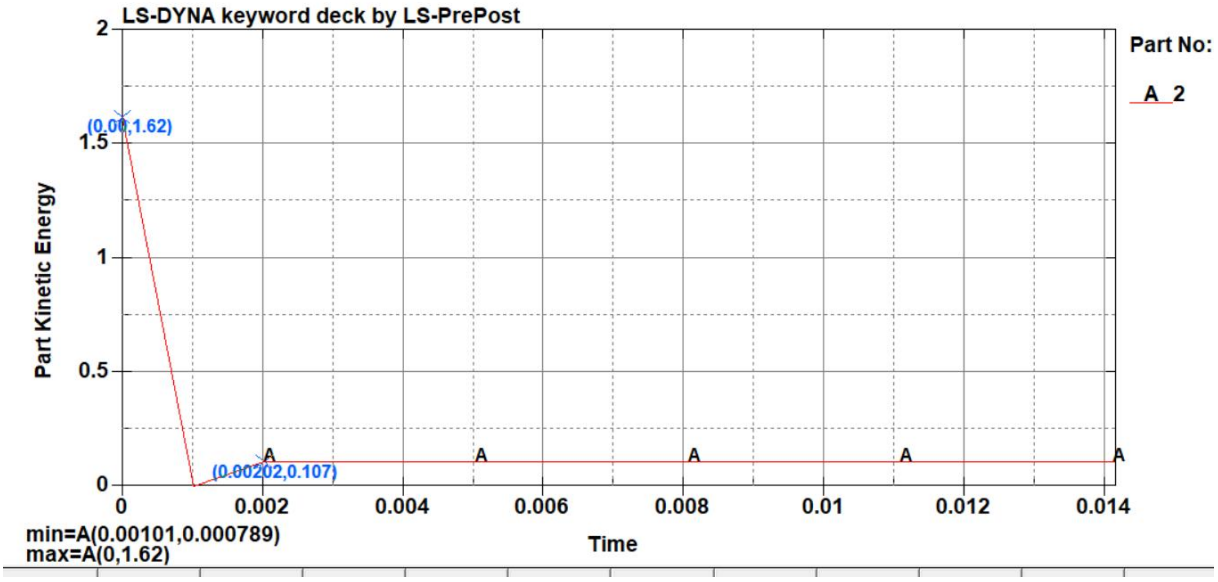

Fig. 9 Kinetic Energy Traction of The Ball.

The results obtained are consistent with the general consensus and analytical calculations, which demonstrate the reliability of the model.

Conclusion

- Metals under high strain rate flow at a high stress level, which can be calculated mathematically.
- The Johnson and Cook model gives a reasonable result for impact loads
- LS-Dyna software allows us to logically model multiple materials and scenarios

Keywords: Fuzzy AHP, UAV Selection, Multi Criteria Decision Making, Fuzzy Logic, Sensitivity Analysis

Aim

The aim of this study is to apply the Fuzzy Analytic Hierarchy Process (Fuzzy AHP) methodology to address the complex UAV (Unmanned Aerial Vehicle) selection problem under multiple criteria. Given the increasing use of UAVs in military and civilian applications, selecting the most suitable UAV requires careful consideration of various operational, technical, and economic factors. These factors include payload capacity, range, endurance, maximum altitude, and maximum speed. The goal is to develop an optimized decision-making framework that incorporates both subjective judgments and quantitative analysis. This study not only provides a ranking of different UAV alternatives but also evaluates the robustness of the decision-making process by performing a sensitivity analysis on the criteria weights. The Fuzzy AHP method used in this study follows the extent analysis method proposed by Chang (1996).

Material and Method

In this study, a comprehensive decision-making process based on Fuzzy AHP is used to select the most appropriate UAV from a list of alternatives. The following steps were followed in the methodology:
Criteria Definition: The primary criteria for selecting UAVs were defined as:
• Payload Capacity: The maximum weight the UAV can carry.
• Range: The maximum operational distance.
• Endurance: The maximum operational time.
• Maximum Altitude: The maximum height the UAV can reach.
• Maximum Speed: The maximum speed at which the UAV can fly.
The data were obtained from the relevant technical documents and websites of the UAVs (Baykar, n.d.; TUSAŞ, n.d.; Elbit Systems, n.d.; Army Technology, n.d.). Fuzzy Pairwise Comparisons: Decision-makers provided pairwise comparisons of the criteria using linguistic variables such as "very low," "low," "medium," "high," and "very high." These linguistic terms were then converted into fuzzy triangular numbers, which represent the subjective judgment of decision-makers about the relative importance of each criterion. Fuzzy numbers were used to account for the inherent uncertainty in human judgment (Chang, 1996; Liu & Rodríguez, 2013). Fuzzy Consistency Check: To ensure the logical consistency of the pairwise comparisons, a consistency check was performed. The consistency ratio (CR) was calculated to assess whether the judgments provided by the decision-makers were consistent enough to support a reliable final ranking (Lin & Hung, 2011). Weight Calculation: The fuzzy weights of the criteria were calculated using the Fuzzy AHP method. These weights reflect the relative importance of each criterion and serve as the foundation for the UAV ranking. The fuzzy weights were defuzzified to obtain crisp values for further evaluation.(Buckley, 1985).
Alternative Evaluation: Each UAV alternative (Bayraktar Akıncı, Aksungur, MQ-9 Reaper, TUSAŞ ANKA-S, Elbit Hermes 900, and MQ-1C Gray Eagle) was evaluated based on the defined criteria. Fuzzy ratings were assigned to each UAV for each criterion based on expert assessments, capturing both the objective data and subjective evaluations (Abrahart & See, 2000).

Final Ranking: The final UAV ranking was determined by calculating the overall scores of each UAV using the weighted fuzzy evaluations. The UAV with the highest score was identified as the most suitable for selection based on the defined criteria.

Sensitivity Analysis: To ensure the robustness of the model, a sensitivity analysis was performed. This analysis assessed how changes in the criteria weights affected the final UAV ranking. By varying the weights, the sensitivity of the model was tested, providing insight into how the decision-making process could be influenced by different scenarios.(Tavana, Azadeh, & Behzadian, 2013; Lin & Hung, 2011).

Findings

The implementation of the Fuzzy AHP methodology resulted in the following findings:
Ranking of UAVs: Based on the fuzzy evaluations and the derived criteria weights, the UAVs were ranked as follows:

1. MQ-9 Reaper
2. Bayraktar Akıncı
3. MQ-1C Gray Eagle
4. Aksungur
5. Elbit Hermes 900
6. TUSAŞ ANKA-S

Discussion on Findings: The MQ-9 Reaper emerged as the most suitable UAV, due to its high performance across multiple criteria, especially in payload capacity, range, and endurance. Bayraktar Akıncı followed closely, with its high payload capacity and range, making it a competitive alternative. MQ-1C Gray Eagle, while slightly lower in range, also performed well in terms of endurance and payload capacity. UAVs such as Aksungur and TUSAŞ ANKA-S were ranked lower due to their relatively shorter endurance and lower maximum speed compared to the higher-ranking UAVs.
Sensitivity Analysis Results: The sensitivity analysis revealed that the final ranking was particularly sensitive to changes in the "Endurance" and "Maximum Speed" criteria. For example, increasing the weight of Endurance slightly shifted the ranking, making Bayraktar Akıncı outperform MQ-9 Reaper due to its higher operational time. Conversely, increasing the weight of Maximum Speed led to MQ-9 Reaper regaining the top position, reflecting its higher speed. These results underscore the importance of carefully considering the weight assignment during decision-making, as small changes in these critical criteria can significantly impact the UAV selection (Chang, 1996; Lin & Hung, 2011).
Detailed Sensitivity Observations:

- A 10% increase in the weight of Endurance resulted in a ranking change where Bayraktar Akıncı and MQ-1C Gray Eagle moved up the ranks.
- A 15% increase in the weight of Maximum Speed caused a noticeable shift in favor of MQ-9 Reaper, which highlighted its superior speed.

Consistency of Results: The fuzzy pairwise comparison matrix was evaluated for consistency, with the consistency ratio (CR) falling within an acceptable range, indicating that the decision-makers' judgments were reasonably consistent (Saaty, 1980). The Fuzzy AHP methodology's ability to handle subjective assessments with imprecision contributed to the robustness of the decision making process (Zadeh, 1965; Buckley, 1985).

Conclusion

The Fuzzy AHP approach provided a reliable and structured framework for UAV selection, effectively handling multiple conflicting criteria and incorporating expert judgments through fuzzy logic (Chang, 1996; Sabo & Cohen, 2012). The results demonstrated that MQ-9 Reaper was the most suitable UAV for selection, based on the defined criteria. However, the sensitivity analysis highlighted that the final ranking is highly dependent on the weightings of key criteria such as Endurance and Maximum Speed (Tavana, Azadeh, & Behzadian, 2013). This reinforces the need for careful weight assignment and consideration of decision-maker preferences in complex decision making problems (Wang, Jing, Zhang, & Zhao, 2009).
In practical terms, the study underscores the importance of utilizing fuzzy decision-making models in selecting UAVs, especially in defense and aerospace applications where uncertainty is inherent, and decisions are often influenced by subjective judgments (Ramirez-Atencia, Rodriguez Fernandez, & Camacho, 2020). The results also suggest that the Fuzzy AHP model could be further improved by incorporating additional criteria, such as operational adaptability or stealth

capabilities, which could provide a more holistic evaluation of UAVs (Qamar, Sarfraz, Rahman, & Ghauri, 2023; Bai et al., 2024).

Optimized Visual Odometry and Satellite Image Matching-Based Localization for UAVs in GPS-Denied Environments

Ömer Sefa Öztürk[a], Alptekin Yıldız[b]

Keywords: Custom UAV Dataset, Satellite Image Matching, UAV, Visual Navigation, Visual Odometry.

Aim

Unmanned Aerial Vehicles (UAVs) are increasingly required to operate in environments where Global Positioning System (GPS) signals are unreliable or unavailable, such as urban canyons or areas subjected to intentional GPS jamming. Traditional navigation systems that rely heavily on GPS often fail in such scenarios, necessitating alternative methods for accurate localization. This study aims to develop and evaluate an innovative visual navigation system for UAVs that integrates continuous visual odometry (VO) with satellite image matching to produce accurate, real-time position estimates. The key contributions include the development of a novel UAV dataset by synchronizing high-rate camera frames with low-rate GPS data, an enhanced VO performance through the optimization of ORB-SLAM3 parameters (DeTone, Malisiewicz, & Rabinovich, 2018), the integration of the Monodepth algorithm (Campos, Elvira, Gómez Rodríguez, Montiel, & Tardós, 2021)

to mitigate scale ambiguity, and the creation of a map retrieval interface for accessing high-resolution satellite maps to determine absolute UAV positions through image matching.

Material and Method

UAV flights were conducted using a DJI Mavic Air 2 over various outdoor locations. The drone's downward-facing camera recorded video at 30 frames per second (FPS), while GPS data was logged at 1 Hz. The GPS coordinates (latitude and longitude) were converted to local North-East-Down (NED) coordinates. Linear interpolation was applied to the GPS timestamps so that every video frame received an accurate ground truth pose, achieving synchronization within ±10 milliseconds. This procedure yielded a unique dataset of ground truth trajectories at 50–100 meters altitude. Visual odometry was implemented by processing the video frames with an optimized version of ORB-SLAM3 (DeTone, Malisiewicz, & Rabinovich, 2018)—a state-of-the-art feature-based Simultaneous Localization and Mapping (SLAM) system. The camera was calibrated to provide the necessary intrinsic parameters, and ORB-SLAM3 extracted Oriented FAST and Rotated BRIEF (ORB) features to track the camera's pose continuously. The algorithm was fine-tuned to the dataset to ensure robust and accurate VO. To address the scale ambiguity inherent in monocular VO, the Monodepth algorithm (Campos, Elvira, Gómez Rodríguez, Montiel, & Tardós, 2021), which estimates depth from single images using deep learning techniques, was integrated to provide scale-consistent depth information. For absolute localization, high-resolution satellite imagery of the flight area was acquired and geo-referenced. Keypoints were detected using SuperPoint (Godard, Mac Aodha, & Brostow, 2017), and correspondences with the satellite map were established via SuperGlue (Sarlin, DeTone, Malisiewicz, & Rabinovich, 2020). These matches allowed the estimation of an absolute drone pose through the Perspective-n-Point (PnP) algorithm, assuming a planar ground. Although this approach provided drift-free position estimates, updates were intermittent, occurring only when a sufficient number of feature matches were detected. Additionally, a user-friendly interface was developed to enable the free download of high-resolution maps, ensuring access to current satellite imagery essential for the matching process. Finally, the estimated trajectories from both the optimized ORB-SLAM3 (VO) and the satellite matching approach were compared against the ground truth using the Robotics and

Perception Group (RPG) trajectory evaluation library, with key metrics (including RMSE for position and orientation) computed.

Findings

The optimized ORB-SLAM3-based visual odometry provided continuous, high-frequency pose estimates with an average error of approximately 2 meters. Despite the dataset-specific optimization enhancing VO performance, the trajectory exhibited cumulative drift over longer distances without global correction. Fig.1 The optimized ORB-SLAM3 model was tested on the custom UAV dataset to assess its accuracy in trajectory estimation. Figure 1 illustrates a comparison between the predicted trajectory and the ground truth for one of the test sequences. The results show that the optimized model provides a smoother trajectory, though some drift is observed over longer distances. In contrast, the integration of Monodepth successfully addressed the scale ambiguity, resulting in more accurate and scale-consistent VO estimates. Satellite image matching, while delivering absolute localization with minimal drift and an average error of about 4 meters, produced updates intermittently. The complementary nature of these methods suggests that combining continuous VO with periodic satellite-based corrections can reduce cumulative drift and improve UAV navigation in GPS-denied environments.

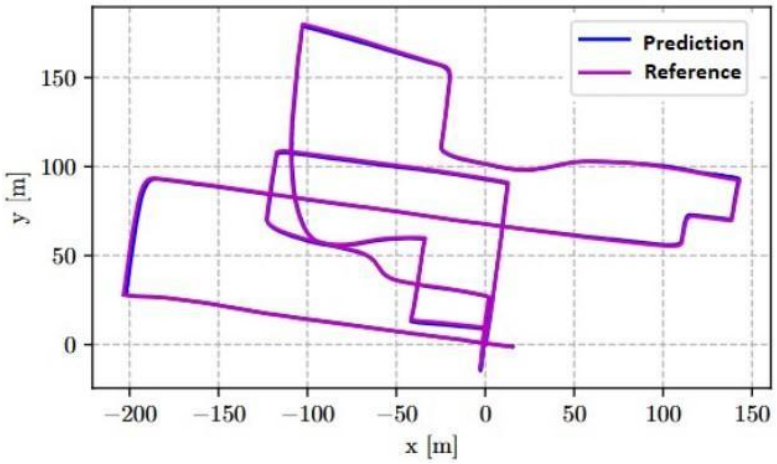

Figure 1. Reference vs. Predicted Trajectory using Visual Odometry.

Conclusion

This study demonstrates that a combined visual navigation system leveraging both optimized visual odometry (via ORB-SLAM3) and satellite image matching can significantly enhance UAV navigation in GPS-denied conditions. The creation of a novel, fully annotated dataset with synchronized ground truth at mid-altitude contributes to the research community and opens new possibilities for sensor fusion strategies. The integration of depth estimation algorithms like Monodepth addresses the scale ambiguity issue, further improving VO accuracy, while the map retrieval interface facilitates the acquisition of necessary satellite imagery for absolute localization. Table 1 presents the quantitative comparison of the two navigation methods. While visual odometry provides continuous real-time motion estimation, it suffers from cumulative drift over long distances. In contrast, satellite image matching provides globally referenced absolute position fixes but at an intermittent rate. However, the current method still has limitations. Its performance can be sensitive to environmental variability—such as changes in lighting, terrain, or the landscape's appearance—which may degrade matching accuracy. Additionally, the approach relies on the availability of high-quality, up-to-date satellite data and assumes a relatively planar ground, conditions that might not hold universally. Future work will focus on enhancing the method's robustness by implementing real-time sensor fusion algorithms (e.g., extended Kalman filtering) and incorporating additional sensors (such as an Inertial Measurement Unit (IMU) and barometer) to complement visual data. Moreover, adapting the image matching process to be more invariant to environmental changes and periodically updating the reference maps could further improve the system's reliability and performance in diverse GPS-denied environments.

Table 1. Comparison of Visual Odometry and Satellite Image Matching Methods.

Method	Average Position Error	Drift Over Distance	Update Frequency	Absolute Accuracy
Optimized ORB-SLAM3 (VO)	~2 m	Increases over time	Continuous (every frame)	No absolute reference
Satellite Image Matching	~4 m	No drift	Intermittent (~every few seconds)	Geo-referenced

Keywords: Object Detection, Tracking Algorithms, Real-Time Performance.

Modern defense technologies are a rapidly developing field with the use of UAVs (unmanned aerial vehicles). Although UAVs used in the defense field generally have limited computational resources, they need to detect and track objects in real-time in highly dynamic and variable environments. Although existing object detection and tracking algorithms provide high accuracy in such environments, they are not optimized in terms of processing speed and resource usage. Solving these problems is of vital importance in terms of increasing the effectiveness of defense systems and ensuring operational security. This study investigates the optimization of object detection and tracking algorithms specifically designed for unmanned aerial vehicles by evaluating their performance through the application of state-of-the-art machine learning models. Experiments have shown that YOLOv8m achieves the highest accuracy with 0.971 mAP@0.5 and 0.709 mAP@0.5:0.95 values. ByteTrack, one of the tracking algorithms, exhibited optimized performance for real-time applications with 50.5 FPS and 0.926 MOTP. The results reveal that the combination of YOLOv8m and ByteTrack offers a balanced solution in UAV-based systems. These findings contribute to improving the effectiveness and reliability of object detection and tracking for UAV systems in complex operational environments.

Aim

The main objective of the study is to increase the sensitivity and speed of object detection and tracking in images obtained from UAVs, to compare the performance of algorithms used in this field with quantitative metrics, and to develop optimization suggestions. In particular, the behavior of YOLOv8 models of different sizes on an extended dataset and the real-time performance of tracking algorithms are analyzed. The study aims to fill the gap in the literature and provide a practical guide for algorithm selection in UAV operations.

Material and Method

Dataset

The dataset, initially consisting of 4415 datasets, is optimized for object detail and tracking, especially in UAV systems. The images include examples of objects taken from different angles, objects of various sizes, and real-world conditions. The data is also manually labeled in COCO format.

In order to increase the overall capacity of the dataset and to ensure that the model gives more robust results, data augmentation techniques were used. These techniques are rotation, reflection, scaling, stretching, and color changing. In this way, the number of data points was doubled, and the model's ability to learn under different conditions was strengthened. As a result of the applied techniques, two examples of the data in the dataset and their augmented versions are shown in Figure 1. The dataset is divided into training (80%), validation (10%), and testing (10%) subsets.

Figure 1. Examples of data and augmented data.

Hardware and Software Infrastructure

All experiments were performed in a Google Colab Pro environment with an A100 GPU (40 GB RAM) and 83.5 GB RAM. The Ultralytics YOLOv8 (v8.0.143) library was used for object detection (Jocher et al., 2023). PyTorch (v2.1.0) and OpenCV (v4.7.0) based codes were optimized for the implementation of tracking algorithms.

Object Recognition Algorithm

YOLO (You Only Look Once) architecture is a widely preferred deep learning model for real-time object detection. In this study, five different models belonging to the YOLOv8 family were used as object detection methods. The models used were developed with different dimensions and effects, and the performance differences were shown for comparison purposes. These models are as follows:

YOLOv8n: The smallest model, notable for its fast processing time and low memory usage. However, it can generally exhibit lower accuracy rates.

YOLOv8s: Slightly larger than YOLOv8n, this model provides intermediate accuracy and speed.

YOLOv8m: This model has high accuracy rates and provides overall results in terms of processing time. According to the research results, this model is the one that exhibits the best overall performance with our dataset.

YOLOv8l: It is a larger model, and although it provides very high accuracy rates, it has a more intensive structure in terms of processing time and resource consumption.

YOLOv8x: It is the largest model in the YOLOv8 family, and although it provides the highest accuracy rates, it creates a significant burden in terms of processing time and memory usage in large data sets.

At each stage of training, Adam Optimizer was preferred as the backup schedule used. The training time of the model varied depending on the size of the model used and the size of the dataset**.**

Object Tracking Algorithms

The main purpose of the tracking programs is to ensure that moving products are stored correctly and to minimize detection errors. The tracking algorithms in the study are as follows:

SORT: Tracks objects using a Kalman filter. It is profitable with its simple structure and fast processing time, but low accuracy may be exhibited.

DeepSORT: Transmits vectors of detected features and makes their registration more robust. This solution uses deep learning models to increase the accuracy of object detections.
ByteTrack: It is a lighter and faster tracking algorithm. Although not complex, it can be preferred in certain applications with its fast processing time and low programming rates.

Evaluation Metrics

Evaluation metrics for object detection algorithms are as follows:

- **Mean Average Precision (mAP):** Evaluates the overall performance of the model by combining the accuracy and coverage rates of detected objects.
- **Precision:** Indicates how many of the detected objects are accurate.
- **Recall:** Indicates how many correct objects have been detected.
- **Inference Duration (ms):** It refers to how much time the model spends making predictions on an image.

Evaluation metrics for tracking algorithms are as follows:

- **FPS:** Real-time processing speed.
- **MOTP:** Estimated and actual bounding average IoU (Intersection over Union) between boxes (Zhang et al., 2022).
- **Tracked Object:** Specifies the number of objects that tracking algorithms have successfully tracked.

Findings

The Impact of Data Augmentation

Data augmentation significantly improved model generalization; the risk of overfitting was reduced by 22%. The validation mAP@0.5 value of YOLOv8m reached **0.971** on the augmented dataset, which increased **by 8.3%** compared to the baseline dataset.

Performance of YOLOv8 Models

Table 1. Evaluation of YOLOv8 Models.

Model	mAP@0.5	mAP@0.5:0.95	Precision	Recall	Inference Duration (ms)
YOLOv8n	0.928	0.656	0.938	0.86	4.91
YOLOv8s	0.960	0.677	0.927	0.93	4.99
YOLOv8m	**0.971**	**0.709**	0.946	**0.93**	**4.92**
YOLOv8l	0.959	0.702	0.986	0.87	5.16
YOLOv8x	0.960	0.698	**0.989**	0.91	5.53

The performance results of the models are as shown in Table 1 below. According to the results obtained, **YOLOv8m** stands out with its balance of both accuracy **(0.971 mAP@0.5)** and speed **(4.92 ms/inference)**. YOLOv8x, 98.9% it can be used in special scenarios with precision but its high resource consumption limits practical use.

Performance of Tracking Algorithms

Table 2. Evaluation of Tracking Algorithms.

Algorithm	Avg. FPS	MOTP	Tracked Object
ByteTrack	**50.5**	**0.926**	632
SORT	49.99	0.905	616
DeepSORT	26.89	0.755	**749**

The performance results of the algorithms are as shown in Table 2 below. According to the results obtained, **ByteTrack** has demonstrated ideal performance for real-time applications with high **FPS (50.5)** and **MOTP (0.926)**. DeepSORT has the most comprehensive tracking capability with 749 objects despite low FPS.

Conclusion

This study showed that the combination of YOLOv8m and ByteTrack is optimal for object detection and tracking in UAV images. Data augmentation significantly increased the model's accuracy. YOLOv8m provides high mAP values with low resource consumption, while ByteTrack provides real-time performance and stable tracking. Large models (YOLOv8l/x) can be preferred in missions requiring high precision. These findings provide the basis for future developments in autonomous UAV systems where efficient and accurate detection and tracking are critical for mission success.

Structural and Geotechnical Earthquake Engineering

Detection of Longitudinal Reinforcement Buckling in Reinforced Concrete Columns by a Deep Learning Method

Bahadir Gulesmen[a], Omer Tugrul Turan[b]

[a]Istanbul Technical University, Graduate School, Structural Engineering Program, Türkiye
[b] Istanbul Technical University, Civil Engineering Departmant, Türkiye
gulesmen21@itu.edu.tr

Keywords: Deep Learning, Post-earthquake Assessments, Reinforced Concrete Buildings, Reinforcement Buckling.

Aim

The objective of this study is to utilize deep learning methodologies to detect longitudinal reinforcement buckling in the columns of reinforced concrete buildings following seismic events. The February 6, 2023, Turkey–Syria earthquakes (Mw 7.8 and Mw 7.5), with epicenters in Pazarcık and Elbistan [1], resulted in significant structural damage and loss of life, thereby underscoring the critical need for structural health monitoring (SHM) systems. This study aims to demonstrate that even with a limited dataset, a deep learning approach based on transfer learning can reliably detect localized damage, such as reinforcement buckling. This, in turn, facilitates post-disaster assessments and assists in emergency and rehabilitation efforts.

Material and Method

The data for this study were collected during field investigations conducted in the aftermath of the February 6, 2023, earthquake. The dataset consists of high-resolution images of damaged reinforced concrete columns, with particular emphasis on sections exhibiting longitudinal reinforcement buckling. Image dimensions were standardized to minimize the effect of variable imaging conditions [2]. A total of 110 images were collected, in which 458 instances of longitudinal reinforcement buckling were identified. These images were annotated to label visible buckling zones, using bounding boxes to indicate their positions. The dataset was then divided into three subsets—training, validation, and test—using an 80:10:10 split. The training set comprised 88 images, while the validation and test sets each contained 11 images. These were associated with 351, 50, and 57 reinforcement buckling instances, respectively.

It is important to note that the dataset size and variability pose certain limitations. Since all images were captured within a limited time frame during post-earthquake site visits, variations in natural lighting—ranging from direct sunlight to overcast conditions—may have affected the visual clarity of the reinforcement details. In some cases, shadows or inconsistent illumination could obscure critical features. Moreover, several reinforcement bars showed signs of surface corrosion or rust, potentially altering the appearance of the buckling zones and influencing model perception.

The Faster R-CNN architecture was employed due to its proven effectiveness in balancing speed and localization accuracy. Its Region Proposal Network (RPN) is known to improve capture efficiency by generating high-quality region proposals [3]. The model utilized a pre-trained ResNet-101 backbone, further enhanced through transfer learning from the COCO dataset. Training was conducted with a batch size of 8 and a cosine decay learning rate schedule beginning at 0.01—an approach shown to prevent premature convergence and promote better generalization [4]. Data augmentation methods included random horizontal flips, hue/contrast/saturation adjustments, and random square cropping with a scale factor between 0.6 and 1.3, all of which increased dataset diversity and model robustness to real-world variability [5].

In addition to the Faster R-CNN model, the YOLOv8 architecture was employed to leverage its capability for real-time object detection with high spatial precision. The unified architecture of YOLOv8 eliminates the necessity for separate region proposal stages, thereby enabling end-to-end detection at substantially accelerated inference speeds while maintaining competitive accuracy [6]. The training process was executed for 200 epochs, employing a batch size of 16 and a 640×640 input image resolution. The Stochastic Gradient Descent (SGD) optimizer, with a momentum value of 0.9, was utilized to ensure stable convergence. Furthermore, advanced data augmentation strategies such as mosaic augmentation (applied at

every batch), mixup with a 50% probability, horizontal flipping (50%), and vertical flipping (20%) were incorporated. These techniques enhance the variability of the training samples and contribute to the model's robustness against scale, orientation, and illumination changes [7], thereby improving its generalization ability in real-world applications. A high patience value (300) was defined to allow extended learning without premature early stopping, a critical consideration when leveraging complex augmentations and extensive training epochs.

The performance of the model was evaluated using standard metrics including Intersection over Union (IoU), precision, and recall. Precision was calculated according to Equation (1) and recall according to Equation (2).

$$Precision = \frac{TP}{TP + FP} \tag{1}$$

$$Recall = \frac{TP}{TP + FN} \tag{2}$$

To ensure precise detections, a 50% IoU threshold was implemented, which indicates that if the IoU between the predicted and ground-truth bounding boxes exceeds 0.5, the detected box is designated as a true positive (TP). Subsequently, precision and recall values were calculated by identifying false positives (FP) and false negatives (FN). In addition to these metrics, we incorporated complementary metrics such as the F1-score (Equation (3)) and the Average Precision (AP) (Equation (4)) to more accurately evaluate the model's detection performance. These metrics offer a quantitative assessment of the model's accuracy and its capacity to identify patterns in test data that the model has not previously observed.

$$F1 = \frac{2\ x\ Precision\ x\ Recall}{Precision + Recall} \tag{3}$$

$$AP = \sum_{i=1}^{N} (R_i - R_{i-1})P_i \tag{4}$$

Findings

The performance of the Faster R-CNN-based deep learning model was evaluated on the test dataset, and the results demonstrated that it performed considerably well. Following several optimizations, the model achieved its highest accuracy at the 90th epoch. An Intersection over Union (IoU) threshold of 0.5 was employed to assess detection accuracy. Within the 11 test images containing 57 ground truth annotations, the model produced 51 true positives (TP), 14 false positives (FP), and 6 false negatives (FN). A precision score of 0.78 indicates that approximately 78% of the model's predictions were correct, while a recall value of 0.89 reflects the model's ability to identify nearly 89% of all reinforcement buckling instances present in the data. The high recall rate is particularly critical for civil infrastructure monitoring applications, where undetected damage (FN) can lead to severe safety risks. Notably, a recent study emphasized that models with a recall lower than 0.85 may be insufficient for deployment in disaster-prone regions [8].

The F1-score, which is the harmonic mean of precision and recall values, was found to be approximately 0.84, thereby supporting the balanced performance of the model. It is crucial to maintain this balance in applications where both false positives and false negatives can lead to significant operational costs[9]. Furthermore, the Average Precision (AP) of 0.88 supports the model's success in the reinforcement buckling detection task. Recent studies underline that AP values above 0.85 are indicative of robust performance in industrial defect detection systems[10].

The model's predictions on the images in the test dataset and the ground-truth buckling regions are presented in Figure 1. Prediction boxes are delineated by orange dashed lines, while ground-truth regions are indicated by blue lines. Additionally, the prediction score is indicated above the prediction boxes, and the IoU value is specified below.

Figure 1. Faster R-CNN Prediction and ground-truth regions.

The YOLOv8 model was also assessed using the test dataset to determine its effectiveness in detecting reinforcement buckling. An IoU threshold of 0.5 was applied for the evaluation process. Out of 57 ground truth instances across 11 images, the model successfully identified 45 true positives, while producing 5 false positives and missing 12 cases (false negatives). With a precision of 0.898, the model demonstrated strong reliability in its predictions, accurately identifying most of the positive cases. The recall rate of 0.772, though slightly lower, indicates a solid capability in detecting the majority of actual buckling events. This balance between minimizing incorrect alerts and capturing real damage is essential in practical field applications.

The calculated F1-score of approximately 0.83 reflects a harmonious trade-off between precision and recall, underscoring the model's stable and consistent performance. Additionally, the mAP@0.5 value of 0.8574 further supports its overall effectiveness in this task, confirming the model's potential for use in automated damage detection systems. Figure 2 illustrates the comparison between predicted regions and ground-truth boxes, where prediction boxes are outlined in orange

dashed lines and reference annotations are marked in blue. Each prediction box is labeled with the confidence level above and the IoU score below, providing insight into the model's detection accuracy and reliability.

Figure 2. YOLOv8 Prediction and ground-truth regions.

Comparatively, the results indicate that while Faster R-CNN achieved higher recall, YOLOv8 delivered better precision. This contrast is rooted in architectural differences: Faster R-CNN's two-stage design enables deeper analysis but requires more computation, whereas YOLOv8's single-stage pipeline offers faster, more efficient performance, well suited for real-time or mobile applications.

Conclusion

This study demonstrates the effectiveness of deep learning in detecting reinforcement buckling in reinforced concrete columns. Despite a limited dataset, the models achieved strong precision and recall, supporting their use in post-earthquake damage assessment. Compared to traditional inspections, this approach offers speed, consistency, and objectivity. While

one model offered broader coverage and the other higher precision, both highlighted the need to align model choice with specific operational goals.

Faster R-CNN and YOLO reflect two different detection strategies. The former provides more precise localization through a two-stage process, while the latter prioritizes speed and efficiency with a single-stage design—making it better suited for real-time, resource-limited applications.

These models also show great potential for integration into UAV-based inspections and edge-device deployments. Their lightweight, fast-inference design makes them ideal for mobile toolkits used in disaster zones, enabling quick on-site evaluations without relying on cloud connectivity.

Keywords: Equivalent Damping Ratio, Machine Learning, Reinforced Concrete Shear Walls.

Aim

A deep insight into the damping properties of structures and structural components is crucial for understanding their behavior under dynamic loads. Nonetheless, estimating the damping properties is a challenging task compared to identifying other structural parameters (e.g., stiffness, dynamic frequencies, etc.) This is because many mechanisms influencing the damping are not comprehensively understood and structural components may show different levels of damping depending on their deformations and experienced damage levels. The equivalent damping ratio is a simplified representation of complex structural damping mechanisms with broad application in the analysis and design purposes due to its straightforward formulation and convenient calculation. The present study aims to estimate the equivalent damping ratio of conventional RC shear walls at 1.0% drift ratio using machine learning-based methods. A dataset of 161 rectangular conventional shear walls subjected to quasi-static cyclic loading was assembled for this purpose. Five different machine learning (ML) methods, namely, Regularized Least Squares Linear Regression (RLR), K-Nearest Neighbor Regression (KNNR), Kernel Ridge Regression (KRR), Support Vector Regression (SVR), and Gaussian Process Regression (GPR) were examined. Analysis results revealed that Gaussian Process Regression exhibited superior prediction performance with a mean coefficient of determination (R^2) of about 0.89, a relative root mean square error (RELRMSE) of about 0.14 and a mean absolute percentage error (MAPE) of 10.44%.

Material and Method

RC shear walls are one of the most commonly used lateral load-resisting mechanisms worldwide. They have been broadly employed to enhance stiffness and reduce lateral deformations of medium-rise and tall buildings. These key structural components may undergo inelastic deformations during their service life due to loads imposed by seismic events or strong winds.

Employing inaccurate values of equivalent damping ratio may result in misleading evaluation of the ductility and energy dissipation capacity of structures. Due to the increasing popularity of displacement and energy-based design methodologies, the equivalent damping ratio of structures and structural components must be estimated properly at deformations beyond the elastic limit. This study uses machine learning techniques to evaluate the equivalent damping ratio of conventional RC shear walls at displacements corresponding to 1.0% lateral drift ratio. The selected reference deformation is the maximum allowable drift level by many building standards for several types of buildings (e.g., Eurocode 8 Part 1 for the ultimate limit state of buildings with non-structural elements, FEMA 356 for life safety limit state performance level of concrete wall structures, etc.)

The formulation used for quantifying equivalent damping ratio ξ_{eq} is based on the method proposed by (Jacobsen, 1930). According to this method, the dissipated energy in a vibrating cycle by the original structure is equated to the energy dissipated by an equivalent linear system with viscous damping under sinusoidal excitation. In resonance conditions, this definition leads to Equation 1:

$$\xi_{eq} = \frac{1}{4\pi}\frac{E_D}{E_{so}} \quad (1)$$

where E_D, the cyclic dissipated energy, is the area of the hysteresis loop and E_{s0} is the elastic strain energy (Figure 1). The latter parameter is calculated as $E_{so} = 0.5 f_0 u_0$ where u_0 is the maximum displacement and f_0 is the corresponding lateral force (Chopra, 2020).

As listed in Table A.1, this study uses a database of 161 rectangular RC shear walls from laboratory experiments carried out around the world to train and validate the ML models. All gathered specimens have concentrated rebars at their extreme ends and a height limit of 3.25 m to represent the common structural walls in Turkish stock. In terms of the failure mechanism, 54 walls failed in shear while 67 and 40 walls experienced respectively flexural and shear-flexural failure modes.

Table 1. Statistical properties of the output parameters.

Output parameter	Minimum	Maximum	Range	Mean	Standard deviation	Coefficient of Variation (%)
f_0 (kN)	15.2	2028.9	2013.7	544.9	507.6	93.2
E_D (kN.m)	0.45	25.74	25.29	5.42	4.41	81.4
ξ_{eq}(%)	3.02	26.6	23.6	11.1	4.9	43.8

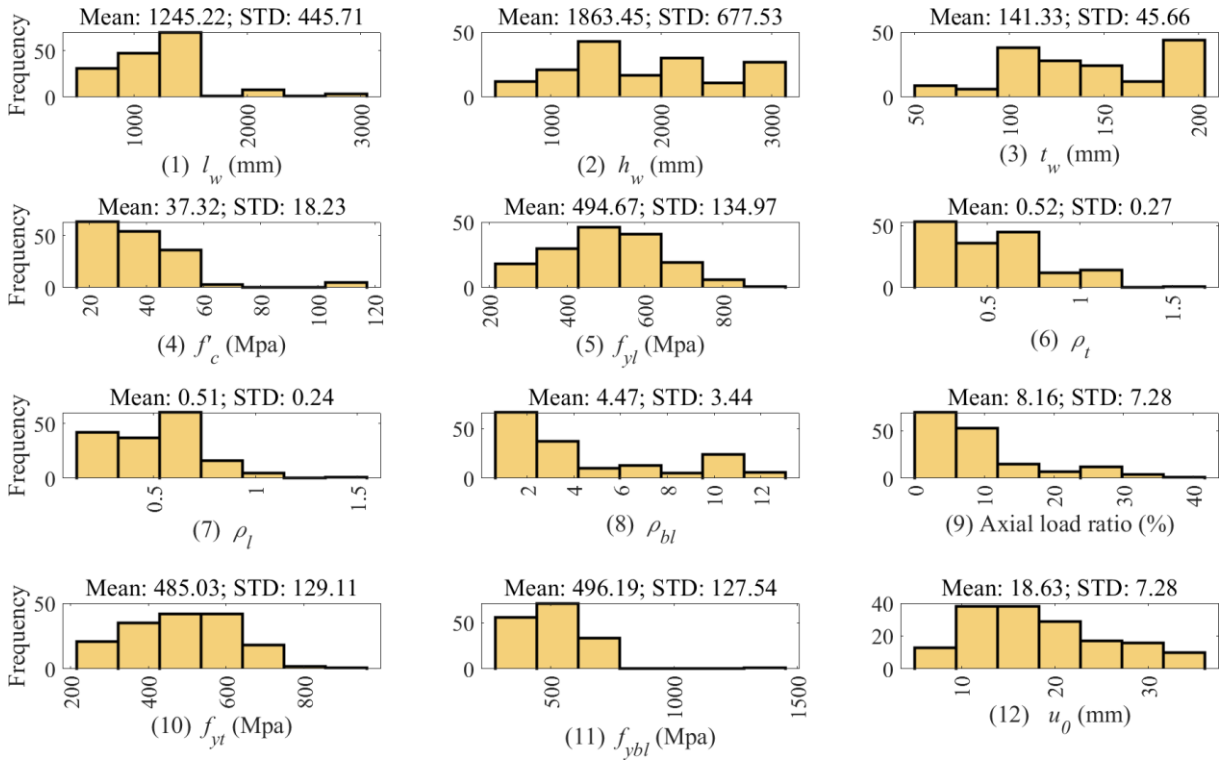

Figure 4. Frequency distribution of input variables (features).

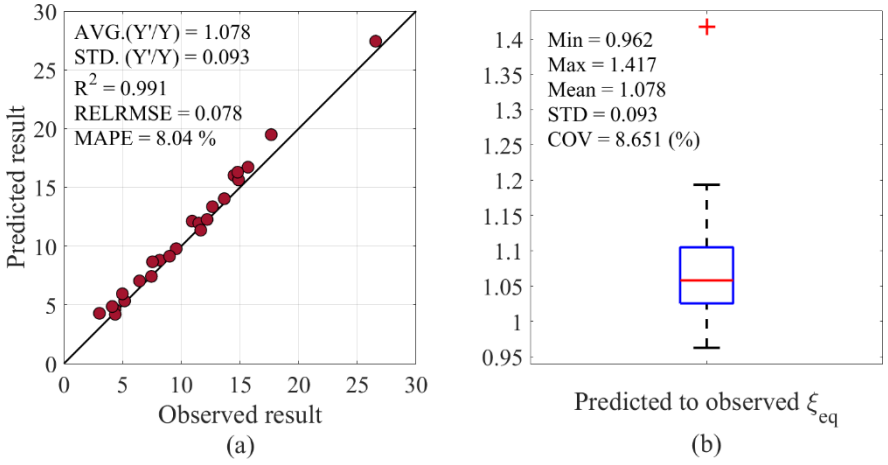

Figure 4. a) Results of the proposed model predicting ξ_{eq}; b) Distribution of the predicted to observed values.

Considering that the damping properties of structures and structural components are influenced by their level of damage (Chopra (2020)), a study was carried out to identify the damage status of the database shear walls at the reference drift level (i.e., 1.0% drift ratio). The damage status of shear walls was determined using their damage evolution reports, pre-failure photographs/figures and lateral load-displacement hysteresis curves. It was found that 18%, 62% and 20% of the walls had respectively experienced moderate, heavy and major damages at 1.0% drift ratio according to the ATC-13 damage index. Code conformity of the database specimens was controlled against the provisions of ACI 318-11 standard, revealing that the vast majority of the database specimens were substandard with only 10 out of 161 walls fully meeting the ACI 318-11

requirements considering the minimum wall reinforcement, boundary element provisions for special structural walls, the minimum material strength, etc.

Developing the machine learning-based model was initiated by defining the equivalent damping ratio as the output variable and its direct evaluation using different ML techniques. However, numerous attempts using various ML algorithms with assorted input variables (features) failed to establish a good correlation between the observed and predicted ξ_{eq} values. Consequently, an algorithm (schematically shown in Figure 2) consisting of two stages was established which treats f_0 and E_D as the intermediate outputs while ξ_{eq} (the final output) is computed according to Jacobsen's method using the approximated f_0 and E_D values in the first phase.

The input variables (feature sets) of the ML algorithms predicting f_0 and E_D were selected based on domain knowledge in the literature review. To this end, parameters known to influence the lateral load and energy dissipation capacity of shear walls were determined from scientific resources. The models predicting f_0 and E_D employ 10 and 11 features respectively, representing geometrical and mechanical properties of the database walls. The feature set for predicting f_0 includes: 1- wall length (l_w); 2- wall height (h_w); 3- wall thickness (t_w); 4- axial load ratio defined as the applied compressive load *P* divided by the wall cross-sectional area (A_g) and concrete compressive strength (f_c'); 5- concrete compressive strength (f_c'); 6- yield strength of longitudinal web rebars (f_{yl}); 7- transverse web reinforcement ratio (ρ_t); 8- longitudinal web reinforcement ratio (ρ_l); 9- longitudinal boundary reinforcement ratio (ρ_{bl}) and 10- yield strength of transverse web rebars (f_{yt}). The feature set for the model predicting E_D includes the first nine features of the model predicting f_0 and the two additional variables of longitudinal boundary rebars yield strength (f_{ybl}) and maximum lateral displacement of the hysteretic loop (u_0). The last feature (u_0) is introduced to provide the model with the actual maximum displacement data of the hysteresis loop. This is because, as demonstrated in Figure 3 for specimen MSW3 (Salonikios et al., (1999)), for some walls the measured deformation may have slight deviations from the reference deformation of 1.0% drift level. Statistical properties of the 12 features and 3 output variables are shown in Figure 4 and Table 1, respectively.

Subsequently, the collinearity of features (the situation when there is a strong correlation between two or more variables) was studied by looking at the Variance Inflation Factor (VIF) parameter:

$$VIF = \frac{1}{1 - R^2} \tag{2}$$

Table 2 summarizes the VIF values for the multicollinearity control. Considering that for VIF values smaller than 10 collinearity is not a significant issue (Hair, JR. et al., (2003)), it is concluded that collinearity only exists between h_w and u_0 in the feature set of the model estimating E_D. Despite this observation, both features (i.e., u_0 & h_w) were retained because their contribution to the prediction efficacy was confirmed through trial and error, and considering that their strong association is expected due to the definition of u_0 (i.e., $u_0 \approx 0.01 h_w$).

Logarithmic transformation of input and output variables was carried out so that their distributions fit the normal distribution in a better manner. Coefficient of determination (R^2), relative root mean square error ($RELRMSE$) and mean absolute percentage error ($MAPE$) were employed as statistical measures to evaluate the performance of the ML models (Equation 3 to 5). In these equations, n is the data number, Y is the observed value and Y' is the predicted value.

Table 2. Collinearity statistics of the input variables.

f_0			E_D		
Feature	R^2	*VIF*	Feature	R^2	*VIF*
l_w	0.61	2.58	l_w	0.62	2.60
h_w	0.32	1.47	h_w	0.95	20.77
t_w	0.70	3.37	t_w	0.84	6.21
f'_c	0.39	1.63	f'_c	0.28	1.39
f_{yt}	0.81	5.32	f_{ybl}	0.65	2.85

ρ_t	0.65	2.83	ρ_t	0.63	2.67
ρ_l	0.68	3.08	ρ_l	0.17	1.21
ρ_{bl}	0.13	1.14	ρ_{bl}	0.59	2.45
ALR (%)	0.39	1.63	*ALR (%)*	0.39	1.64
-	-	-	u_0	0.95	19.97

$$R^2 = \left[\frac{n\sum YY' - (\sum Y)(\sum Y')}{\sqrt{n(\sum Y^2) - (\sum Y)^2} \times \sqrt{n(\sum Y'^2) - (\sum Y')^2}}\right]^2 \quad (3)$$

$$RELRMSE = \sqrt{\frac{1}{n}\sum (Y - Y')^2} \Big/ \left(\frac{1}{n}\sum Y'\right) \quad (4)$$

$$MAPE = \frac{100\%}{n}\sum \left|\frac{Y - Y'}{Y}\right| \quad (5)$$

Findings

The performance of the five machine learning algorithms (RLR, KNNR, KRR, SVR & GPR) was evaluated after carrying out 10 analysis trials. Each trial was repeated 1000 times, and in each repeat, the database was randomly split into training and validation sets with a train/validation ratio of 85%-15%.

The kernelized methods (KRR, SVR and GPR) all use the radial basis function (RBF) kernel. Hyperparameter optimization for RLR, KRR, SVR and KNNR methods (i.e., shrinkage factor in RLR, the Gaussian kernel variance and penalty parameter in KRR, threshold, penalty and γ parameters in SVR, the number of nearest neighbors in KNNR) was carried out using grid search, while GPR hyperparameters (including the length/scale parameter, the signal and noise variance) were optimized via the conjugate gradient method (Rasmussen & Nickisch (2010)) by maximizing log marginal likelihood. The

Gaussian Process Regression algorithm (Rasmussen (2004)) exhibited significantly superior performance in comparison to the other four ML algorithms estimating the intermediate and final outputs.

Table 3 summarizes the regression analysis results on the validation set by the GPR-based model. Figure 5 demonstrates the performance of the model with the highest R^2 in predicting ξ_{eq} ($R^2 = 0.991$). The regression results for the four remaining ML methods are omitted for brevity.

Table 3. Performance scores of the GPR-based model.

Output Parameter	Maximum R^2	Mean R^2	Mean RELRMSE	Mean MAPE (%)
f_0	0.997	0.939	0.231	24.47
E_D	0.982	0.818	0.354	28.49
ξ_{eq}	0.991	0.890	0.141	10.44

Conclusion

The possibility of estimating the equivalent damping ratio of conventional RC shear walls at 1.0% drift ratio using machine learning-based methods was investigated using five different ML methods.

A database including 161 planar RC shear walls with a height limit of 3.25m subjected to quasi-static cyclic loading was assembled. The database mostly consists of substandard experimental walls with a relatively homogenous distribution of shear, flexural and shear-flexural failure mechanisms. All specimens had experienced beyond elastic deformations at 1.0% drift ratio with 82% undergoing heavy or major damage levels according to ATC-13 damage index. The equivalent damping ratio values of the gathered experimental walls were quantified using their lateral load-displacement hysteresis curves at displacements corresponding to 1.0% drift ratio. The calculated equivalent damping ratios had a minimum of 3%, a maximum of 26.6% and the mean value of 11.1%.

An algorithm based on predicting the equivalent damping ratio (final output) using the estimated values of cyclic dissipated energy and lateral force (intermediate outputs) was developed. The GPR-based model showed superior performance over other examined methods in terms of establishing a strong correlation between the observed and predicted values of both the intermediate and final outputs.

Future efforts will include enhancing the model's interpretability and explainability. In particular, SHAP (SHapley Additive exPlanation), a model-agnostic method, is of interest due to its efficiency in describing the contribution of each feature to the model's prediction.

Keywords: Seismic Retrofitting, Buckling-Restrained braces, Substandard RC Beam-Column Joints, Shake Table Testing.

Aim

The seismic vulnerability of reinforced concrete (RC) frames, particularly those constructed prior to the implementation of modern seismic codes, continues to pose a significant risk to built environments. Many existing RC buildings, characterized by limited ductility and inadequate detailing, are inherently deficient when subjected to the dynamic loads generated during moderate to severe earthquakes (Oyguc et al., 2018). The financial impracticality of demolishing and reconstructing these structures necessitates the development of cost-effective and efficient retrofitting techniques. This study investigates the efficacy of employing an all-steel tube-in-tube buckling-restrained brace (TnT-BRB) system as a retrofit strategy for substandard RC frames. The primary aim is to evaluate whether the integration of TnT-BRBs can substantially improve the lateral strength, stiffness, energy dissipation capacity, and overall seismic performance of deficient RC frames while mitigating damage during intense seismic events.

The research leverages a state-of-the-art experimental approach involving shake table tests on one-third-scale specimens representing typical non-seismically detailed RC frames. One specimen serves as a control (bare frame), while the other is retrofitted with a diagonal TnT-BRB. Through this comparative investigation, the study seeks to elucidate the potential of TnT-BRB systems to function as primary seismic energy dissipation devices, thereby reducing excessive drift demands and preventing structural damage during earthquake excitations. This extended abstract further discusses the design rationale behind TnT-BRBs, details the experimental protocol including similitude requirements and instrumentation, and synthesizes the key findings that underscore the benefits and limitations of this retrofit technique.

The ultimate goal is to provide a rigorous, evidence-based recommendation for the adoption of TnT-BRBs as a feasible seismic retrofit solution that can be generalized for application in real-world scenarios, particularly for older RC buildings in seismically active regions.

Material and Method

To address the seismic deficiencies of substandard RC frames, an experimental program was designed and executed at the Allianz Teknik Earthquake and Fire Test and Training Center in Istanbul, Türkiye. Two one-story, one-bay RC frame specimens, scaled down to one-third of the prototype dimensions, were constructed based on the similitude rules derived from dimensional analysis and Buckingham's π theorem (1914). The control specimen (Specimen 1) represents a typical RC frame lacking seismic detailing, while the retrofitted specimen (Specimen 2) is enhanced with a single diagonal TnT-BRB system. Figure 1 shows the details of the specimens.

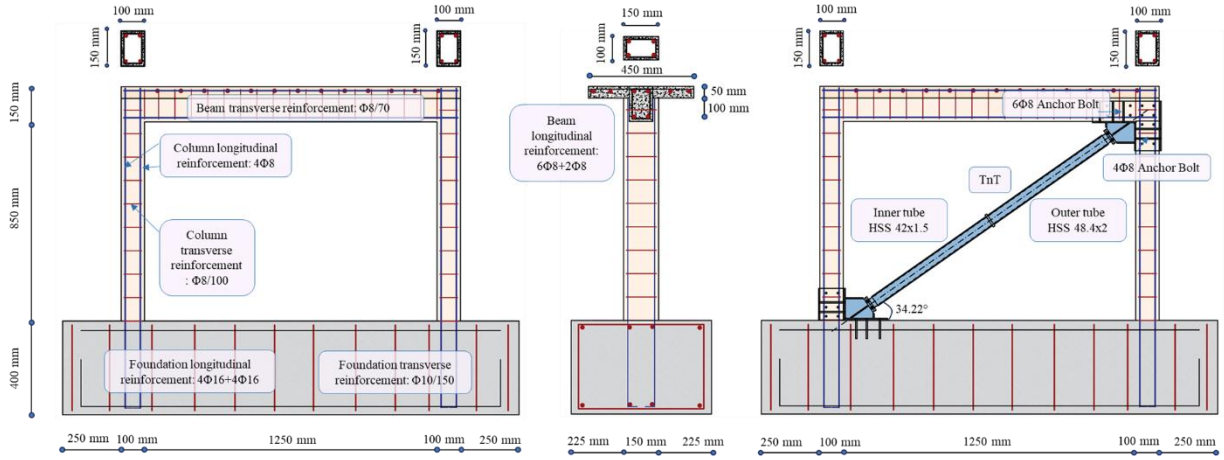

Figure 1. Details of the specimens.

The TnT-BRB, which is the cornerstone of this retrofit strategy, is an all-steel brace consisting of a load-bearing inner tube and an outer tube that functions as a buckling restrainer. The inner tube is fabricated from a circular hollow structural section (HSS) that is designed to undergo significant plastic deformations under seismic loading. The outer tube, segmented and attached via a ring-shaped stopper plate, provides continuous lateral support along the length of the brace to prevent global buckling. Notably, a deliberate gap between the two tubes allows the load-bearing tube to deform independently under axial loads while ensuring that the outer tube does not contribute to the compressive capacity. Connector plates and end connection assemblies, reinforced with pretensioned bolts, facilitate the integration of the TnT brace with the RC frame without imposing excessive additional stiffness on the structural elements.

The experimental protocol incorporated dynamic shake table tests for global stability evaluation. The shake table, equipped with hydraulic actuators and capable of delivering accelerations up to 1g across a frequency range of 0–50 Hz, was used to subject both specimens to scaled ground motion records. The primary seismic input was derived from the 2023 Kahramanmaraş earthquake (AFAD, 2023), and its time-history record was carefully scaled according to the similitude law established during the experimental design phase. In particular, the scaled acceleration time histories were applied to simulate various seismic intensity levels, from moderate (0.35g) to full-scale (1g) excitations, thus allowing for a detailed comparison between the bare and retrofitted frames. The physical variables are detailed in Table 1.

Table 1. Calculated physical quantities for shake table tests.

Physical Quantity	Scale Factor
Length, l_r	3
Modulus of elasticity, E_r	1
Time, t_r	1.732
Gravitational acceleration, g_r	1
Strain, ε_r	1
Acceleration, a_r	1
Frequency, ω_r	0.577
Velocity, v_r	1.732

Instrumentation played a critical role in capturing the dynamic response of the specimens. Linear voltage displacement transducers (LVDTs) were strategically placed at the top of the frame and along the length of the TnT brace to monitor lateral displacements and axial elongations. Accelerometers were deployed at key locations on the foundation, slab, and shake table surface to record the acceleration responses during testing. In addition, strain gauges embedded within the RC frame provided valuable data on the distribution of strains during dynamic loading. These measurement systems were synchronized with a computer-aided data acquisition system, ensuring high-resolution recording of transient responses and allowing for subsequent signal processing, such as baseline correction and low-pass filtering, to remove noise artifacts.

Findings

The shake table tests revealed a marked difference in the performance of the bare RC frame (Specimen 1) compared to the TnT-retrofitted frame (Specimen 2). Under a moderate excitation of 0.35g, Specimen 1 exhibited significant damage in the form of shear cracks at the beam-column connections and spalling of concrete at the lower portions of the columns. In contrast, Specimen 2, equipped with the TnT brace, demonstrated a nearly elastic response with only minor hairline cracks observed at similar excitation levels. The experimental data indicate that the TnT-BRB system effectively reduced lateral displacements: while Specimen 1 recorded a maximum lateral displacement corresponding to a story drift ratio of approximately 0.055 radians, Specimen 2 exhibited displacements well below the damaging threshold, with a drift ratio near 0.02 radians even under a full-scale 1g ground motion.

Quantitative analysis of the recorded acceleration responses further substantiated the benefits of the TnT retrofit. The damping ratios calculated via the half-power bandwidth method revealed that Specimen 2 had a significantly lower acceleration amplification factor compared to Specimen 1. This reduction in vibrational response is directly attributed to the energy dissipation mechanism of the TnT brace, which yielded symmetrically in both tension and compression. Axial displacement measurements from the LVDTs on the TnT brace indicated that the load-bearing tube experienced minimal elongation, remaining within the elastic range at 0.35g and achieving a peak ductility demand of less than three under 1g excitation. These observations confirm that the brace not only provides additional lateral stiffness but also acts as a controlled fuse that dissipates seismic energy, thereby protecting the primary RC frame from excessive stress.

Furthermore, the base shear force recorded for Specimen 2 was notably higher than that for Specimen 1 under similar ground motion levels. At 0.35g excitation, the bare frame's peak shear force was measured at approximately 18.17 kN, whereas the retrofitted frame experienced a peak force of 30.65 kN. Although the absolute shear force increased with the retrofit, the corresponding reduction in story drift ratio indicates a more favorable distribution of forces, with the TnT brace effectively absorbing and redirecting the seismic energy. The results suggest that, by acting as the primary seismic line of defense, the TnT-BRB system mitigates the adverse effects of horizontal forces on the main structural components. This conclusion is further reinforced by post-test inspections, which revealed that the retrofitted specimen maintained the integrity of its beam-column connections and overall structural configuration even after exposure to high-intensity ground motion.

A detailed comparison of the cyclic responses, illustrated in Figure 2, demonstrates that the TnT brace maintained stable, symmetrical hysteretic behavior throughout the testing cycles. This behavior is critical for ensuring that the brace can reliably dissipate energy without suffering premature failure due to local buckling or connection deficiencies.

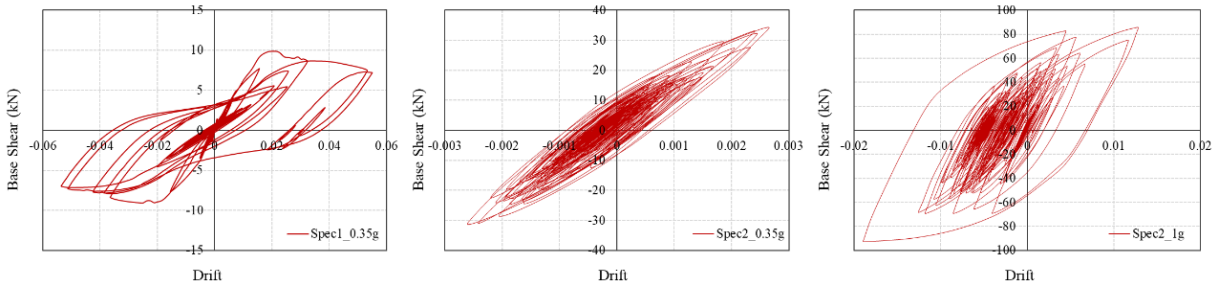

Figure 2. Hysteretic response of the specimens.

Additional insight was provided by the detailed analysis of the damage patterns observed during and after testing. Specimen 1 exhibited significant cracking and spalling, particularly in the vicinity of beam-column joints, a common failure mechanism in inadequately detailed RC structures. In contrast, Specimen 2, with the TnT retrofit, showed minimal superficial cracking and no evidence of damage in the critical joint regions. The absence of such damage underscores the potential of the TnT-BRB system to maintain structural integrity under severe seismic loading. Furthermore, the minimal axial elongations recorded along the TnT brace imply that the retrofit does not impose undue stress on the connected RC frame, thus ensuring that the primary structure can continue to perform effectively during subsequent seismic events.

Conclusion

The experimental investigation demonstrates that retrofitting substandard RC frames with all-steel tube-in-tube buckling-restrained braces markedly improves seismic performance. The TnT-BRB system not only enhances lateral stiffness and energy dissipation but also significantly reduces excessive lateral displacements and associated damage under seismic loading. The shake table tests, corroborated by finite element simulations, confirm that the TnT brace serves as an effective primary seismic defense mechanism, thereby protecting critical structural elements from inelastic deformations and catastrophic failure.

In summary, the incorporation of TnT-BRBs into RC frames offers a promising retrofit strategy for aging and deficient structures in seismically active regions. The retrofit enhances the overall ductility and resilience of the frame while maintaining cost-effectiveness and ease of installation. Future work should focus on large-scale and three-dimensional testing to further generalize these findings and to address additional uncertainties related to multi-directional seismic inputs. The present study provides a robust experimental and analytical basis for the widespread adoption of TnT-BRB systems in seismic retrofitting applications.

Aim

Earthquakes have been among the most devastating natural disasters throughout human history and will continue to cause significant destruction in the future. The losses caused by earthquakes are not limited to casualties but also extend to economic and social dimensions, clearly indicating that the impact of this hazard will not diminish in the coming years. From past to present, numerous scientific studies and engineering solutions have been developed in the field of earthquake engineering, particularly focusing on earthquake-structure interaction. Throughout history, significant advancements have been made in seismic codes, and extensive academic research has been conducted on the design of earthquake resistant structures.

The fundamental philosopy of earthquake resistant design is based on ensuring that structures experience little to no damage during frequent small earthquakes, sustain repairable damage during moderate earthquakes, and maintain their structural integrity to preserve life safety during rare, large scale seismic events. Following the 1994 Northridge and 1995 Kobe earthquakes, the concept of performance based earthquake engineering emerged, proposing that structures should meet different performance objectives under varying levels of seismic hazard.

The nonlinear analysis and performance assesment methods used in performance based design aim to provide practical yet realistic results by combining the nonlinear static pushover analysis of multi degree of freedom (MDOF) models with the spectral analysis of equivalent single degree of freedom (SDOF) systems. One of these methods, and the basis of this study, is the N2 method developed by Fajfar (1999) at the University of Ljubljana. In conventional pushover based methods like the N2 method, it is assumed that the structure primarily vibrates in a single mode, typically the first mode. While this approach can yield accurate results for structures where higher mode effects are negligible, it may not provide satisfactory results for tall, irregular, asymmetric structures where torsional and higher mode effects are significant.

To address these limitations, Fajfar et al. (2005) proposed and extended N2 method, which accounts for plan-wise higher mode effects and can be applied to asymmetric structures. More recently, Kreslin and Fajfar (2011) introduced a further extension of the method to consider higher mode effects in the vertical (height) direction.

The aim of this study is to compare the story drift results obtained from Incremental Dynamic Analysis (IDA) -a more realistic analysis method- for two plan-irregular structures an done vertically irregular structure, with the results obtained from the conventional N2 method and extended N2 method considering higher mode effects. In this context, the study evaluates whether the extended N2 method can predict seismic demands more accurately than the conventional N2 method.

Material and Method

Within the scope of this study, a total of three reinforced concrete building models were developed, two of which are plan-irregular and one vertically irregular. All structures are four-story buildings, with material strengths selected as C16 for concrete and S420 for reinforcement steel. Irregularity parameters were calculated according to Eurocode 8 standards, and values such as eccentricities, torsional radii, and radii of gyration were determined for both X and Y directions.

For the Incremental Dynamic Analysis (IDA) of the structures, acceleration records from the Pazarcık (Table 1) earthquake (M_w 7.7) and the Elbistan (Table 2) earthquake (M_w 7.6), which bot occurred on February 6, 2023, were utilized. The shallow focal depths of these earthquakes (8.6 km and 7.0 km, respectively) significantly intensified the ground shaking.

Furthermore, the occurrence of two major earthquakes within a 9-hour interval severely challenged the performance levels of structures, leading to the complete collapse of many buildings that had already sustained moderate or severe damage after the first event. These characteristics highlight the importance of analyzing these earthquakes from the perspective of performance based earthquake engineering.

Table 1. Pazarcık earthquake records.

Table 2. Elbistan earthquake records.

	Station	R_{jb} (km)	R_{rup}(km)	R_{epi}(km)	PGA_{EW}(cm/s^2)	PGA_{NS}(cm/s^2)	Soil Type	Vs_{30}
Elbistan	4405	60,32	66,23	100,81	158,052	155,411	B	579
	2308	177,65	180,07	185,23	48,254	69,798	B	450
	3144	104,09	78,92	162,37	78,108	59,115	B	485
	0127	112,56	112,56	119,52	62,723	56,093	B	583
	7901	87,32	102,59	153,88	49,814	50,910	B	463
	3138	98,71	73,95	156,81	68,715	49,268	B	619

The selection of earthquake records for IDA analyses is critically important for obtaining accurate and reliable results. Parameters such as the epicentral distance (R_{epi}), the closest distance to the surface projection of the fault (R_{jb}), and the closest distance to the rupture (R_{rup}) were considered. To avoid near-fault effects and pulse like ground motions, short distance records were not preferred. Additionally, the shear wave velocities (V_{s30}) of the recording stations were selected within the range of 360-800 m/s, corresponding to soil class B as defined in Eurocode 8.

The selected ground motion records were obtained from the AFAD database and processed using the SeismoSignal software. To preserve the authenticity of ground motions, no spectral mathcing to a target design spectrum was performed. Instead, all records were scaled based on the Accelaration value corresponding to the average of the first two mode periods of the structure. This approach allowed the scaling process to be performed without altering the original frequency content of the records (Figure 1).

The building models were subjected to nonlinear time history analyses with increasing intensity under the selected ground motions using the SeismoStruct software. The results obtained from these analyses were evaluated using Excel software. Additionally, eigenvalue analyses were performed for each building model to determine parameters such as mode shapes, natural periods, and modal participation factors.

For the application of the N2 method, nonlinear static pushover analyses were first conducted on the building models. During these analyses, the structures were pushed under a predefined lateral load pattern until significant plastic behavior developed, and the capacity curves of the structures were obtained. These capacity curves were then transformed into equivalent single-degree-of-freedom (SDOF) capacity curves using modal transformation techniques to simplify the multi-degree-of-freedom (MDOF) system behavior.

The equivalent SDOF capacity curves were then compared with the elastic demand spectrum defined in Eurocode 8. The intersection point between the capacity curve and the demand spectrum was used to determine the target displacement and

the corresponding performance level of the structure. In the conventional N2 method, only the first mode of vibration was considered. While this approach yields sufficient accuracy for low-rise and regular structures, it may be inadequate for irregular, high-rise, or torsionally sensitive structures (Figure 1).

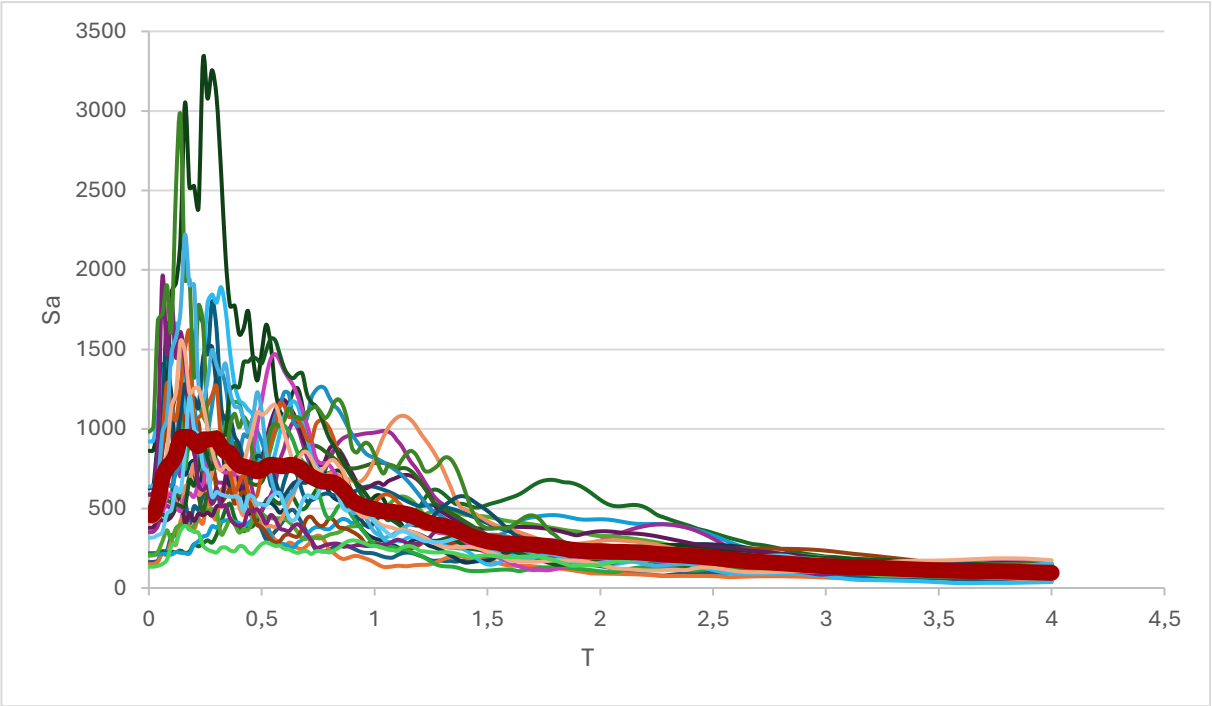

Figure 1. Sa (cm/s^2) – T (s) graph for different earthquake stations.

Therefore, in the later stages of the study, the extended N2 method, which accounts for higher mode effects, was applied. In this method, correction factors obtained from the elastic modal analyses were utilized to calculate the contribution of higher mode effects, particularly on the demands at the upper stories, and the existing capacity curve was updated accordingly. This approach ensured a more realistic assessment of structural performance by incorporating higher mode contributions. Finally, displacements and story drift obtained from both the conventional and extended N2 methods were compared with the IDA results to evaluate the accuracy of these methods (Figure 2).

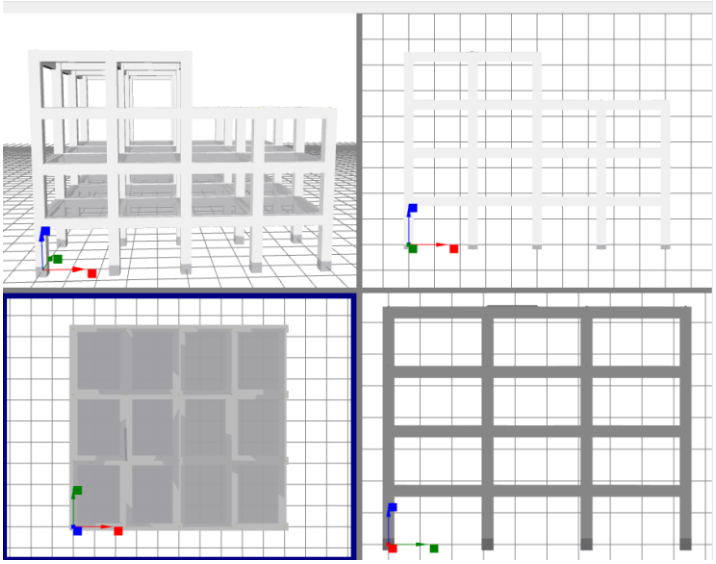

Figure 2. Vertically irregular structure.

Findings

The findings obtained from the analyses are summarized as follows:

- It was observed that story drift values increased significantly, particularly at the upper stories, as the degree of irregularity increased.
- It was found that the extended N2 method provided story drift predictions closer to the IDA results compared to the conventional N2 method, especially at the upper stories. The use of correction factors in the extended N2 method improved the accuracy of results for structures where higher mode effects were significant.
- In the vertically irregular structure, the effects of the second and third vibration modes became more pronounced, significantly influencing the distribution of story drifts throughout the structure.
- As the level of irregularity increased, a notable rise in residual displacement values was also observed in the structures.
- It was concluded that in structures with advanced irregularities, due to the intensified interaction between different modes, predictions made using single-mode approaches were insufficient, confirming the necessity of considering multi-mode effects.
- It was observed that in structures with plan irregularities, increased torsional effects led to irregular distributions in story drift and interstory drift ratios, particularly at the corner regions of the structures.

Conclusion

Based on the results obtained, the following general conclusions were drawn:

- Existing irregularities in structures, especially under conditions dominated by higher mode effects, led to significant changes in story drift distributions and damage patterns. In particular, in the vertically irregular structure, higher mode effects became markedly more significant, causing deviations from the predictions of the conventional N2 method. Therefore, employing analysis approaches that account for higher mode effects is critically important.
- Torsional effects in plan-irregular structures locally amplified story drift demands, and these amplifications were not adequately represented in the conventional N2 method.
- The extended N2 method, by considering higher mode effects, provided more accurate predictions compared to the conventional N2 method, yielding story drift values closer to IDA results, particularly at the upper stories (Figure 3).
- An increase in the degree of irregularity led to greater residual displacements, highlighting the necessity of developing performance assesment methods tailored for irregular structures.
- Overall, considering higher mode effects in the performance based evaluation of plan irregular and vertically irregular structures, and enhancing conventional methods, is crucial for achieving safer and more accurate engineering predictions.

Keywords: Reinforced Concrete Coupled Beams, Replaceable Components, Shape Memory Alloy (SMA).

Aim

This study investigates the potential of shape memory alloys (SMAs) to improve the seismic performance of reinforced concrete (RC) coupled beams. In conventional systems, permanent damage and difficult post-earthquake repairs highlight the need for replaceable and resilient components. This study explores the feasibility of using SMAs as replaceable diagonal reinforcement in coupled beams. Superelastic (SE) and shape memory effect (SME) properties were evaluated via tensile testing, along with connection techniques such as laser welding, TIG welding, and mechanical splicing. Findings showed SME materials were unsuitable due to heat activation requirements, whereas SE materials exhibited desirable mechanical behavior. Welding methods proved unreliable, while mechanical splicing—particularly double splicers—offered effective performance. SE SMA wires, when properly shaped and mechanically connected, are concluded to be suitable for seismic applications in RC coupled beams.

Introduction

Reinforced concrete (RC) shear walls play a crucial role in resisting lateral forces in structures. To enhance lateral stiffness and meet architectural needs, they are often designed as coupled systems. However, conventional RC coupled beams can run into construction and performance issues, mainly due to the complex reinforcement detailing, especially when it comes to diagonal bars that need proper confinement (Foroughi & Yuksel, 2024; Han et al., 2022; Subramanian, 2021). To address these issues, replaceable coupling beams (RCBs) have been identified as viable options. The RCBs are specifically designed to localize damage during seismic events, thereby preserving the main structural system and facilitating cost-effective post-earthquake repair. Research shows that RCBs improve energy dissipation, lessen the force demand on shear walls, and postpone wall yielding, ultimately enhancing overall seismic performance (Chen et al., 2017; Lü et al., 2014; Lu et al., 2018; Sun, 2021).

Incorporating SMAs into RCBs further improves energy dissipation and re-centering. Used as diagonal reinforcement, SMAs reduce damage to beams and adjacent walls and minimize residual displacements (Ghassemieh, Rezapour, et al., 2017). Studies showed that SMA dampers enhance nonlinear seismic behavior in RC frame-wall systems (Mao et al., 2013). Also, the numerical studies confirming superior dynamic performance compared to conventional steel reinforcement (Ravi & Krishnan, 2019). Moreover, SMAs contribute to better energy dissipation and reduced residual deformations during earthquakes (Ghassemieh et al., 2012; Ghassemieh, Nojoumi, et al., 2017).

Material and Method

There are many types of SMAs, but the most common are those that contain nickel and titanium (NiTi), commonly referred to as Nitinol, known for its favorable mechanical properties. SMAs show two main behaviors: the SME and SE. SMAs with SME undergo plastic deformation and keep their deformed shape upon loading. The shape returns to the original upon heating. Conversely, SMAs with SE recover to their original shape upon unloading, without heating.

Additionally, using SMAs in coupled beams incurs some challenges, which depend on the properties of the SMAs. Materials with (SME) require heating to return to their original shape. However, it is almost impossible to apply heat to the SMA

during loading in a real structure. On the other hand, (SE) SMAs do not need heating, but they have other issues. One challenge is shaping the material correctly before using it. Another challenge involves developing reliable connection techniques between SMA wires.

The shape of the SMA can be set by using a proper mold and heating the material to around 500°C. The mold can be arbitrarily dimensioned based on manufacturability considerations and made of steel for adequate strength and thermal resistance. For connecting the wires, welding methods or mechanical splicers can be used.

In this study, both types of SMAs were tested to understand their mechanical behavior and select the most suitable one for use in a replaceable coupled beam. Standard tensile tests were performed on several specimens to measure their ultimate tensile strength (UTS) and Young's modulus. These tests help identify the failure point and provide a reference for future experiments.

Experimental Test

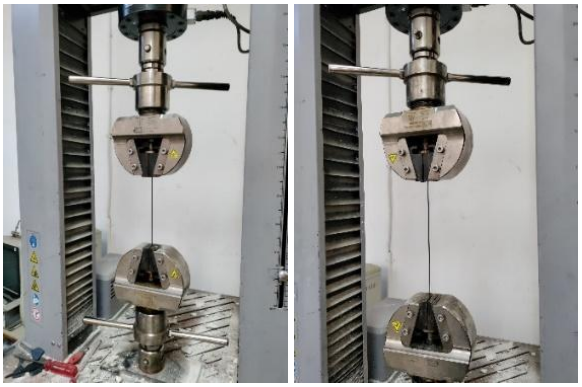
Tensile tests were carried out on SMA materials to identify their basic mechanical properties of different types and compared different welding methods with mechanical splicing to help solve practical challenges. The tested specimens are summarized in Table 1.

Table 1. Test program.

Specimen	SMA Property	Number of Specimens	Explanation*
SME	SME	3	Wire
SE	SE	3	Wire
SE-LW-2	SE	3	Wires connected using 2 cm laser welding
SE-LW-4	SE	3	Wires connected using 4 cm laser welding
SE-TW	SE	1	Wires connected using TIG welding
SE-O-1-1	SE	1	single oval with single splice
SE-O-1-2	SE	1	double oval with single splice
SE-O-2-1	SE	1	single oval with double splice
SE-O-2-2	SE	1	double oval with double splice

* All wire specimens have identical dimensions: 18 cm in length and 2 mm in diameter.

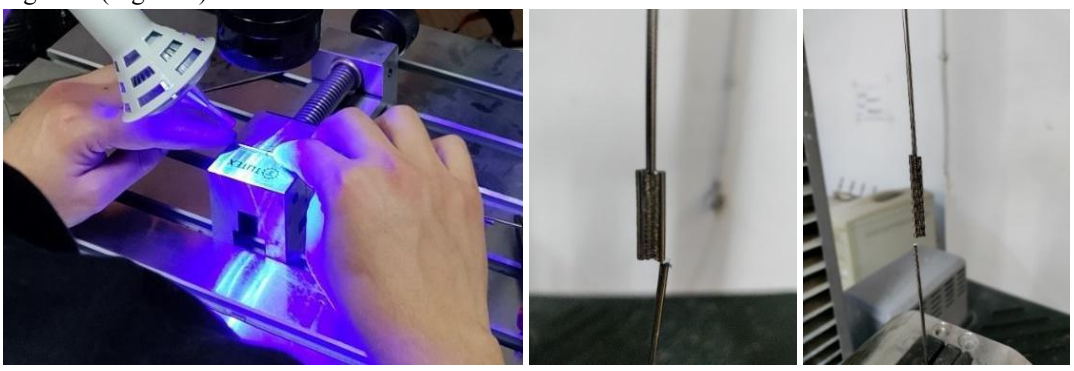
The SME and SE wires were first tested using a simple tensile test to understand their mechanical behavior. Owing to equipment limitations and the absence of advanced control systems, advanced tests could not be conducted. However, critical data such as ultimate stress and strain, and the material's ductility were successfully observed in the simple tensile test (Figure 1).



(a) (b)

Figure 1. (a) SME and (b) SE specimens.

After selecting the SE material as suitable for use in the coupled beam, several methods were used to connect the wires. Initially, the well-known laser welding method was employed to connect the SMA wires. Three specimens were welded using a 2 cm supporting section in the welding zone. Another three specimens were welded using a 4 cm supporting section in the welding zone (Figure 2).



(a) (b) (c)

Figure 2. (a) laser welding, (b) 2 cm laser welding specimen and (c) 4 cm laser welding specimen.

Secondly, TIG welding, which uses inert gas with non-consumable tungsten electrode, was employed to join the SMA wires while minimizing contamination in the weld zone, (Figure 3).

Figure 3. Specimen connected with TIG welding method.

Finally, a mechanical method was employed to connect the wires. To achieve this, a mold was designed with an oval shape to better accommodate splicing, to limit stress concentrations, and to remove the need to connect the SMA wires to other elements. The dimensions of the mold were arbitrarily chosen based upon considerations of how to actually make it, and the mold was manufactured in steel for sufficient strength and thermal resistance. The SMA wires were heated to approximately 500°C and then cooled to retain the desired shape. This heating and cooling thermal treatment retains the superelastic property and provides mechanical stability when loaded. (Figure 4). Subsequently, oval specimens with splicers were tested (Figure 5).

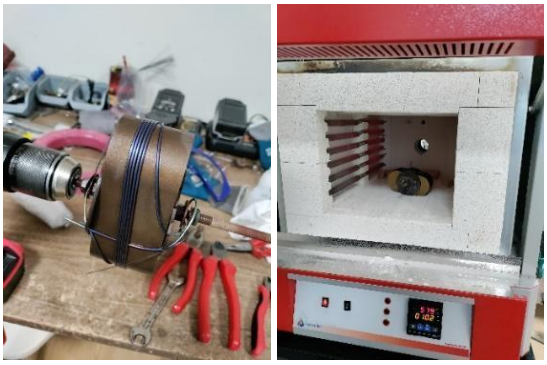


Figure 4. Reshaping the SMA wire.

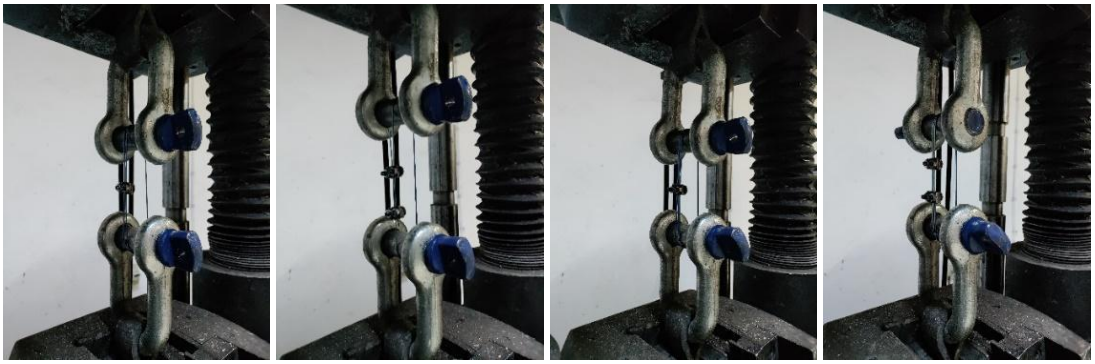

Figure 5. The oval specimen tensile tests.

Findings

To evaluate the mechanical properties of the tested specimens, force–displacement and stress–strain diagrams were obtained. The diagrams of the wire tests are shown in Figure 6. The SME specimens exhibited superior ductility, as evidenced by a gradual stress increase and an extended plateau. In contrast, SE-type specimens demonstrated higher initial strength but lower ductility, with a sudden drop in stress after reaching peak values. As illustrated in the diagrams, it is seen that none of the welded specimens withstood significant loading due to premature fracture, confirming the inadequacy of welding methods.Figure 7 shows the results of specimens connected with mechanical splicers. The results indicate that specimens SE-O-1-1 and SE-O-2-2 displayed higher peak stresses and extended strain capacities, suggesting improved ductility behavior compared to SE-O-2-1, which failed prematurely. SMAs connected with double splicers achieved an acceptable level of performance in both diagrams.

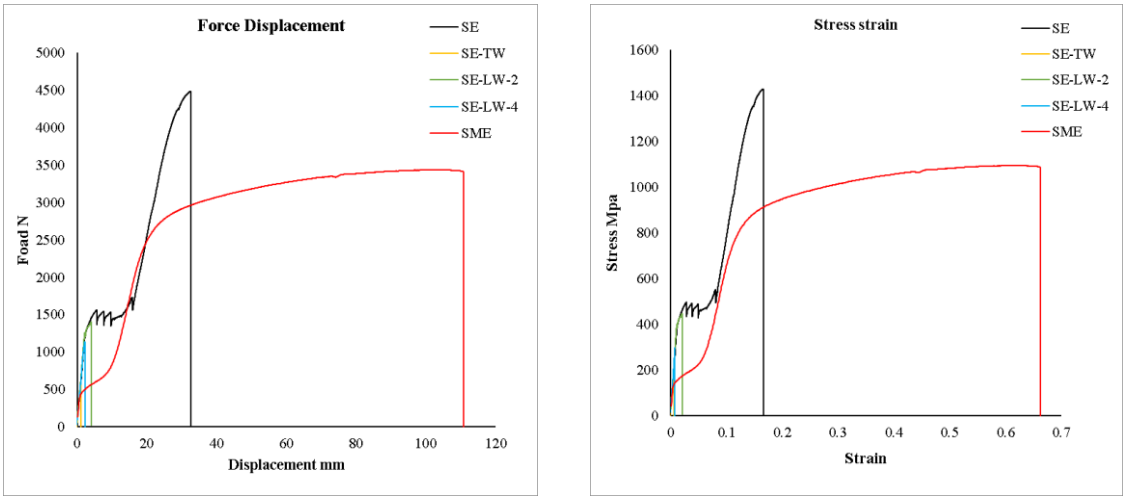

Figure 6. The force-displacement and stress strain diagrams of wire specimens.

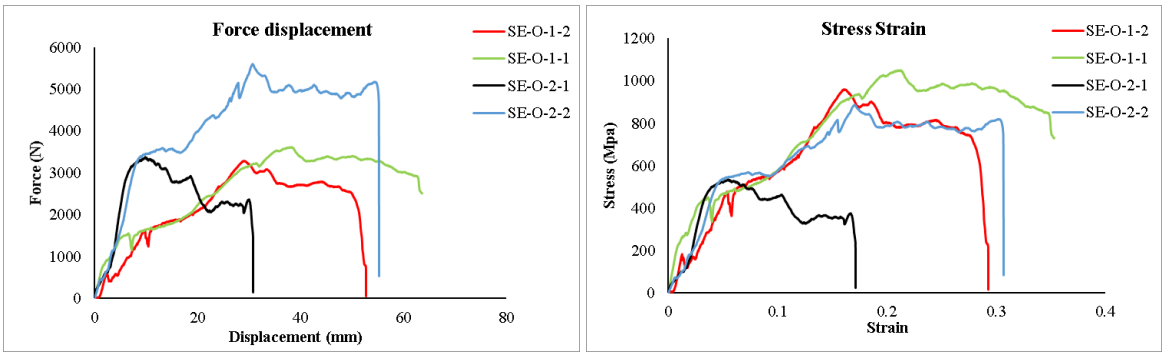

Figure 7. The force-displacement and stress strain diagrams of oval specimens.

Conclusion

This study concludes that while SME SMAs possess favorable ductility, their reliance on heat activation makes them impractical for seismic applications. In contrast, SE SMAs offer suitable mechanical properties without requiring external heat. Welding methods such as laser and TIG welding led to embrittlement and early failure. Mechanical splicing emerged as the most effective connection technique, particularly with double splicers, due to improved stress distribution and enhanced ductility. To incorporate SMA coupling mechanisms into seismic design standards, future research should focus on cyclic, low-cycle fatigue, or pseudo-dynamic tests, which require high-performance actuators, real-time data acquisition, accurate loading control. Further numerical research should involve in nonlinear time-history simulations and detailed finite element modeling to predict the seismic performance of SMA-based coupling systems at a structural scale. Comparative studies between conventional steel-reinforced and SMA-integrated coupling beams are also recommended to develop performance-based design guidelines and repair strategies.

Acknowledgment

The authors gratefully acknowledge Assist. Prof. Dr. Oğuz Güneş and Dr. Kerem Peker for their guidance. Experimental tests were conducted at the ITU Materials Laboratory with support from the staff. SMA materials were provided by Aksoz Arge Mühendislik.

Aim

The aim of this study is to describe preliminary experimental and numerical investigations conducted on a historical church as part of an ongoing comprehensive study to understand the behaviour of historical churches that were affected by the 2023 Kahramanmaraş Earthquakes.

Material and Method

St. Ilyas Greek Orthodox Church, which is the subject to the study, is located in Hatay province of Türkiye. It is understood from the inscription at the main entrance of the church that the church was built in the late 1800s. The photograph of the historical structure is presented in Figure 1. Post-earthquake field studies were carried out to determine the load-bearing system of the building and damage status, to reveal its structural elements and components, and to determine its geometric dimensions and material properties. The load-bearing system of the church consists of unreinforced irregular stone masonry walls, pillars, vaults and arches.

Figure 1. The photograph of St. Ilyas Greek Orthodox Church.

Studies on Creating a 3D Model of the Church:
Point clouds obtained from terrestrial laser scanning and photogrammetry (Figure 2) were utilized to extract an accurate 3D model of structural geometry and to assess damage. Two different scanners, Faro Focus S70 and M70, were used for the terrestrial laser scanning. The resulting point cloud included 44 million points with a point spacing of 6 mm. The manufacturer of the laser scanning reports that the accuracy of each point is 2 to 3 mm at a ranging distance of 25 m. In

addition to laser scanning, a Canon EoS 6D Mark II camera and a Mavic 2 Pro drone (Figure 2) were used for complementary point clouds of the church. Details of this measurement system are available in Yang et al. (2024).

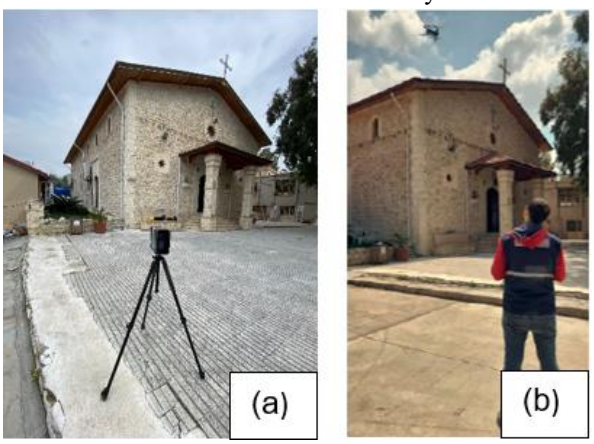

Figure 2. (a) the terrestrial laser scanning and (b) aerial photogrammetry (modified from Bozyigit et al., 2024).

Material Characterization with In-Situ Tests:
A Schmidt rebound hammer (SRH) with a mushroom plunger was used for non-destructive stone compressive strength estimation. During the application of the SRH, the instructions of ASTM C805/C805M-18 was followed whenever possible.

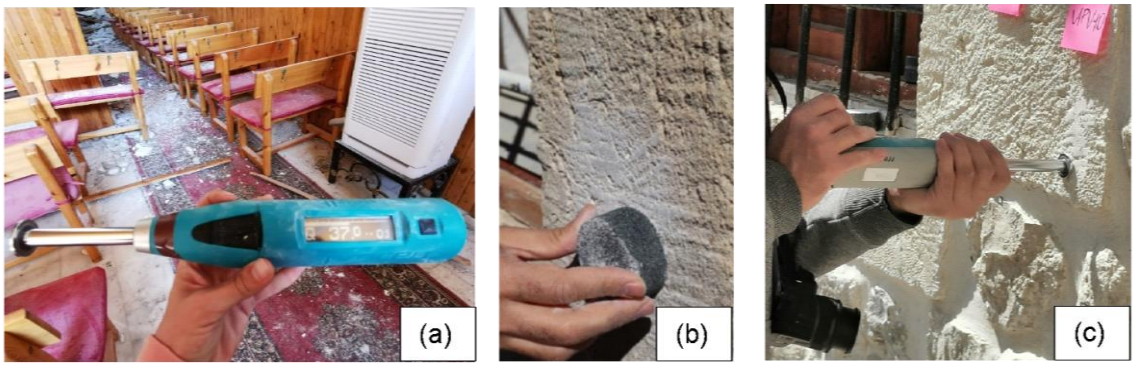

Figure 3. Application of Schmidt rebound hammer on stone unit.

The Proceq Silver Schmidt Hammer was used, Figure 3a. Before applying SRH to the specified small surface of the stone unit, the surface was cleaned and 10 readings of the Q value were taken by applying SRH in this surface (Figure 3b-c). This procedure was applied to 11 different stone samples. The median of these readings was used to estimate the compressive strength of the stone units (f_s) using Equation 1:

$$f_s = 0.0108Q^2 + 0.2236Q \quad (MPa) \tag{1}$$

Equation 1 is applicable solely for values of Q ranging from 13 to 44, which are associated with compressive strengths of approximately 5 MPa and 31 MPa, respectively (Kocáb et al 2019).
Mortar penetrometer (MP) tests are non-destructive and slightly destructive test techniques, conducted to estimate the compressive strength of the mortar which is based on the dynamic penetration of a steel needle (Gambilongo et al 2023; Žalskỳ et al 2023). The test measures the response of the mortar to needle penetration and relates the measurement to the compressive strength of the mortar (f_m). In this study, Diagnostic Research Company's (DRC) MP device shown in Figure 4 was used to perform mortar penetrometer tests.

Figure 4. Mortar penetrometer test device and its use in the field.

The tests of nine different bed/head mortar joints were performed. Following manufacturer guidance, each test was performed by striking the needle 10 times and measuring the penetration depth (d_m). Using Equation 2, the compressive strength of the mortar was estimated as in the studies of Bozyigit et al. (2024) and Gambilongo et al. (2023).

$$f_m = \frac{5970-\sqrt{(1.58d_m-5.3)10^6}}{1580} \quad (2)$$

Compressive strength and elasticity modulus values of masonry are needed for finite element analysis studies. Compressive strengths of stone and mortar determined by non-destructive test methods were used to estimate the mean compressive strength of stone masonry (f_{mas}). For the characteristic compressive strength estimation ($f_{ck,mas}$), Equation 3 recommended by Eurocode 6 was used and then the calculated value was divided by 0.67 to obtain the mean strength (f_{mas}).

$$f_{ck,mas} = 0.45 f_s^{0.7} f_m^{0.3} \quad (3)$$

The modulus of elasticity was calculated as 750 times the mean compressive strength of the masonry according to TSC (2018).

Establishing the Finite Element Model and Modal Analysis:
The finite element model of the church was created using the software Abaqus. A macro modelling approach was adopted for the structural components of the church and they were modelled using shell elements (S4R). A mesh sensitivity analysis was conducted to decide mesh size. The finite element model is shown in Figure 5.

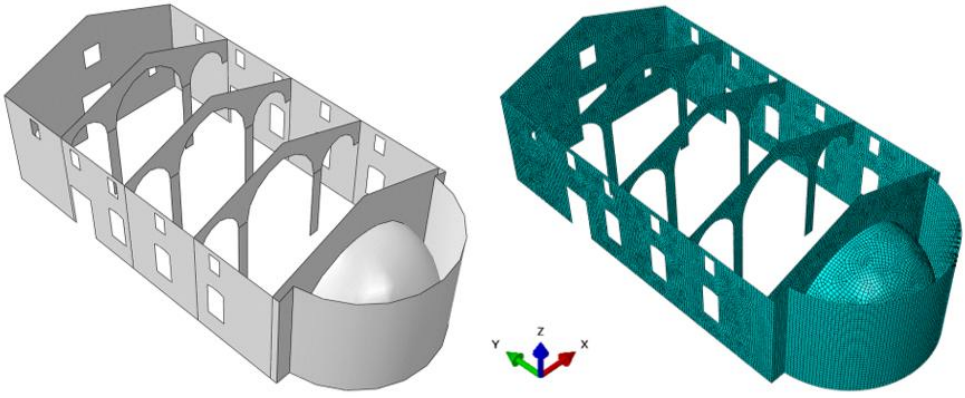

Figure 5. Finite element model views of the church.

After the church finite element model was completed, the above-mentioned elasticity modulus values were assigned to the relevant elements for modal analysis. The frequency values and corresponding mode shapes of the church were obtained from modal analysis.

Findings

On-site experimental and preliminary numerical studies are used to provide a general description of the existing damage, construction details, geometry, material and seismic behaviour of the historic church.

Damage Status:

The damage to the church was determined through observations made after the earthquake. The locations of the visible cracks on the exterior walls and the localized collapse on the roof are indicated in Table 1. It was also observed that some arches had cracks and that the voussoirs had slid.

Table 1. Damages due the 2023 Kahramanmaraş Earthquakes.

Damage location	Damage photograph	Note
		The separation between the apse and the external wall The stepped diagonal crack on apse
		Approximately vertical crack following head mortar joints Approximately diagonal crack

		The separation between the apse and the external wall The stepped diagonal crack
		Approximately vertical crack between window openings
		Partial collapse of the spandrel wall above the apse

Masonry wall type :
The church has unreinforced stone masonry structural components. The faces of the walls are made of irregular stonework, Figure 6. The pillars were constructed with cut stone units without mortar joints.

Figure 6. Face appearances of masonry walls.

Geometric Dimensions :
Point cloud data obtained by terrestrial laser scanning and photogrammetry were processed using the Cloud Compare program. The 3D and plan views of the church and the transverse arched frame system are shown in Figures 7-9.

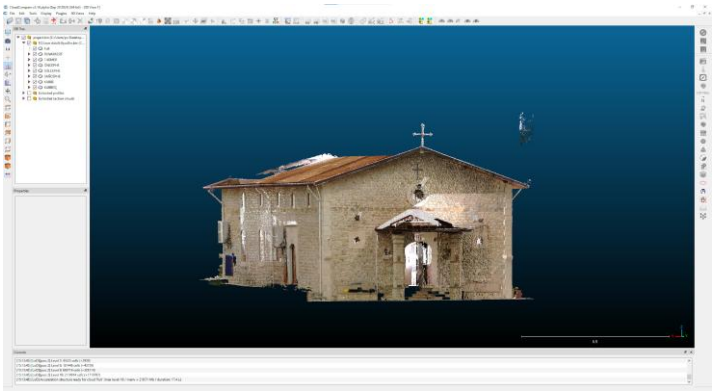

Figure 7. 3D view of the church.

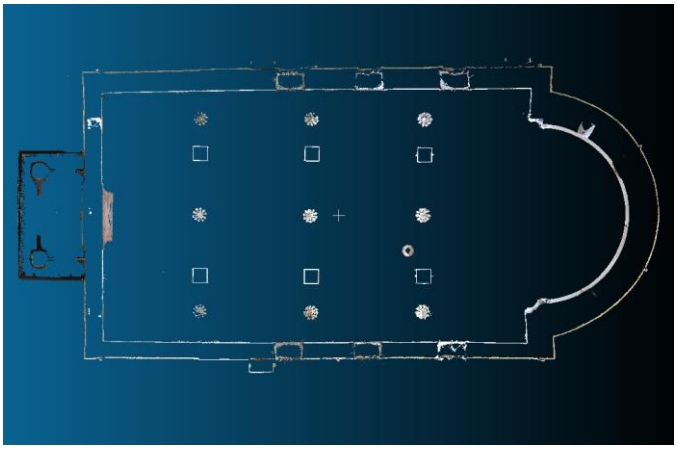

Figure 8. Plan view of the church.

The plan dimensions of the church are obtained from the Cloud Compare program as 11.38 m and 22.89 m. The average wall thickness was measured as 750 mm. The cross-sectional size of each pillar was determined as 550×550 mm.

Figure 9. An arched frame system along the building transverse axis.

Material Characteristics:
In order to determine the compressive strength of the stone units, SRH tests were carried out. Based on the Q values obtained from these tests, the compressive strengths were calculated using Equation 1. Table 2 shows the Q values obtained from the SRH readings, the calculated compressive strengths, and descriptive statistics (average and standard deviation).

Table 2. Compressive strength values of stone units.

Stone ID	Q	f_s (MPa)
STİLY-1	31.15	17.44
STİLY-2	26.5	13.51
SS2	31.25	17.53
SS4	39.5	25.68
SS7	42.5	29.01
Average	34.18	20.64
Standard Deviation	6.60	6.45

The average results of Mortar penetrometer (MP) tests are listed in Table 3. The compressive strengths of mortar (f_m) was calculated using Equation 2. The penetration depths, the compressive strengths, and descriptive statistics (average and standard deviation) of mortar are listed in Table 3.

Table 3. Compressive strength values of mortar.

Test ID	d_m (mm)	f_m (MPa)
MP2	15	1.06
MP3	8	2.06
MP4	5	2.76
MP6	8	2.06
MP8	17	0.84
Average	10.6	1.76
Standard deviation	5.13	0.79

As a result of the tests, the average compressive strengths of the stone and mortar were determined as 20.64 MPa (Table 2) and 1.76 MPa (Table 3), respectively. To use Equation 3, the masonry wall was accepted as homogeneous material. In Equation 3 and the coefficient of 0.67 is applied, the average compressive strength of the wall masonry is obtained as 6.6 MPa. The modulus of elasticity is calculated as 4950 MPa, which is 750 times the compressive strength. The compressive strength of the dry-stone pillars was calculated as 9.3 MPa, taking 0.45 times the average compressive strength of the stone units considering the study of Demir (2012). The modulus of elasticity of the pillars was calculated as 6975 MPa using the coefficient of 750 adopted for the masonry wall.

Dynamic characteristics:

Finite element model of the church was created using shell elements in the Abaqus program. The masonry material was accepted as a homogeneous material and was defined with its modulus of elasticity in the program. After a sensitivity analysis was performed to find the appropriate mesh size, resulting in a mesh size of 150 mm. By performing modal analysis of the FEM of the church, frequency values and mode shapes were obtained. The first ten frequency/period values are given in Table 4.

Table 4. Frequency and period values.

Mode No	Frequency (Hz)	Period (s)
1	6.2776	0.159
2	6.3297	0.158
3	6.3626	0.157
4	7.4213	0.135
5	8.8731	0.113
6	10.695	0.094
7	14.850	0.067
8	15.596	0.064
9	15.857	0.063
10	16.097	0.062

Mode shapes of the church, along with mass participation ratios, are illustrated in Table 5. Except for Mode 4, the modes given in the table show the existence of local behaviours. This situation manifests itself in lower mass participation ratios. The mode shapes indicate that out-of-plane behavior can be expected in the transverse arched frame systems and gable walls. In structures such as churches with large openings or high walls, it has been observed that mode shapes are mostly formed on individual walls rather than on the entire structure (Kılıç, 2025; Illimpas et al., 2020; Valente&Milani, 2018; Betti&Vignoli, 2011).

Table 5. Mode shapes, periods and mass participation ratios**.**

Mode number	Mode shape	Period (s)	Mass participation ratio (%)
Mode 3		0.157	5.6
Mode 4		0.135	28.2
Mode 5		0.113	8.6
Mode 8		0.064	4.0

Conclusion

In this study, preliminary experimental and numerical investigations carried out in a historical church affected by the 2023 Kahramanmaraş Earthquakes are described. The study ensures the attainment of the following main outputs.

- The 3D geometric model of the church was created using terrestrial laser scanning and photogrammetry.
- The damage to the church was understood through on-site observations.
- The compressive strengths of stone and mortar were obtained from non-destructive tests performed on these materials.
- A FEM model of the church was created using geometric and material data obtained from field measurements, and modal analysis of the church model was performed to obtain mode shapes and corresponding frequency values.

In future work, the church structure can be modeled with the micromodel approach and finite element analysis can be performed under real ground motion acceleration data.

Design and Comparison of Different Types of Reinforced Concrete Slab Systems for Multi-Storey Buildings

Ahmet Jabban[a], Kadir Güler[b]

[a]Istanbul Technical University, Graduate School, Earthquake Engineering Program,Türkiye.
[b]Istanbul Technical University, Civil Engineering Department, Türkiye
aljabban23@itu.edu.tr

Keywords: Dynamic Behavior, Multi-storey, Reinforced Concrete, Slab System.

Aim

The escalating demand for multi-storey buildings is a global phenomenon driven by relentless population growth, proliferation of smaller family units, and increasing preference for individual housing solutions. This trend is particularly acute in densely populated metropolitan regions such as Istanbul, where the imperative for efficient land utilization is paramount. The concentration of urban populations necessitates vertical expansion to accommodate residential and commercial needs, thereby mitigating encroachment on valuable land resources. Recent seismic events in Türkiye have highlighted critical vulnerabilities in structural design practices, underscoring the urgent need for reassessment of construction methodologies. The catastrophic earthquake of February 6, 2023, triggered a comprehensive investigation by Turkish scientists and engineers to meticulously identify design flaws and formulate strategies to prevent their recurrence. Properly engineered multi-storey buildings, incorporating advanced seismic resistance features, offer a viable solution for urban renewal and transform aging infrastructure into resilient, modern structures. Furthermore, these tragic events reinforced the indispensable role of rigorous numerical analyses and strict adherence to building codes to safeguard urban populations against seismic hazards. The enduring consequences of inadequate earthquake-resistant designs are profound, potentially impacting communities for generations.

The objective of this study is to conduct a comparative analysis of different slab designs in multi-storey reinforced concrete buildings, assess their respective seismic performance without undertaking a full design process, and explore the influence of diverse slab systems on structural behavior. The primary objective is to analyze the impact of slab design on critical structural parameters, ensuring compliance with the Turkish Building Earthquake Code 2018 (TBEC 2018), TS 498, TS 500 standards, and related American standards, including ASCE 7-16 and ACI 318. A comparative analysis of the distinct design methodologies for slabs, as delineated in these standards, will be conducted to highlight their respective strengths and limitations. A strength-based design approach utilizing the ETABS software will be employed to develop detailed three-dimensional building models, enabling a comprehensive assessment of structural behavior under seismic loads. Specifically, this study aims to determine the optimal slab system for seismic performance, as defined by TBEC 2018, and to evaluate the performance variations of different systems under a spectrum of earthquake intensities. For instance, while flat slab construction offers advantages in terms of rapid on-site construction speed in terms of preparing to pour concrete and architectural flexibility such as divide the internal space in different way or change it later, its contraction with unwanted characteristics, such as increased structural weight, necessitates a thorough comparison with alternative systems such as two-way slabs.

Material

The primary construction material utilized in this study was reinforced concrete of class C50, conforming to the stringent specifications outlined in TS 500. This material selection ensured a robust structural framework capable of withstanding significant loads. Steel reinforcement, specifically B500C, was employed for all primary structural components, including shear walls, columns, beams, and slabs. This high-grade reinforcement provided essential tensile strength and ductility, enhancing the overall seismic resistance of the building. The rebar steel specifications adhered meticulously to TS 708, guaranteeing data reliability and providing detailed guidelines on the mechanical properties and strength characteristics of

the materials used in the structural models. Adherence to established standards ensured the accuracy and validity of the research findings. The applied loads included a dead load of 2 kN/m² for the ground floor and 3.5 kN/m² for upper floors. The live load was 5 kN/m² on the ground floor and 2 5 kN/m² on upper floors, while 3.5 kN/m² was used in corridors and near staircases.

Method

A strength-based design methodology was implemented using ETABS software to develop comprehensive three-dimensional models of multi-storey the buildings. The structures consist of 17 floors with a total height of 58.9 meters and the general layout for all model as in (Figure 1). Four distinct models were created that differed only in the slab design each slab system have different thickness as list in (Table 1), and the other variables were kept the same, each characterized by unique vibration periods, weights, and dynamic behaviors. These variations allow for a thorough investigation of the influence of slab systems on structural response. Initial analyses were conducted to determine the internal forces within the structural elements using a strength-based method. Subsequently, the fundamental natural vibration period was determined and employed in the equivalent seismic load method. This method, utilizing DD-2 earthquake parameters derived from TBEC 2018, serves as the principal method for comparing storey displacements and evaluating structural performance. Finally, response spectrum analysis was performed by incorporating model combination techniques to achieve realistic and representative results. This comprehensive analytical approach ensured the reliability and accuracy of the findings.

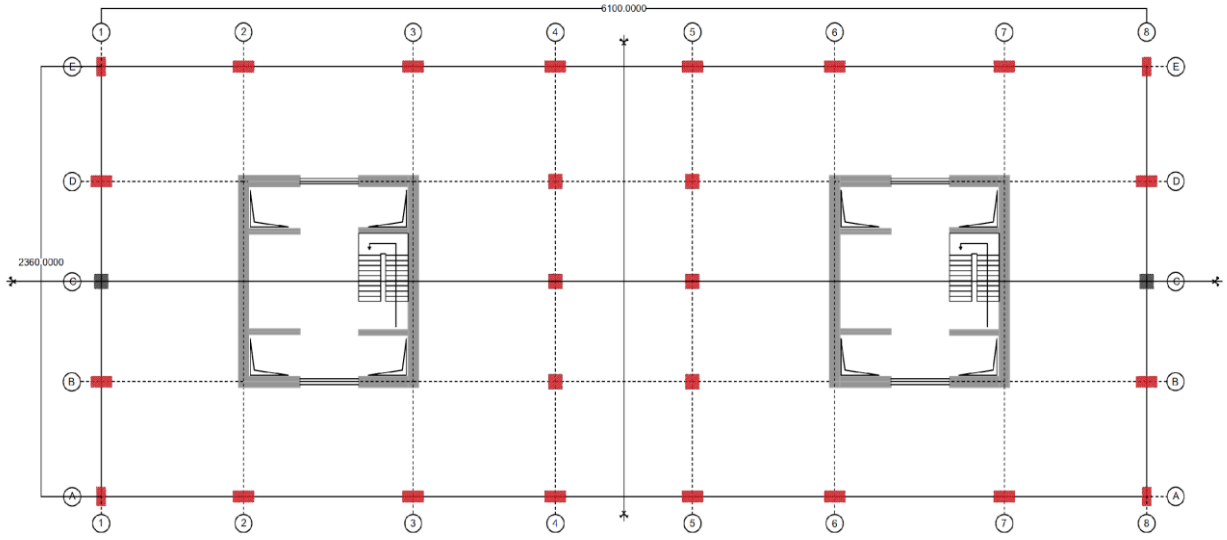

Figure 1. General structural layout.

Table 1. Model types and thicknesses of slab.

Model	Type of slab	Thickness
First	Flat slab without edge beams	32 cm
Second	Flat slab with edge beams	30 cm
Third	2-way slab	22cm
Fourth	2-way slab with cross beam	18cm

Findings

The study revealed that slab design exerts a profound influence on the rigidity and weight of structural systems, significantly affecting free vibration periods as illustrated for the first three mode in (Figure 2), and, consequently seismic behavior. Given that slabs constitute a substantial portion of a building's mass and area, their design critically affects the overall structural weight and rigidity. Notably, ACI 318 provides more detailed and nuanced specifications for flat slabs with perimeter beams compared to TS 500 and related standards, which treats flat slabs with or without beams in a generalized manner. This study demonstrated the advantages and disadvantages of each slab system with respect to storey drifts, weight, free vibration periods, and dynamic behavior. For example, flat slabs without spandrel beams exhibit lower rigidity, leading to increased story drifts and potentially compromising the structural stability under seismic loads. Conversely, two-way slab systems demonstrate enhanced resistance to deformation and story drift, indicating a superior seismic performance.

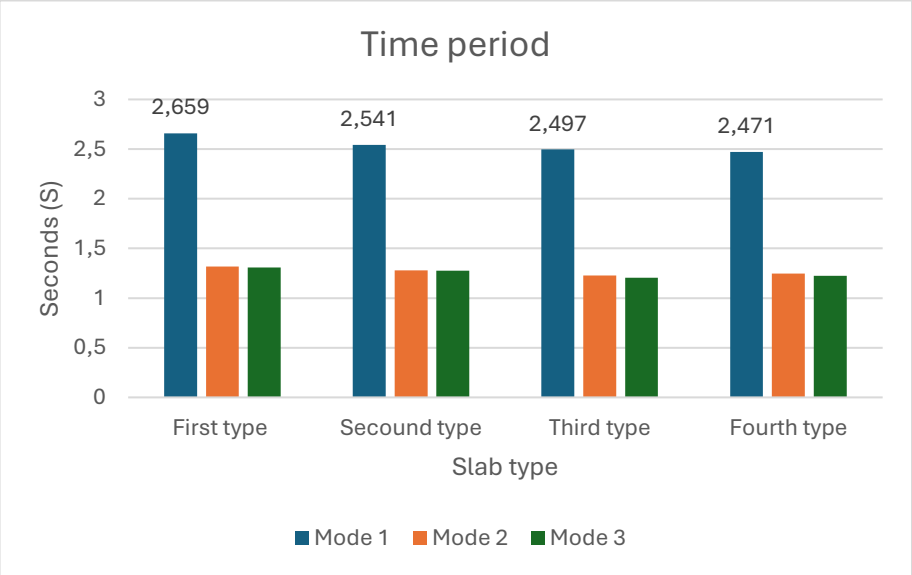

Figure 2. Free vibration mode periods for different slab types.

Conclusion

The findings of this research confirm the important role of rigidity and weight in structural systems, particularly in relation to free-vibration periods and seismic responses. This study provides a comprehensive analysis of the advantages and disadvantages of various slab systems, focusing on their impacts on story drifts, weight, free vibration periods, and dynamic behavior. Specifically, flat slabs without spandrel beams have lower rigidity and higher weight on the other hand adding spandrel beams to flat slab give the structural more resistance and lateral stability as, whereas two-way slab systems show superior resistance to deformations and story drifts with far less weight. As illustrated in (Figure 3 and 4**)**. Detailed comparisons and data illustrating the performance characteristics of each system were provided to enhance the understanding of the critical impact of slab design choices on structural performance and seismic resilience. This research provides valuable insights into the optimization of multi-storey building design, fostering the development of safer and more resilient urban infrastructures. Further studies are required to develop more information on each slab design, their effect on the nonlinear characteristics and dynamic behavior of each slab system, and how this will affect design decisions. Future research would benefit significantly from the inclusion of pushover or nonlinear time-history analyses to provide a more comprehensive understanding of the structural behavior of different slab systems under seismic loading. While the current study offers valuable insights based on linear elastic analysis methods, pushover analysis would enable the evaluation of progressive structural yielding and failure mechanisms specific to each slab system when subjected to incrementally increasing lateral loads. Additionally, nonlinear time-history analyses using suites of ground motion records would capture the complex dynamic responses and energy dissipation characteristics that are not fully represented in equivalent static or response spectrum methods.

Exploring the Biodiversity Patterns of Anatolia Under Changing Climatic Conditions

Batuhan Atıf Tunç[a], Emrah Çoraman[b]

Keywords: Biodiversity , Climate Change , Spatial Ecology , Species Distribution Models.

Aim

Global change and ecological crises are pressing issues threatening Earth's systems. Climate change and its effects on biodiversity present an urgent challenge to contemporary ecological research (Pereira et al., 2012). Anatolia, with its rich biodiversity, faces considerable uncertainty regarding how its ecosystems will respond to the challenges posed by global change (Ohlemüller et al., 2008; Trew & Maclean, 2021). The biodiversity of Anatolia remains underexplored, particulary in spatial terms. And we believe that spatial analyses provide crucial contributions to global change studies.
We aim to assess spatial biodiversity patterns of Anatolia and how these patterns evolve under changing climatic conditions. These assessments, though biologically coarse, are geographically detailed, and aim to explore climate-biodiversity relationships, inform conservation efforts, and most critically address the spatial biodiversity knowledge gap in Anatolia.

Materials and Methods

Correlative methods play a central role in analyzing the relationships between organisms and their environment. Among these, ecological niche modeling has been widely used by ecologists to model species distributions. Ecological niche models are mathematical frameworks that relate species occurrence records to environmental predictors, thereby allowing researchers to quantify and project species distributions (Guisan & Thuiller, 2005). Given its established utility in the field, we employed ecological niche models to examine the spatial biodiversity distribution patterns in Anatolia. We obtained biodiversity data from the Global Biodiversity Information Facility, an open-access repository that integrates datasets from various sources, including field studies and citizen science observations. The dataset consists of presence-only species occurrence records for Türkiye, covering amphibians, birds, insects, mammals and plants (GBIF.org, 2024a, 2024b, 2024c, 2024d, 2024e).
The environmental predictors in this study consist of 19 bioclimatic variables, which provide biologically meaningful representations of temperature and precipitation patterns. We obtained bioclimatic data from WorldClim 2 as the averages for the years 1970-2000 at 2.5 arc-minutes resolution (Fick & Hijmans, 2017). Future projections include the time periods 2041-2060 and 2081-2100, and the shared socio-economic pathways SSP1-2.6, SSP2-4.5, SSP3-7.0, SSP5-8.5 (Calvin et al., 2023). Future climate data were sourced from CMIP6 by averaging the outputs of six different models (Boucher et al., 2018; Peano et al., 2020; Shiogama et al., 2019; Tang et al., 2019; Volodin et al., 2019; von Storch et al., 2017). We chose these six models with the aim of representing different climate modeling approaches such as earth system models which take an holistic outlook to modeling and include many processes such as biogeochemical cycles, and global circulation models which model how air moves through the atmosphere, focusing on the physics of vortices.
After preparing the data, we fitted ecological niche models using split sample cross-validation with statistical and machine learning methods. The modeling approaches employed included Maxent, random forests, and boosted regression trees which are top performing methods in multi model benchmarks.

Maxent is a Bayesian inference method that provides the least biased probability distribution of the target variable given specified constraints set by the modeler (Jaynes, 1957a, 1957b; Phillips et al., 2006; Phillips & Dudík, 2008). Random forests are decision-tree based methods, in which multiple trees, that are fitted to bootstrapped subsamples of training data with random subsamples of predictor variables, are combined into an ensemble model (Breiman, 2001). Similarly, boosted regression trees are also decision-tree based models. However, in this approach, simpler trees are iteratively fitted, with each subsequent tree focusing on the remaining unexplained variance (Elith et al., 2008; Schapire, 2003).
We repeated the modeling process for each species and combined successful models into ensembles. The results were then aggregated by higher taxa to construct a biodiversity metric representing species richness. Finally we projected the models to future time periods under different climate scenarios and analyzes shifts in biodiversity patterns.

Findings

The results consist of ecological niche models for 519 species, including 5 amphibians, 118 birds, 126 insects, 5 mammalians, and 265 plants. These models reveal broad patterns of high biodiversity concentrated along the coastal regions of Türkiye, with notable variations in distribution patterns across taxonomic groups. In contrast, the inner Anatolia and southeastern Anatolia exhibit relatively low biodiversity. Among the taxa, insects exhibit the most pronounced deviations in biodiversity patterns, displaying particularly high biodiversity in northeastern Anatolia.
From a geographic perspective, the results highlight strong associations between high biodiversity patterns and environmental features such as water bodies, forested areas, and topographical complexity. When compared to biodiversity range maps from the International Union for Conservation of Nature (IUCN) (IUCN (International Union for Conservation of Nature), 2024)—despite fundamental differences in their objectives and methodologies—the two approaches show considerable agreement (Figure 1).

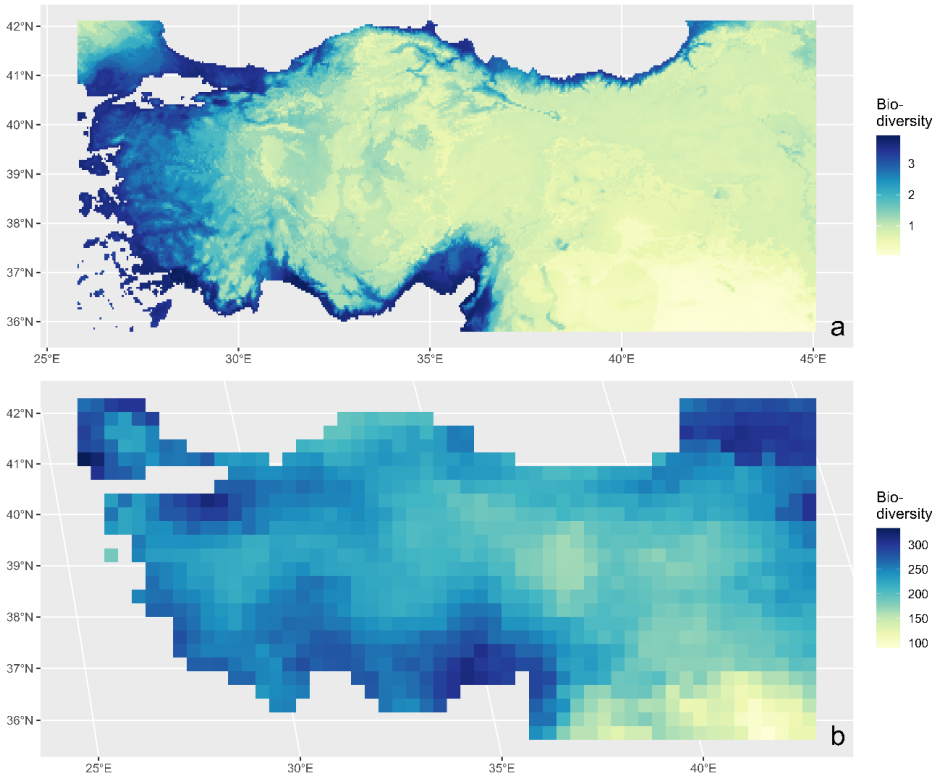

Figure 1. Species richness patterns in Anatolia based on a) ecological niche models for amphibians, birds, insects, mammals, reptiles; and b) IUCN biodiversity maps for amphibians, birds, mammals, reptiles. Note the differences in coordinate systems; this study employs WGS84, whereas the IUCN maps use the Mollweide projection.

Model projections under future climatic conditions indicate a general northward and northeastward shift in biodiversity patterns. These shifts become more pronounced over successive time periods and climate scenarios. Additionally, complex biodiversity patterns emerge around elevation gradients, water bodies, and forest cover, suggesting that these features play a critical role in shaping biodiversity patterns under changing climatic conditions.

Conclusion

In this study, we employed ecological niche models to map the spatial biodiversity patterns of Türkiye, addressing a notable gap in spatial approaches to biodiversity analyses in Anatolia. Our results highlight the coastal regions of Türkiye as high biodiversity areas and the inner Anatolia and southeastern Anatolia as low biodiversity areas across different taxa. Projections under future climate scenarios indicate biodiversity shifts toward the north and northeast. Additionally, geographical features such as elevation gradients, water bodies, and forest cover play a critical role in shaping biodiversity patterns, particularly in the context of climate change. This study contributes to our understanding of how climate change may shape the spatial distributions of biodiversity in Anatolia.We anticipate that this study will contribute to future research, enhance biodiversity studies in Anatolia, and support conservation decision-making.

Defining the Character of Turkey's Biodiversity Policies

Süleyman İlteber Uçar[a]

[a]Istanbul Technical University, Eurasia Institute of Earth Sciences, Geoanthropology Program, Türkiye
ucars22@itu.edu.tr

Keywords: Biodiversity Policies of Turkey, International Agreements, Policy Adoption, Semi-Periphery, World-Systems Analysis.

Aim

This study aims to examine the characteristics of Turkey's biodiversity policies and assess its adoption process of international biodiversity agreements. In order to do that, the study analyzes the international agreements to which Turkey has signed, assessing the extent and pace of their implementation. Furthermore, using World-Systems Analysis as a framework, this study investigates whether Turkey's semi-peripheral position in the global economic system influences its approach to biodiversity-related policies. By doing so, it seeks to deepen our understanding of how economic dynamics shape societies' relationships with the environment. In other words, this study aims to demonstrate that the position and role of countries within the global economic system are key factors influencing environmental policies, particularly biodiversity policies, in the case of Turkey.

Material and Methods

This study examines the extent and pace of Turkey's implementation of international biodiversity agreements by analyzing official documents, national policy reports, and external evaluations. The agreements under review include but are not limited to the Ramsar Convention, the Convention on Biological Diversity (CBD), and CITES.

The research focuses on three key aspects. First, the signing and ratification timelines of the agreements. The study examines the years in which Turkey signed and ratified these agreements to determine whether it has acted as an early or late adopter in comparison to other nations. Second, performance of implementation. The study reviews national reports published by the Turkish government, including policy documents, strategy reports, and implementation updates, to assess the extent to which commitments under these agreements have been fulfilled. Additionally, independent evaluations conducted by international organizations and research institutions are considered to provide a broader assessment of Turkey's compliance. Third, using World-Systems Analysis as an analytical framework. The study applies Wallerstein's classification of world systems to contextualize Turkey's policy adoption behavior. A literature review is being conducted on World-Systems Analysis to examine how Turkey's position as a semi-peripheral country influences its biodiversity policies.

The analysis follows a qualitative approach, utilizing document analysis to track Turkey's policy progress. Key indicators outlined in each agreement are examined to measure the degree of implementation, considering factors such as the number of completed policy actions, established conservation targets, and compliance with reporting obligations. Additionally, the timing of implementation is assessed by comparing the gap between ratification and concrete policy action that helps to identify whether commitments were fulfilled promptly or delayed over extended periods. By integrating World-Systems Analysis, this study examines whether Turkey's delayed adoption of biodiversity policies results from structural constraints tied to its semi-peripheral status in the global system or other internal political and economic factors. This framework allows for a deeper understanding of whether Turkey's position in the world economy has contributed to its classification in biodiversity governance.

Findings

The preliminary findings suggest that Turkey has signed some agreements generally close to other semi-peripheral countries like Argentina, Brazil, and Spain. For instance, Turkey ratified the CBD in 1996, making it the 166th country to do so, while Argentina, Brazil, and Spain ratified it in 1993 and 1994 (Convention on Biological Diversity, n.d.). Similarly, Turkey ratified the CITES in 1996, whereas Argentina, Brazil, and Spain signed it in 1981, 1975, 1986 respectively (CITES, n.d.). In the case of the Ramsar Convention, Turkey became a party in 1994, while Argentina, Brazil, and Spain joined in 1992, 1993, 1982 respectively (Ramsar Convention, 2023). Although these ratification dates are generally close among semi-peripheral countries, Turkey has approved these agreements later than core countries, reflecting a pattern of delayed commitment. Although legal regulations and policies have been introduced to fulfill the obligations of these agreements, there are gaps in implementation (OECD, 2019). The country often falls behind the targets set by these agreements, and sometimes policies that contradict these targets are also adopted. For example, while protected areas have been designated for wetland conservation, new projects that could put pressure on these areas continue to be proposed (Arslan, Çiçek, Döndüren, Ernoul, 2021; Doğa Derneği, 2024). This situation may be explained by Turkey's limited institutional capacity and the priority given to economic development goals.

World-Systems Analysis explains the hierarchical structure of the global economy. According to this approach, the world is divided into core countries, which have advanced industries and strong institutions; peripheral countries, which are low-income, dependent economies based on raw material trade; and semi-peripheral countries, which share characteristics of both. These countries have progressed in industrialization but are not as politically strong as core countries, and their environmental policies are often shaped by economic priorities (Wallerstein, 2004).

From a World-Systems Analysis perspective, the economic development efforts of semi-peripheral countries have a significant impact on their environmental performance. Frame (2019) suggests that industrialization pressures in semi-peripheral countries increase raw material production and trade, leading to greater environmental degradation. Turkey is classified as a semi-peripheral country (Babones, 2005; Cairó-i-Céspedes & Palacios Cívico, 2022), and its development model, which prioritizes economic growth, may explain why environmental and biodiversity policies lag behind. Its participation in international agreements is also shaped by economic concerns and limited institutional capacity (Turhan, Cerit Mazlum, Şahin, Şorman, & Gündoğan, 2016).

Conclusion

The findings indicate that Turkey's adoption of international biodiversity agreements aligns with other semi-peripheral countries but lags behind core nations. While legal and policy frameworks have been established to meet international commitments, implementation remains inconsistent. I argue that these challenges may stem from limited institutional capacity and the dominance of economic development priorities.

Using World-Systems Analysis as a framework, this study suggests that Turkey's semi-peripheral status influences its biodiversity policies. Similar to other semi-peripheral countries, Turkey faces industrialization pressures that drive resource exploitation, potentially hindering effective environmental governance. The analysis highlights how economic position within the global system can shape a country's commitment to biodiversity policies. By examining Turkey's case, this study seeks to deepen our understanding of how economic dynamics shape societies' relationships with the environment, demonstrating that biodiversity governance is not solely a matter of policy choices but also of broader economic structures.

ECONOMY

Financial Crises and Macroprudential Policies

Financial Contagion: Dynamic Correlations Approach

Esra Çakır[a]

[a] Istanbul Technical University, Economics Program (MA), Türkiye
cakires19@itu.edu.tr

Keywords: Dynamic Correlations, Financial Contagion, Stock Markets, Volatility Transmission.

Aim

Globalization has strengthened financial market linkages over time. However, this development has also increased the vulnerability of the global financial system to cross-market shock transmission. In this context, the following questions become crucial for market participants, policymakers, and academicians: Do shocks in one market lead to greater volatility in others? Is volatility transmitted across financial assets? Are the effects of positive and negative shocks symmetric? Do correlations change over time, particularly during crises?

Despite the extensive literature on asset market linkages and shock transmission, there is no single definition of financial contagion. Generally, both theoretical and empirical studies define contagion as "a significant increase in cross-market linkages after a shock" (Claessens, S., & Forbes, K., 2013, p.44). Broadly, three main approaches have been employed to test for contagion: correlation analysis, ARCH-type models and copula-based models. A wide body of research has examined contagion effects across countries and periods by using different methodologies and focusing on various financial shocks, analyzing equities, bonds, currencies, and commodities (see King & Wadhwani, 1990; Baig & Goldfajn, 1999; Longin & Solnik, 1995; Dimitriou et al., 2013).

The existence of a higher degree of co-movement in the financial markets during the period of instability leads to several challenges for agents since the lower correlation between financial assets means higher diversification benefit and the lower the portfolio risk (Porras, E. R., 2016). Therefore, understanding these additional linkages (if it exists) which emerge during the crisis periods is crucial. In this context, this study aims to investigate the presence of financial contagion by modeling time-varying correlations between the U.S. and Fragile Five stock markets using a DCC-MGARCH framework. The empirical analysis focuses on two episodes of financial turmoil: the Global Financial Crisis (GFC) and the post-COVID-19 Federal Reserve policy shock.

Material and Method

Volatility modeling originated with the Autoregressive Conditional Heteroskedasticity (ARCH) model introduced by Engle (1982) and subsequently extended to the Generalized ARCH (GARCH) model by Bollerslev (1986). Over time, these models have evolved into a broad family of ARCH-type frameworks that are widely applied in financial market analysis (Bollerslev, 2008).

Multivariate GARCH (MV-GARCH) models have been widely used to model volatility transmission. These models enable the analysis of interrelationships between financial markets by capturing not only the mean but also the variance of the variables (Aydemir, 2021). Building on Bollerslev's (1990) constant correlation model, Engle (2002) introduced the DCC-GARCH framework, which allows for the analysis of time-varying correlations.

In this framework, the DCC-MGARCH model is employed to examine contagion between the U.S. and Fragile Five stock markets using daily return data from January 2007 to December 2022. The analysis focuses on two crises: the Global Financial Crisis (*September 2008)* and the 2022 Fed Policy Shock (*March 2022*), which followed the COVID-19 pandemic and marked the beginning of an aggressive monetary tightening cycle. These periods were selected due to their origin in the U.S., which allows for the examination of potential contagion from the U.S. to the Fragile Five economies. The stock indices analyzed include the BIST 100 (Turkey), BOVESPA (Brazil), SENSEX (India), IDX (Indonesia), FTSE/JSE (South Africa), and the S&P 500 (U.S.). Data obtained from DataStream.

Findings

Firstly, the daily returns are calculated as a percentage log difference. Figures 1 and 2 display the price and returns of the stock indices.

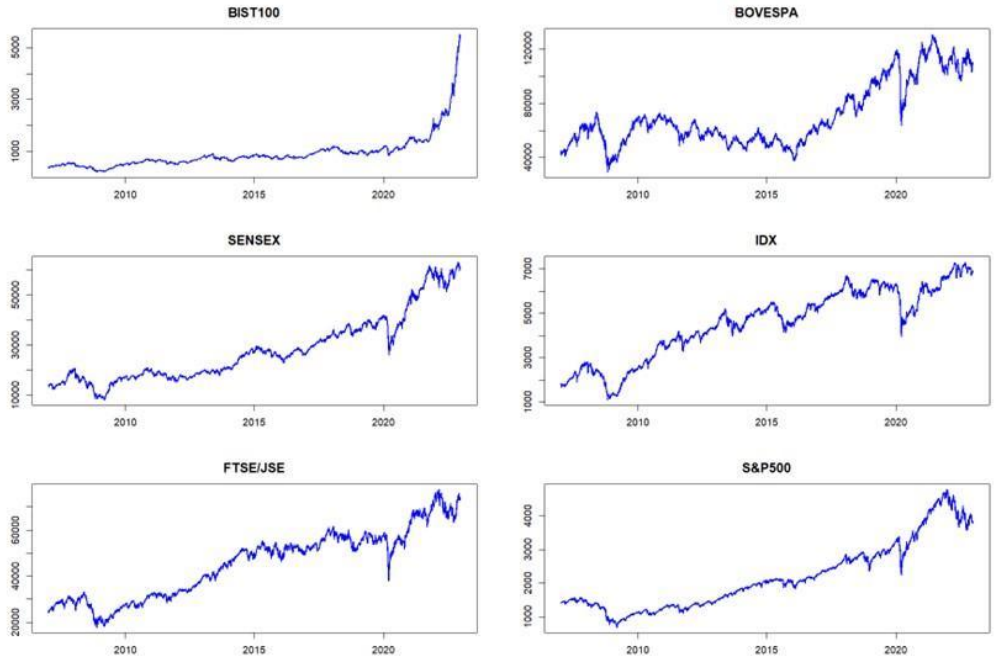

Figure 1: Time series plots of stock indices for S&P 500 and Fragile Five.

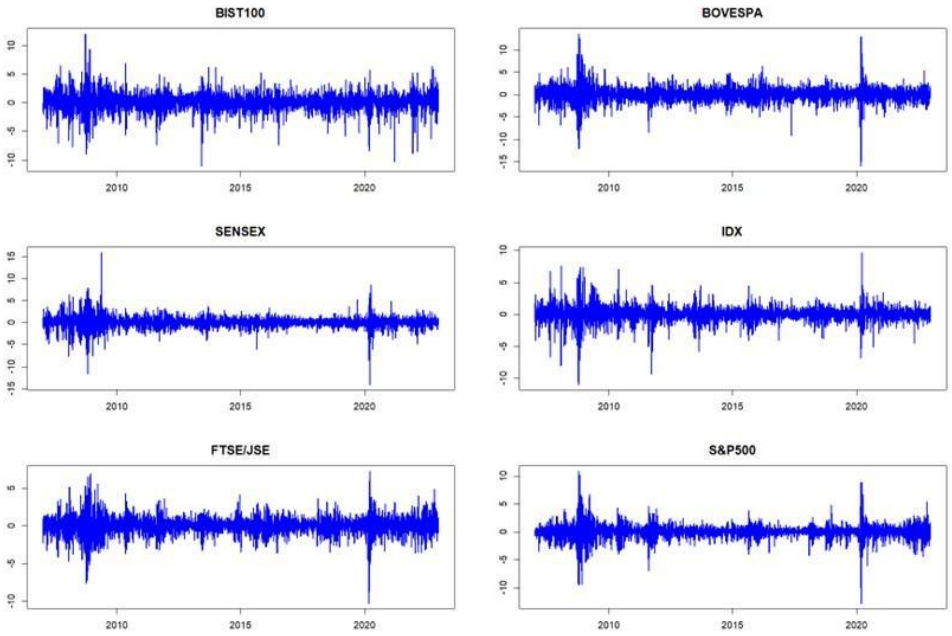

Figure 2: Time series plots of stock returns for S&P 500 and Fragile Five.

Descriptive statistics for the return series are presented in Table 1. The return series demonstrate common characteristics observed in financial time series: they are stationary, non-normally distributed, and exhibit negative skewness and excess kurtosis. The Jarque-Bera tests confirm the departure from normality, while the Augmented Dickey-Fuller (ADF) tests indicate stationarity. Additionally, the Box-Ljung tests applied to both raw returns and squared returns reveal the presence of serial correlation and volatility clustering, respectively. Furthermore, significant ARCH effects detected by ARCH-LM tests suggest the presence of conditional heteroskedasticity. These findings strongly justify the use of GARCH-type models.

Table 2 shows the estimation results of DCC-GARCH models for each US-Fragile Five country pairs. An AR(1)-GARCH(1,1) specification is employed for all return series for simplicity. Also, DCC parameters, which are obtained the conditional standard deviations derived from the first stage, are presented. Model adequacy is assessed based on parameter significance, diagnostic test outcomes, and theoretical constraints such as the positivity of variance parameters. Since normal distribution hypothesis is rejected for all returns, student t distribution is used. The changes in DCC during the crisis periods can be observed in Figure 3.

Table 2: DCC model estimation results.

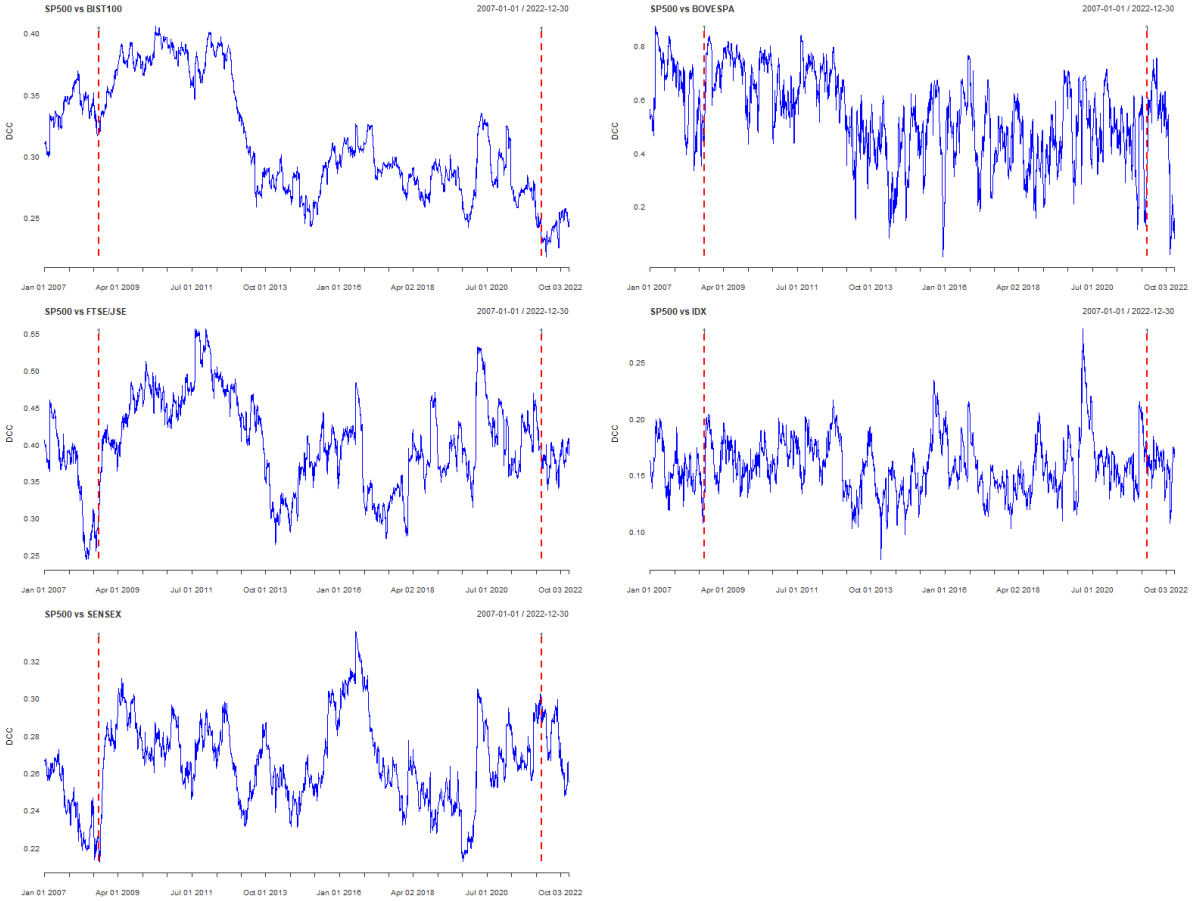

Figure 3: DCCs for stock returns.

Conclusion

The empirical findings of this study provide strong evidence of financial contagion from the U.S. to the Fragile Five stock markets. The DCC-GARCH model results indicate statistically significant increases in dynamic correlations across most market pairs. The DCC plots visually confirm these findings, with notable spikes in correlations. During the Global Financial Crisis, sharp increases are observed across nearly all markets, particularly for Brazil, India and South Africa. Similarly, the 2022 Fed policy shock is associated with moderate increases in correlations, most notably in Brazil and South Africa, indicating some sensitivity to U.S. market movements, though less pronounced than during the Global Financial Crisis.

However, the standard symmetric GARCH (1,1) model may not fully capture volatility behavior, especially in emerging markets. During periods of financial instability, returns often respond differently to positive and negative shocks. A more flexible model, such as EGARCH or APARCH, which allows for asymmetry in volatility, may capture these effects more accurately and improve models.

Future research could also examine how other shocks impact the Fragile Five, as well as how contagion patterns evolve across different stages of a crisis (e.g., early, peak, recovery). It would also be interesting to explore the determinants of dynamic conditional correlations - one of the major debates in literature. For example, examining the role of different types of funds and other financial intermediaries could be interesting, particularly in emerging markets, to assess the presence of financial panics or herding behavior during the crisis periods.

Keywords : Nuclear Energy, Net-Zero Emissions, PLEXOS, Energy Security, Grid Stability.

Aim

The global pursuit of net-zero emissions has intensified the demand for reliable, low-carbon energy sources. Nuclear energy, characterized by stable, dispatchable electricity generation, emerges as a critical solution. Nuclear energy accounts for approximately 9% of global electricity production, generating around 2,600 TWh annually and preventing approximately 2.1 billion tons of CO_2 emissions each year, playing a critical role in the transition to low-carbon energy (World Nuclear Association, 2024). This study evaluates the importance of nuclear energy and its potential contributions to Türkiye's energy transition process.

Türkiye's electricity generation is largely dependent on fossil fuel imports. Although renewable energy accounts for approximately 42% of electricity generation, energy supply security remains a significant concern (Republic of Türkiye Ministry of Energy, 2023). Fluctuations in fossil fuel prices and supply disruptions threaten energy security. To address these issues, Türkiye aims to achieve net-zero emissions by 2053. As part of this target, the Akkuyu Nuclear Power Plant (4,800 MW) is being commissioned, and once fully operational, it is expected to meet approximately 10% of Türkiye's electricity demand (Güler & Kavaz, 2023). Additionally, the İğneada Nuclear Power Plant is also planned, with a total capacity of 5,300 MW, further enhancing Türkiye's clean energy capacity and supporting the country's net-zero ambitions.

This study investigates the techno-economic integration of nuclear energy into Türkiye's electricity system, specifically focusing on the Akkuyu and İğneada Nuclear Power Plants. Using PLEXOS, a sophisticated energy modeling tool, the research assesses the impact of nuclear power on energy security, fossil fuel dependency, and grid stability. The analysis includes scenario-based simulations, exploring various configurations of nuclear and renewable energy. Findings indicate that nuclear power enhances energy reliability while supporting Türkiye's net-zero goals.

This study aims to evaluate the techno-economic integration of nuclear energy into Türkiye's electricity grid, with a specific focus on the Akkuyu and İğneada Nuclear Power Plants. This project does not advocate for a pro-nuclear approach; instead, it objectively and scientifically analyzes the advantages and disadvantages of nuclear energy. The objectives are to:

- Assess the role of nuclear energy in enhancing energy security and grid stability.
- Investigate the economic viability of nuclear energy in the Turkish context.
- Analyze the potential of nuclear energy to reduce carbon emissions. The analysis is conducted using PLEXOS, leveraging real-world data from EPİAŞ, TEİAŞ, and international energy reports.

Material and Method

This study employs the PLEXOS software platform, a robust tool for power system optimization, to explore the impact of nuclear energy integration within Türkiye's electricity system. The analysis begins with the development of three scenarios: a base scenario without nuclear energy, a scenario integrating the Akkuyu Nuclear Power Plant, and a third scenario including both Akkuyu and İğneada Nuclear Power Plants. These scenarios are designed to capture the range of possible outcomes, from a non-nuclear future to a nuclear-dominated energy mix.

The model incorporates fixed capacities for existing power plants across various fuel types, including coal, natural gas, hydro, solar, wind, and nuclear. These capacities are held constant for 2024, while electricity demand is projected to grow at an annual rate of 3.49%, as indicated by the TR-Power Report (Kat, 2021). Real-world data from EPİAŞ and TEİAŞ provide insights into generation and consumption patterns, while international sources, such as the International Energy Agency (IEA), inform fuel prices and demand forecasts (IEA, 2022).

The optimization process utilizes a combination of Linear Programming (LP) for cost minimization, Mixed-Integer Programming (MIP) for generator scheduling, and Quadratic Programming for complex growth modeling. Shadow pricing is applied to co-optimize energy and reserves.

The outputs of the model include generation profiles, offer prices, pool revenue, net revenue, and CO_2 emission intensity for each scenario. These results provide a comprehensive understanding of the economic and environmental implications of nuclear energy integration in Türkiye.

Findings

The scenario analysis reveals the following numerical results (2024-2049):

Table 1. Comparative Analysis of Scenario-Based Results for Türkiye's Electricity System (2024-2049).

Scenario	Average Offer Price ($/MWh)	Total Pool Revenue ($ Billion)	Total Net Revenue ($ Billion)	CO_2 Emission Intensity (tCO_2/GWh)
Base With Nuclear (Akkuyu)	84.67	6.51	4.83	473.24
Base With Nuclear (Akkuyu + İğneada)	75.43	6.60	4.93	460.87
Base Without Nuclear (NoN)	62.15	5.91	5.34	482.51

Table 2. Annual Electricity Generation for the Base Without Nuclear Scenario (2024-2049).

Base Without Nuclear NoN_medGR	Fiscal Year	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038	2039	2040	2041	2042	2043	2044	2045	2046	2047	2048	2049
	Generation (TWh)	361	371	381	391	402	411	420	430	440	448	458	467	478	486	496	505	516	524	534	543	554	562	572	581	592	600

Table 3. Annual Electricity Generation for the Base With Nuclear Scenario (Akkuyu) (2024-2049).

Base With Nuclear BAU_medGR Akkuyu	Fiscal Year	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038	2039	2040	2041	2042	2043	2044	2045	2046	2047	2048	2049
	Generation (TWh)	361	371	381	392	402	411	420	430	440	449	458	467	478	487	496	506	517	526	536	547	559	568	579	589	602	611

Table 4. Annual Electricity Generation for the Base With Nuclear Scenario (Akkuyu + İğneada) (2024-2049).

Base With Nuclear BAU_medGR Akkuyu + İğneada	Fiscal Year	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038	2039	2040	2041	2042	2043	2044	2045	2046	2047	2048	2049
	Generation (TWh)	361	371	381	392	402	411	420	430	440	449	458	472	490	501	511	521	533	541	552	562	574	584	594	605	618	628

In the "Base With Nuclear BAU_medGR Akkuyu" scenario, the presence of Akkuyu Nuclear Power Plant ensures consistent and substantial electricity production over the years. As a stable and reliable baseload source, nuclear energy provides continuous generation, unaffected by external factors like fuel price volatility or weather conditions. This stability translates into a steady increase in production, supporting energy security and maintaining grid reliability.

The "Base With Nuclear BAU_medGR Akkuyu + İğneada" scenario further amplifies this effect by incorporating the İğneada Nuclear Power Plant, leading to a significant boost in total electricity generation, particularly after 2035 when İğneada is fully operational. The combined output of the two nuclear plants not only enhances energy supply security but also increases the overall share of low-carbon electricity in the generation mix. This dual-nuclear setup demonstrates the critical role of nuclear energy in achieving consistent and reliable electricity supply.

In contrast, the "Base Without Nuclear NoN_medGR" scenario exhibits a more volatile production pattern. This is primarily due to the reliance on a mix of fossil fuel and renewable energy sources. Fossil fuel plants are susceptible to market price fluctuations, while renewable sources such as wind and solar are inherently variable, depending on weather conditions. This combination leads to irregular production patterns, with lower overall generation compared to the nuclear scenarios. The lack of nuclear energy's stable baseload contribution highlights the challenges of achieving a balanced and secure energy supply without nuclear power.

The scenario-based average offer prices reveal notable differences between the nuclear and non-nuclear scenarios. In the "Base With Nuclear BAU_medGR Akkuyu" scenario, the average offer price is $84.67/MWh, reflecting the high fixed costs associated with nuclear power, including construction, maintenance, and staffing. Although nuclear plants provide stable and continuous generation, their inflexibility in adjusting prices results in higher average offer prices.

The addition of the İğneada Nuclear Power Plant in the "Base With Nuclear BAU_medGR Akkuyu + İğneada" scenario leads to a reduced average offer price of $75.43/MWh. This reduction is due to the higher total production, which helps spread the fixed costs across more generated electricity, effectively lowering the cost per unit.

In contrast, the "Base Without Nuclear NoN_medGR" scenario exhibits the lowest average offer price at $62.15/MWh. This is primarily because fossil fuel and renewable energy plants can operate with more flexible pricing strategies. Renewables, such as wind and solar, generate electricity at nearly zero marginal cost, contributing to a lower overall average offer price in this scenario.

Total pool revenue is highest in the scenario with both Akkuyu and İğneada, benefiting from increased production capacity. However, net revenue is slightly lower in nuclear scenarios due to the high fixed costs associated with nuclear plants, including construction and maintenance expenses. Despite this, the nuclear scenarios exhibit significantly lower CO_2 emission intensity, highlighting their environmental advantage. The Akkuyu + İğneada scenario achieves the lowest emission intensity, demonstrating the significant role of nuclear energy in reducing carbon emissions and enhancing sustainability.

Conclusion

Nuclear energy significantly contributes to Türkiye's energy transition by providing stable, low-carbon electricity. This study demonstrated that integrating nuclear power, particularly through the Akkuyu and İğneada Nuclear Power Plants, offers notable benefits for energy security, grid stability, and carbon emission reduction. Scenario analysis revealed that nuclear-inclusive scenarios deliver higher average electricity generation and lower CO_2 emissions compared to non-nuclear scenarios, supporting Türkiye's net-zero target for 2053.

Despite high fixed costs, nuclear energy maintains competitiveness due to its stable generation and high capacity factors. The analysis highlighted a trade-off between reliable electricity supply and economic profitability, with nuclear scenarios having slightly lower net revenues due to their significant capital costs.

Environmental benefits were evident, with the lowest CO_2 emission intensity in the scenario including both Akkuyu and İğneada. This supports Türkiye's climate targets and emphasizes nuclear power's role in decarbonization. The PLEXOS model further demonstrated that nuclear energy enhances grid reliability, providing a stable supply regardless of external conditions, unlike the variability of renewable sources.

Future research should refine the model by incorporating capacity growth rates for each power plant, enhancing cost analysis with dynamic CO_2 shadow prices, and improving simulation accuracy using regional demand growth rates. Scenario-specific CO_2 emission factors should be developed, and machine learning techniques could be employed to model growth rates of demand and power plant capacities.

Overall, this study offers a balanced evaluation of nuclear energy's potential in Türkiye's electricity system, highlighting its benefits for energy security and emission reduction while acknowledging its economic and regulatory challenges.

Investigation of the Effect of Space Vector PWM Technique on Zero-Sequence Voltage Formation in Open-End Windings

Arda Tüfekçi[a,b], İlker Şahin[b] , Derya Ahmet Kocabaş[a]

tufekci22@itu.edu.tr

Keywords : Circulating Current, Open-end Windings, Zero-sequence Voltage.

Open-end winding Permanent Magnet Synchronous Machine (OEW-PMSM) drives offer several advantages over traditional star-connected configurations, making them a preferred choice in various high-performance applications. Their benefits include an extended modulation range, multilevel voltage characteristics, and enhanced fault tolerance, all of which contribute to improved system performance and reliability. However, these advantages come with increased complexity, particularly in the form of zero-sequence voltage (ZSV) formation and its associated zero-sequence current (ZSC). ZSV arises due to multiple factors, including modulation strategies, dead-time effects, machine harmonics, and inverter nonlinearities [1]. If not properly controlled, ZSV can lead to circulating currents, increased power losses, and degraded machine efficiency. In non-isolated systems where the inverters share a common DC bus, the presence of ZSV exacerbates these issues, making it a critical factor in system design and control.

Aim

The primary aim of this study is to analyze the formation of ZSV in OEW-PMSM drives under different modulation strategies and identify key sources contributing to its occurrence. Specifically, the research seeks to investigate how one of the most commonly used pulse- width modulation (PWM) techniques influence ZSV generation, examine the effects of different modulation angle pairs (0-120°, 0-150°, and 0-180°) between the inverters on ZSV behavior, and identify the contributions of dead-time effects, machine harmonics, and inverter nonlinearities to ZSV formation [1,2]. Additionally, the study aims to validate these findings through experimental testing to determine optimal strategies for minimizing ZSV. By addressing these objectives, this study provides valuable insights into the underlying mechanisms of ZSV formation and offers guidance on selecting effective modulation strategies to mitigate its impact. Understanding these interactions is essential for improving the efficiency and operational stability of OEW-PMSM drives, enabling their wider adoption in applications where high performance and reliability are paramount.

Material and Method

The OEW-PMSM drive system consists of an Open-end Winding Permanent Magnet Synchronous Machine (PMSM), supplied by two independent voltage source inverters (VSIs). The two inverters (inverter-1 and inverter-2) operate synchronously to generate the desired voltage waveforms while maintaining precise control over the motor's torque and speed. The experimental setup consists of an OEW-PMSM drive controlled by a dual-inverter configuration. An oscilloscope, high voltage differential probes were used to measure ZSV levels, as well as a current probe to capture phase current.

$$u_{a12} = (u_{a10} - u_{a20}) \quad (1)$$
$$u_0 = (u_{a12} + u_{b12} + u_{c12})/3 \quad (2)$$

In (1), ua10 is the voltage of phase-to-ground for phase a of inverter-1. (2) is used for scope captures, u0 is the zero-sequence voltage from inverter-side which equals to sum of voltage of phases across machine divided by three.

Key Contributors to ZSV Formation

To systematically analyze ZSV formation, several key sources were considered, including dead-time effects, machine harmonics, and inverter nonlinearities. Dead time is introduced in inverter switching to prevent short circuits between power devices, but it causes voltage distortions that lead to unwanted ZSV components. Machine harmonics, particularly the third harmonic in back-EMF, contribute to circulating currents and additional ZSV, further degrading system performance. Additionally, inverter nonlinearities such as switching device voltage drops and non-ideal switching transitions introduce small but significant distortions, further influencing ZSV behavior. After presenting key contributors of zero-sequence voltage, equation for ZSV is provided below.

$$u_0 = R_s i_0 + L_0 \frac{di_0}{dt} - 3\omega_r \psi_0 \, sin \, sin \, (3\theta_e) \, i_0 \qquad (3)$$

In (3), u0 is zero-sequence voltage (ZSV), i0 is circulating current (ZSC), L0 is zero-sequence inductance, ψ0 is the amplitude third-harmonic flux linkage, Rs is stator resistance, ωr is rotor angular velocity, θe is electrical angle.

Modulation Strategies

The study focuses on the most common modulation technique: Space Vector PWM (SVPWM), which is an advanced technique that optimizes switching sequences to improve voltage utilization and overall system performance. In this study, three different SVPWM modulation angle pairs between the inverters: 0-120°, 0-150°, and 0-180° modulation [3]. Each angle pair affects the synchronization and interaction between the two inverters, significantly impacting the resulting ZSV levels and the operational efficiency of the OEW-PMSM drive.

Influence of Dead-Time Effects

Despite improvements achieved through modulation angle selection, dead-time effects remain a persistent source of ZSV. Dead-time voltage errors are highly dependent on current polarity and switching sequence, leading to the introduction of unwanted ZSV components at every switching cycle [4]. Therefore, the magnitude of dead-time-induced ZSV varies with switching frequency and dead-time itself, making it a dynamic challenge in system performance. Even with optimal modulation strategies, dead-time effects cannot be fully eliminated, emphasizing the need for compensation techniques to mitigate their impact and improve overall drive efficiency.

Contribution of Machine Harmonics to ZSV

Machine harmonics, particularly third harmonic components in back-EMF, introduce additional circulating currents, which contribute to ZSV formation [3]. The study finds that the presence of third harmonic components increases ZSV ripple, negatively impacting system performance. Additionally, these harmonics interact with inverter switching states, sometimes amplifying the effects of dead-time distortions, further exacerbating ZSV issues. To mitigate these effects, filtering or compensation techniques may be necessary to suppress harmonic-induced ZSV, ensuring improved drive efficiency and stability.

Findings

The analysis of the three SVPWM modulation angles reveals that 0-120° modulation provides the lowest ZSV RMS values making it the most effective choice for minimizing ZSV formation. In contrast, 0-150° and 0-180° modulations result in higher ZSV due to increased switching interactions and harmonic content which amplify circulating currents and voltage distortions. These findings emphasize that proper modulation angle selection plays a crucial role in reducing ZSV, demonstrating that choosing the right SVPWM modulation angle is just as important as the modulation technique itself in optimizing OEW-PMSM drive performance.

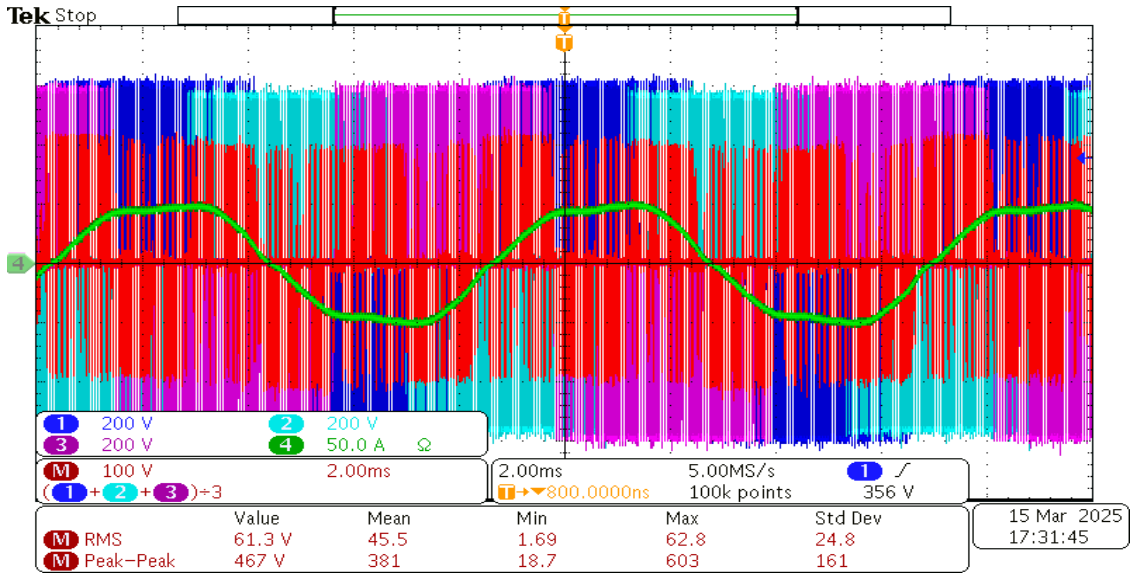

Figure 1. Space Vector PWM with 0-120°.

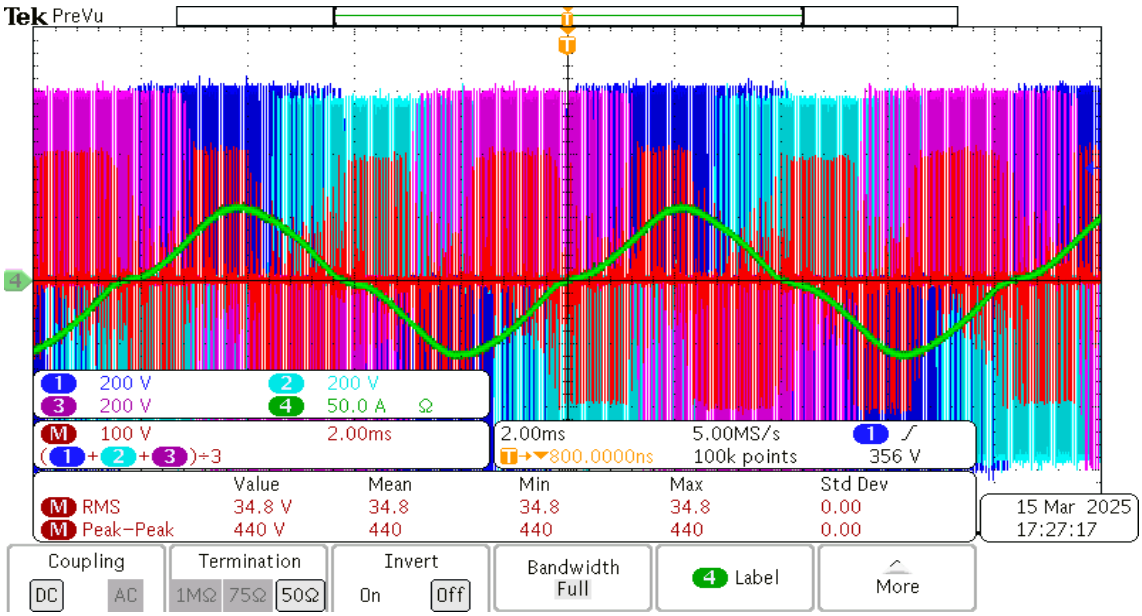

Figure 2. Space Vector PWM with 0-150°.

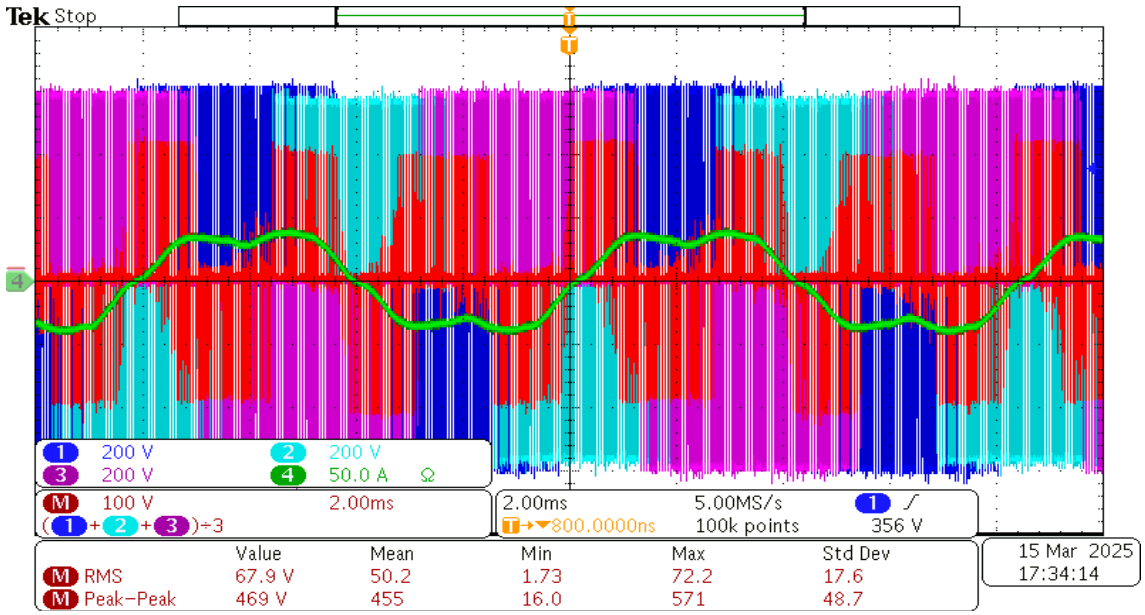

Figure 3. Space Vector PWM with 0-180°.

Table 1: Comparison of Modulation Angles.

Modulation	ZSV RMS (V)	ZSV PP (V)
SVPWM 0-120°	34.8	440
SVPWM 0-150°	61.3	467
SVPWM 0-180°	67.9	469

Conclusion

This study systematically investigates the formation of zero-sequence voltage (ZSV) in open-end winding PMSM drives, analyzing the effects of different modulation strategies and identifying key contributors to ZSV generation. The findings demonstrate that: Modulation strategy significantly affects ZSV formation, with 0-120° modulation providing the lowest RMS ZSV values. Dead-time effects remain a persistent challenge, introducing unavoidable ZSV components due to switching delays in the inverter legs. Selecting the appropriate modulation angle pair (e.g., 0-120°) is crucial for minimizing ZSV, as it helps balancing inverter switching states and reducing unwanted interactions. While 0-120° modulation was found to be the most effective in reducing ZSV, although it does not completely eliminate it. Future research should explore dead-time compensation techniques, advanced harmonic suppression methods, and alternative inverter topologies to further mitigate ZSV and enhance OEW-PMSM drive performance. Additionally, adaptive control strategies that dynamically adjust modulation parameters based on operating conditions could provide further improvements in minimizing ZSV-related issues. Understanding the interactions between modulation strategies, machine harmonics, and inverter nonlinearities is essential for optimizing OEW-PMSM drives. By carefully selecting modulation parameters and compensating for known sources of ZSV and ZSC, engineers can enhance system efficiency, reduce power losses, and

improve the reliability of OEW-PMSM-based applications.

Determination of Altitude Dependent Insulation Breakdown of Brushed DC Starter Generators

Ayşe Nur Köklü Ulusoy[a], Derya Ahmet Kocabaş[a]

[a] Istanbul Technical University/Department of Electrical Engineering, Turkey
koklu15@itu.edu.tr

Keywords: DC Starter Generator, Altitude-dependent, Insulation Breakdown, Electrostatic Analysis.

Aim

Brushed direct current (DC) machines have a widespread market application in Unmanned Aerial Vehicles (UAVs) and small-scale aircraft because of their compact size, economical price, and easily controllable capabilities. Brushed DC machines are mostly used as starter generators in aircraft engine starters and electrical power generation systems. Aircraft operate at different altitudes, which presents several changes in environmental conditions. Aircraft must be able to operate all components safely at all operating altitudes. Therefore, it is important that starter generators can operate safely under variable environmental conditions, maintaining both functionality and insulation integrity. Change in altitude, air pressure, ambient temperature, and relative humidity result in significant insulation breakdowns, and poses a great danger to the reliability and safety of operation.

This study aims to examine the potential consequences of attitude dependent environmental changes on the winding insulation of brushed DC starter generators from an electrostatic view which is one of the most important components of aircraft electrical power systems. The objective is to understand the relationship between altitude-dependent environmental variables and brushed DC starter generator insulation failures like winding-to-winding and winding-to-frame insulation failure.

Material and Method

This study presents a simulation-based approach. ANSYS Maxwell 2D Electrostatic solution is used as a simulation environment. ANSYS Maxwell 2D is a Finite Element Method (FEM) based simulation software used to perform two-dimensional analysis of electromagnetic devices, especially effective in the design and optimization of systems based on magnetic fields such as motors, transformers, and actuators. FEM is used in numerical solutions to engineering and physics problems. It helps to model the characteristics of the components in complex systems by dividing the structure or system into many small and finite element parts and solving differential equations on these elements.

In the simulation, a two-dimensional model of a separately excited brushed DC machine was created. In the electric machine model, field windings, armature windings, and auxiliary windings were detailed. Various insulation defects were created separately in the field, as well as in the armature and auxiliary windings. Insulation defects were simulated as gaps, tears, and microcracks between the winding and between the winding and the body.

These insulation defects were analyzed in terms of electric fields at different altitudes. The altitude variable was simulated by the dielectric constant of the insulator materials in the brushed DC starter generator design. The environmental conditions changing with altitude were determined as air pressure, temperature, and relative humidity. The dielectric constant of the insulator materials was calculated for each altitude level depending on the air pressure, temperature, relative humidity parameters in the air gap, and the relative humidity parameter in the winding insulators and simulations were performed. Polyimide material, which is frequently used in space and aviation applications, was preferred for winding insulations. The reason for performing the analysis of the polyimide material only depending on the humidity parameter is that the temperature and air pressure parameters do not cause a significant change in the polyimide dielectric constant. International Standard Atmosphere data were used for the altitude-dependent humidity, temperature, and ambient pressure data. The dielectric coefficient calculation of the air gap was performed with the formula given in Equation 1, which is also based on

the International Standard Atmosphere data. Simulations were performed for altitudes of 10,000 ft, 20,000 ft, 30,000 ft, and 40,000 ft, and the electric field distributions in various parts of the machine at these levels were examined.

$$\varepsilon_{hava} = \varepsilon_0 \cdot \left[1 + \frac{311}{T}\left(P + \frac{48\,P_s}{T}\,RH\right)10^{-6}\right] \quad (1)$$

Findings

Various damages were created in the windings of the brushed shunt DC starter generator and simulations were performed at different altitudes with these damages to investigate the electric field distributions. The electric field distributions were compared for each deformation and altitude value. The results showed that insulation deterioration was significantly affected by altitude changes. Analysis results showed that as altitude increases, the dielectric strength of the air decreases, thus decreasing the insulating properties and increasing the possibility of an insulation breakdown at lower voltages compared to ground level. In addition, it was observed that the dielectric strength of the winding insulations decreased to a certain altitude and then increased up. The dielectric strength of the winding insulation material polyimide is directly related to the relative humidity, and as the humidity increases, the dielectric constant increases. While the relative humidity decreases up to 30,000 ft, it increases from 30,000 ft to 40,000 ft. Therefore, the dielectric strength of polyimide decreases up to 30,000 ft and increases from 30,000 ft to 40,000 ft.

When this situation is evaluated in terms of starter generators, it is predicted that the possibility of insulation damage will increase due to high currents passing through the armature windings in cases where the engine needs to be started at high altitudes. It has been evaluated that this situation may cause the starter generator to become unable to start the engine and may negatively affect flight and operational safety by not being able to start the engine. In addition, it has been evaluated that the possibility of a short circuit in the windings and frame increases when the starter generators are in generator operating mode, which may lead to system failures and power loss.

Conclusion

The study confirms that altitude changes play a critical role in insulation defect induced breakdown and short circuit events in brushed shunt DC starter generators, which are commonly used in aviation. These findings highlight the need for improved insulation materials or protective coatings that can withstand variable altitude and therefore variable weather conditions. The results demonstrate the importance of selecting advanced insulation materials for high altitude applications and suggest that predictive maintenance strategies can help extend the operational life of starter generators and increase reliability.

Future studies should focus on developing predictive models using machine learning techniques to assess insulation degradation trends in real time. Additionally, research should continue the use of advanced nanocomposites and hybrid insulation systems to increase insulation life and reliability. Implementation of real time monitoring systems to monitor insulation health will help prevent electrical failures that may occur during flight by providing early fault detection.

Development And Validation Of A Dynamic Energy Consumption Model For A 12-Meter Electric Bus Using SORT-2 Test Data

Mehmed Demirtaş[a], Mehmet Onur Gülbahçe[a]

[b] Istanbul Technical University, Department of Electrical Engineering, Türkiye
demirtasm15@itu.edu.tr

Keywords: Dynamic Modelling, Electric Bus, Energy Consumption Model, Sustainable Transportation.

Aim

The growing use of electric buses in the transportation sector presents a significant opportunity to reduce environmental impacts, particularly in urban areas where air pollution and carbon emissions from traditional vehicles are a major concern. However, to fully utilize their potential, accurate and reliable consumption calculations are necessary.

The aim of this study is to develop a dynamic model of a 12-meter electric bus and to compare its energy consumption with SORT-2 data to validate the model's accuracy. By building a comprehensive model that represents the electric bus's energy usage, this study aims to verify how closely the predicted consumption aligns with actual test data. Modeling the energy efficiency of electric buses accurately provides critical insights for both manufacturers and consumers. This can contribute to designing more efficient buses, enhancing battery life, and lowering operational costs. In this context, one of the primary objectives of the study is to validate the model by comparing its output with real-time data from actual bus operations, focusing on driving cycles that reflect real-world conditions. Another objective of this study is to adapt the model to different driving profiles and road conditions. By incorporating realistic driving scenarios into the model, a more robust and reliable understanding of energy consumption patterns can be achieved.

Material and Method

The bus dynamic model is developed in this study in MATLAB. The input parameters of the model represents energy consumption in kWh and km. Additionally, a comparison between the developed model and the real-world data collected during SORT-2 tests will be conducted.

Energy consumption calculations for electric buses are usually validated using specific tests and standards. For passenger vehicles, the WLTP (Worldwide Harmonized Light-Duty Vehicles Test Procedure) standard is commonly used, while for buses, SORT (Standardized On- Road Test) tests are utilized. The SORT tests are divided into three categories: SORT 1, SORT 2, and SORT 3 (UITP, 2017). In this study, the real data collected during the SORT 2 test will be used for the 12-meter electric bus.

In the model, it is essential to calculate the distance traveled by the bus to determine the energy consumption accurately. Average speed and the time the bus has been in motion will be used as input parameters. The model will integrate these parameters with SORT test data to ensure that the simulation reflects real-world driving behavior.

Moreover, the model primarily calculates energy consumption by analyzing the bus's instantaneous voltage and the current flowing into and out of the battery. Energy consumption in electric buses depends largely on the electrical components of the drive system, including the battery, electric motor, power electronics, thermal management systems. The model will take into account these components' performance under different operational conditions, such as acceleration, deceleration, and cruising.

During motion, vehicles encounter various resistance forces that must be overcome by engine power. Reducing these resistances enhances energy efficiency and extends the driving range in electric vehicles. A vehicle experiences four primary resistance forces: aerodynamic resistance, rolling resistance, hill resistance, and acceleration resistance. To replicate real-world driving conditions, these resistances are applied during operation (Karakaş, Şeker, & Solmaz, 2021). The effect of

wind, which directly influences the vehicle's energy consumption, has been neglected in this study which aligns with the SORT-2 test conditions. Since the SORT-2 test is conducted on a flat road, gradient resistance is neglected, and the model has been developed accordingly. Moreover, the application of different driving dynamics will increase the vehicle's energy consumption due to the forces caused by the road gradient. On inclined roads, the gradient can be included as an input parameter in the model, allowing for its impact on energy consumption to be assessed.

A study has investigated the impact of internal losses in high-voltage lithium-ion batteries on EV range estimation and proposed a method to predict these losses by integrating a vehicle consumption model with trip-based data and a battery model that accounts for future losses based on the control strategy's predicted energy use (Enthaler & Gauterin, 2013). In the battery model of this study, a battery cell with the same chemistry as that used in the 12-meter electric bus was tested under different temperatures. The Hybrid Pulse Power Characterization (HPPC) test was conducted. Although various types of HPPC tests are defined in the literature, the methodologies described in the study by Christophersen (2015) were adopted for this study.

For accurate energy consumption estimation, an appropriate relationship between electric motor power and applied force must be established. Efficiencies of the electric motor, the inverter for the electric motor, and the DC-DC converter are also taken into account. Furthermore, there are other high-voltage components that may influence energy consumption, such as HVAC (heating, ventilation, and air conditioning), pre-heater, and BTMS (battery thermal management system). However, these components are not considered in the SORT-2 test.

Findings

The model developed and tested according to the SORT-2 duty cycle data. Comparison between the model and the SORT-2 data is essential since it allows to identify any discrepancies between the predicted energy consumption and the actual performance of the bus.

The results show that there is a 4.55% difference between the energy consumption obtained from the vehicle's dynamic model and the SORT-2 data. Despite a minor discrepancy, the model demonstrates a high level of accuracy in predicting energy consumption based on the SORT-2 test. It is important to note that discrepancies between modeled and measured data can arise from factors such as sensor calibration, road conditions, and real-time adjustments that are difficult to replicate in simulations. Nonetheless, the close match suggests that the model provides a reliable estimate of the energy consumption for the 12-meter electric bus.

Conclusion

This study developed a bus dynamic model to predict the energy consumption of a 12-meter electric bus. The model's accuracy was successfully tested by comparing the results with real-world data from the SORT-2 test. This validation demonstrates the model's reliability and usefulness for manufacturers. The findings suggest that accurate energy consumption models can contribute to improved fleet management, better cost forecasting, and a more sustainable transportation infrastructure.

Moving forward, the model's accuracy can be further enhanced using different driving cycles. By incorporating additional real-world data and refining the model through continuous feedback, its predictive capability can be improved. This model will aid in more accurate energy efficiency predictions for electric buses and will serve as a valuable reference for future research in this field. Incorporating additional high- voltage components such as HVAC, pre-heaters, and BTMS into the model would further enhance its accuracy. With continued advancements in data collection and modeling techniques, future models are expected to be even more precise, enabling greater optimization of electric bus fleets and reduced overall energy consumption.

Three Phase LLC Resonant DC/DC Charger for Railway Applications

Abdulkadir Balikçi[a], Murat Gümüş[a]

[a] Gebze Technical University/Institute of Science, Engineering Department, Electronic Engineering, Turkey
a.balikci@gtu.edu.tr, muratgumus150@gmail.com

Keywords: Three Phase System, LLC Converter , Multiphase Converter.

This study introduces the topology of a three-phase LLC resonant converter design. The three-phase LLC resonant converter retains the advantages of conventional LLC resonant converters, such as zero-voltage switching (ZVS) on the primary side, zero-current switching (ZCS) on the secondary side, high-frequency operation capability, and high efficiency. Additionally, it offers unique benefits beyond those of traditional LLC converters, including reduced output capacitor current ripple, natural current sharing among the three resonant currents, and suitability for high-power applications. Due to these features, LLC topology is widely used in electric vehicle charging systems, server power supplies, and other high-power applications.

However, as power levels increase, the input voltage tends to be higher to reduce conduction losses, and the output current also rises. This creates challenges in transformer design, as higher currents lead to increased core and copper losses, making heat dissipation more difficult. Three phase transformer provides a direct and effective solution to this issue. By employing three phase transformers with primary windings connected in series and secondary windings connected in parallel, primary voltage stress and secondary current stress can be reduced, while output current distribution is improved.

Aim

The traditional LLC resonant converter is among the most widely adopted resonant topologies due to its ability to achieve soft switching and maintain high efficiency across the entire load range. Nonetheless, in high-current scenarios, the single-phase LLC converter exhibits certain limitations. Specifically, the output capacitor is subjected to substantial current ripple, which can impose significant stress. As a result, a large output filter capacitor is typically required to mitigate these ripple effects. To overcome these issues, multiphase LLC resonant converters offer notable benefits over their single-phase counterparts. By distributing the total load current across multiple phases, conduction losses are reduced, and thermal stress on power components is alleviated. Furthermore, when three identical sinusoidal waveforms with 120° phase displacement are rectified, the resulting output exhibits significantly lower ripple, enhancing filter performance. A schematic of the three-phase LLC resonant converter is shown below.

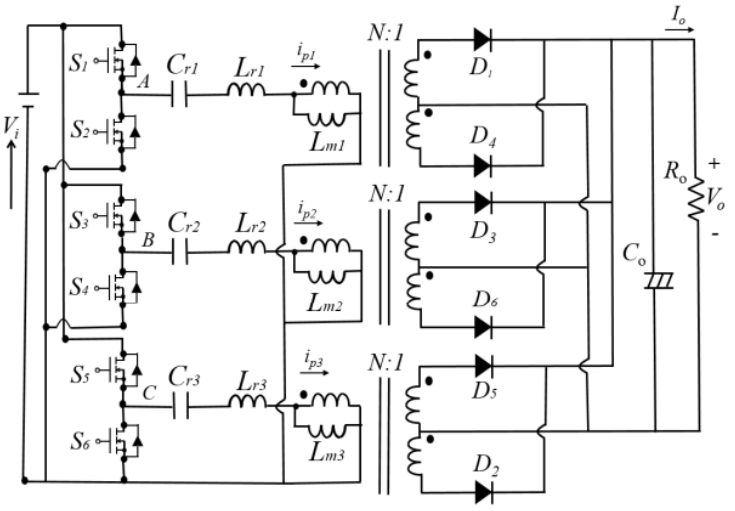

Figure 1. Three-phase LLC resonant converter with three-discrete transformers.

The Resonant Tank system Gain depending on frequency is shown below.

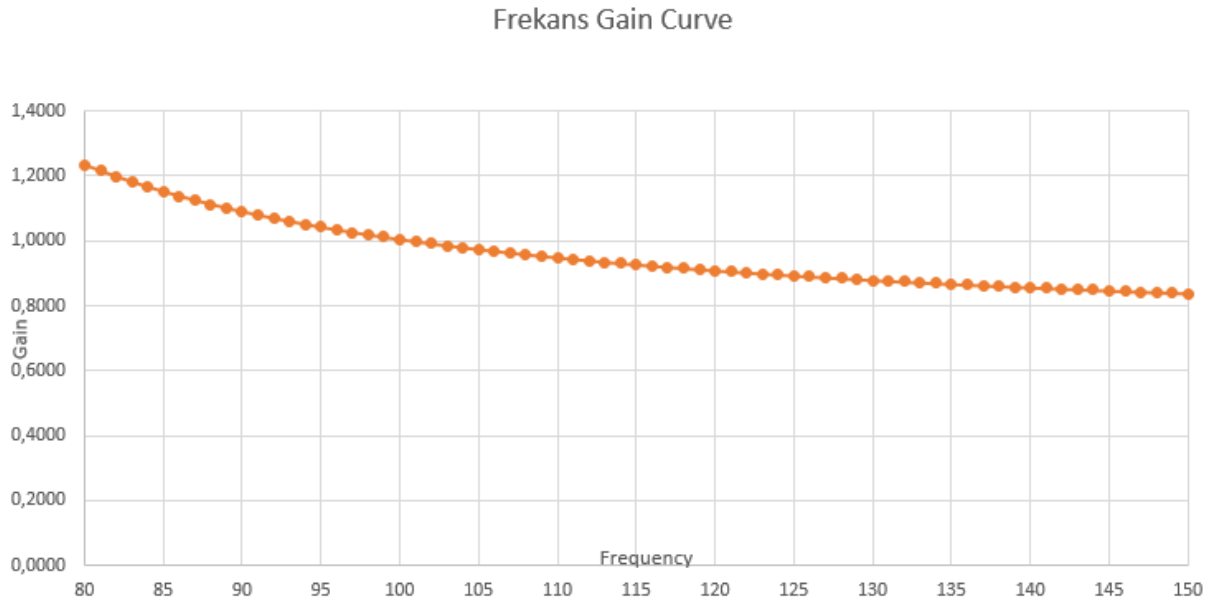

Figure 2. Three-phase LLC resonant converter Gain Curve.

Material and Method

The resonant inductor, capacitor, transformer ratio and other components required for the Three Phase LLC Resonant Converter Design are given in Table 1.

Table 1. Resonance Tank and Other Components.

Component	Value
Resonance Inductance (Lr)	47µH
Resonance Capacitor	56nF
Transformer Ratio	5:1
Operating Frequency Range	80kHz-150KHz
Resonance Frequency	~100KHz
Input Voltage	600V DC
Output Voltage	77.5V-110V
Output Current	60A

As a result of the simulation study performed with the LTspice program with these values, the Transformer Primary Current waveform appears as in the Figure.

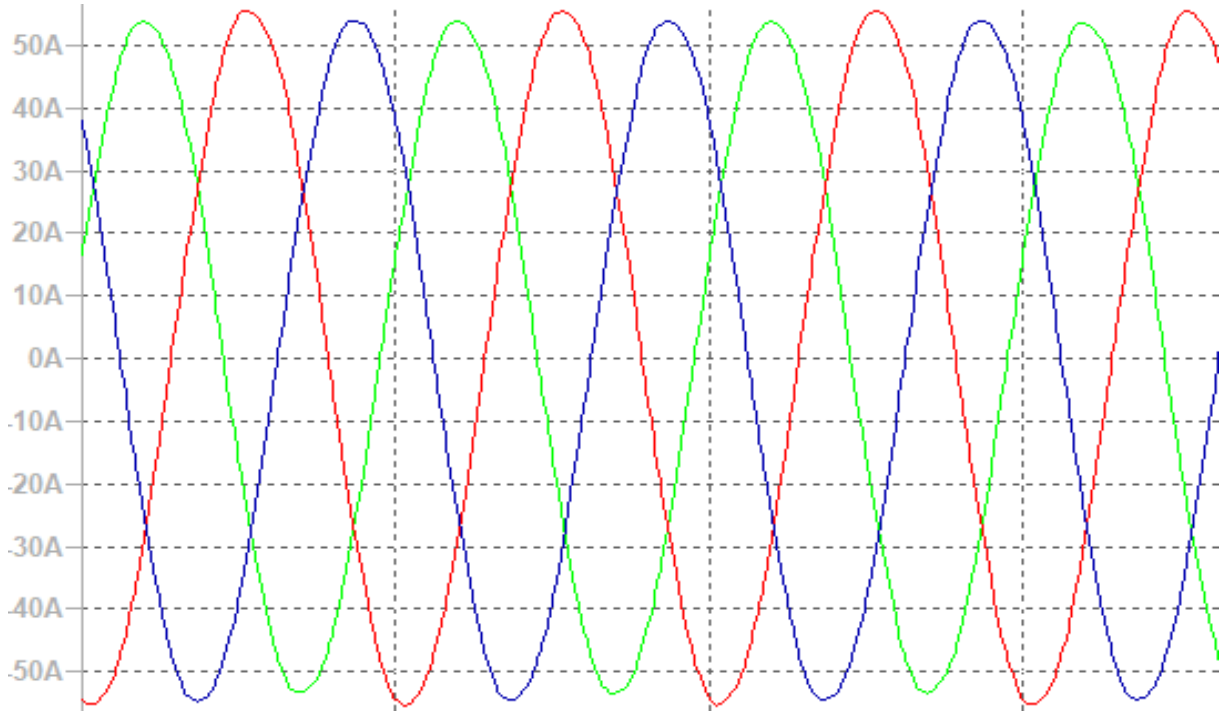

Figure 3. Current Wave of Three Transformer Primary Current.

Findings

Single and three phase LLC Resonant Converter analyses were performed using the LTSpice program. These analyses show that the output load resistance and output capacity of single LLC and three phase LLC Resonant Converters are the same. Therefore, the output current ripple of the three phase Resonant Converter was compared with the single LLC converter. According to the comparison result, the output voltage ripple can be seen in the visual below.

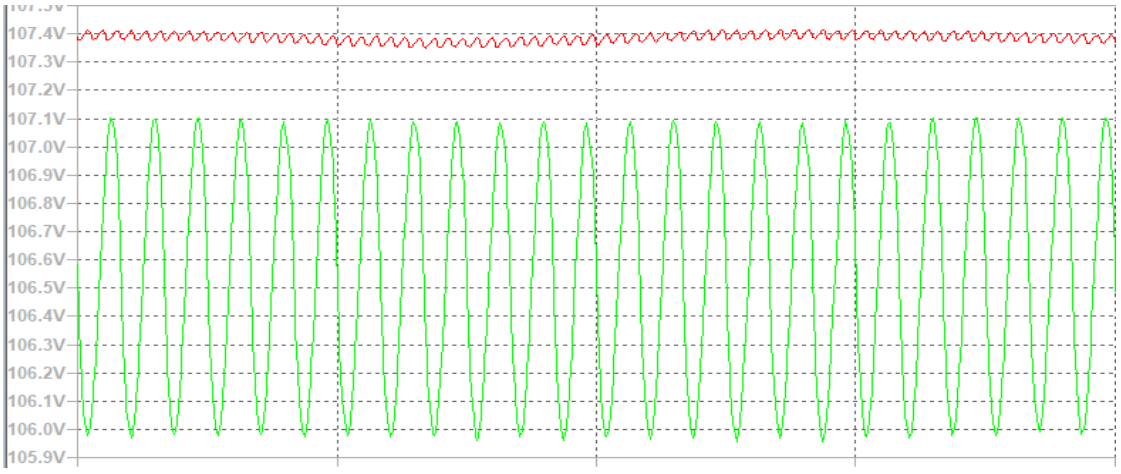

Figure 4. Green: Single Phase LLC Output Voltage Ripple, Red: Three Phase LLC Output Voltage Ripple.

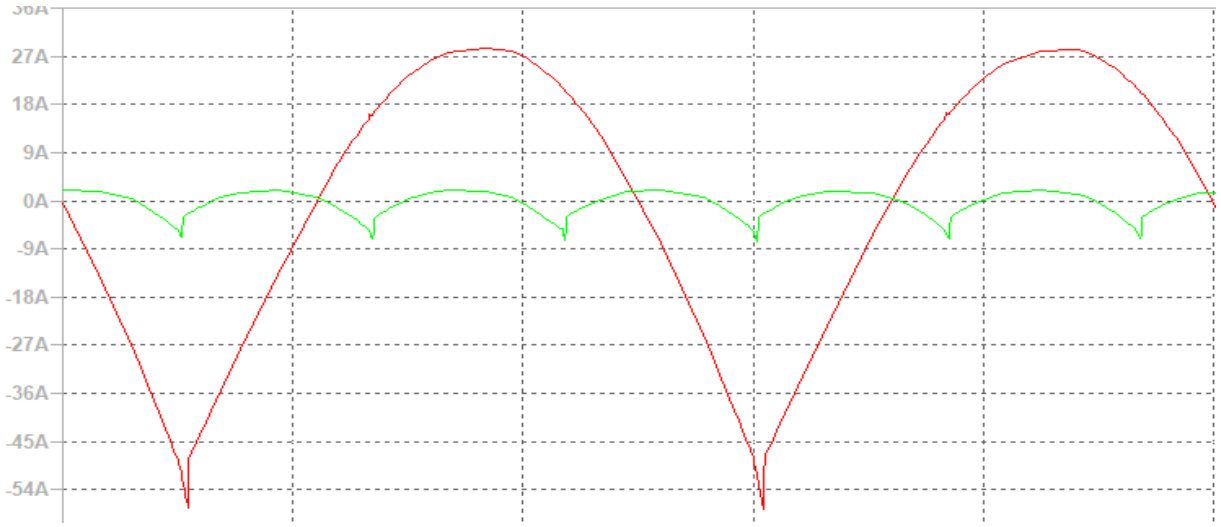

Figure 5. Output Capacitor Current, Green: Three Phase LLC, Red: Single Phase LLC.

Conclusion

As a result of the study carried out using the LTspice program, both input and output current ripple were minimized with the three phase LLC resonant converter. As a result, the capacity requirement used in traditional LLC converters was reduced. As a result, the electrolytic capacity requirement in DCDC converters is eliminated.

A Real-Time Resonance Detection and Mitigation Method for Shunt Active Power Filters

Ramazan Berkan Tut[a], Veysel Tutku Buyukdegirmenci[b], Mustak Erhan Yalcin[c]

[a] Istanbul Technical University, Electronics and Communication Engineering, Graduate Program, Turkiye
tut23@itu.edu.tr

Keywords: Active Power Filter, Harmonic Filtering, Resonance Mitigation, Resonance Damping, Filter Instabilities.

Aim

This study aims to present a novel real-time resonance detection and mitigation technique tailored for shunt active power filters (APFs), which are integral to enhancing power quality in industrial systems. These filters can become unstable in the presence of capacitive and resonant loads, necessitating a dynamic approach to ensure continuous and reliable operation. The primary goal is to develop an adaptive control mechanism that preserves system stability under varying load conditions.

Material and Method

The research is based on the modeling of a three-phase, three-wire power system that includes a supply transformer, a shunt APF modeled as a controlled current source, and nonlinear loads. Resonance conditions were investigated using the following equations:

$SH = 3 * \Sigma(Vh * Ih)$
$Jh = h * HDvh * HDih$

Here, SH represents harmonic apparent power, and Jh is an objective function formed by harmonic distortion components. The proposed method introduces a supervisory control algorithm with closed-loop selective harmonic filtering using finite gain integrators. The filtering rate is adaptively tuned via a perturb-and-observe (P&O) strategy. Validation was performed through both simulations in PLECS and hardware experiments using a 100 kVA laboratory APF prototype.

Findings

Simulation outcomes demonstrate a significant reduction in harmonic distortion under resonant conditions. Specifically, the proposed method enabled the APF to maintain THDi levels below 7%, even with highly capacitive loading. Experimental results supported these findings, showing effective resonance identification and mitigation within two grid cycles. The adaptive control strategy dynamically adjusted the virtual damping resistor and successfully suppressed harmonic amplification.

Conclusion

The proposed method provides a reliable solution to resonance-induced instabilities in shunt APFs. By leveraging a harmonic power-based detection strategy and a dynamic adaptive control framework, the system enhances operational robustness in fluctuating grid environments. This advancement is a step forward for power quality management in modern power electronics. Future work will explore machine learning integration for predictive damping and expansion to multi-inverter systems and microgrid applications.

Adaptation of a Generalized Observer Scheme for False Data Injection Detection in Load Frequency Control Systems

Arslan Mete Baybars[1], Fikret Çalışkan[2], V.M. İstemihan Genç[1]

[1]Istanbul Technical University, Faculty of Electrical and Electronics, Department of Electrical Engineering
[2]Istanbul Technical University, Faculty of Electrical and Electronics, Department of Control and Automation Engineering
baybars@itu.edu.tr, caliskanf@itu.edu.tr, gencis@itu.edu.tr

Keywords : False Data Injection (FDI), Load Frequency Control, Generalized Observer Scheme, Residual Analysis.

Aim

The aim of this study is to adapt and evaluate a Generalized Observer Scheme (GOS), originally designed for sensor fault detection, for the purpose of detecting false data injection (FDI) attacks in a two-area Load Frequency Control (LFC) system. The approach leverages a bank of Unknown Input Observers (UIOs) to monitor critical measurement signals, including frequency deviations in both control areas and tie-line power flow.

By analyzing the behavior of residual norms under various FDI scenarios, the study seeks to determine whether the observer-based framework can successfully identify malicious data injections that target specific measurement channels. Particular attention is given to the structure and interpretability of residual signals, as well as the potential limitations of conventional threshold-based detection logic in detecting stealthy or short-lived anomalies.

The study ultimately aims to demonstrate that observer-based monitoring systems—when properly adapted—can serve as an effective cyber-security layer in modern power systems, capable of enhancing detection robustness without requiring major changes to system architecture.

Material and Method

In this study, a two-area Load Frequency Control (LFC) system is modeled using MATLAB/Simulink to evaluate the capability of an observer-based approach in detecting false data injection (FDI) attacks. Each control area includes primary components of load frequency dynamics, namely the governor, turbine, and generator, as well as frequency deviation feedback and tie-line power exchange between areas. The model tracks three critical measurements: frequency deviations in Area 1 (Δf_1), Area 2 (Δf_2), and the tie-line power flow (ΔP_{12}).

To detect anomalies in these measurements, a Generalized Observer Scheme (GOS) is employed. This structure consists of a bank of Unknown Input Observers (UIOs), where each observer is designed to be insensitive (decoupled) to unknown disturbances such as load changes, but sensitive to anomalies in specific measurement channels. While traditionally applied to sensor fault detection, in this study, the GOS framework is adapted for identifying FDI attacks that mimic sensor anomalies by injecting falsified data into communication channels.

FDI attacks are introduced into the system by artificially manipulating the measurement signals. Each attack scenario targets one signal at a time (Δf_1, Δf_2, or ΔP_{12}) and is implemented as an additive deviation, with controlled amplitude and timing to simulate a stealthy intrusion. These injected values are designed to preserve overall system dynamics superficially, making detection challenging under conventional methods.

The residual output of each observer is continuously monitored, and norms of each residual vector is computed in real-time. Three separate simulation scenarios are carried out, each corresponding to an FDI attack on a different measurement signal. The performance of the detection structure is evaluated by observing the residual norms and analyzing their patterns over time to determine whether the attack has been effectively revealed and isolated.

Findings

To assess the performance of the proposed observer-based structure in detecting cyber-attacks, three separate false data injection (FDI) scenarios were simulated—each targeting a different measurement signal in the two-area LFC system: frequency of Area 1 (Δf_1), frequency of Area 2 (Δf_2), and tie-line power flow (ΔP_{12}). In each scenario, only one measurement signal was corrupted at a time using an additive injection profile with defined amplitude and activation time.

The detection process was carried out using a Generalized Observer Scheme (GOS), consisting of three Unknown Input Observers (UIOs), each responsible for generating a residual signal that ideally remains insensitive to system disturbances (e.g., load changes) but reacts to anomalies in specific measurement channels. The Euclidean norm of each residual was continuously monitored to detect abnormal behavior.

The results revealed distinct detection characteristics depending on the type of attack:

- FDI attacks on Δf_1 and Δf_2 led to a sustained deviation in the residuals associated with the unaffected observers. These residuals exhibited a relatively constant offset during the attack period, while the residual associated with the compromised signal remained near zero due to the inherent decoupling feature of the GOS structure.
- FDI attack on ΔP_{12} (tie-line power flow) produced a significantly different pattern. The residual output showed a brief but sharp transient spike at the moment the attack was triggered. However, this response rapidly decayed and returned to zero within a short time interval. As a result, detection based on simple thresholding logic could easily fail to identify this type of transient anomaly.

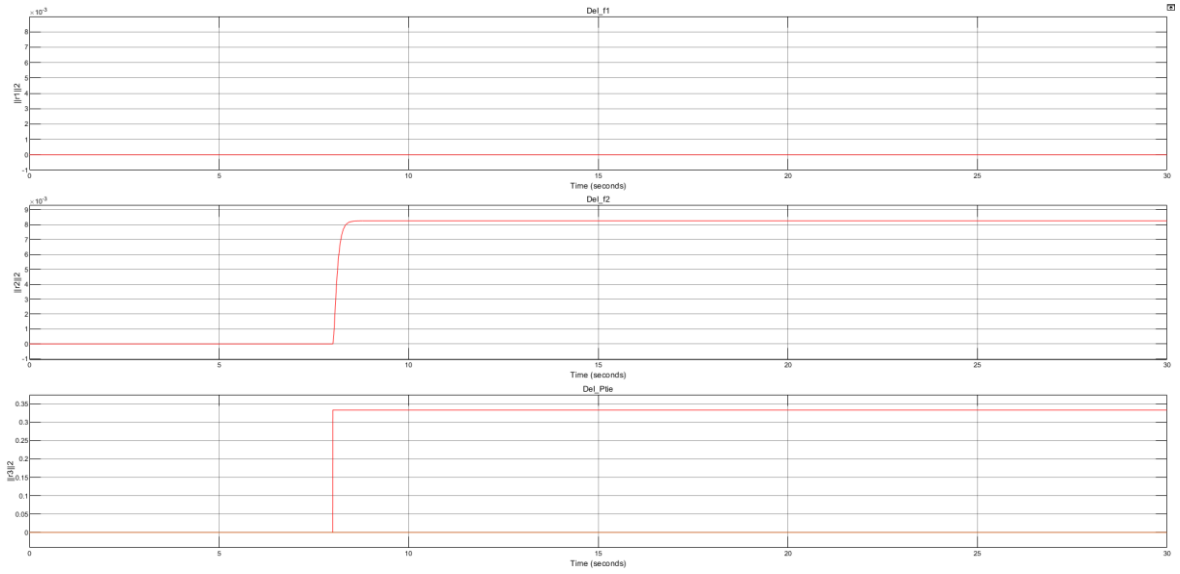

Figure 1. Frequency sensor (Δf_1) under FDI attack condition.

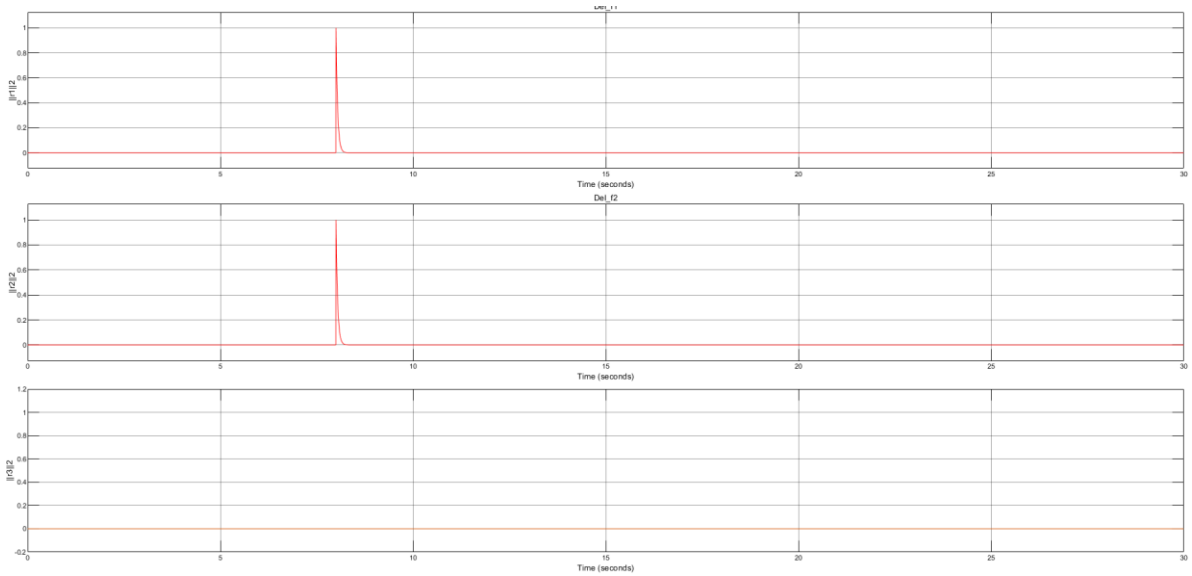

Figure 2. Tie-line power flow sensor (ΔP_{12}) under FDI attack condition.

Overall, the observer structure was able to expose the presence of falsified data through cross-residual reactions; however, the detection capability was highly dependent on the temporal characteristics of the attack and the choice of measurement being targeted. The study emphasizes the need for additional signal-processing layers or logic structures to ensure detection reliability, especially in the case of stealthy or short-duration attacks.

Conclusion

This study has investigated the use of a Generalized Observer Scheme (GOS), originally developed for sensor fault detection, as a detection mechanism for false data injection (FDI) attacks in a two-area Load Frequency Control (LFC) system. By adapting the observer framework to a cyber-security context, the study aims to leverage residual-based monitoring as a lightweight, model-driven layer of protection against data integrity threats.

Simulation results demonstrated that the GOS structure can effectively react to injected anomalies in measurement channels, even when the attack is designed to be stealthy and short-lived. In the case of frequency signal attacks (Δf_1, Δf_2), the system generated stable residual deviations in unaffected observers, indicating the presence of anomalous behavior. However, in the case of tie-line attacks (ΔP_{12}), the residual response was transient and quickly returned to zero—highlighting a fundamental limitation of relying solely on threshold logic for detection.

The key insight from the findings is that the observer structure, due to its decoupling nature, may suppress the very residual in the channel under attack. This behavior is inherent in the GOS methodology and must be accounted for in practical implementations. Relying only on instantaneous thresholds may lead to false negatives, especially in cyber-attack scenarios that exploit system dynamics to remain undetected.

To address this challenge, it is recommended to integrate a discrete-time integrator or cumulative logic block after the threshold comparison, which would accumulate residual energy over time. Such an approach could improve the detection of short-duration anomalies and enhance the robustness of the overall system against cyber threats.

In conclusion, the proposed adaptation of a GOS-based observer framework shows promising results for FDI detection in power systems. With minor structural improvements, it can serve as a scalable and non-invasive cyber-security tool for modern smart grid environments.

Aim

Modern power systems are undergoing a significant transformation through the digitalization of the smart grid. The integration of next-generation components—such as phasor measurement units (PMUs), smart relays, and advanced communication networks—has enhanced real-time monitoring and control capabilities. These advancements offer improved operational flexibility and efficiency, yet they also present critical challenges in maintaining transient stability and ensuring robust cybersecurity. Transient stability, defined as the power system's ability to remain synchronized after disturbances, is essential for preventing cascading failures and ensuring uninterrupted power delivery (Lee et al., 2024; Zhu et al., 2020). Traditional stability-assessment methods, which rely on offline simulations or conventional state-estimation techniques, are increasingly inadequate for meeting real-time operational demands, particularly when confronted with sophisticated cyber threats such as false-data-injection attacks (Kazemi et al., 2020).

This study aims to develop and validate a comprehensive, cyber-resilient framework that delivers accurate, real-time transient stability prediction in modern power systems. By integrating advanced state-estimation techniques (Zhou et al., 2014), deep-learning-based anomaly detection (Radhoush et al., 2023), measurement-recovery methods, and an ensemble prediction strategy (Aygul et al., 2023), the proposed framework is designed to sustain high prediction accuracy even in the presence of cyber-attacks. The ultimate objective is to facilitate proactive control measures and enhance the overall security and reliability of grid operations under both normal and adverse conditions.

Material and Method

The proposed methodology is structured as a multi-layer framework that seamlessly integrates wide-area monitoring, dynamic state estimation, cyber-attack detection, measurement recovery, and an ensemble learning based post fault transient stability prediction. Figure 1 illustrates the architecture of the proposed TSP classifier, while Figure 2 provides an overview of the complete framework.

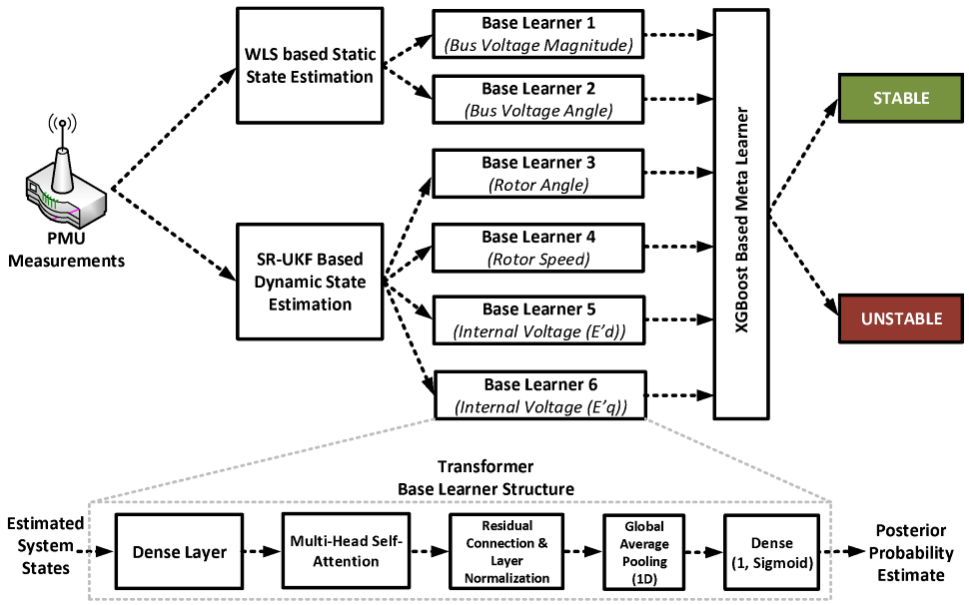

Figure 1. Proposed TSP Classifier Structure.

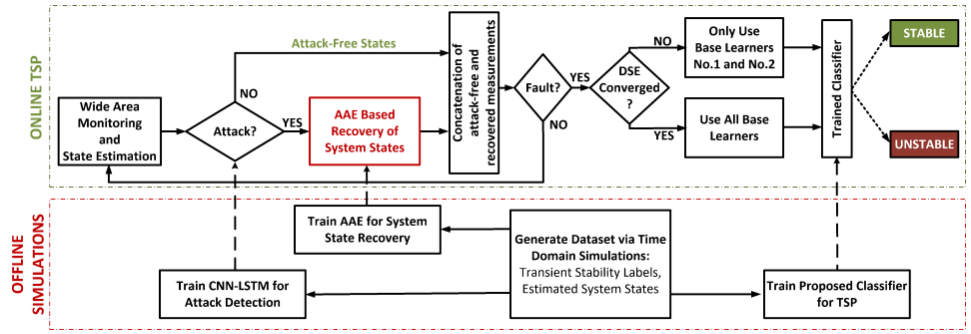

Figure 2. Proposed Framework.

Wide-Area Monitoring and State Estimation:

A. Static State Estimation (SSE):

Synchronized measurements obtained from PMUs are processed using a linear Weighted Least Squares (WLS) estimator. This estimator corrects for measurement inaccuracies and produces rapid snapshots of the power system's state, providing an initial estimate that supports immediate monitoring and control decisions (Radhoush et al., 2023).

B. Dynamic State Estimation (DSE):

To capture the system's dynamic behavior during and after disturbances, the framework employs a Square-Root Unscented Kalman Filter (SR-UKF), which is adept at managing the nonlinear dynamics of power systems and updating state estimates over time (Zhou et al., 2014). While static state estimation (SSE) reliably monitors measurable parameters, the dynamic state estimation (DSE) module is pivotal for providing non-measurable states—such as rotor angle and rotor speed—that are essential for assessing system stability and performance. This combined estimation strategy ensures that both static and dynamic aspects of the system are accurately captured, significantly enhancing the overall predictive capability of the framework.

Cyber-Attack Detection and Measurement Recovery:

A. FDIA Detection via CNN-LSTM:

Modern power systems are vulnerable to FDIAs that subtly manipulate measurement data to evade traditional bad data detection techniques. To address this, the framework incorporates a hybrid Convolutional Neural Network–Long Short-Term Memory (CNN-LSTM) architecture. (Z. Li et al., 2024) The CNN component extracts spatial features from the system states, while the LSTM component captures the temporal dependencies inherent in system dynamics. This combined architecture is highly effective at identifying coordinated and stealthy FDIA patterns, ensuring that compromised data is flagged for further processing.

B. Measurement Restoration using Adversarial Autoencoder (AAE):

Upon detection of an FDIA, the corrupted measurements are not discarded but instead are restored using a Wasserstein GAN-based adversarial autoencoder (AAE). (Y. Li et al., 2019) The AAE maps the compromised data into a latent space and then decodes it to produce reconstructed power system states that closely approximate the true state. The use of Wasserstein loss with gradient penalty ensures that the latent representations are well-regularized, significantly reducing the impact of the cyber-attack on state estimation accuracy.

Ensemble Transient Stability Prediction

A. Base Learners – Deep Transformer Models:

The clean and verified state estimates are then fed into an ensemble classifier designed for transient stability prediction. Multiple Deep Transformer (Y. Li et al., 2024) models are employed as base learners. These models are particularly suited for extracting long-range spatiotemporal features from high-dimensional PMU data, which is critical for understanding the complex dynamics of power systems during transient events.

B. Meta-Learner – XGBoost Aggregation:

The predictions generated by the Deep Transformer base learners are aggregated using an XGBoost meta-learner. This ensemble strategy leverages the strengths of each individual model, combining them to produce a final, robust prediction. The integration of XGBoost (N. Li et al., 2020) helps to mitigate the effects of any residual errors from the base learners and further enhances the accuracy and robustness of the overall TSP module.

Findings

The proposed framework was rigorously validated using simulations on the NPCC 48-machine, 140-bus test system. A comprehensive dataset was generated through time-domain simulations, encompassing both normal operating conditions and scenarios involving various intensities of FDIA. Key experiments were designed to evaluate the performance of each component of the framework under realistic conditions.

State Estimation Performance:

The proposed state estimation approach demonstrated high accuracy under attack-free conditions, with both SSE and SR-UKF providing reliable estimates of system states. However, when subjected to FDIA scenarios, state estimation techniques showed significant degradation in performance, as indicated by increased Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) values in critical state variables such as rotor angles, rotor speeds, and internal voltages. The incorporation of the AAE-based measurement recovery module effectively restored these values to near-normal levels. For instance, under a moderate attack vector, rotor speed RMSE values were reduced by more than 90% after recovery. Tables 1, 2, and 3 summarize the error metrics for the estimated states under attack conditions, both with and without measurement recovery.

FDIA Detection Efficacy:

The CNN-LSTM based detection module achieved exceptional performance, with Precision and Recall metrics approaching 100%. This hybrid model consistently outperformed standalone CNN, LSTM, and GRU architectures in identifying both isolated and coordinated FDIAs. The high detection rate enabled the prompt activation of the measurement recovery

process, preventing erroneous data from adversely impacting the transient stability predictions. Table 4 presents a performance comparison between the proposed FDIA detection method and the benchmark methods.

Table 4. Performance Metrics of FDIA Detection Models.

Model	Precision	Recall	F-Measure
LSTM	0.9918	0.9919	0.9918
GRU	0.9921	0.9921	0.9921
CNN	0.9833	0.9839	0.9836
Transformer	0.8938	0.8749	0.8842
CNN-LSTM	0.9997	0.9997	0.9997

Transient Stability Prediction Accuracy

The ensemble classifier, combining Deep Transformer base learners with an XGBoost meta-learner, maintained high accuracy even under severe cyber-attack conditions. In tests conducted with attack vectors of up to 10%, the ensemble system sustained an overall prediction accuracy above 98%, with only a minimal decline in F1 scores. The robust performance of the ensemble approach is attributed to the effective extraction of spatiotemporal features by the deep transformers and the complementary aggregation provided by XGBoost. Figures 3 and 4 illustrate the impact of FDIA on TSP performance, while Figure 5 demonstrates how recovery via AAE influences the performance of the proposed TSP model.

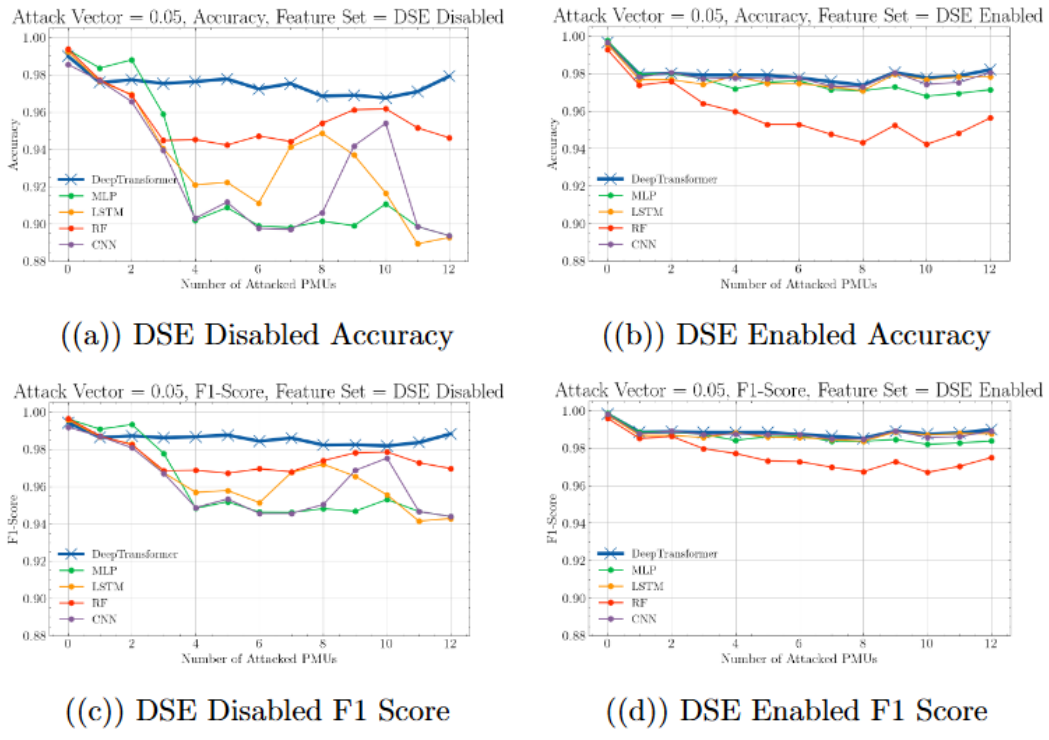

Figure 3. Impact of FDIA (5% Attack Vector) on Accuracy and F1 Score.

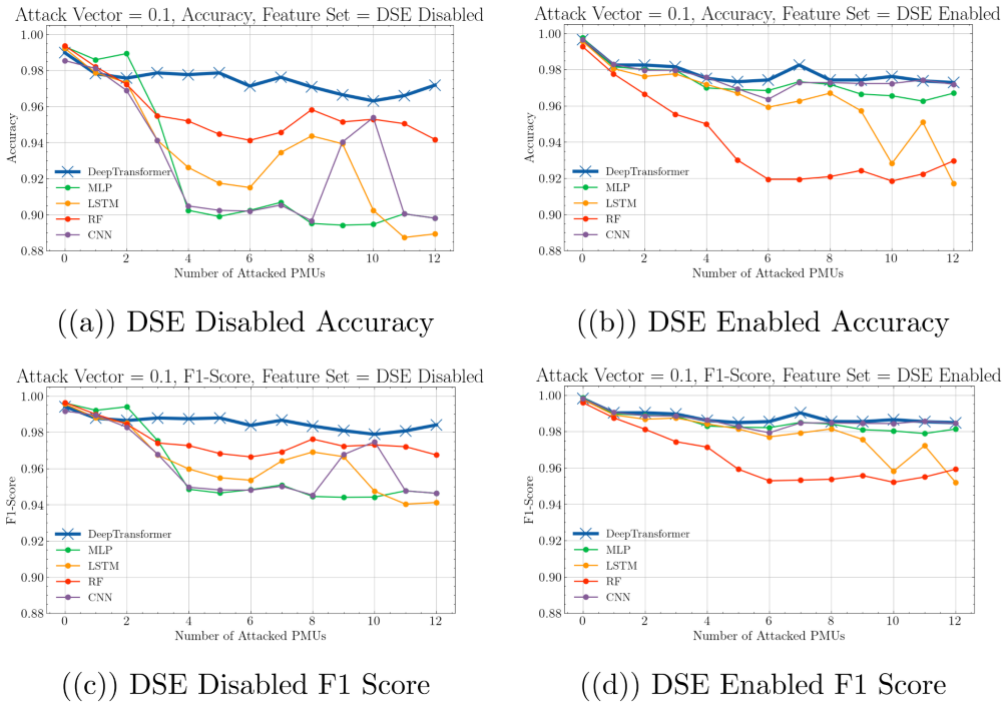

Figure 4. Impact of FDIA (10% Attack Vector) on Accuracy and F1 Score.

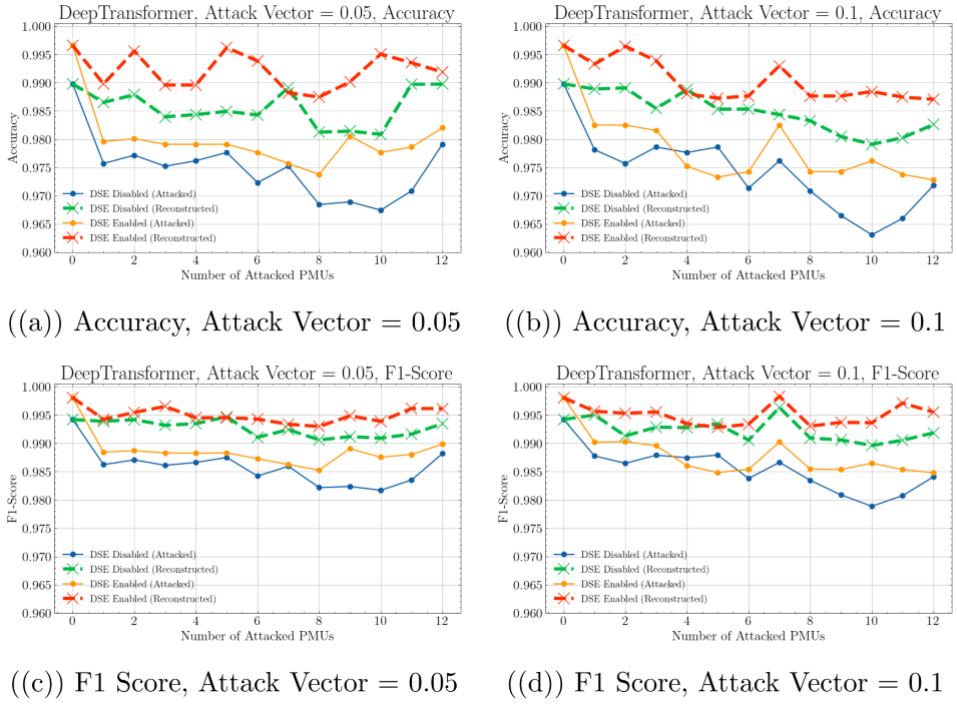

Figure 5. Comparison of TSP performance under different attack intensities with and without AAE-based measurement recovery.

Summary

The experimental results confirm that the proposed cyber-resilient framework significantly enhances both the accuracy and reliability of transient stability prediction in modern power systems.

Key findings include:

- FDIA conditions induce significant state estimation errors, which are largely mitigated by the AAE-based recovery module.
- The hybrid CNN-LSTM model effectively detects subtle, coordinated FDIA patterns, enabling prompt recovery.
- The ensemble TSP classifier—combining Deep Transformer models with an XGBoost meta-learner—consistently achieves over 98% accuracy even under sophisticated cyber-attacks.
- Integrating advanced dynamic state estimation, deep learning-based FDIA detection, and measurement recovery offers a robust enhancement over traditional transient stability prediction methods, addressing both technical and cybersecurity challenges.

Conclusion

This study presents a comprehensive, cyber-resilient framework for real-time transient stability prediction in modern power systems. By integrating the proposed state estimation approach, a hybrid CNN-LSTM detector for FDIA, an adversarial autoencoder for measurement recovery, and an ensemble-based transient stability predictor, the proposed methodology addresses the dual challenges of ensuring rapid and accurate stability assessment while safeguarding against cyber threats.

The validation on the NPCC 48-machine, 140-bus system demonstrates that the framework not only restores compromised measurements and maintains high prediction accuracy under cyber-attacks but also satisfies stringent real-time processing requirements. These results underscore the potential of the proposed methodology to serve as a critical tool for enhancing the resilience and security of modern power grids.

The promising results of this study lay a strong foundation for the development of next-generation, data-driven power system monitoring and control systems that are resilient in the face of both operational disturbances and cyber-attacks.

Keywords: Buck Converter, LDO, PMU, Power Managements.

Aim

The primary aim of this study is to develop an efficient internal power management unit (PMU) for a 22-nm Fully Depleted Silicon On Insulator (FD-SOI) process. The designed PMU integrates a Bandgap Reference (BGR) circuit and three Low Dropout (LDO) regulators: a high-voltage LDO, an auxiliary always-on LDO, and a current sink LDO and Buck Converter. Figure 1 illustrates the relationship between these blocks, providing a clear representation of their interactions and dependencies. This PMU autonomously adjusts its operation based on the input supply voltage (1.8V to 3.6V) and ensures stable power distribution while maintaining transistors within the Safe Operating Area (SOA). The system is optimized for minimal power consumption and high efficiency, making it suitable for low-power analog and mixed-signal applications.

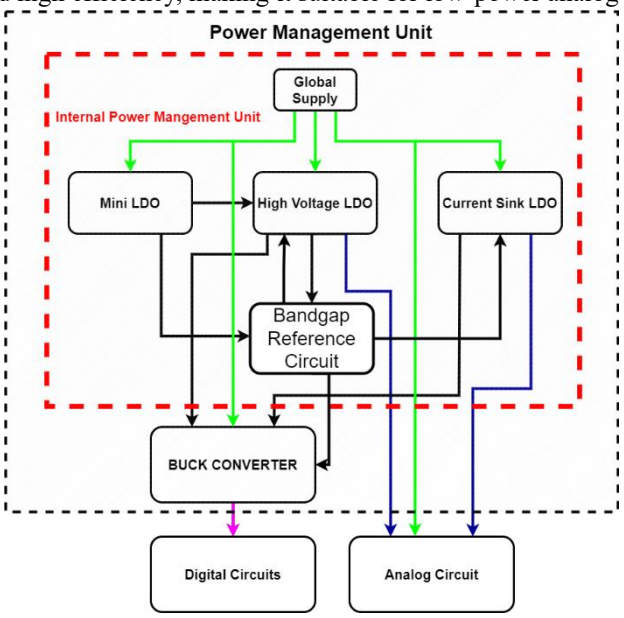

Figure 1. The overall structure of the PMU.

With the increasing demand for efficient power management solutions in modern semiconductor designs, the integration of advanced internal PMUs is essential. Conventional power management architectures often rely on external components, leading to increased complexity, power loss, and design constraints. By incorporating an advanced PMU within the 22-nm FD-SOI process, this study aims to overcome these limitations, offering an integrated solution with enhanced performance, reduced power consumption, and improved voltage regulation across diverse operational conditions. The PMU is designed to provide robust performance while ensuring process scalability and adaptability for various applications. Moreover, the study explores novel techniques for optimizing power efficiency in ultra-low-power systems, ensuring long-term viability for next-generation semiconductor devices.

Material and Method

The PMU is implemented using a 22-nm FD-SOI process, leveraging its inherent advantages such as low leakage current, high efficiency, and enhanced control over transistor behavior. The Bandgap Reference (BGR) [1] serves as the primary voltage and current reference, ensuring stability across variations in Process, Voltage, and Temperature (PVT). The BGR provides a stable output crucial for powering analog and digital sub-circuits within the PMU.

The high-voltage LDO is responsible for maintaining a consistent 1.8V output across a broad input supply range of 1.8V to 3.6V, ensuring optimal performance of low-power circuits. Its design integrates noise-reduction techniques and transient response optimization to enhance reliability. The auxiliary always-on LDO plays a crucial role in the power-up sequence, preventing startup failures and ensuring smooth operation. This LDO operates with an ultra-low quiescent current, making it highly power-efficient while maintaining system integrity during initial startup phases.

The current sink LDO dynamically adjusts ground voltage levels, facilitating stable digital circuit operation across varying supply voltages. This LDO adapts to changes in the power supply while keeping transistor stress within acceptable limits, extending the lifespan of the integrated circuits. The layout design emphasizes compactness, with a total area of 292.4 µm x 98.3 µm, ensuring minimal silicon real estate utilization while maximizing functionality [2-3].

Simulation methodologies include post-layout verification, stability analysis, transient response evaluation, and power supply rejection ratio (PSRR) assessments. Extensive Monte Carlo simulations were conducted to assess variation tolerance and ensure reliability across manufacturing processes. Noise analysis and thermal simulations were also performed to confirm robustness under extreme conditions. Additionally, parasitic extraction analysis was conducted to validate layout-dependent effects, ensuring optimal power distribution efficiency within the PMU [4-8].

Findings

Simulation results demonstrate that the BGR achieves a temperature coefficient of 12.43 ppm/°C, ensuring minimal voltage variation across temperature extremes. This low variation is critical for maintaining consistent performance in temperature-sensitive applications. The high-voltage LDO successfully maintains a stable 1.8V output across varying supply inputs, with a worst-case PSRR of -55 dB at 3.6V, signifying excellent noise immunity. Load regulation analysis reveals minimal voltage deviations under dynamic load conditions, further reinforcing the LDO's effectiveness.

The auxiliary always-on LDO provides reliable startup functionality while consuming less than 1 µA quiescent current, ensuring minimal power overhead. The current sink LDO efficiently adjusts ground voltage levels in digital circuits, eliminating the need for additional external protection circuits. It maintains stable operation across all tested process corners, confirming its adaptability to different manufacturing variations.

Further evaluations of transient responses indicate that the designed PMU successfully mitigates voltage spikes and fluctuations, preserving signal integrity across power-sensitive circuits. The integration of specialized filtering techniques within the PMU enhances PSRR performance, effectively isolating noise from power sources and improving the overall stability of the system. The PMU's ability to sustain a steady voltage level under rapidly changing load conditions highlights its robustness in real-world scenarios, making it suitable for mission-critical applications. Additionally, power efficiency metrics confirm significant reductions in overall power dissipation, contributing to enhanced battery life in portable applications.

Conclusion

The proposed 22-nm FD-SOI internal PMU effectively regulates power across a wide input voltage range while ensuring stability and reliability. Its compact design and autonomous voltage adaptation eliminate the need for external calibration. The integration of high-performance BGR and LDOs enables efficient power management for modern SoCs, reducing external component dependency and overall system complexity.

This study demonstrates that a well-designed PMU can significantly enhance power management efficiency while reducing power loss and layout constraints. The proposed system is suitable for a wide range of applications, including low-power analog and mixed-signal circuits, energy-efficient SoCs, and mobile devices requiring adaptive voltage regulation. The

automated self-adjusting features incorporated into the PMU architecture provide an advantage in minimizing design iterations, improving scalability, and ensuring robust operation under varying power conditions.

The results highlight the potential of the designed internal PMU for widespread adoption in advanced semiconductor technologies. Future work includes further miniaturization, adaptive power-saving techniques, and the integration of machine learning algorithms for real-time power optimization, paving the way for next-generation power management solutions in ultra-low-power applications. Moreover, research into alternative reference generation methods and innovative regulation strategies will be explored to further improve energy efficiency and system resilience in future semiconductor advancements.

Keywords: 5G, Blind Zone, Dead Zone, Low-Power, Phase-Frequency Detector.

Aim

This paper improves the development of a low-power CMOS phase frequency detector (PFD) circuit for phase-locked loop (PLL) applications in 5G New Radio (NR) 78 standard. The circuit ensures the detection of phase and frequency variations in the reference signal and input signal (same as PLL, V_{IN}). This work is based on the circuit architecture presented in [1], with a redesign aimed at improving its performance. Specifically, the work is focused on reducing power consumption while maintaining dead zone and blind zone efficiency.

Material and Method

The phase frequency detector (PFD) circuit in a phase-locked loop (PLL) environment is important to ensure locking of the reference signal (V_{REF}) and the input signal (same as PLL input, V_{IN}), thereby providing the best possible oscillation at the frequency of interest. In 5G new radio (NR) 78 mobile applications, the operating frequency is 3.5 GHz with 500 MHz bandwidth [2]. To ensure smooth oscillation at 3.5 GHz, PFD circuit is employed to provide up (Up) and down (Down) signals to the charge pump (CP). The reference signal is chosen to be 10 MHz because most base stations in 5G networks use 10 MHz reference to be compatible with Global Positioning System (GPS) [3]. According to [2], 10 MHz is within allowable bandwidth range in time division duplex (TDD) signal necessary for NR78.
Several PFD architectures are used to resolve main PFD problems such as dead zone and blind zone. PFD experiences a region of near-zero phase difference around phase locking when it is unable to detect this small phase difference and it can cause an increase in phase noise of PLL. The PFD is unable to respond to voltage variations when the phase difference is near zero, a phenomenon known as the dead zone issue. The dead zone is an important specification as it limits operating frequency and introduces jitter to the PLL system. One solution is to introduce a delay at the PFD output to ensure proper reset operation [4]. However, some random glitches occur in this structure. Furthermore, the reset pin limits the maximum operating frequency as depicted in equation 1. Another solution can be to provide delay in both input signals [5]. Although the dead zone is eliminated since it is no longer dependent on the reset signal, power consumption increases significantly.

$$f_max = 1/(2 \times T_reset\ ) \quad (1)$$

The second common issue in PFDs is the blind zone, which occurs near a 2π phase differences when the rising edge of VREF appears moderately after VIN while the reset feedback path is activated. Then, PFD misses this rising edge phase differences and produces a wrong output. The blind zone reduces the PLL acquisition speed, enhances the linearity of PFD, increases energy consumption and degrades phase noise. To solve this issue, the reset path is removed, as designed in [6]. Although this architecture obliterates the blind zone, it leads to an increase in both the dead zone and power consumption.
The PFD is designed in reference to the architecture presented in [1]. The designed PFD, shown in Figure 1, improves the dead zone and the blind zone, eliminates glitches and reduces reference spurs [1]. The PFD operates in both frequency-aligned and non-aligned frequency scenarios under the following conditions: (1) V_{REF} phase leads V_{FB} (2) V_{REF} phase lags V_{FB} and (3) V_{REF} is in-phase with V_{FB}.

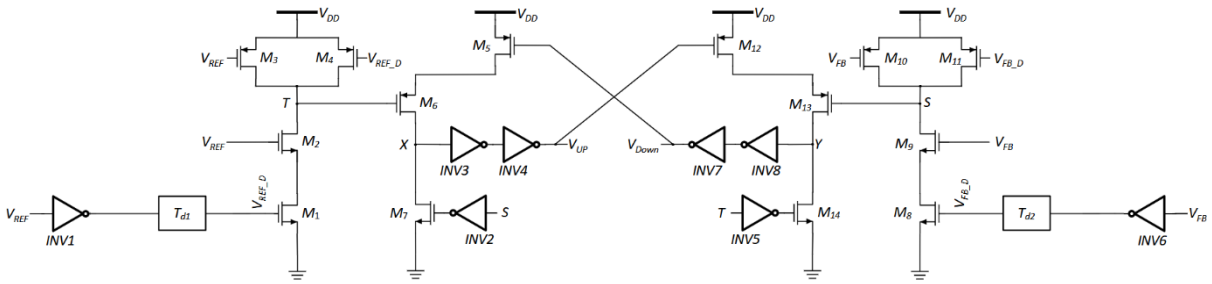

Figure 1. The Designed PFD Architecture.

To explain the working principle of the designed PFD, frequency-aligned condition (1) is selected as an example: When both inputs are logic low, the T node is in the logic high state as switch M_3 pulls this node to V_{DD}. When V_{REF} goes logic high and V_{FB} stays in logic zero, node T is pulled down to ground by M_1 and M_2 on the rising edge, and thus node X reaches the high state when M_6 turns on. After the time delays in T_{d1} and INV1, V_{REFD} goes
low as the rising edge of the reference signal occurs. Therefore, M_1 turns off and forces the T node to reach V_{DD} again. M_6 turns off, and node X holds the logic high. When V_{FB} goes logic high, node S is triggered to pull down by M_8 and M_9, but node Y cannot go to logic high and stays in logic low because M_{12} is off as UP is applied to its gate. After the time delays in T_{d2} and INV6, V_{FB_D} goes to logic low when the rising edge of the V_{FB} signal occurs. Therefore, M_8 turns off and forces the S node to reach V_{DD} again. At this moment, the PFD is reset by the inverted output of S node, which is applied to the gate of M_7. Additionally, nodes X or Y are in a middle state, preventing the establishment of either a logic high or logic low. INV3 and INV4 (INV7 and INV8) are employed to ensure correct switching mechanism of CP. The reader may find Figure 2 helpful for understanding the working principle of the designed PFD. The same analysis can be made further for the other scenarios, which is left for the reader's discretion.

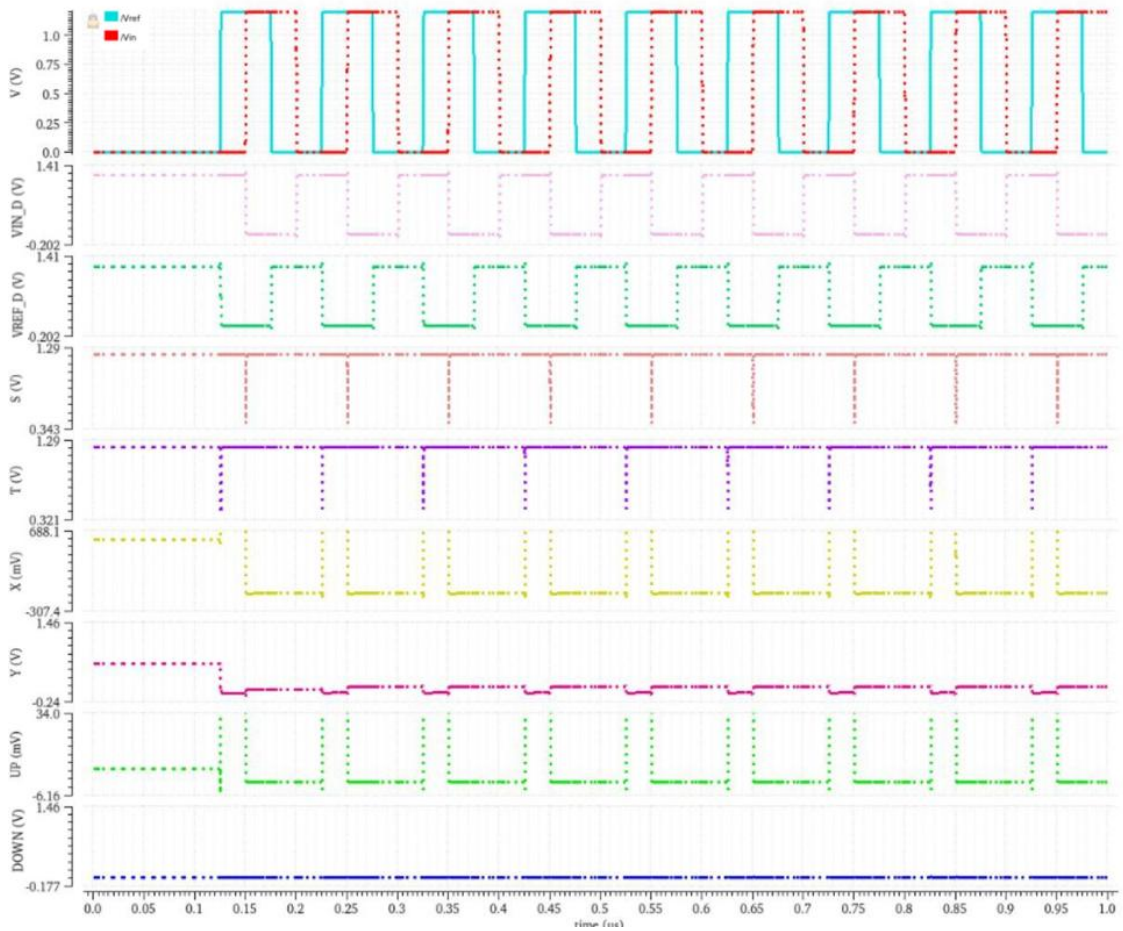

Figure 2. Transient Response of Key Nodes in the Designed PFD Under V_{REF} Leading V_{IN} at the Same Frequency Condition.

It is crucial to emphasize that the time delays, T_{d1} and T_{d2}, are essential in the design, ensuring that the applied V_{REF} and V_{IN} signals are sufficiently delayed to drive M_6 (M_{13}). Additionally, the duration of these delays must be shorter than the reset pulse width to trigger switching pulse width spikes at the nodes in PFD.

Aspect ratios are adjusted to force this architecture to be compatible for 10 MHz input signals. The fundamental idea here is focused on transition time of NMOS devices to voltage changes. Taking as an example, when V_{REF} is leading V_{IN} and its rising edge occurs, M_1 and M_2 needs to react to this change in order to pull node T to ground. M_1 and M_2 need slow transition time to its input signal therefore small aspect ratios are used.

Besides, the frequency of V_{IN} signal can differ between 9 MHz to 11 MHz depending on choice of divider used in the PLL structure. The reason to this difference belongs to 5G NR 78 standard as VCO generates its output signal within a frequency range between 3.3 GHz to 3.8 GHz. Thus, the circuit is also tested for this frequency range.

Lastly, power consumption is another important specification in the design and is closely managed. Power hungry devices in this architecture are M_5, M_6 and M_7 (M_{12}, M_{13} and M_{14}). When the node T (S) is grounded, M_7 (M_{14}) conducts current and creates logic high at node X (Y).

If the width of M_7 (M_{14}) is reduced, using the width and drain current relationship Equation 2, the drive current also decreases. This reduction is managed while ensuring that the correct switching of Up (Down) occurs. Additionally, the aspect ratios of the inverters are lowered to reduce power consumption while ensuring that sufficient invertor gain and bandwidth are maintained for the topology.

$$I_D = \left(\frac{1}{2} \times \mu_n \times C_{ox} \times \frac{W}{L} \times (V_{GS} - V_{th})^2\right) \quad (2)$$

where I_D, μ_n, C_{ox} , W, L, V_{GS} and V_{th} are the drain current of the NMOS transistor, electron mobility, oxide capacitance per unit area, width of the NMOS transistor channel, length of the NMOS transistor channel, gate-source voltage, and threshold voltage of the NMOS transistor, respectively.

Findings

The designed circuit is simulated by Virtuoso tools using TSMC 65 nm CMOS technology. The supply voltage is 1.2 V. The aspect ratios are provided in Table 1. The reference frequency is selected as 10 MHz. As mentioned earlier, the latency applied to the V_{REF} and V_{IN} signals is controlled by T_{D1} and T_{D2}, which introduces delays of 14.2 ps to these signals. Figure 3 illustrates the dead zone analysis of the designed PFD, where V_{REF} leads V_{IN} by 25 ps when the equal 10 MHz frequency signals applied. In this dead zone, the PFD is able to generate correct output signals.

Table 1. Aspect ratio of transistors used in the designed PFD.

Device	W/L
M_1, M_2, M_8, M_9, PMOS transistor of: (INV_3, INV_4, INV_7, INV_8)	1.2 µm/65 nm
M_3, M_4, M_{10}, M_{11}	8 µm/65 nm

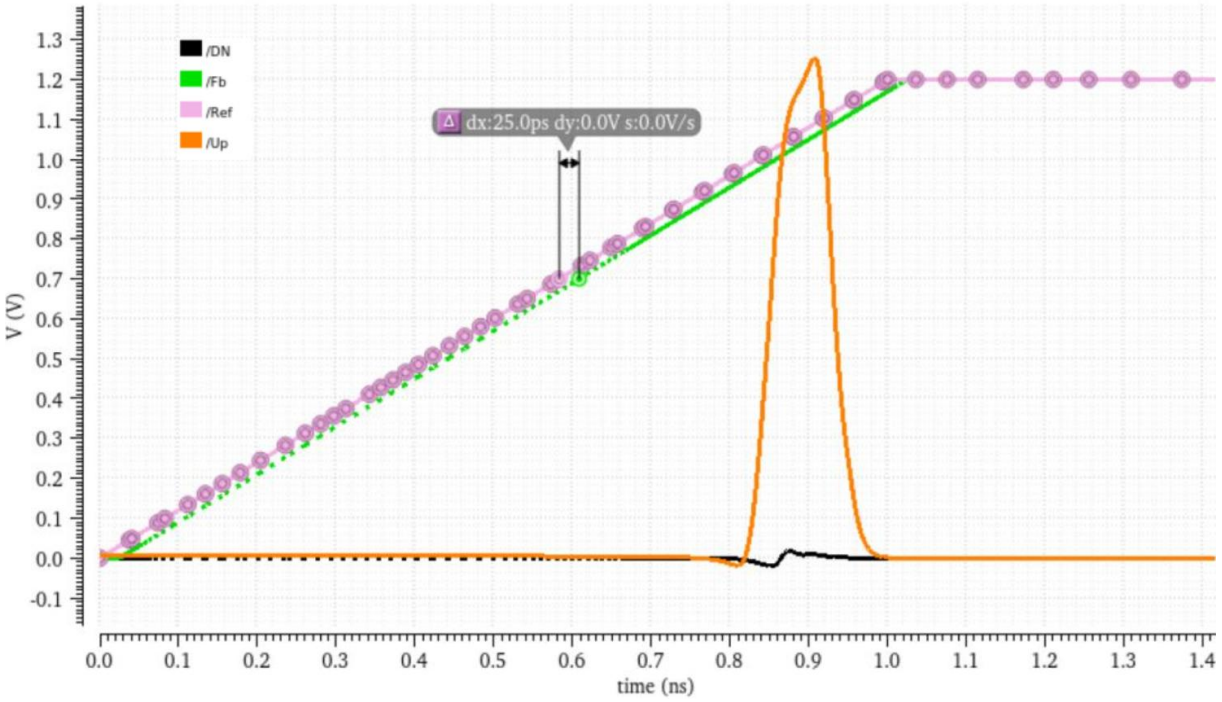

Figure 3. Dead Zone Analysis of the Designed PFD when V_{REF} leads V_{IN} by 25 ps.

The blind zone analysis of the designed PFD is performed. For better view of blind zone analysis, V_{REF} leads V_{IN} by 1 ns is shown in Figure 4. The simulations resulted that the blind zone of the PFD is 39.46 ps.

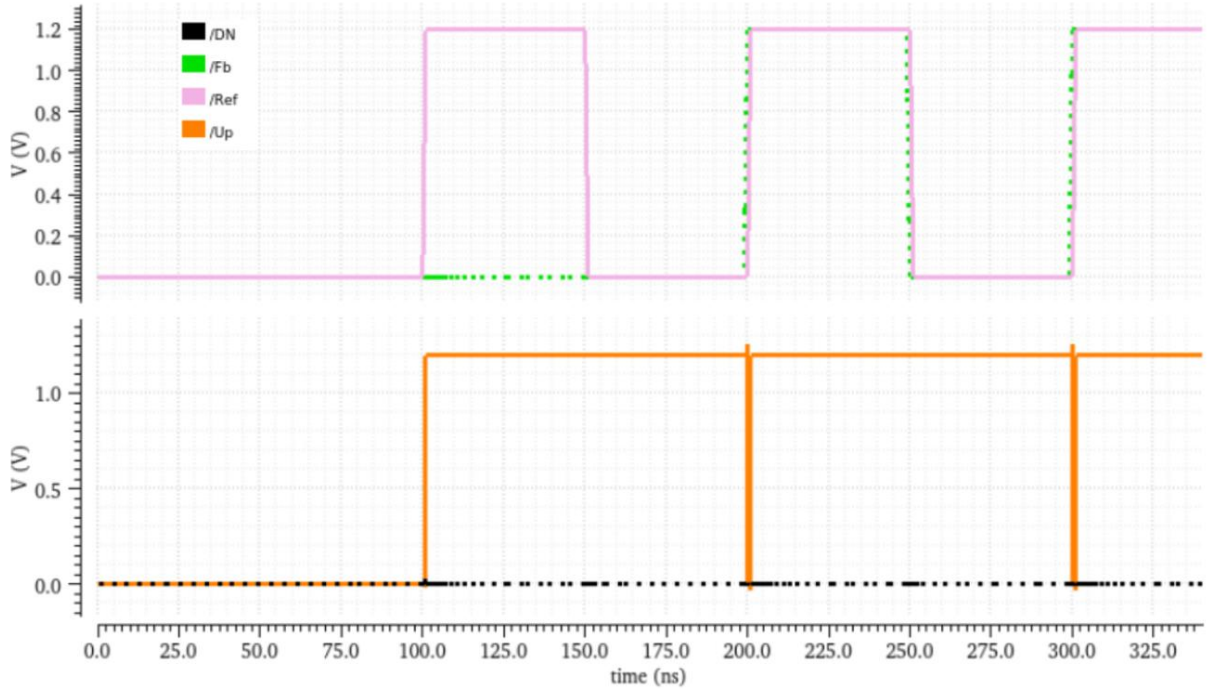

Figure 4. Blind Zone Analysis of the Designed PFD when V_{REF} leads V_{IN} by 1 ns.

The maximum operating frequency of designed PFD is limited by Equation 1. To determine the frequency, we must consider

the maximum delays during the charging and discharging durations of node X. The charging duration of node X is the sum of the maximum delays in INV_1, T_{d1}, INV_3, INV_4 and the required time to charge X node through M_5 and M_6. Similarly, the discharging duration of node X is the sum of the maximum delays in INV_2, INV_3, INV_4, and the required time to discharge X node through M_7. The same analysis applies to the calculation of node Y. Although calculating the duration of reset time is an option, it can be derived by the following equation:

$$f_max = 1/(4 \times max\{T_(dead\ zone),\ T_(blind\ zone)\}) \quad (4)$$

where $T_(dead\ zone)$, $T_(blind\ zone)$ are dead zone and blind zone values, respectively. The maximum operating frequency is calculated as 6.34 GHz and applied to V_{REF} and V_{IN} signals, considering the phase delay that arises in the blind zone. Figure 5 shows that when the rising edge of V_{REF} occurs, up transitions to logic high while Down maintains logic low state. The reset of Up occurs on the rising edge of V_{IN}. In summary, the circuit correctly responds to this frequency as anticipated.

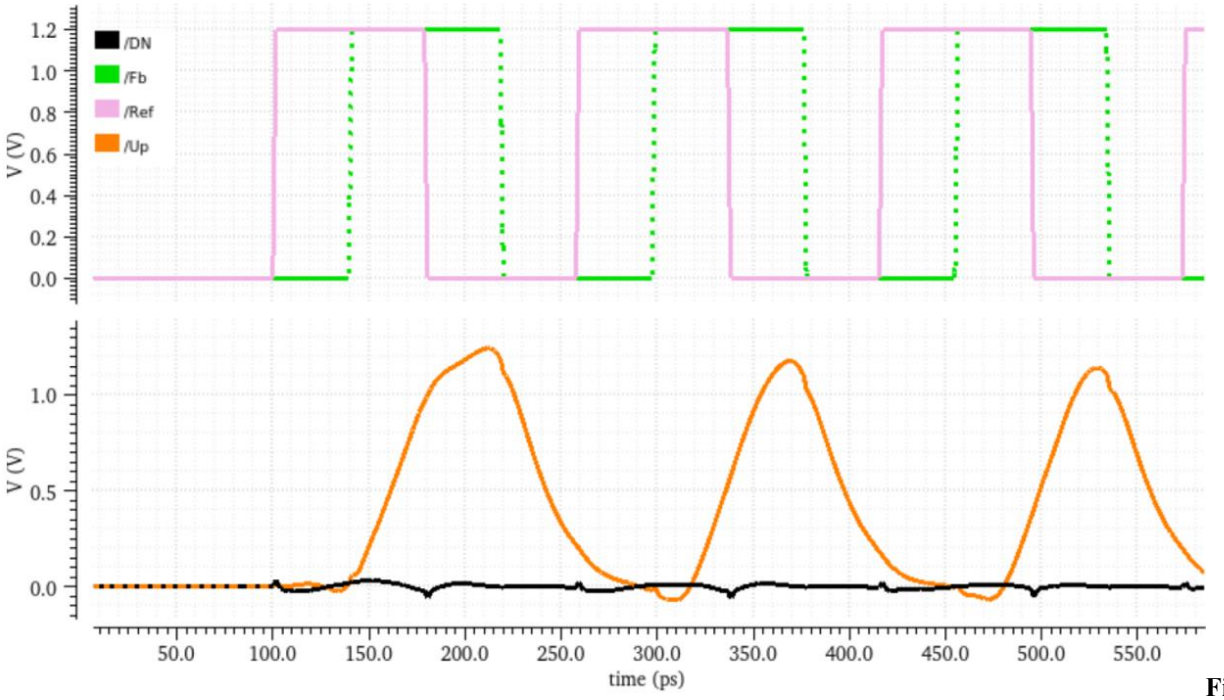

Figure 5. Performance of the Designed PFD at 6.34 GHz when V_{REF} leads V_{IN} by 39.46 ps.

The performance parameters of this work and recent works are depicted in Table 2. Compared to other references, the designed PFD achieves lower power consumption while maintaining detection range, dead zone and blind zone durations within optimal performance limits for the desired application use.

** Fabrication, *Simulation

Conclusion

In this work, a low-power CMOS phase frequency detector (PFD) is designed using TSMC 65 nm CMOS technology. The designed PFD is compatible with 5G NR 78 mobile applications and operates with a reference signal at 10 MHz. The designed PFD consumes 50.88 μW, achieves 25 ps dead zone and 39.46 ps blind zone durations under $\pm 2\pi$ detection range. The simulation results validate the advantages of the designed PFD, demonstrating improvements in power consumption and the efficiency of dead zone and blind zone.

Aim

Cancer is one of the most critical health problems on a global scale, and early diagnosis and treatment of the disease are of paramount importance in reducing mortality rates. Microfluidic-based cell three-dimensional (3-D) culture systems are instrumental in in vitro cancer research, including observation of angiogenesis and evaluation of cancer cell responses to chemotherapeutic drugs. In the production of these systems, a flexible and biocompatible silicone elastomer such as polydimethylsiloxane (PDMS) [1] or thermoplastic materials such as polymethyl methacrylate (PMMA) [2], cyclic olefin copolymer (COC), cyclic olefin polymer (COP) and polycarbonate (PC) are commonly used. In cell studies, PDMS is often preferred for its flexible, biocompatible, gas-permeable, and transparent properties, which facilitate optical imaging. However, its drawbacks include incompatibility with high-volume manufacturing, limited mechanical stability, and hydrophobicity. In contrast, thermoplastic materials are biocompatible, optically transparent, more hydrophilic than PDMS, and offer organic solvent resistance along with high mechanical strength. These characteristics make them suitable for rapid prototyping techniques such as laser ablation, micromilling, and mass-production methods like injection molding and hot embossing [3].

These platforms utilize hydrogels made from macromolecules like collagen and fibrin, as well as synthetic hydrogels such as Matrigel, to simulate the cellular microenvironment, which facilitates the development of 3D cell cultures. They provide a continuous supply of nutrients, creating a 3D extracellular matrix (ECM) and minimizing sample volumes. This leads to cost-effective systems that provide precise control and faster analysis. The systems may contain different compositions of channels and regions that house the hydrogels. Two or more microchannels can house the hydrogels and replenish the culture media. Cells are added through one of the side channels and the system can also include structures such as microwells [4] or microchambers [5] where cells accumulate. Some designs enable cells to interact and spontaneously form spheroids. Test chemicals, such as anticancer drugs that are targeted to interact with cells, are introduced through the opposing side channel. Separation of interconnected channels and intrachannel structures can be achieved by implementing virtual walls, using structural elements such as micropillars [6]. In the design outlined in this study, virtual walls that divide the channels are created by employing channels that exhibit level differences.

Here, we present a thermoplastic microfluidic cartridge with a groove-based design that supports 3D cell culture and can be easily imaged using a confocal imaging system. PMMA is used for fabrication, and CNC micromilling is used to create three parallel channels and also two grooves for the cells. This cartridge is designed to facilitate the imaging of cells isolated from cancerous tissue and the subsequent examination of their response to the drug. It is intended for use in medical facilities, such as hospitals and cancer centers, to ensure effective medication and treatment for patients.

Material and Method

1. Fabrication of the Microfluidic Cartridges

The channel design in this study is inspired by the design generated in Coşkun et al. from Dr. Ahmet Erten's research group, and uses a groove-based design concept that allows the interface between the hydrogel channel and the side channels to be fully utilized [7]. The design consists of three microchannels: a middle channel with a height of 150 µm and two side channels, each with a height of 400 µm. Two pockets, each with a diameter of 1200µm, are connected to one of the side channels. In addition, a retention groove with a height of 50 µm surrounds the entire design, which helps to form a strong and leakproof seal by the solvent.

The microfluidic cartridge designs were modeled using Computer-Aided Design (CAD) software.To ensure the precise fabrication of the microstructures in the design, Computer Numerical Control (CNC) micromilling is employed (Roland MDX-50) on 75×25×2 mm transparent PMMA substrates (SDS Plastic, Türkiye). After the inlets and outlets of the PMMA microfluidic cartridges are drilled using the DREMEL® Workstation 220, the cartridges undergo a sonication process. The cartridges are then treated with isopropyl alcohol (IPA), rinsed with DI water, and subsequently dried with nitrogen gas. Once these procedures are completed, the final PMMA cartridges are produced using a solvent bonding technique involving a mixture of acetone (ACE-ISOLAB Chemicals) and IPA (ISOLAB Chemicals).

This study uses a solvent mixture comprising 80% IPA and 20% ACE, determined on the basis of the solvent equation and Hildebrand solubility parameters [8]. PMMA substrates are exposed to oxygen plasma for one minute. After this treatment, the solvent mixture is poured onto one of the plasma-treated surfaces. The PMMA substrates are stacked on top of each other with a microscope slide positioned on both the top and bottom surfaces using paper clips. As illustrated in Figure 1, the assembled structure is placed in an oven at 65°C for 10 minutes, followed by an additional 5 minutes at room temperature. After this process, the cartridges are soaked in DI water for one day to remove any residual solvent before being used in cell studies. They are then exposed to nitrogen gas for desiccation prior to utilization. In the final cartridges, a mixture of DI water and dye is introduced into the channels to assess hydrogel confinement. Cartridges that exhibit no confinement issues in this preliminary control test are subsequently prepared for cell culture studies.

Figure 1. Schematic illustration of fabrication process of microfluidic cartridge.

2.Preparation of the Hydrogel and Cell Culture in Cartridges

2.1. Preparation of Hydrogel

In this study, we chose collagen I; a natural component of the ECM, that can readily form a hydrogel that provides a model closer to in vivo conditions by promoting cell attachment, proliferation, and cell-cell interactions. Following their assembly, microfluidic cartridges are sterilized under UV light in a laminar flow cabinet before hydrogel formation and cell culture studies. For filling the middle channel, 1X DMEM, 10X Dulbecco's Modified Eagle's Medium (DMEM, F-12 Ham with 15 mM HEPES and sodium bicarbonate, without L-glutamine, Sigma-Aldrich Inc), $NaHCO_3$ (7.5% w/v, sodium bicarbonate, Sigma-Aldrich), NaOH (1M, sodium hydroxide, Sigma-Aldrich), and collagen (Type-I, bovine, 6 mg/mL, Sigma-Aldrich Inc.) is mixed to make a 3% collagen end concentration on ice. The prepared mixture is introduced in 5 µL volume into the central channel and the cartridges are placed in sterile culture plates. These are incubated in the incubator at 37°C for approximately 1 hour for collagen gelation. Afterward, 10 µL of Trypan blue was applied to each side channel

to test collagen confinement and observed with a microscope. Microfluidic cartridges that pass these confinement tests are used for cell studies [7].

2.2. Gastric Cancer Cell Culture

The gastric cancer cell line SNU 484 was cultured in DMEM/F12 containing 10% fetal bovine serum (FBS) and penicillin/streptomycin in cell culture plates. During collagen gelation, the cells were detached by trypsin and pelleted. The pelleted cells were resuspended in the culture medium and counted. The cell number was adjusted to 30–60 × 10^3 per 100 µL. Following the addition of the cells to the side channel, the cartridges were placed vertically (with the cell channel on top) to aid cell seeding on the collagen surface [7].

2.3. The Response of Cancer Cells to Anticancer Drug 5-FU

In this study, experiments were conducted to investigate the response of gastric cancer cells (SNU-484) to chemotherapeutic drugs when plated in PMMA cartridges. The chemotherapeutic drug 5-fluorouracil (5-FU) was utilized in experiments using SNU-484. Cells were seeded in the side channels of the PMMA cartridges, and 5-FU was added in culture solution (50 µM) to the opposite channel of some cartridges. In the cartridges designated as the control group, incubation was continued without adding any drug to facilitate comparison (Figure 3.II.). Following a 72-hours incubation period, cell viability was analyzed. This analysis used a reduced biohazard cell viability kit, LIVE/DEAD™ (Invitrogen), to mark cells, distinguishing between live and dead cells using a confocal microscope. The LIVE/DEAD™ staining method labels dead cells with red fluorescence, while live cells exhibit green fluorescence. After the labeling step, the cells were incubated at 37°C, and measurements were performed using a confocal microscope (Leica TP8).

Findings

1. Fabrication and Solvent Bonding

In the fabricated microfluidic cartridges, a noticeable surface height difference was observed, which was attributed to machining marks from the micromilling process. This surface unevenness impacted the adhesion profile of the cartridges. To reduce this effect, as the Figure 2C shown that the microstructured PMMAs were sanded using sandpaper. Additionally, the solvent volume used in the solvent bonding technique was optimized to 150 µL, as excessive solvent usage led to significant clogging and residue formation in some cartridges. These modifications in the fabrication process resulted in cartridges with an improved adhesion profile, enhanced optical transparency, and eliminated clogging in the microchannels. As a result of the confinement tests conducted on the cartridges, successful results were achieved, demonstrating that the DI water mixed with dye supplied to the middle channel could fill the channel completely without any gaps and did not overflow into the side channels (Figure 2D).

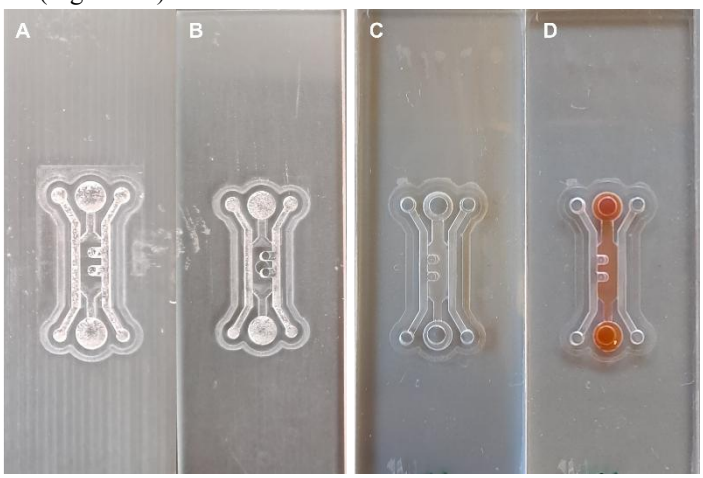

Figure 2. Cartridge images. A: Micromilled PMMA, B: After sandpaper process, C: After. bonding, D: Confinement test.

2. Response of Gastric Cancer Cells to 5-FU

Images were acquired with a confocal microscope to quantify the number of dead and live cells in the cartridges of the control group (Figure 3.II) and those treated with chemotherapeutic drugs (Figure 3.I). The fluorescent labeling method enabled the quantification of dead-to-live cell ratios in SNU-484 cells seeded in PMMA cartridges. As shown in Figure 3, treatment with 5-FU for 72 hours resulted in increased cell death in SNU-484 cells cultured in grooves compared to the control group. Figure 3.I.B exhibits a higher number of dead cells than Figure 3.II.B, whereas Figure 3.II.C presents more live cells than Figure 3.I.C.

In conclusion, these findings demonstrate that PMMA cartridges are effective for studying cellular responses to chemotherapeutic drugs. In experiments carried out in SNU-484 cells, the impact of chemotherapeutic agents such as 5-FU on cell viability and death was effectively analyzed.

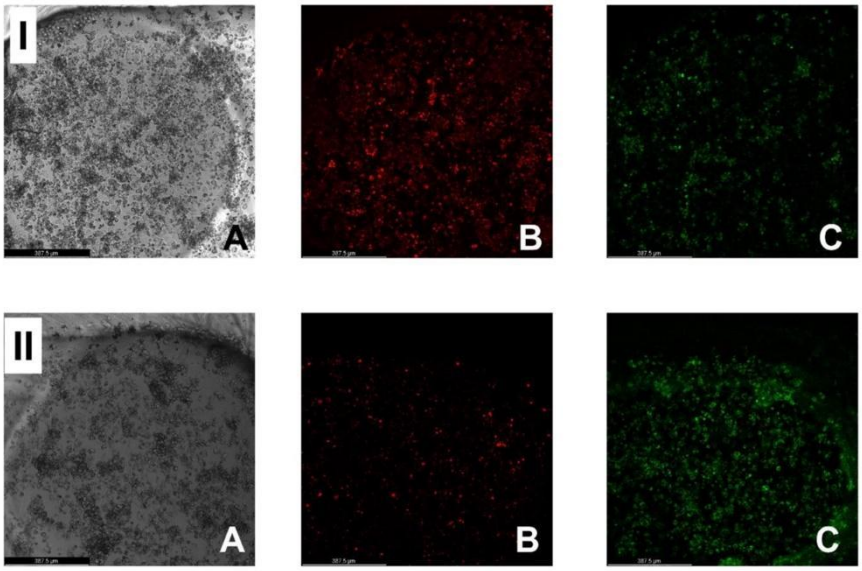

Figure 3. An imaging experiment with SNU 484 cells was performed in the groove channel of the cartridges. Confocal images were taken after a 72-hour experiment in which cells in some cartridges were treated with 5-FU (I) or were untreated as controls (II). Then, SNU-484 cells were labeled using dead-live fluorescence labeling. A : images under a light microscope, B: dead cells, C: live cells.

Conclusion

In this study, we successfully designed and fabricated a thermoplastic microfluidic cartridge to support 3D cell culture for cancer research applications. The groove-based design enables imaging of tumor cells and their interactions with chemotherapeutic drugs, facilitating studies on drug responses. The fabrication process used CNC micromilling, and solvent bonding techniques were optimized to ensure the structural integrity of the device. The results demonstrated that the fabricated PMMA cartridges effectively confined hydrogels, enabling controlled cell culture and drug testing. Preliminary drug response studies with SNU-484 cells confirmed the capability of the platform for in vitro chemotherapeutic testing. Fluorescence-based viability assays provided insights into the effects of 5-FU on cancer cells, highlighting the potential of this system for personalized drug screening. The developed microfluidic cartridge is a promising tool for advancing cancer research by enabling physiologically relevant in vitro models with precise control over the tumor microenvironment.

A Deep Learning Network for Automatic Grade Classification of Renal Cell Carcinoma

Süeda Kaya[a], Mürvet Kırcı[a]

[a] Istanbul Technical University/Graduate School, Electronics and Communication Engineering, Biomedical Engineering, Türkiye
kayasued19@itu.edu.tr

Keywords: CNN, Histopatology Images, Medical Image Classification, Renal Cell Carcinoma.

Aim

Renal Cell Carcinoma (RCC), the most common type of kidney cancer, accounts for approximately 90% of all kidney malignancies and originates from the lining of the proximal convoluted tubule, which is part of the kidney's filtration system. RCC is often asymptomatic in its early stages, making it difficult to detect until it is advanced. Early diagnosis and accurate grading are essential to improving patient outcomes. Therefore, histopathological analysis of tissue samples is a critical step in diagnosing and grading RCC, and grading evaluates the level of abnormality exhibited by cancer cells based on comparison of tissue samples with normal cells under the microscope. Although different grading schemes have been used for RCC to date, this study is based on Fuhrman's four-step grading system (Fuhrman et al., 1982). In Fohrman's system, Grade-1 nuclei closely resemble normal nuclei in terms of their tubular structure and uniformity. Grade-2 nuclei exhibit irregular contours, while Grade-3 nuclei show more pronounced irregularities. Finally, Grade-4 nuclei are characterized by pleomorphic cells, mitoses, and multilobed structures that contain the features observed in Grade-3 nuclei (Moch et al., 2016). Table 1 provides examples of images from each grade taken from the KMC dataset.

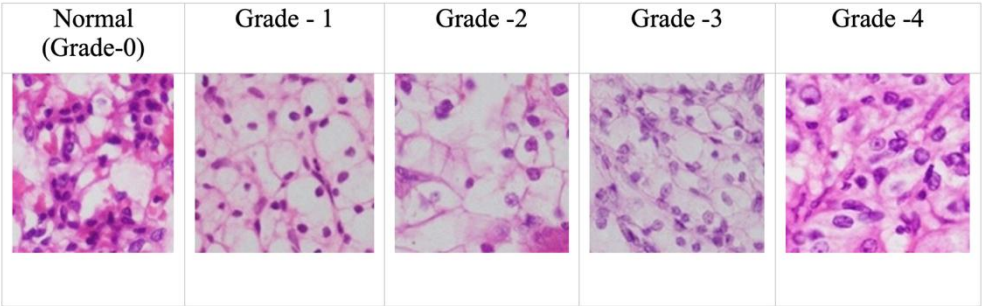

Figure 1. Example patches of kidney tumors of different grades.

Table 1. Class distribution of KMC dataset (Chanchal et al., 2023).

Class	Training	Validation	Test
Grade – 0 (Normal)	693	102	41
Grade – 1	708	104	27
Grade – 2	648	96	25
Grade – 3	735	105	21
Grade – 4	648	96	28
Total	3432	503	142

Pathologists obtain valuable information about the tumor growth rate and metastatic potential based on information about the tumor stage and grade. This information allows the development of personalized treatment strategies for the specific characteristics of the patient's cancer. However, grading complex histological patterns is a challenging and error-prone process that requires the expertise of highly experienced pathologists. Therefore, an automated and accurate system based on histopathology images is essential for grading RCC.

The aim of this study is to demonstrate the success of rapidly developing computer vision methods in the classification of complex histopathological images. In this way, it can support pathologists in their medical decision-making processes (Nahid et al., 2021; Tajbakhsh et al., 2020). Cell detection using convolutional neural networks (CNNs) is an important step in histopathological analysis (Xie et al., 2015).

Material and Method

The KMC kidney histopathology dataset used in our study contains normal (Grade-0) and cancerous (Grade-1 to Grade-4) images of RCC. These images were collected at Kasturba Medical College (KMC), India [8]. The images were labeled by expert pathologists. The preprocessing process was done automatically and except for the area selection, everything was kept the same for all images. Each part of the dataset was obtained by randomly cropping and horizontally and vertically flipping 722 images of 1920×1440. Non-overlapping square parts were extracted and resized to 224 and normalized to zero mean and unit variance before being passed through the deep learning architecture for training and testing (Chanchal et al., 2023; Dong et al., 2018; Moch et al., 2016).

Before the training images were normalized using ImageNet mean (0.485, 0.456, 0.406) and standard deviation (0.229, 0.224, 0.225) values. Data augmentation was applied only to the training set to enhance model generalization.

We implemented a modified U-Net architecture for histopathology image classification. The model features an encoder path with five consecutive down-sampling blocks, each consisting of a max pooling operation followed by two convolutional layers with batch normalization and ReLU activation. Unlike the traditional U-Net, we replaced the decoder path with a classification head that includes:

1. Global average pooling to extract features from the bottleneck layer (1024 channels)
2. A three-layer fully connected network (1024→512→256→5 neurons) with dropout (0.3) between layers to prevent overfitting

The network contains approximately 57 million parameters, with the majority in the encoder's convolutional layers. This architecture leverages U-Net's ability to capture multi-scale contextual information while adapting it for classification tasks. The model was trained for 100 epochs using the RMSprop optimizer with a learning rate of 1e-4, alpha of 0.99, and weight decay of 0. Cross-entropy loss was used as the optimization objective. Training was conducted on an NVIDIA GPU with a batch size of 32. To prevent overfitting, we implemented early stopping with a patience of 10 epochs, saving the model with the highest validation accuracy. Through applied early stopping mechanism effectively identified the optimal model checkpoint at epoch 23, which achieved a validation accuracy of 90.66%.

Table 2. Hyperparameter used in U-Net classification model.

Input Size	224x224x3
Batch Size	32
Optimizer	RMSProp (with alpha: 0.99, epsilon 1e-8)
Learning Rate	1e-4
Loss Function	Cross Entropy
Stopping Epoch	23

Model performance was evaluated using accuracy, F1 score, and confusion matrices. These metrics were chosen to account for potential class imbalance in the histopathology dataset and to provide detailed insights into classification performance across the five grades.

Findings

The final model achieved strong performance on the test set, with an overall accuracy of 91.55% across the five histopathological grades. The confusion matrix (Figure 2) reveals that:

1. Grade 0 samples were classified with the highest precision (39/41 = 95.1%)
2. Grade 1 samples showed good classification performance (26/27 = 96.3%)
3. Grade 2 had the lowest accuracy (20/25 = 80.0%), with 4 samples misclassified as Grade 3
4. Grade 3 achieved 84.0% accuracy (21/25), with 4 samples incorrectly classified as Grade 4
5. Grade 4 showed strong performance (24/28 = 85.7%), with all misclassifications being Grade 3The findings section should be written in Times New Roman font, justified-alignment and in 10-point size.
6.

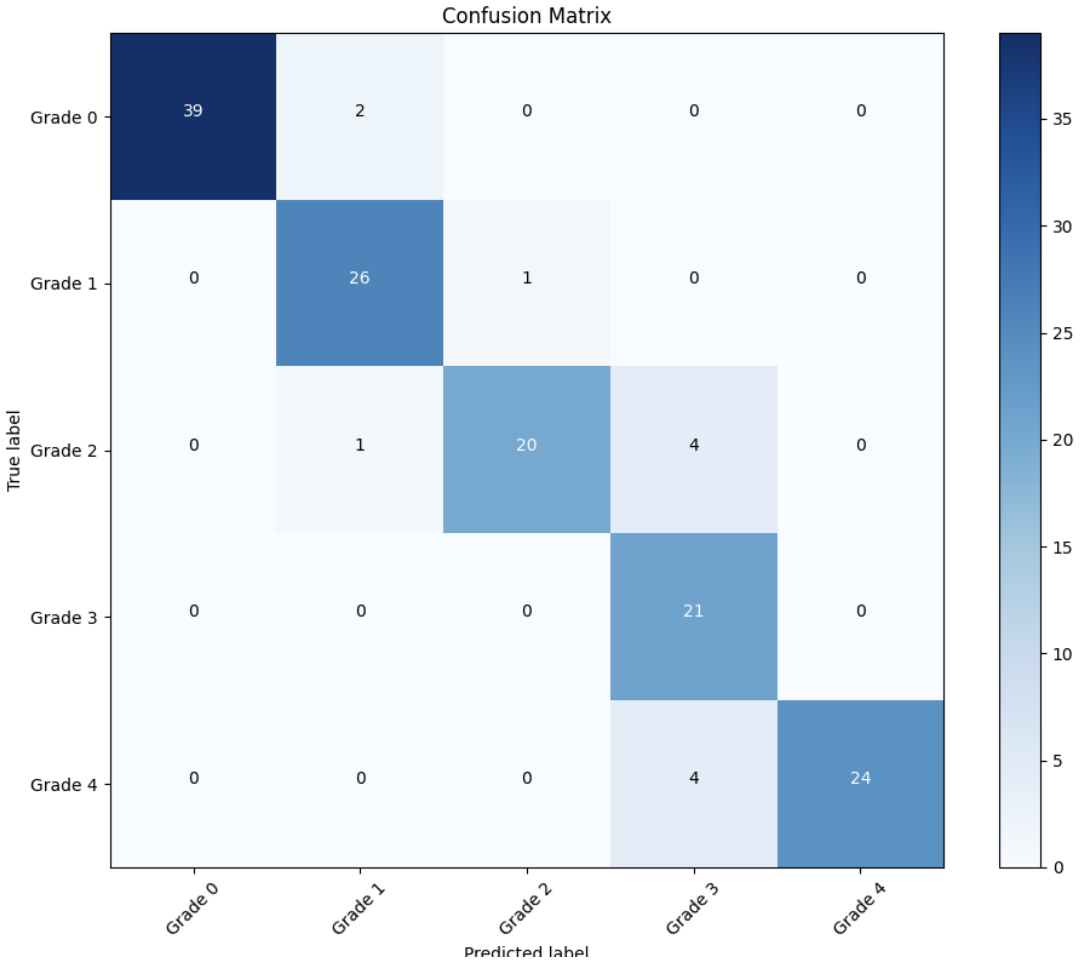

Figure 2. Confusion matrix.

Conclusion

The most common misclassification pattern occurred between adjacent grades (particularly Grades 2-3 and 3-4), which is consistent with the inherent difficulty in distinguishing between proximate histopathological grades.
The macro-averaged F1 score of 0.886 further confirms the model's balanced performance across all grades. This indicates that despite some class-specific variations, the modified U-Net architecture effectively learned discriminative features for histopathological grade classification.
Ablation studies and hyperparameter comparisons performed within the scope of the study are not included in the extended summary and will be presented through tables in the oral presentation.
In the future, the scope of our work will be expanded by training on larger datasets and will also be used for different grading and or classification of histopathology images.

Image Reconstruction and Restoration with Diffusion Network

Onur Parapan[a], Ender Mete Ekşioğlu[b]

[b] Istanbul Technical University, Electronics and Communication Engineering Department, Türkiye
parapan@itu.edu.tr

Keywords: Image Reconstruction, Image Restoration, Deep Learning, Diffusion Networks, Residual Shifting.

Aim

This study focuses on exploring the effectiveness of diffusion models in addressing two key challenges in digital image processing: image reconstruction and image restoration. The motivation behind this research lies in the frequent occurrence of image degradation in real-world settings. Various types of distortion—such as random noise, motion blur, downsampling, or missing pixels—are commonly encountered in domains like medical imaging, satellite photography, and consumer media.

Diffusion models, originally developed for high-quality image generation, have recently been applied to inverse problems such as denoising and super-resolution (Ho et al., 2020). These models are based on a simple concept: they learn how to reverse a degradation process by modeling how data transitions from a clean state to pure noise, and then teaching a neural network to invert this process.

In particular, this study also examines the role of recent innovations, especially the residual shifting technique (Zhang et al., 2023), which improves denoising performance during inference by modifying the residual flow between time steps. The primary aim is to assess whether such models can serve as effective tools for high-fidelity restoration of degraded images in a variety of settings.

Material and Method

Diffusion models consist of two sequential processes: a forward process that gradually adds noise to clean data, and a reverse process that learns to remove this noise. The forward process is typically fixed and Gaussian, while the reverse process is parameterized by a deep neural network that is trained using gradient-based optimization.

As shown in Figure 1 (see top of the second page), the forward diffusion process transforms a clean image into progressively noisier versions until it becomes indistinguishable from pure noise. The reverse process begins with random noise and reconstructs the original image by iteratively denoising each intermediate result. This bidirectional learning procedure enables the model to learn the entire data distribution.

In this research, a U-Net-based architecture is adopted for the reverse denoising network. The U-Net's encoder-decoder design, along with skip connections, allows the model to capture both fine-grained details and high-level semantics. To improve denoising fidelity, we apply the residual shifting technique as introduced by Zhang et al. (2023). This approach adjusts the model's intermediate denoising steps, improving stability and image clarity.

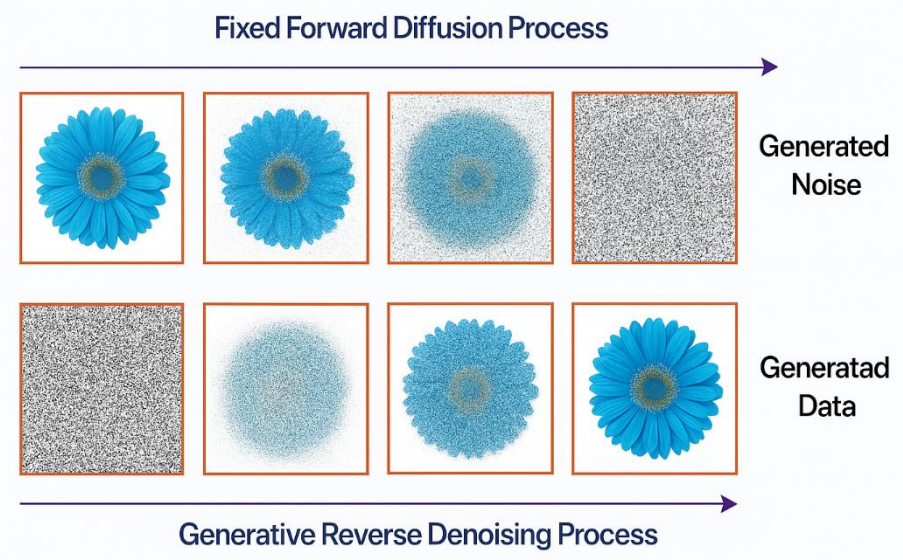

Figure 1. Forward Diffusion (Top) and Reverse Denoising (Bottom) Showing Progressive Degradation and Recovery of an Image.

Training is conducted using synthetic datasets where noise, blur, or missing patches are artificially introduced. The datasets include:

- Synthetic super-resolution data (bicubic downsampled images),
- RealSet65 and RealSet80 datasets for real-world super-resolution,
- Natural and facial image inpainting datasets, where central or random areas of images are removed,
- Blind face restoration data, involving low-resolution, degraded face images.

The models are implemented using PyTorch and trained using Adam optimizer. The loss functions include Mean Squared Error (MSE) and Structural Similarity Index Measure (SSIM) loss. Some experiments also employ perceptual loss to improve visual fidelity.
In addition to the residual shifting-based diffusion model and the standard diffusion model, a baseline U-Net model is also trained using the same datasets and training setup. This comparative framework allows a consistent evaluation of all three models—U-Net, standard diffusion, and ResShift—under identical conditions. This setup provides a clearer understanding of the benefits each model offers, particularly in terms of restoration accuracy, visual quality, and computational efficiency. Performance evaluation includes:

- Peak Signal-to-Noise Ratio (PSNR),
- Structural Similarity Index Measure (SSIM),
- Visual inspection for perceptual quality assessment.

Findings

Experimental results indicate that diffusion models are highly effective in both image restoration and reconstruction tasks. In denoising experiments, the model successfully removed both low- and high-intensity Gaussian noise, yielding clean outputs with minimal artifacts. As shown in Figure 2, in super-resolution settings, the model recovered detailed high-resolution content from severely downsampled inputs.

Figure 2. Super Resolution Processing with ResShift.

Inpainting results were particularly impressive. The model not only restored the missing regions but also generated visually coherent content that matched the surrounding context. When using the residual shifting strategy, structural consistency and edge sharpness improved significantly. For facial image restoration, the model was able to recover facial features that were heavily blurred or occluded in the input.

Table 1 summarizes the model's performance on different tasks, demonstrating high PSNR and SSIM values across the board. In many scenarios, diffusion models outperformed traditional restoration methods such as BM3D (Dabov et al., 2007) and total variation minimization, as well as other deep learning-based methods.

Table 1. Diffusion Model's Performance on Different Tasks**.**

Task	PSNR (↑)	SSIM (↑)
Gaussian Denoising	31.6 dB	0.92
Super-Resolution (x4)	28.4 dB	0.88
Natural Image Inpainting	33.2 dB	0.94
Blind Face Restoration	27.5 dB	0.89

To further evaluate the relative performance of different model types, a comparative analysis was conducted between the U-Net baseline, the standard diffusion model, and the residual shifting-enhanced ResShift model. The results show that:

- The U-Net model provides fast inference and decent restoration, particularly in low-complexity degradation scenarios.
- The standard diffusion model delivers improved perceptual quality and better PSNR/SSIM scores but requires more inference steps and computation.
- The ResShift model significantly reduces the number of sampling steps needed while maintaining or improving quality. It strikes a balance between performance and efficiency, outperforming both the U-Net and standard diffusion in most tasks.

This comparison highlights the superiority of ResShift for complex restoration problems, particularly when computational efficiency is also a priority.

An additional observation is the model's robustness. Even in cases of extreme degradation—such as when more than 50% of the image pixels were missing—the ResShift model was still able to generate plausible and coherent reconstructions. This supports previous findings from the DDRM framework proposed by Wang et al. (2022), where diffusion models are used as flexible priors for solving inverse problems.

Conclusion

This study confirms that diffusion networks can serve as powerful tools for solving image restoration and reconstruction problems. They provide a unified and general-purpose approach capable of addressing various types of degradation without requiring task-specific architectures.

Their performance in denoising, super-resolution, and inpainting tasks is not only competitive but often superior to traditional and even many deep learning-based methods. The inclusion of residual shifting further improves the model's accuracy and robustness, making it suitable for real-world applications.

The direct comparison between U-Net, standard diffusion, and ResShift models further reinforces the value of diffusion-based methods, especially when enhanced with techniques like residual shifting. Overall, diffusion models represent a promising direction for future research in image processing. Further work may focus on reducing computational costs during inference and adapting these models for real-time or mobile applications.

Customizable Fluidic and Anisotropic Vocal Fold Phantom for Biomechanical Analysis

Afarin Sarrafzadeh[a], Onur Ferhanoğlu[a], Ahmet C. Erten[a]

[a] Istanbul Technical University, Department of Electronics and Communication Eng., Turkey
Sarrafzadeh22@itu.edu.tr

Keywords: Vocal Fold Phantom, Anisotropy, Young's Modulus, Tunable Biomechanics, Fluid Inclusion.

Aim

The vocal folds, situated within the larynx, play a vital role in the process of phonation. They span across the laryngeal opening, forming a narrow gap that allows airflow from the lungs. As air passes through this gap, it induces self-sustained vibrations of the vocal folds, thereby generating sound [1]. A key mechanical property of the vocal folds is their anisotropy — their material behavior varies depending on the direction of applied force. Specifically, parameters such as Young's modulus change in relation to the direction of airflow originating from the lungs. This directional dependence significantly influences sound production, making it essential to accurately capture this behavior in biomechanical models. Such models are critical for advancing our understanding of vocal fold function and for developing effective treatments for voice disorders [2].

Synthetic vocal fold models have long been utilized to investigate the mechanics of phonation, significantly advancing the understanding of tissue dynamics and vocal pathologies. These models are generally categorized into two main types: membranous and solid elastic [3]. Membranous models, extensively studied by Titze et al. (1995) and Ruty et al. (2005) [4], capture certain vibratory behaviors of human vocal folds but lack precision in structural design. To address this, Thomson et al. (2005) and Murray and Thomson (2012) proposed solid elastic models using soft polymers like silicone to better replicate tissue properties. However, the inherent isotropic nature of these materials limits their ability to accurately mimic vocal fold mechanics [5]. More recently, multilayer silicone models with graded stiffness across layers, introduced by Greenwood and Thompson (2021), have demonstrated improved similarity to native vocal fold structures [6]. Nevertheless, these designs rely on discrete stratification rather than a truly heterogeneous architecture. An alternative approach involving fiber-reinforced hydrogels by Ferri-Angulo et al. (2023) has shown enhanced replication of anisotropic mechanical behavior [7]. Despite these advances, hydrogels pose challenges such as limited long-term durability, susceptibility to dehydration, and overall stability, restricting their use in prolonged phonation studies.

To overcome these limitations, this study introduces a novel approach to achieving anisotropy by embedding a natural latex rubber tube within a polydimethylsiloxane (PDMS) cube representing vocal fold tissue. Unlike previous methods that involve intricate layering or specialized reinforcement, the proposed design offers a simpler and more practical fabrication process. To assess the model's ability to replicate anisotropic behavior, both computational simulations and experimental analyses were performed. The results closely match the anisotropic properties observed in real vocal folds, validating the effectiveness of the proposed phantom for biomechanical phonation research.

Materials and Methods

Computational modeling

Simulations were conducted in COMSOL Multiphysics using the Solid Mechanics module. A cube with 15 mm sides and Young's modulus of 2.401 kPa was modeled. The 15 mm dimension was selected as an average, considering the typical human vocal fold length ranges from 11 mm to 21 mm [1]. Anisotropy was introduced by embedding a natural latex rubber tube, characterized by Young's modulus of 350 kPa, at the center of the cube. To incorporate tunability, the tube was simulated with varying water fill levels, from 0% to 80%, with the remainder filled by air. The bulk modulus was defined as 2.2 GPa for water and 101 kPa for air [8]. A total force of 98 mN was applied in both longitudinal and transverse directions. The resulting displacements were measured to deduce Young's modulus values [9].

Fabrication of Phantoms

Initially, a cubic mold with an internal cavity of 15 mm and wall thickness of 1.1 mm was designed in SolidWorks and fabricated using PLA filament via 3D printing. This mold was used to cast a silicone cube with dimensions of 15 mm × 15 mm × 15 mm. Next, a cylindrical insert measuring 3.1 mm in diameter and 15 mm in height was also designed in SolidWorks and 3D-printed. This insert was positioned at the center of the mold to reserve space for the natural latex rubber, which was introduced after the silicone had fully cured. The mold setup is illustrated in Figure 1.

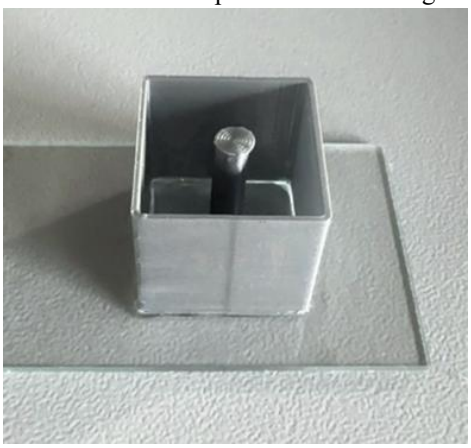

Figure 1. The PLA mold for the vocal fold phantom.

A silicone mixture containing 88% silicone, with Young's modulus of 2.401 kPa, was poured into the prepared mold and allowed to cure for 48 hours. Once the silicone had fully set, the central cylindrical insert was removed to make space for the tube. A natural latex rubber tube—15 mm in height, with an outer diameter of 3.2 mm, an inner diameter of 1.6 mm, and Young's modulus of 350 kPa—was then inserted into the center of the cube. The tube was filled with varying percentages of tap water, which has a bulk modulus of 2.2 GPa [10], to enable tunability. To prevent water leakage, a thin layer of adhesive was applied to both ends of the tube, as shown in Figure 2. Image analysis software, ImageJ, was used to process the captured images and calculate the displacement of each sample under applied force**.**

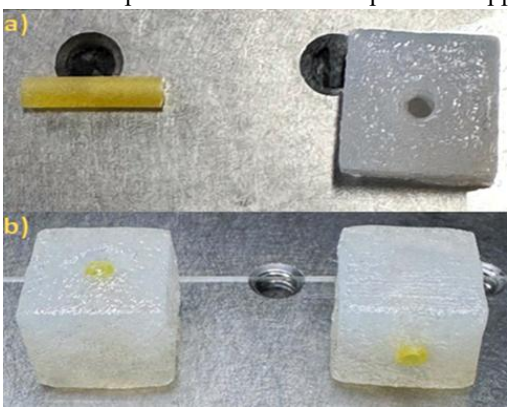

Figure 2. (a) The cured silicone structure with a hole in the center with a latex tube next to it, and (b) two complete vocal fold phantoms with latex tubes inserted.

Experimental setup

The experimental setup consisted of a digital scale and a camera connected to a laptop for image-based displacement measurements. A reference image of each sample was captured prior to loading, and this image was used in ImageJ software to set the initial cube length at 15 mm. A 10-gram weight, corresponding to a force of 98 mN, was then applied to the top

surface of the cube, while the bottom was held fixed. This procedure was carried out for both longitudinal and transverse orientations as shown in Figure 3.

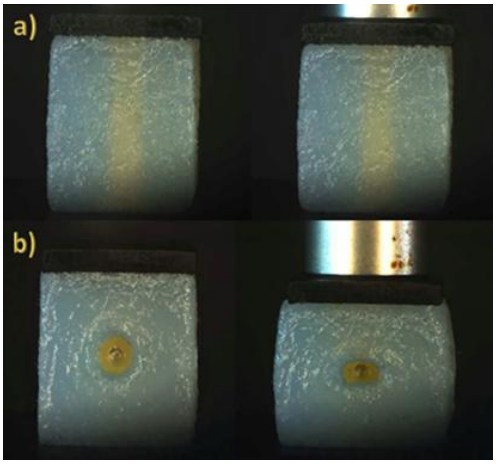

Figure 3. (a) Displacement in the longitudinal direction, and (b) Displacement in the transverse direction.

Following the application of force, a second image was taken to record the deformed state of the sample. The post-deformation length was measured in ImageJ, and displacement was calculated by comparing the initial and deformed lengths. Using this data, the mechanical response of each sample was quantified through the calculation of Young's modulus.

Findings

Simulation

In COMSOL Multiphysics, a compressive force of 98 mN was applied to the cross-sectional area of the cube in both longitudinal and transverse directions. For each configuration, with varying water-to-air ratios inside the latex tube, the resulting displacement was recorded and used to calculate Young's modulus. The Young's modulus in the transverse direction remained constant at 2.6 kPa, while in the longitudinal direction, it varied significantly, ranging from 12.18 kPa to 47.34 kPa, depending on the water content as presented in Table 1.

Table 1. The simulation and experimental results are based on longitudinal displacement (mm), the corresponding Young's modulus (kPa), the transverse displacement (mm), and the corresponding Young's modulus (kPa) for varying water percentages.

		Simulations		**Experiments**	
Sample	**Water %**	**E_L Young's modulus (kPa)**	**E_T Young's modulus (kPa)**	**E_L Young's modulus (kPa)**	**E_T Young's modulus (kPa)**
1	0	12.18	2.6	11.58	2.3
2	20	14.08	2.6	13.9	2.3
3	40	18.88	2.6	18.09	2.3
4	60	26.23	2.6	25.42	2.3
5	80	47.34	2.6	47.68	2.3

Experimental

Using ImageJ software, the displacement of each deformed sample under a 10-gram load was measured. The experimental findings closely match the simulation results, confirming that Young's modulus in the transverse direction consistently remains at 2.3 kPa across all samples. In contrast, variations in the water content within the latex tube significantly influence the longitudinal Young's modulus. Displacement and corresponding Young's modulus values for both directions are also summarized in Table 1. Additionally, a comparison of water content and longitudinal Young's modulus, illustrating both simulation and experimental data, is presented in Figure 4.

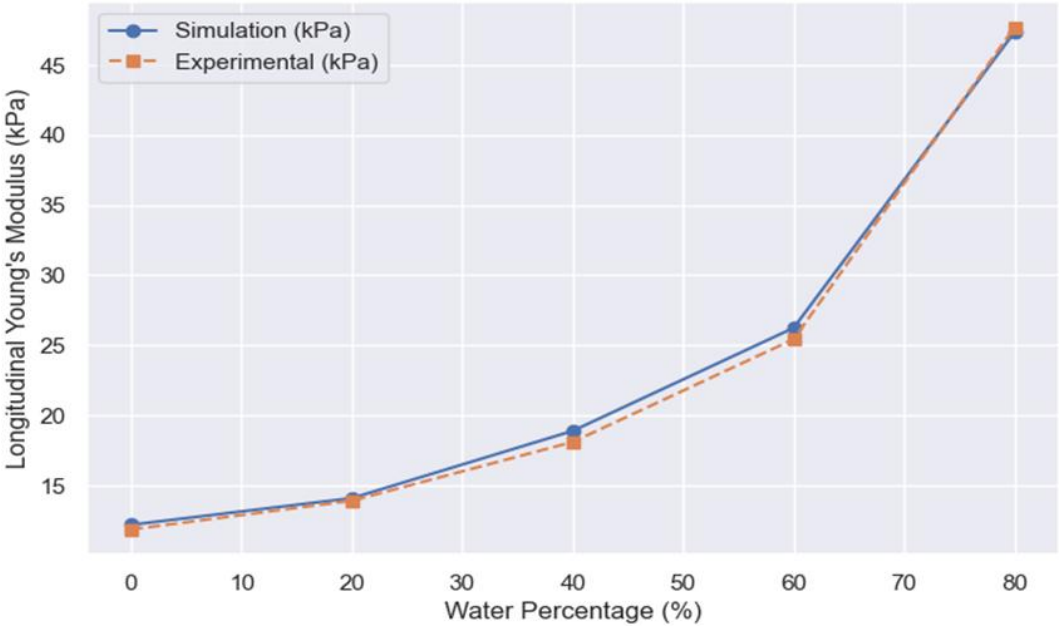

Figure 4. Longitudinal Young's Modulus vs. Water Percentage.

Conclusion

This study successfully presents a tunable vocal fold phantom that effectively replicates the anisotropic characteristics of human vocal folds. The strong correlation between simulation and experimental results confirms the validity and reliability of the proposed method. By embedding a latex tube within a PDMS cube and adjusting the internal water-to-air ratio, the model achieved a tunable Young's modulus range from 2.3 kPa to 47.68 kPa. Notably, modulating the water content between 0% and 75% enables coverage of the physiological stiffness range of human vocal folds (2 kPa to 40 kPa) [11]. Moreover, the ability to remove, refill, and reinsert the latex tube minimizes the need for fabricating multiple samples, thereby reducing both production complexity and preparation time. This simple yet effective approach to mimicking anisotropy and enabling adjustable stiffness offers a practical and versatile tool for studying vocal fold mechanics, advancing phonation research, and investigating voice disorders.

Aim

Capsule endoscopy-assisted GI tract analysis has revolutionized endoscopy procedures since its emergence in 2000, and due to its minimal invasiveness and patient-friendly mechanism, it has been widely adopted by clinicians since then. Early gastrointestinal examinations were performed by endoscopy or/colonoscopy tubes, which involved sedation medications and invasive tube insertions. In contrast to conventional endoscopy and colonoscopy procedures, WCE has introduced a patient-friendly and minimally invasive GI tract examination by providing enhanced imaging techniques. This imaging procedure enables early detection of gastrointestinal diseases such as inflammatory bowel conditions like Crohn's disease, autoimmune diseases like Celiac, obscure bleeding in the intestines, and various tumors [1].

Besides the wireless capsule endoscopy's commercial success, it is limited only to imaging procedures. However, researchers have introduced various techniques through their ongoing studies to develop new capabilities for the capsules, focusing on locomotion and navigation systems. A couple of studies have innovatively been done to improve capsule mobility, including magnetic actuation using external solenoids [3], robotic appendages for controlled movement [4], biomimetic propulsion inspired by jellyfish-like movements reducing tissue damage [5-6], spiral-based motion mechanisms [7], using magnetic soft robotic for MagCap functionality with the integration of drug release capabilities of capsules [8].

Single-capsule endoscopy in conventional procedures struggled to perform complicated medical tasks such as biopsy, drug delivery, and real-time diagnostics due to functionality limitations. To overcome such limitations, literature has revealed other functionalities for WCE, such as a real-time polyp-detection system integrated with WCE based on AI and deep learning algorithms [9], introducing micro positioning and holding mechanics for drug delivery uses in WCE [10], and integration of a robotic device to WCE for biopsy procedures [11].

Besides the broad clinical applications of WCE, the conventional single capsule endoscopy system has space limitations that limit its multifunctionality, however, multiple capsule endoscopy trains can operate in coordination to perform various clinical tasks. Although we previously approached the multi-capsule endoscopy mobility by introducing coil-based inductive power systems [12] and magnetic-based remote actuation locomotion [14], these methods have encountered challenges in navigating the capsule-train through complex GI environment, particularly in sharp radius of curvature (ROC), less than 50mm, transitions. In this study, we introduce a multi-capsule endoscopy train model connected via flexible magnetic springs designed to traverse tight ROCs while maintaining stable inter-capsule connectivity.

This study focuses on the development of the WCE train, mainly on locomotion limitations through sharp GI tract turns, by introducing spiral spring modifications to the capsule's cap that assist the intracapsular connectivity. The primary objectives of our research include:

- Developing a new approach by using magnet-equipped springs that support the capsule connection during sharp turns.
- Analyzing the pre-designed springs' mechanical behaviors by performing COMSOL simulation and physical testing.
- Administering phantom experiments with different intestine-like surfaces to compare different intestinal conditions, mimicking the movement of the capsule trains in realistic simulations.

Materials and Methods

System Design & Components

Our capsule-train system consists of two capsules attached, each equipped with a custom-designed spiral spring. The springs encompass magnets that enable stable attachment between capsules while allowing for necessary flexibility during movement. The capsule train in this study, unlike the designs discussed in the literature, provides a physical connection that can tolerate the natural peristaltic forces when it passes through sharp turns of the GI tract.

- The study overviews three different capsule designs with different spring Characteristics in order to find the most suitable capsule-spring configuration, which is represented in Figure 1.
- Intestinal phantoms with a sharp radius of curvatures, indicated in Figure 2, were designed with a SolidWorks program to simulate the curvature parts of the GI tract.

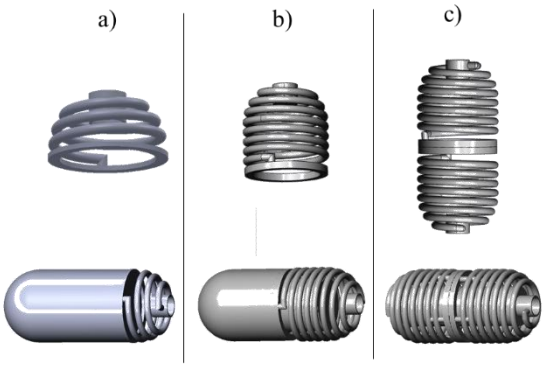

Figure 1. Different capsule-spring prototypes were designed in SolidWorks. (a) A 6 mm spring, 4 coils, 1.1 mm wall thickness integrated with a 22 mm length capsule; (b) A 14 mm spring, 8 coils, 1.1 mm wall thickness with a capsule; (c) The full spring design, which encompasses a 28 mm length spring, 16 coils, 1.1 mm wall thickness with an inter-capsule configuration. These different arrangements were tested to determine their ability to resist the forces while keeping the capsules connected during locomotion.

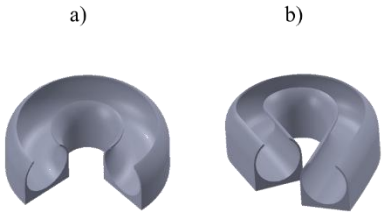

Figure 2. Human bowel designs indicate the curved paths of the GI tract, which multi-capsule endoscopies would face challenges in locomotion. (a) An intestinal model with a 50mm radius of curvature; (b) an intestinal model with a 25mm radius of curvature designed in SolidWorks.

Optimization of the Springs

To ensure the optimal performance of the springs, a finite element analysis based on COMSOL Multiphysics was conducted, and various metrics were tested. Key mechanical characteristics of the spiral springs were tested to attain the most suitable designs for the study.

Spring constant (K) was evaluated to reach a balance between stability and flexibility under peristaltic forces, stress**,** and yield point analysis were executed to prevent the springs from deformation under bowel contractions, and the expected displacement was calculated under the known forces to ensure the avoidance of the tissue damage, these metrics have been shown in Table 1. Finally, by considering all the factors, three of the many spring designs were selected for further experimental analysis.

Table 1. Finite-element analysis of spring information.

Parameters	***Values***
Spring constant	*50.9 N/m*
Stress	*0.0303 GPa*
Young's Modulus	*18.49 MPa*
Displacement	*4.44mm*

An experimental assessment was conducted to compare the printed spring constant ($K_{Simulation}$ = 50.9 *N/m*) with the finite-element analysis. the K constant was calculated by a setup, and the result was $K_{experimental}$ = 40 *N/m***.** The discrepancy between the simulation result and the experimental one is caused by variations in PLA characteristics and the thickness differences between 3D-printed PLA and simulated springs. In Table 2, we tabulate the material properties of the fused-deposition modeling printed capsule and phantom parts.

Table 2. Polylactic acid characteristics.

Parameters	***Values***
E_{pla}	*2636+-330 MPa*
ρ_{pla}	*1250 kg/m³*
v_{pla}	*0.3*

Experimental Setup

The setup was arranged with a stepper motor connected to a motor driver, which is controlled by an Arduino Uno, and the stepper motor was connected to the capsules with a nylon string as illustrated in Figure 3. Experiments were conducted to ensure the capability of the proposed designs to maintain inter-capsule connectivity through different ROCs. In the first step, bowel phantoms, printed with PLA, were used with a smoothened surface, testing the model accuracy in two different radii of curvatures (50 and 25mm). After getting the expected result from three different spring-capsule configurations, the next step was to imitate the human-like intestinal structure. We introduced a silicon layer with 90% silicon and mimicked a villus-like configuration on the surface of the intestinal phantoms, which were tested under the same setting.

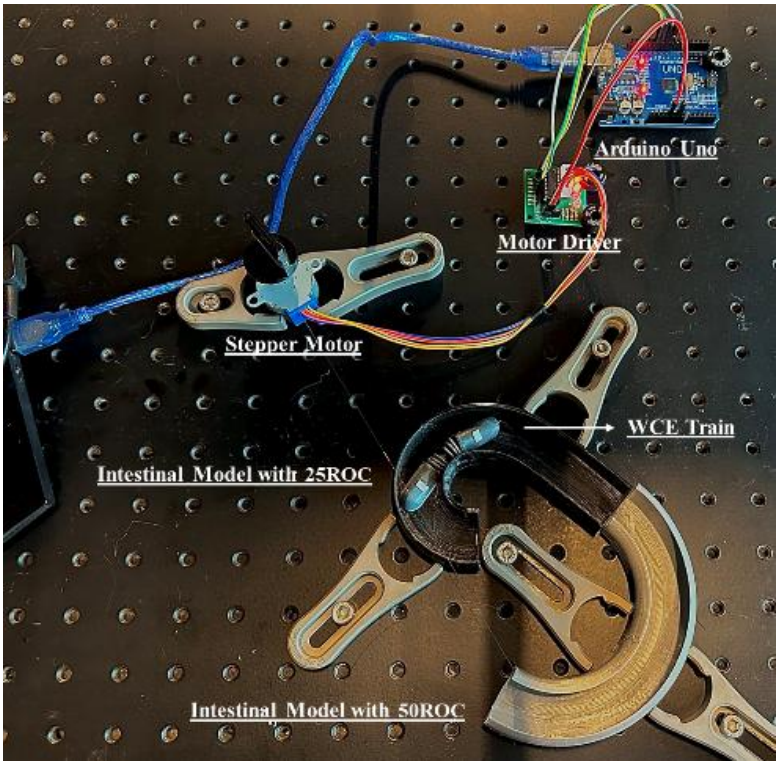

Figure 3. Experimental setup components.

The locomotion of the capsules was mimicked using a stepper motor, which was controlled by an Arduino-uno system; the motor was programmed to pull a fish rope attached to the first capsule. The pulling speed was conducted at 0.1 mm/s, which is a rounded average speed used following the average peristalsis speed of 0.5-4.3 cm/min in humans [15]. Also, 10x peristalsis speed(1mm/s) was used to survey the train mobility in harsh circumstances. Each experiment setup was captured in video recordings and was post-processed using MATLAB-based movement tracking algorithms to assess the capsule-distance variations during passing the bowel model and its attachment stability through sharp turns. The post-processed locomotion process is shown in Figure 4.

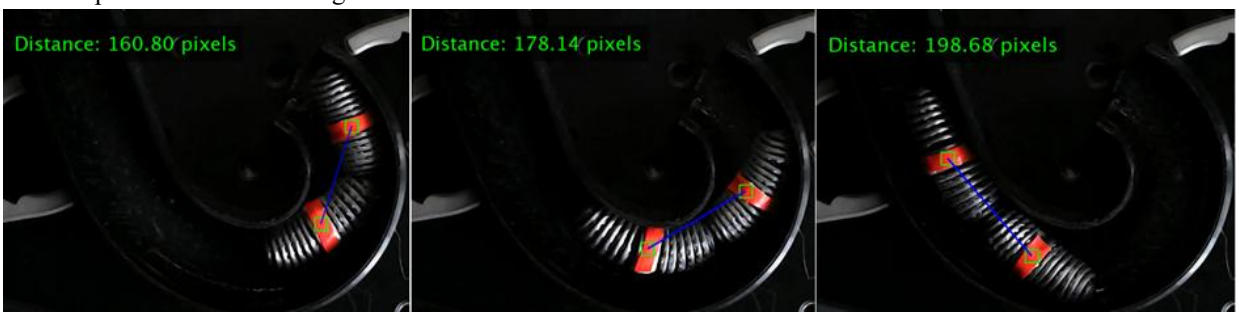

Figure 4. Post-processing shots from the distance evaluation in MATLAB.

Findings

Through all the examinations with various intestinal configurations and capsule-spring models, the results yielded satisfaction when the WCE train navigated through sharp turns with 50 mm and 25 mm ROCs. The evaluation of the capsule train interconnectivity and capsule distance modifications showed success. Also, the distance variation, based on different spring stiffness (K-values) between capsules, reveals that the suggested model supports the development of capsule endoscopy train locomotion.

Conclusion

Our findings suggest that multi-capsule endoscopy trains with magnetic spring connections provide a viable solution for traversing complex intestinal pathways while maintaining stable inter-capsule connectivity. Compared to previous coil-based and passive magnet configurations, which had limitations in ROCs 50mm and below, the proposed design is more adaptable to sharp ROCs and real GI conditions. Future work will focus on integrating advanced sensors, improving real-time control algorithms, and conducting in vivo testing to further validate the approach.
