Keywords: Driving Monitoring System, Pupil Detection System, Pupil Diameter Detection, Pupil Tracking System.

Aim

Eye tracking, or pupil tracking, is a key method for monitoring an individual's health. Eye-tracking technology comes up with some optimal solutions to health monitoring, such as noninvasiveness and easy placement for various scenarios. Typically, Eye tracking is achieved with a device that consists of a video camera and generally a constant wavelength and intensity IR light source as hardware. The software component processes captured images to detect the pupil—an aperture at the center of the eyeball—and determine the gaze point. This method can be used to detect both psychological [1] and physiological [2] symptoms. Besides, it can be used for driver monitoring in cars or trucks. Nowadays most high-segment cars have this monitoring system to measure driver tiredness, as shown in the illustration in Image I, drowsiness or gaze location, and the system creates some alerts for unintentional situations to prevent accidents [3]. However, environmental lighting conditions, IR source intensity and even eye color can affect the accuracy of pupil detection. This study aims to compare the quality of pupil detection under varying lighting conditions, eye colors, light source intensities, and wavelengths.

Material and Method

Hardware Setup and Data Collection:

The developed hardware setup includes a webcam and three types of IR LEDs with wavelengths of 730 nm, 850 nm, and 940 nm. Each type includes two 1 W LEDs.The camera used is the Piranha-9635 webcam (shown in Image 2), with its IR filter removed to allow IR light capture. Two eye-tracking techniques—bright pupil and dark pupil methods—exist [4]. This study uses the dark pupil method by positioning the LEDs at a specific distance from the camera sensor.
Images were collected with the lights both on and off, to mimick day and night time conditions. For eye color evaluation, images were taken of blue- and brown-eyed participants under all three wavelengths, with a constant current applied to the LEDs. Participants looked directly at the camera and sequentially at each corner of the screen, as illustrated in Image 3.
Secondly, for intensity examination again, three different wavelengths have been used, and input current has been changed between 0 A and 1.5 A with respect to the LED's specification during environmental lights being on and off. Similarly, the participant looked at 4 points of the screen and camera as seen in Image 4 and Image 5. Additionally, a picture with 10 different dots in it has been shown on the monitor, and the participant has looked at the 10 dots in order.

Image processing:

After collection has been done, the image processing part has been realized. For processing images, a Python script has been created. The image processing package, open computer vision library, has been mainly used in scripts. Color conversion, adaptive thresholding, and edge detection methods have been applied to images. Detected edges classified with respect to their circularity. Finally, the pupil and the pupil center have been marked on the images. A total of 65 pictures have been taken for the eye color study and 451 pictures for the light effect study. The algorithm can detect pupils in 267 images, while 39 of these pictures belong to the eye-color study. In comparison, manual marking has also been done to image center points and pupil diameters generated.

Findings, Results and Discussion

As a result, comparison with respect to the changing wavelengths has been done. Firstly, for different eye color studies, blue eye color has shown a 1.72 pixel error for the center point and a 1.26 pixel error for the pupil diameter value at 730 nm wavelength. In contrast, brown eye color has shown a 2.28 pixel error for the center point of the pupil and a 3.17 pixel pupil diameter error at a 730 nm wavelength. At 850 nm, again the blue-colored eye has given a better result, with 1.14 pixel center point error and 0.90 pixel pupil diameter error, while the brown eye has 3.35 pixels and 1.97 pixels, respectively. Finally, at the 930 nm source wavelength, both eye colors have shown worse results with 5.51 and 5.57 pixel center point error for brown and blue, 5.55 and 4.22 pixel pupil diameter error. With this study, it can be specified that eye color changes the pupil detection method success rate. Secondly, a source current change effect has created a discernible result, as it can be seen in Table I. Considering all-day scenarios, 730 nm sources with currents of 0.60 A and 0.84 A are proposed as the best solution when a center point wants to be detected. When pupil diameter is added as a parameter that is looked for, an 850 nm source with 0.65 A gives the best result and has the most detectable number of images. When Table I is observed, from the total calculations the best result for the diameter error can be seen at 940 nm and 0.79 A. However, 940 nm results mostly stay at the day images. Therefore, 940 nm is not made a part of the best solution for an all-day scenario. Now, it is mentioned, 850 nm wavelength with 0.78 A gives the best result for pupil center estimation for only the daylight condition scenario, while 850 nm wavelength gives the best result for pupil diameter with 1.04 A. In contrast, when night conditions are mentioned, again the 850 nm wavelength source gives the best results but with a 0.65 A current in that situation.

Conclusion

This study demonstrates that variations in LED wavelength and current significantly affect pupil detection performance under different lighting conditions and for different eye colors. To improve driver monitoring systems, adaptable LED configurations with variable voltage control and integrated ambient light sensors are recommended. Furthermore, incorporating eye color information could enhance the robustness and accuracy of real-time driver monitoring.

Multi-Class Classification for Skin Lesions Using Deep Learning Techniques

Ümmühan Kopal[a], Mürvet Kırcı[a]

[a] Istanbul Technical University/ Graduate Institute, Department of Electronics and Communication Engineering, Biomedical Engineering Program, Türkiye
kopal21@itu.edu.tr

Keywords: Skin Lesion, Multiclass Classification, Deep Learning.

Aim

Skin cancer is one of the most prevalent and deadly types of cancer globally, with early detection being a critical factor in improving patient outcomes. Traditional diagnostic methods rely heavily on dermatologists' expertise, which can be time-consuming and prone to human error. Recent advancements in deep learning have shown significant promise in automating the classification of skin lesions, thereby aiding in early and accurate diagnosis.(Esteva et al., 2017) This study aims to develop a robust multi-class classification system for skin lesions using deep learning techniques, specifically leveraging the ResNet (Residual Network) architecture. The primary objective is to classify dermoscopic images into multiple categories, including melanoma, basal cell carcinoma, and benign keratosis, using a publicly available dataset such as the ISIC 2019. (Isic2019 dataset, 2023) By employing advanced techniques such as data augmentation and transfer learning, this work seeks to improve the generalization and accuracy of the model, ultimately contributing to more efficient and reliable skin cancer diagnosis.

Material and Method

Dataset: The study utilizes the ISIC archive, a publicly available dataset containing thousands of dermoscopic jpeg images of skin lesions. The dataset includes images labeled with various categories, such as melanoma, basal cell carcinoma, benign keratosis. (Kaggle, 2023)

Model Architecture: The ResNet architecture is chosen due to its proven effectiveness in image classification tasks. ResNet residual blocks address the vanishing gradient problem, enabling the training of deeper networks without performance degradation. A pre-trained ResNet model is fine-tuned using transfer learning to adapt it to the specific task of skin lesion classification.

Data Augmentation: To enhance the model generalization ability and prevent overfitting, data augmentation techniques are applied. These include random rotations, flips, and brightness adjustments, which artificially increase the diversity of the training dataset.

Training Process: The model is trained using a split of the dataset, with 80% allocated for training, 10% for validation and 10% for test. Transfer learning is employed by initializing the model with pre-trained weights from ResNet, followed by fine-tuning on the skin lesion dataset. The model is optimized using the AdamW optimizer. The model was trained for 100 epochs with a mini-batch size of 64 and an initial learning rate of 0.0001. Table 1 demonstrates the hyperparameters of the Resnet-18 classifer used in the experiments.

Table 1. Hyperparameters of the Resnet-18 Model.

Parameters	Values
Input Size	224*224*3
Batch Size	64
Loss Function	Cross Entropy
Activation	ReLU
Optimizer	AdamW
Learning Rate	0.0001
Train/Validation/Test Split	80% / 10% / 10%

The cross-entropy loss is used as loss function. The loss function quantifies the difference between predicted andactual values during training. Lower loss values indicate better model performance. The prediction and actual labels can be seen in Figure 1.

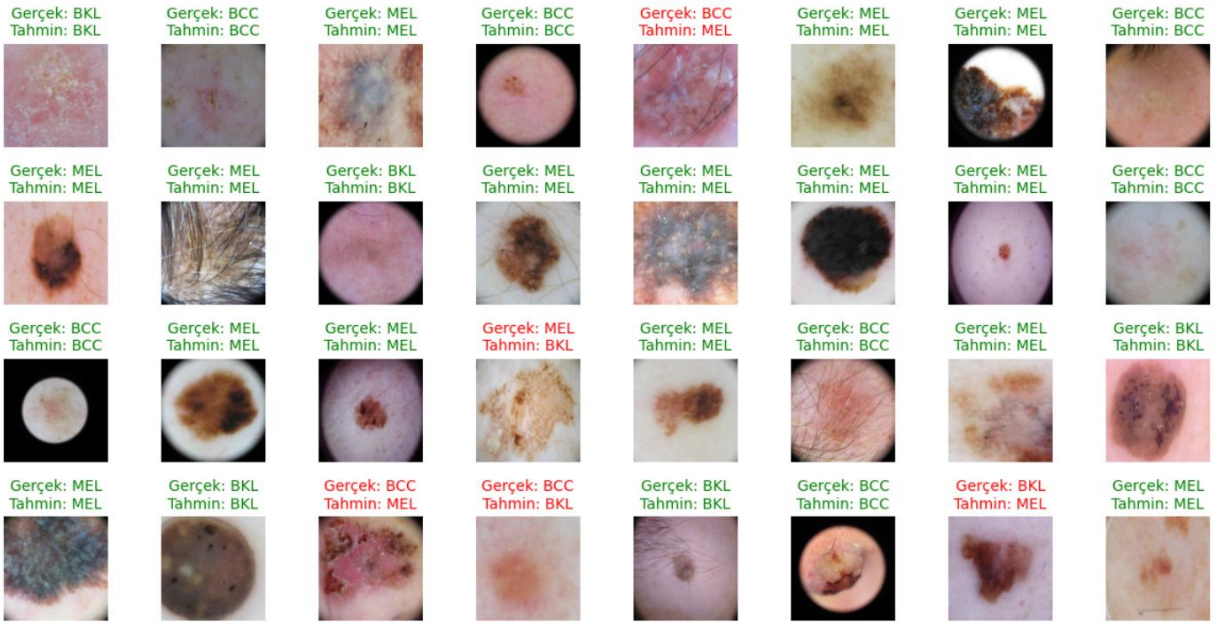

Figure 1. Label and Expected Label Comparison.

Evaluation Metrics: The performance of the model is evaluated using standard metrics such as accuracy, precision, recall, and F1-score. A confusion matrix is also generated to analyze the classification performance across different categories. (Nigar et al., 2022) The confusion matrix results can be seen in Figure 2.

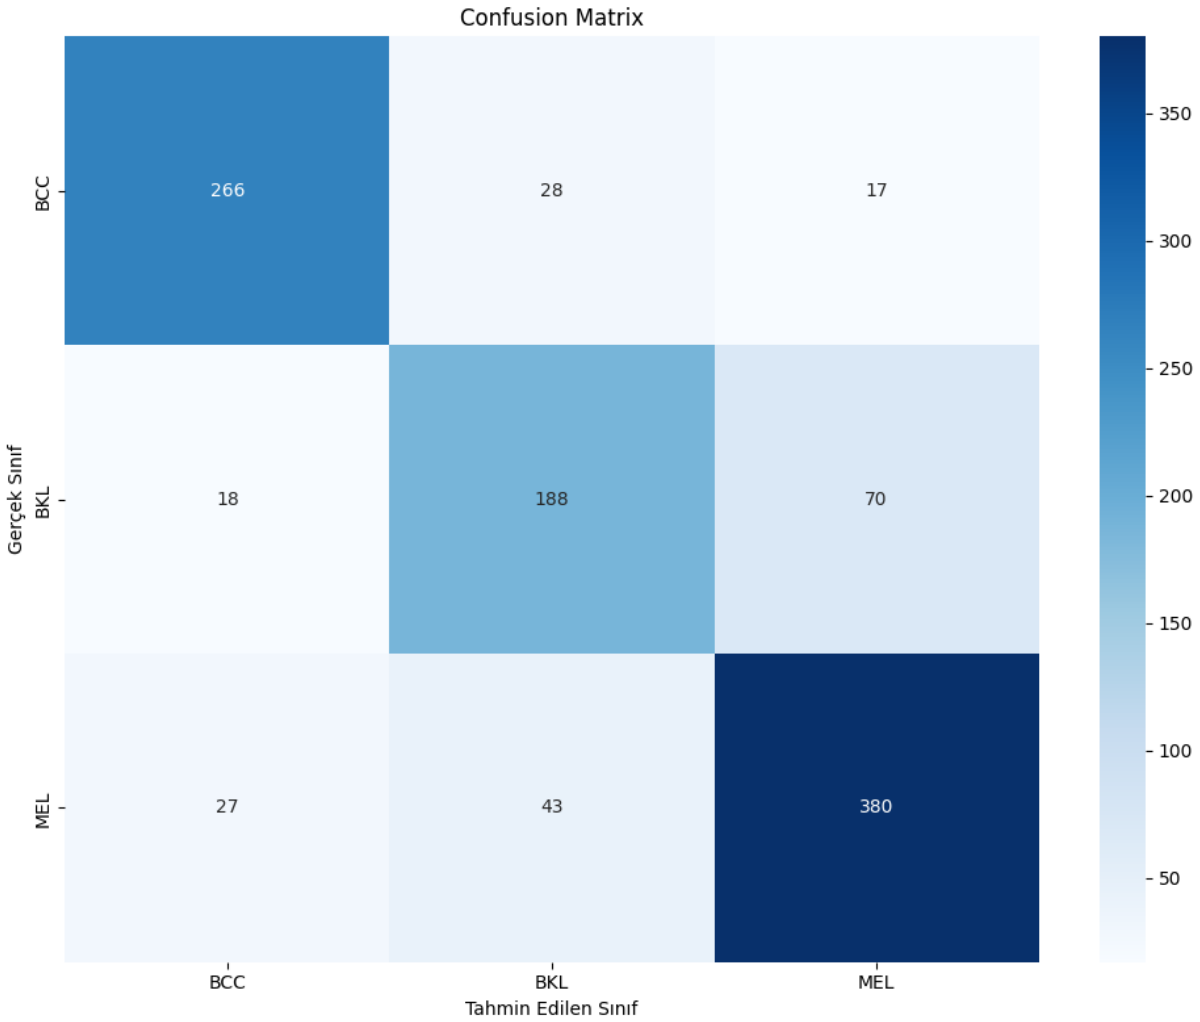

Figure 2. Confusion Matrix of Model.

Findings

The results from the model training and evaluation provide valuable insights into its performance.

Performance Metrics on Test Set

Accuracy: **80.42%**

Accuracy is a metric used to evaluate the overall performance of a classification model. It measures the proportion of correct predictions out of all predictions made (Equation 1)**.**
This is a relatively strong result, suggesting that the model performs well overall. However, in medical applications, accuracy alone may not be sufficient, as it does not account for class imbalances or the specific costs of false positives and false negatives.

$$Accuracy = \frac{TP + TN}{FP + TN + TP + FN} \quad (1)$$

Precision: **80.28%**

Precision is a metric used in classification models to measure how many of the predicted positive instances are actually correct**.** It helps evaluate how well the model avoids false positives (Equation 2).
This indicates that the model has a good ability to avoid false positives. In the context of skin lesion classification, this means that when the model predicts a lesion as malignant (e.g., melanoma), it is correct 80.28% of the time. This is important for reducing unnecessary biopsies or treatments.

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

Recall: **80.42%**

Recall is a classification metric that measures how many of the actual positive instances the model correctly identified**.** It helps evaluate how well the model avoids false negatives (Equation 3).
This is a strong result, indicating that the model is effective at capturing most of the true positive cases. In medical diagnostics, high recall is critical because missing a positive case (e.g., failing to detect melanoma) can have severe consequences.

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

F1 Score: **80.32%**

F1 Score is a metric that combines Precision and Recall into a single value. It is useful when you need a balance between avoiding false positives **(**Precision**)** and avoiding false negatives **(**Recall) (Equation 4).
This score reflects the model's ability to maintain a balance between avoiding false positives (precision) and avoiding false negatives (recall). In the context of skin lesion classification, this is particularly important because both false positives and false negatives carry significant costs.

$$1 = 2\,\frac{(Recall).(Precision)}{Precision + Recall} \quad (4)$$

Class-Based Performance Metrics:

BCC (Basal Cell Carcinoma):
Precision: **85.53%**
Recall: **85.53%**
F1 Score: **85.53%**
The model's performance for this class is excellent. High values were obtained in terms of both precision and sensitivity.

BKL (Benign Keratosis Lesions):
Precision: **72.59%**
Recall: **68.12%**
F1 Score: **70.28%**
The model struggles most with the BKL class, particularly due to its low recall value (68.12%). This suggests that BKL samples are often misclassified, especially as MEL.

MEL (Melanoma):
Precision: **81.37%**

Recall: **84.44%**
F1 Score: **82.88%**
The model also performed very well for this class. Especially the high sensitivity (recall) value shows that it can correctly detect the majority of melanoma cases.

Conclusion

Skin cancer remains one of the most significant health challenges worldwide, and the accurate classification of skin lesions is crucial for early and effective diagnosis. In this study, we developed a ResNet18-based model to classify skin lesions into multiple categories, including melanoma, basal cell carcinoma, and benign keratosis. According to these results, we achieved an accuracy of 80.42%, a precision of 80.28%, a recall of 80.42% and an F1 score of 80.32% with our skin lesions classification model on the test set. The developed multi-class classification system using the ResNet architecture demonstrates promising results in classifying skin lesions. The model is generally successful in the task of classifying skin lesions. An F1 score above 80% indicates that the model has potential for clinical use.
When we evaluate the class-based metrics, the performance of the model is high for the BCC and MEL classes. Especially the detection of a serious condition such as melanoma (MEL) with high recall shows that the model is clinically valuable. The fact that the performance is low for the BKL class compared to other classes indicates that this class should be enriched with more examples or the model should learn the features specific to this class better. Techniques such as oversampling, class weighting, or advanced data augmentation can be applied to improve the model's performance on the BKL class. These results show that the model is promising for clinical use and that performance can be further increased by making improvements, especially for the BKL class.
To enhance model results, several improvements are necessary. Since the results obtained in another study conducted with the same data set were better, we will continue to work on improving the results of our model. (Kassem et al., 2020) These improvements include enhancing data quality through advanced augmentation techniques or additional data collection, implementing regularization techniques to reduce overfitting, addressing class imbalance through methods such as oversampling or class weighting. Furthermore, exploring more advanced architectures, and leveraging transfer learning from suitable datasets could significantly improve the model's performance.
In conclusion, while the current model shows promise, there is substantial area for improvement. We are actively working on refining the model by addressing the identified issues and optimizing its architecture and training process. These efforts aim to enhance the model's classification performance, ultimately contributing to more accurate and reliable skin cancer diagnosis. Future work could focus on implementing more sophisticated data augmentation techniques, exploring ensemble methods, or testing alternative architectures to further enhance performance. These efforts aim to improve the model's classification accuracy and reliability, ultimately contributing to more accurate and efficient skin cancer diagnosis.

Hardware Implementation of FALCON's ffSampling Algorithm

Yasin Yılmaz[a], Sıddıka Berna Örs Yalçın[b], Mustafa Mert Esen[c]

yasinxyilmaz@gmail.com

Keywords: Circuit Design, FALCON, FPGA, Post-Quantum.

Aim

The emergence of quantum computing poses a significant threat to classical cryptographic schemes, necessitating the development and implementation of post-quantum cryptographic algorithms. One such algorithm, FALCON (Fast-Fourier Lattice-based Compact Signatures over NTRU), has been selected by the National Institute of Standards and Technology (NIST) for post-quantum cryptography standardization (NIST, 2023). FALCON is a lattice-based digital signature scheme that adheres to the Gentry-Peikert-Vaikuntanathan (GPV) framework, which constructs signatures by sampling short vectors from a lattice using a trapdoor mechanism (Gentry et al., 2008).

At its core, FALCON employs the novel Fast Fourier Sampling algorithm, a variant of the nearest-plane algorithm, a technique introduced by Babai (1986) for solving the closest vector problem (CVP) in lattices. This modified approach ensures that signatures are compact while maintaining security against quantum attacks. To achieve efficient computations, FALCON leverages the Fast Fourier (FFT) for polynomial arithmetic, significantly improving performance over traditional lattice-based schemes. Also, a novel algorithm Fast Fouirer Sampling (Ducas et al., 2018).

This study aims to identify key aspects of FALCON that can be further investigated for efficient implementation through detailed analysis and inspection. Furthermore, it seeks to design and propose a circuit that enhances the performance of FALCON's primary signature generation function, ffSampling, which is the realization of the Fast Fourier Sampling algorithm.

Material and Method

The initial phase of the study involves a comprehensive analysis of the FALCON algorithm, utilizing reference documentation and existing C implementations (NIST, n.d.). A C profiler is employed to quantify the proportion of total execution time attributed to each sub-function within FALCON. This analysis provided insights into the computational workflow, identified performance bottlenecks, and pinpointed critical operations requiring acceleration. Preliminary findings indicate that floating-point operations account for the majority of execution time.

It was aimed to use an open-source RISC-V processor alongside designed circuits on an FPGA platform for the implementation. Accordingly, the reference C code was modified to be compatible with the RISC-V compiler. By utilizing a RISC-V simulator, the required clock cycles for each sub-function's execution within the RISC-V instruction set were measured and analyzed (Spike RISC-V Compiler, n.d.). These measurements will be used as a comparison basis to determine performance improvements of the study.

Both analyses showed that the function ffSampling takes most of the time and clock cycles. The ffSampling function is a Gaussian sampling algorithm that leverages Fast Fourier Sampling to efficiently sample short lattice vectors, which will form the signature. Specifically, ffSampling uses Gram-Schmidt orthogonalization in the Fourier domain to produce samples maintaining Gaussian distribution properties. This function is the core of FALCON and constitutes FALCON's compact signatures and resistance to quantum attacks.

According to the analysis results, ffSampling function was chosen for hardware implementation. Design process started with analyzing the function in depth. The function is constructed in a recursive way, results from the previous call are used in the next recursive call to calculate new results. Consequently, its sub-functions are executed in a structured sequence,

processing relevant data in each recursion step to construct short lattice vectors in the end. Its sub-functions and their calling pattern are inspected using the reference C code. A Python model replicating the ffSampling function is formed and used for further analysis. Sub-functions' calling sequence was unraveled using the model. The model is later used for testing the circuit design methodologies.

The ffSampling sub-functions primarily involve complex number operations, such as complex addition and multiplication, with both real and imaginary components represented as floating-point values. Additionally, the function incorporates floating-point vector operations, like element-wise floating-point addition and multiplication.

With sub-functions and their sequence analyzed, a circuit that will realize the ffSampling function was designed. Firstly, sub-functions are designed using Xilinx's floating-point IPs. These IPs can be used for a variety of operations, and can be configured to construct pipelined structures. To ensure flow of data and therefore high throughput, submodules that realize the subfunctions are designed using the pipelined IPs. These sub-modules are tested separately with test vectors generated using the reference C code.

Following the analysis of sub-functions and their execution order, a hardware circuit to implement the ffSampling function was designed. Initially, sub-functions were implemented using Xilinx's floating-point intellectual property (IP) cores. These IP cores support various mathematical operations and can be configured to establish pipelined architectures. To maintain a steady data flow and ensure high throughput, the submodules implementing the sub-functions were constructed using pipelined IP cores. Each submodule was individually tested using test vectors derived from the reference C code. Subsequently, a control circuitry was developed to manage the data flow to sub-modules from memories in the correct sequence. This control circuitry generates appropriate control signals, mirroring the recursive behavior of ffSampling. Additionally, the control mechanism ensures that results from the sub-modules are correctly stored at designated memory addresses.

With the submodules and control mechanisms finalized, a complete circuit integrating these components and memory components was assembled, effectively realizing the ffSampling function in hardware.

Findings

Through this study, an in-depth understanding of FALCON, particularly its signature generation process and the ffSampling function, has been achieved. Additionally, the significant role of floating-point operations in FALCON's computational performance has been identified.

The proposed hardware circuit was evaluated in terms of execution speed and resource consumption. Given that speed optimization was prioritized over resource efficiency, the design partly serves as a proof-of-concept; however, it remains a viable approach for FPGA-based implementations. The minimum execution time of the circuit was measured using a simulator and subsequently compared to the reference C implementation running on a RISC-V core. A speed-up factor relative to the baseline implementation was computed.

The designed circuit operates at a maximum clock frequency of 200 MHz, executing a single ffSampling function within 316,159 cycles, which corresponds to an execution time of 1.58 ms per computation. In comparison, the ffSampling function, when executed using the reference C implementation on a RISC-V core, requires 8,465,252 cycles when simulated using spike, resulting in an execution time of 84.6 ms at a clock frequency of 100 MHz. When implemented on a RISC-V processor on an FPGA, ffSampling function took 418.1 ms to complete, now accounting events like hazards and branch mispredictions that occur in real implementations.

Based on these results, the proposed hardware implementation achieves an approximate 265× speed-up compared to the reference C code, compared to the used RISC-V core. This performance enhancement is highly promising, as the circuit would significantly accelerate the overall signature generation process when integrated with a RISC-V core in a complete system.

These findings are derived from the first version of the circuit. A detailed analysis of the simulation has identified potential optimizations, such as parallelizing sub-functions where applicable and improving hardware efficiency by designing custom floating-point circuits. Future research will focus on refining both speed and area utilization to further optimize the circuit's performance.

Conclusion

The analysis of FALCON has underscored the extensive utilization of floating-point operations and their impact on computational performance. The study has reaffirmed that the ffSampling function constitutes the core of FALCON's signature generation process and entails a significant number of floating-point calculations. The proposed hardware implementation of ffSampling, which incorporates floating-point IP cores and a memory-based data and control structure, has resulted in a performance improvement in signature generation.

Furthermore, this study highlights the advantages of integrating custom accelerator cores to enhance the efficiency of FALCON. Similar circuit design for many other parts of the algorithm can be designed in the same fashion, accelerating other critical operations. Although the current design prioritizes computational speed over resource efficiency, future research could explore additional optimizations to achieve a more balanced trade-off between speed and hardware resource utilization.

Design of a Clutchless Automated Gear Control System for Electric Tractors

Bertuğ Bingöl[a,b], Ece Olcay Güneş[a], Murat Gündoğdu[b]

[a] Istanbul Technical University, Electronics and Communication Eng.,Electronics Program, Türkiye
[b] Turk Traktor and Agricultural Machinery Inc., R&D Department, Türkiye
bingolb21@itu.edu.tr

Keywords: Battery-powered Agricultural Vehicle, Automated Transmission, Drivetrain Control Architecture.

Aim

Replacing fossil fuels with cleaner and more sustainable electric alternatives is crucial for reducing agricultural emissions. Therefore, electrification has become inevitable. In addition to reducing emissions, electrification offers advantages such as improved energy efficiency and easier system control. In particular, electric motors provide constant torque over a wide speed range, enabling more flexible and efficient operation. Moreover, electrification not only enhances motor performance but also improves the reliability and effectiveness of other subsystems within the vehicle architecture.

Conventional tractors powered by internal combustion engines (ICEs) are commonly used in agricultural applications, requiring specific torque and speed values for tasks such as planting and harvesting crops like tomatoes and potatoes. When analyzing the torque-speed characteristics of ICEs, their maximum efficiency is approximately 40% (A. Rajagopalan, 2003). To operate within efficient regions while meeting these torque and speed demands, tractors are often equipped with transmissions featuring up to 32 gears (Elia Scolaro, 2021). However, if appropriate gear ratios are not selected, unnecessary power consumption and fuel waste become unavoidable. In contrast, electric motors of equivalent power can achieve efficiencies of up to 95% based on their torque-speed characteristics.

The primary objective of this study is to achieve the torque-speed characteristics of a 32-speed ICE tractor using only a 2-speed electric tractor. Additionally, by eliminating complex components such as traditional clutch packs, the simplicity and efficiency offered by electrification will be integrated into the gear system as well.

Material and Method

The electric tractor features an architecture that incorporates multiple electronic control units (ECUs). These units are managed by the Vehicle Management Unit (VMU) through the CANBus communication protocol. The tractor used in this study is equipped with a VMU containing a 32-bit NXP SPC5746C microcontroller.

In an electric vehicle, the traction motor's motion is transmitted to the wheels via drivetrain components, including gearboxes with various ratios. From the field, the wheel torque-speed graph of an equivalent ICE tractor was analyzed (Müjdat Ersarı, 2024). To match its torque-speed characteristics using an electric motor with two gears, optimal ratios were determined. This resulted in two gear requirements: a field gear for 0–16 km/h and a road gear for 16–40 km/h. Unlike conventional transmissions, this tractor does not include a clutch or synchronizer. The coupling mechanism that transfers the electric motor's motion to the wheels utilizes a dog clutch mechanism. Consequently, gear engagement in a moving vehicle is achieved by locking two rotating gears together.

The key components of the system include the Vehicle Management Unit (VMU), valve box, position sensor, gear lever, and traction motor.

The valve box is a hydraulic unit with two proportional valves that control high-pressure input. These valves generate the necessary pressure for gear shifting based on the user's selection, moving the shift fork accordingly. In the literature, this is typically done with electrically controlled servo motors in trucks and race cars. The limited research on hydraulic actuator-based shift fork control adds value to this study.

The position sensor reads the analog position of the shift fork responsible for gear shifting. This analog data is transmitted to the VMU, which continuously monitors the position in real time to ensure proper system operation.

The gear lever has buttons for user-selected gear positions, generating digital outputs for field or road mode. These activations are read by the VMU's GPIO units.

A permanent magnet synchronous motor (PMSM) is used as the electric traction motor. Thanks to the field and road gears, the motor power is transmitted to the wheels. Specific requirements must be met for the dog clutch to engage while the vehicle is in motion. The most critical requirement is the synchronization of the motor speed with the transmission speed, as there is no clutch pack or synchronizer. Rapid execution of this synchronization process is essential to minimize torque interruption during gear shifting. The electric motor's ability to be
controlled quickly and precisely makes it more advantageous than ICEs for such applications.
The VMU manages the entire gear-shifting process. The software was developed using the integrated development environment (IDE) provided by the VMU supplier, utilizing the C programming language. In the software, each hardware component is controlled using task loops operating in multiples of a 20ms period.
Fundamentally, the gear-shifting process begins with a user request. The VMU detects the requested gear and then zeroes the electric motor's torque to disengage the currently engaged gears. Once the torque is neutralized, the gear position is set to neutral. Subsequently, the motor control mode switches from torque mode to speed mode. The electric motor speed is then matched with the transmission speed associated with the target gear. If the speed difference between the transmission and the electric motor falls below a specific threshold, the VMU controls the valve box using a PWM signal to initiate the shift fork movement. Once the shift fork movement is complete and the gears are engaged, the motor control mode switches back to torque mode. Finally, the user's torque demand via the gas pedal is transmitted to the wheels.
In this study, two algorithms were tested. In one, speed synchronization was implemented, whereas in the other, speed synchronization was omitted, and gear shifting was performed solely by zeroing the torque.

Findings

Electric tractor testing was conducted using two different test scenarios. The first scenario did not involve active speed synchronization, whereas the second scenario incorporated it. In the first scenario, the tractor was tested on dedicated test rigs in the absence of counter torque. In contrast, the second scenario was conducted under field conditions, where the tractor's wheels were in contact with the ground and counter torque was present.
During testing, all system parameters were recorded and analyzed using Vector CANalyzer. In the first scenario, gear shifts were successfully performed while the vehicle was stationary. However, when shifting gears while the vehicle was in motion, audible squealing noises were detected. This outcome highlighted the importance of speed synchronization.
In the second scenario, the algorithm incorporating active speed synchronization was tested. When the vehicle was stationary, gear shifts were completed successfully. While the vehicle was in motion, the advantages of active speed synchronization became evident. When the target gear's transmission speed was synchronized with the motor speed before shifting, the gear change was completed without generating any disturbing noise.
This observation underscores the effectiveness of the synchronization algorithm in eliminating mechanical stress and enhancing overall gear shift durability.

Conclusion

Although studies in the literature on the feasibility of clutchless and synchronizer-free gear shifting are limited, this study contributes to the literature by evaluating the suitability of a dog clutch gear system in an electric tractor through real-world tests using various control-based approaches.
Dog clutch systems, due to their direct engagement of gears at high relative speeds, can lead to mechanical stress and material wear over time (Mohamed El Morsy, December 2014). However, the design of the gear geometry and the infrequent occurrence of road-to-field gear shifts in agricultural operations provide a practical advantage by minimizing wear and tear within the transmission system.
This study advances transmission systems for agricultural applications by emphasizing the effectiveness and straightforward integration of electric motors in tractor gear shift mechanisms. The proposed architecture enhances user convenience while also providing substantial benefits to the industry, especially in terms of maintenance and aftersales support.

Keywords: 3rd Party IP, Encrypted Bitstream, FPGA, Logic Locking, Security.

Aim

Nowadays, hardware designs are implemented on Field Programmable Gate Arrays (FPGAs) due to the convenience they offer to users, their diverse capacities, and low costs. With the increasing prevalence of solutions implemented with FPGAs, designers often want to use certain predefined operations as ready-to-use intellectual property (IP) cores to reduce labor and time costs when creating their designs. Some of these ready-to-use IPs are provided by the FPGA development tool, while others may need to be sourced externally. Since a third party is involved with these ready-to-use IPs, they are referred to as third-party intellectual property (3rd party IP). Currently, some 3rd party IPs are provided in an encrypted form through licensing within FPGA development tools. However, when users include the IP in their design, the encryption is decrypted before being loaded onto the FPGA, revealing the structure of the user's design. It has been demonstrated by Zhang et al. (2019) that the netlist, and subsequently the original design, can be extracted from the bitstream file format through reverse engineering.
The aim of this study is to design a security feature for FPGA systems that will protect 3rd party IPs used in FPGAs, based on the logic locking technique used to protect the IP rights of Application Specific Integrated Circuits (ASICs). When the designed solution is applied to the produced FPGAs, 3rd party IPs will be able to be used securely in post-development stages.

Material and Method

Logic Locking Technique:

Logic locking has been described as a holistic countermeasure that protects an integrated circuit (IC) throughout the globalized IC supply chain against hardware-centric threats such as design intellectual property piracy and unauthorized overproduction (Patnaik, Limaye, & Sinanoglu, 2022). Essentially, this technique involves adding an additional key input (K) and integrating XOR/XNOR gates into the existing circuit structure to obfuscate the design. The circuit functions correctly only when the correct key is applied to the K input. Various attacks have been carried out against logic locking, prompting the continuous development of more resilient techniques. Among these, the SAT (Satisfiability) attack is considered one of the most effective, leveraging the scan chain used for testing purposes in ASIC circuits. SAT attack is defined by Subramanyan at al. (2015).

Proposed FPGA Security Architecture Solution:

As a solution, a security module (Logic Unlocker - LUL module) intended to be part of the FPGA system architecture has been designed. The schematic structure of the LUL module is shown in Figure 1. The proposed solution involves the use of the logic locking technique, where the 3rd party IP netlist is locked by the developer and unlocked by the FPGA vendor through cryptographic architectural steps. In this study, the term 'IP' will refer to 3rd party IP.

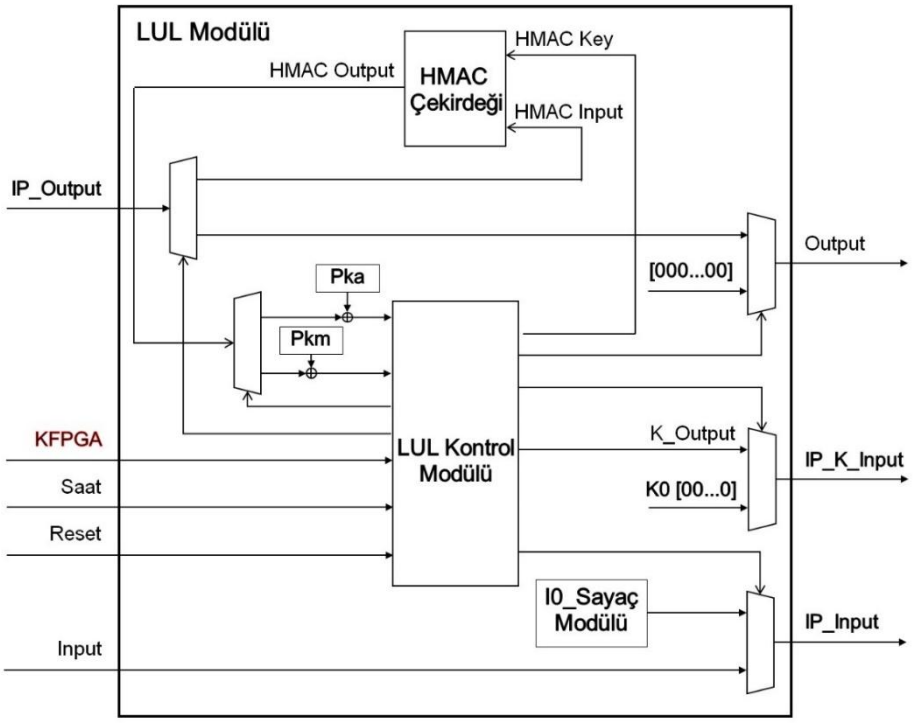

Figure 1. Schematic Design of the LUL Module.

Developer Procedures:

The IP developer obtains IP-L by using a K key of appropriate size corresponding to the number of gates in the IP, applying the logic locking technique. The schematic representation of the IP and IP-L is shown in Figure 2. The developer then sends IP-L and K to the FPGA vendor.

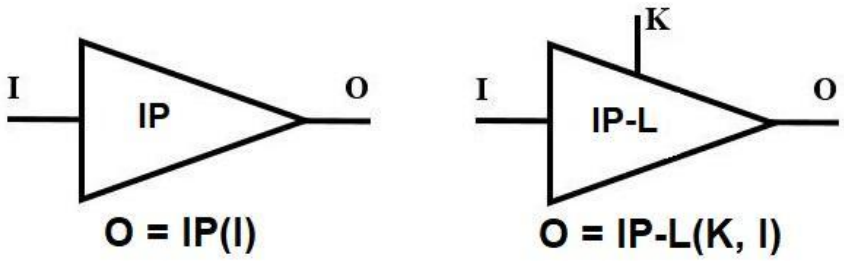

Figure 2. Functional Representation of IP and IP-L Structures.

FPGA Vendor Procedures:

The FPGA vendor performs the cryptographic operations defined below to obtain the key masking parameter (Pkm) and the authentication parameter (Pka). Then, the vendor signs the IP-L file using a Digital Signature Algorithm (DSA) with their private key to generate the signature value Sign(IP-L). The obtained parameters (Pkm and Pka), and the signature value Sign(IP-L) are then sent to the IP developer.

1. The vendor applies the key K_0 and input data I_0 to the IP-L netlist circuit for n clock cycles to obtain the output data sequence O_0^n from IP-L using the following formula (1).

$$O_0^n = IP_L(K_0, I_0) \quad \text{(for n clock cycles)} \qquad (1)$$

Here, K_0 represents the constant key value defined by the FPGA vendor for the K input, and I_0 is the input sequence provided through the I input, starting from 0x00...0 and incrementing by one on each clock cycle up to n (where $n \gg 0$).

2. The vendor calculates the HMAC value of the output data O_0^n from IP-L using the following formula (2)

$$HMAC(IP_L) = HMAC(K_FPGA, O_0^n) \quad (2)$$

Here, K_FPGA represents the secret key defined by the FPGA vendor for logic locking, which is embedded within each FPGA.

3. The vendor computes the key masking parameter Pkm in (3)

$$Pkm = HMAC(IP_L) \text{ xor } K \quad (3)$$

4. Using the key K and the input data I_0 defined in Step 1, the vendor obtains the output data sequence O_1^n from IP-L using the following formula (4).

$$O_1^n = IP_L(K, I_0) \quad \text{(for n clock cycles)} \quad (4)$$

5. The vendor computes the HMAC value of the output data O_1^n from IP-L using the key K_FPGA in (5)

$$HMAC(IP) = HMAC(K_FPGA, O_1^n) \quad (5)$$

6. The calculated value is also used as the authentication parameter Pka in (6)

$$Pka = HMAC(IP) \quad (6)$$

Usage of IP:

When the IP developer presents the IP to the customer, it is sent in the form of IP-L along with the parameters Pkm, Pka, and Sign(IP-L). When the IP customer creates their own IP (C-IP), they use IP-L and the parameters within the Integrated Development Environment (IDE), as shown in Figure 3. During the synthesis of C-IP, the FPGA vendor's IDE first performs a signature verification of the IP-L file. Once the signature verification is successful, the synthesis is carried out, and an FPGA bitstream file is generated.

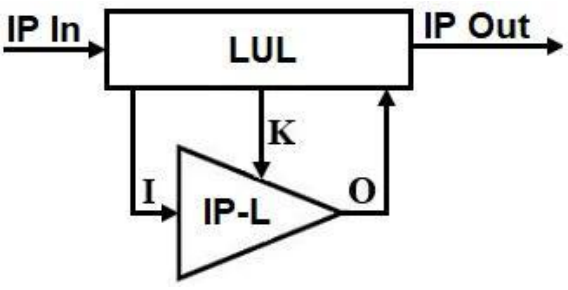

Figure 3. Integration of the LUL Module with IP-L.

When the FPGA is powered on, the LUL module uses the Pkm and Pka parameters to generate the correct K key, ensuring that the IP-L operates in its original form. If the correct K key cannot be derived, the Pka value also cannot be correctly obtained. In this case, the LUL module outputs a sequence of zeros from the IP-L.

Findings

The LUL module has been implemented using VHDL, with ITC99 benchmark circuits in Url-1 used as the IP. The benchmark circuit has been logic locked using the Neos tool in Url-2. Using Xilinx Vivado as the IDE, the locked benchmark and the prepared LUL module were tested through simulation to verify their correct operation, ensuring that the correct K value was obtained and the IP-L functioned properly.

Security Analysis:

The following threat situations and scenarios have been identified for obtaining the IP, and an evaluation of whether the attacks can be carried out using the proposed method is provided below.

Obtaining K_FPGA:
K_FPGA is written to secure memory during the production stage within the FPGA. If the algorithm using K_FPGA is implemented in a way resistant to side channel attacks, it will not be possible to obtain K_FPGA.

Obtaining the K key:

1. Scenario
Obtaining K by generating the K key using a fake IP-L. When the proposed cryptographic architecture is applied, the Pkm and Pka verification will not be successful, so this attack cannot be performed. Additionally, the signature verification process will prevent synthesis.
2. Scenario
Obtaining K by generating the K key using a counterfeit IP-L. By choosing an n value large enough to ensure that IP-L does not fit into the FPGA, this attack becomes impossible. Furthermore, the signature verification process will prevent synthesis.
3. Scenario
Obtaining K by generating the K key using a wrapper IP-L-Plus containing IP-L. Since the signature verification will fail, synthesis cannot be performed, making this attack infeasible.
4. Scenario
Obtaining K by using a SAT attack. A scan chain is required for the SAT attack. Since scan chains are not used in the FPGA environment, this attack cannot be carried out.

Conclusion

With the proposed FPGA architecture, 3rd party IP designs are protected in the stages following the developer. In this approach, FPGA vendors are assumed to be trusted entities. The proposed method does not impose any limitation on the number of times the 3rd party IP can be used. In future work, a solution that also enforces usage restrictions can be explored.

Numerical Investigation of the Effects of Interfacial Contact Resistance in PEM Fuel Cells with Coated Metal Bipolar Plates

Özgün Önen[a,b], Mehmet Suha Yazıcı[a], Dilek Kumlutaş[b], Utku Alp Yücekaya[b]

[a] Istanbul Technical University, Energy Institute, Turkiye
[b] Dokuz Eylul University, Mechanical Engineering Department, Turkiye
oneno22@itu.edu.tr

Keywords: ICR, Interfacial Contact Resistance, Metal Bipolar Plate, Numerical Analysis, Pem Fuel Cell.

Aim

Fuel cells have emerged as promising next-generation electrochemical energy converters due to their high power density and low emissions, making them attractive for transportation and stationary energy applications (S. Wang et al., 2017) .In particular, replacing conventional internal combustion engines with fuel cells is expected to play a crucial role in transitioning to sustainable energy systems [(Qasem & Abdulrahman, 2024).

Fuel cells comprise various components, including the bipolar plate and membrane electrode assembly. Due to its crucial role in efficient thermal and electrical management, as well as ensuring proper gas distribution and mechanical stability, the bipolar plate is one of the most important components of the system (Xiong et al., 2021).

Graphite, traditionally used as a bipolar plate material, requires a significant volume to achieve adequate mechanical strength, which limits its application in compact fuel cell designs such as automotive systems. To address this challenge, metal bipolar plates offer superior mechanical properties, allowing more fuel cell units to be integrated within the same volume. However, metal bipolar plates suffer from poor corrosion resistance, requiring protective coatings to enhance their durability. These coatings not only provide benefits in terms of corrosion resistance but also have an impact on interfacial contact resistance (ICR) (Xiong et al., 2021).

ICR is an electrical resistance that occurs at the interface between two contacting surfaces in a fuel cell, such as between the bipolar plate and the gas diffusion layer (GDL). It arises due to surface roughness, material properties, and contact pressure (Lædre et al., 2022). Additionally, each coated metal bipolar plate has a different ICR value, which affects the overall performance and efficiency of the fuel cell (Leng et al., 2020).

It has been observed that the ICR of coatings is not typically included in simulations of metal bipolar plate PEM fuel cells. In this study, The numerical model was first validated using data from an experimental study, and then ICR values of three widely used coatings were obtained from the literature and incorporated into the study. The results were presented comparatively.

Material and Method

This study uses Ansys Fluent PEM [6] modules to analyse the effect of ICR on PEM fuel cell performance. Different coating materials are considered, and their influence on interfacial resistance is examined through numerical simulations. The model incorporates key electrochemical and transport phenomena within the fuel cell structure. The numerical model, which has also been used in experimental studies in the literature (L. Wang et al., 2003) , was utilized in this study to examine the effect of coatings on ICR. The numerical model is presented in Figure 1.

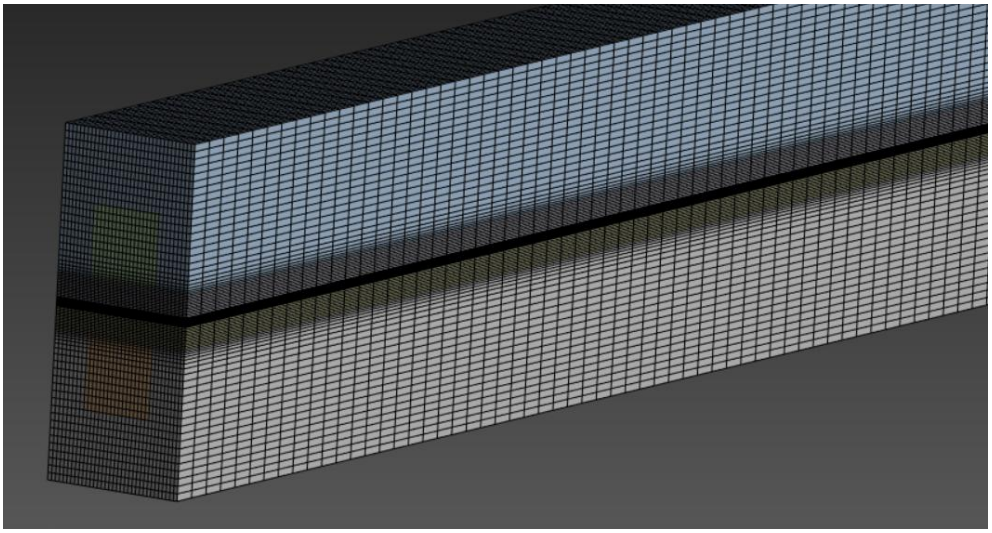

Figure 1: Mesh Structure of PEM Fuel Cell.

The numerical model presented in Figure 1 was meshed using Ansys Meshing (Fluent, A. N. S. Y. S. (2011). Ansys Fluent Theory (2011). The mesh parameters were configured in accordance with the low skewness and high orthogonality values recommended in the literature (Choopanya et al., 2016.). A skewness value of 0 and an orthogonality quality value of 1 were achieved, ensuring the accuracy of the numerical study (Choopanya et al., 2016).

Parameters for numerical study were obtained from the literature study used for validation (L. Wang et al., 2003.). Additionally, the diffusivity values of H_2, O_2, and H_2O reference diffusivity (m^2/s) and Equivalent weight of membrane (kg/kmol) were taken from a study that included the numerical analysis of the uncoated model (Chen et al., 2021). Parameters used in the analyses are presented in Table 1.

Table 1: Parameters used in the PEM fuel cell simulation (Chen et al., 2021; L. Wang et al., 2003).

Parameters	Value	Ref
Operating temperature (K)	343	(L. Wang et al., 2003)
Operating pressure (atm)	2,7	(L. Wang et al., 2003)
GDL porosity	0,4	(L. Wang et al., 2003)
CL porosity	0,4	(L. Wang et al., 2003)
Anode exchange coefficient	0,5	(L. Wang et al., 2003)
Cathode exchange coefficient	2	(L. Wang et al., 2003)
H_2 reference diffusivity (m^2/s)	1.10×10^{-4}	(Chen et al., 2021)
O_2 reference diffusivity (m^2/s)	3.23×10^{-5}	(Chen et al., 2021)
H_2O reference diffusivity (m^2/s)	7.35×10^{-5}	(Chen et al., 2021)
H_2O reference concentration(mol/m^3)	56,4	(L. Wang et al., 2003)
O_2 reference concentration (mol/m^3)	3,39	(L. Wang et al., 2003)

Equivalent weight of membrane (kg/kmol)	1100	(Chen et al., 2021)

The numerical analyses were conducted at 343 K and 2.7 atm pressure, in accordance with the experimental study used for validation. The current density-voltage curve reflects the general electrochemical behavior of the fuel cell and serves as a fundamental tool for validation, enabling a direct comparison between the numerical and experimental performance (Energy S, 2011) Through numerical analyses, current and voltage values were obtained, and the corresponding current density values at different voltage levels were compared with experimental data from the literature (L. Wang et al., 2003.) and presented.

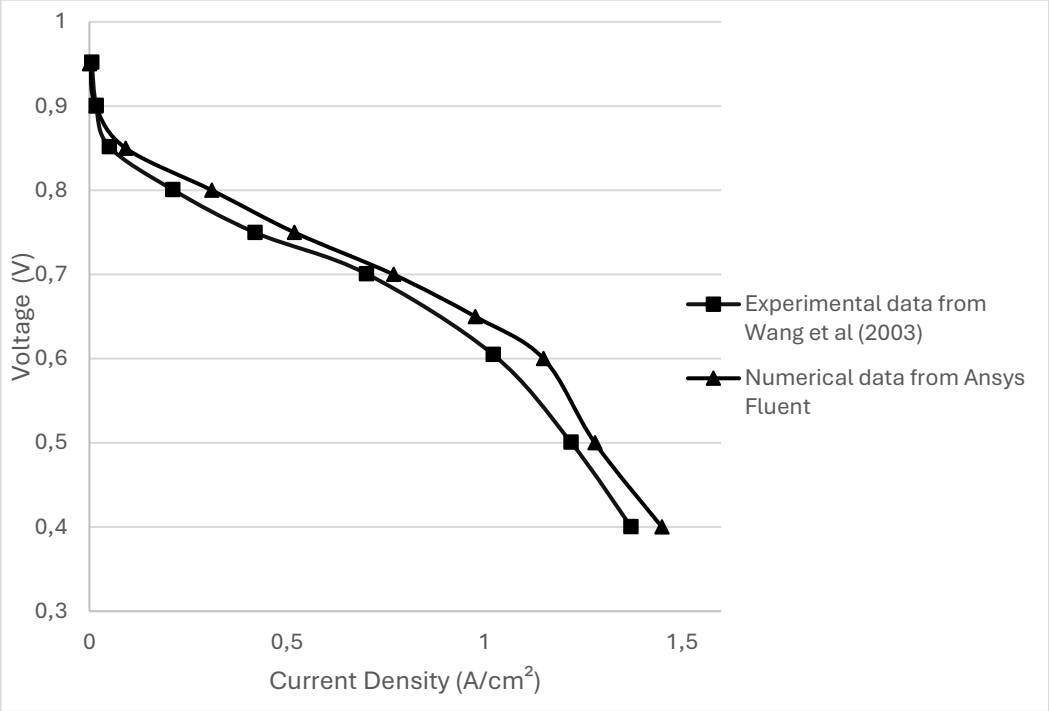

Figure 2: Validation using Data from Experimental Studies.

When examining Figure 2, the analyses were validated with a maximum error of 10% within the operating range of fuel cells, which is between 0.5 V and 0.65 V (Qasem & Abdulrahman, 2024) Using the validated numerical model, ICR definitions were assigned to Using the validated numerical model, ICR definitions were assigned to the interfaces between the bipolar plate and the GDL at surfaces A, B, C, and D, as shown in Figure 3, to investigate the effects of coatings.

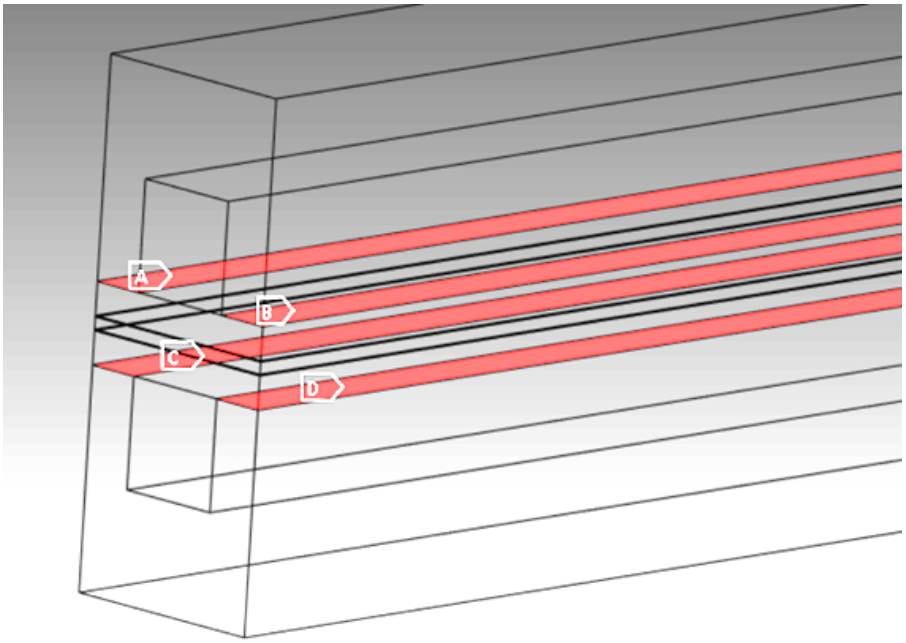

Figure 3: Interfacial Contact Resistance between GDL and Bipolar Plate.

(ICR) assigned to the surfaces shown in Figure 3 vary depending on the coating material. The coating materials used in the literature are CrN (Chromium Nitride), TiN (Titanium Nitride), and Ti/TiN (Titanium/Titanium Nitride), and the corresponding contact resistance values are presented in Table 2.

Table 2: ICR values of coatings used in metal bipolar plates (Haghighat Ghahfarokhi et al., 2016; Jannat et al., 2019; Lee et al., 2013).

Metal Material	Coating	ICR (mΩ·cm²)	References
SS316L	CrN	23	(Lee et al., 2013.)
SS316L	TiN	7,41	(Haghighat Ghahfarokhi et al., 2016)
SS316L	Ti\TiN	11	(Jannat et al., 2019.)

ICR of different coatings presented in Table 2 were defined on PEM module. The results of the numerical analyses are presented in the Findings section.

Findings

As shown in Figure 4, variations in ICR caused by different coating materials influence fuel cell performance. In this study, numerical analyses were conducted to examine how current density varies at a constant voltage level depending on the ICR of the coating material.

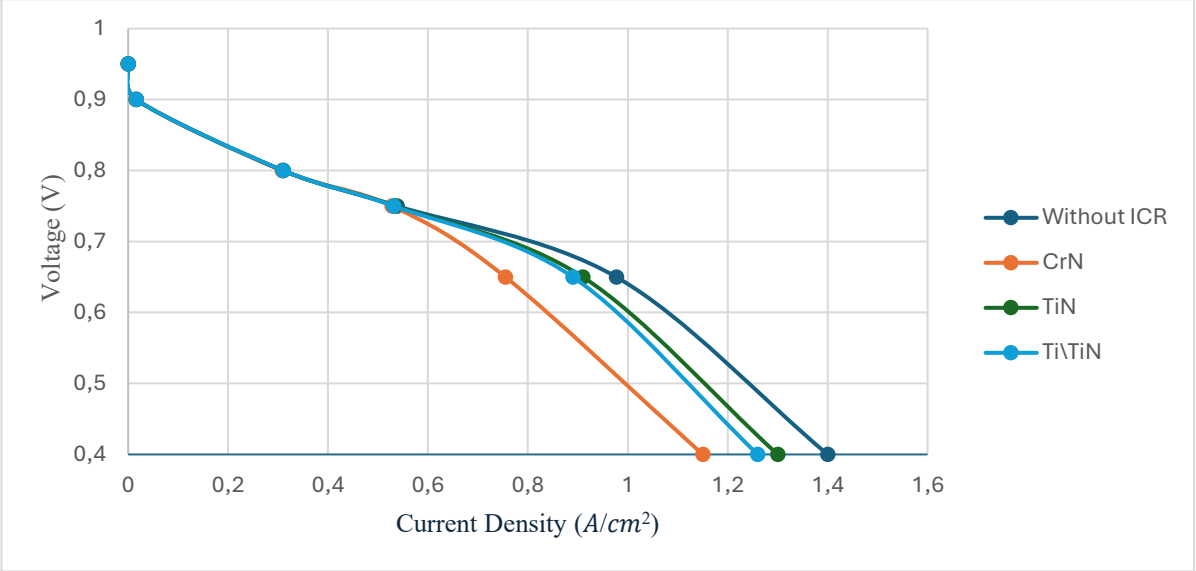

Figure 4: Effect of Electrical Contact Resistance on the Voltage-Current Density Curve.

Figure 4 shows that the ICR of the coatings significantly affects the fuel cell performance. The current density per unit voltage has considerably decreased compared to the case without contact resistance. Consequently, this has led to a significant reduction in the power density per unit area of the single-cell PEM fuel cell.

At an operating voltage of 0.65 V, the current density is 0.97 A/cm² without contact resistance. However, with the application of a CrN coating, it decreases to 0.82 A/cm², while Ti/TiN and TiN coatings result in reductions to 0.89 A/cm² and 0.91 A/cm², respectively.

In the absence of ICR the power density was determined to be 0.63 W/cm² at an operating voltage of 0.65 V. However, due to ICR of the CrN coating, the power density decreased to 0.49 W/cm², while for the Ti\TiN and TiN coatings, it was observed to decrease to 0.57 W/cm² and 0.59 W/cm², respectively. This indicates that the CrN coating has an effect of 24.62%, while the Ti\TiN and TiN coatings have effects of 12.31% and 9.23%, respectively. Additionally, it is noted that the impact of ICR becomes more evident at lower voltage levels (0.4 V - 0.6 V).

Conclusion

The conclusions of this study emphasize the significant impact of ICR on coated metal bipolar plates in fuel cells, affirming that the effect of coatings on ICR should not be neglected, as observed in previous simulation studies. As the voltage decreases, the impact of ICR becomes more pronounced, and its influence on the system becomes increasingly significant. For CrN coating at 0.65 V, there is a 15.46% decrease in current density and a 24% decrease in power density. For TiN and Ti/TiN coatings, current density decreases by 6.19% and 8.25%, while power density decreases by 9.23% and 12.31%, respectively. Furthermore, the results indicate that the influence of the TiN coating is lower compared to the other two coating types, suggesting that TiN is currently the most suitable coating for metal bipolar plate fuel cells.

Keywords: Engine Cooling, Nanofluids, Internal Combustion Engines, Natural Gas Engine.

Aim

With increasing power densities of internal combustion engines due to the competitive environment of engine technologies and the latest developments in automotive industry, the thermal load on engine components continues to increase. Consequently, reducing temperatures while consuming less hydraulic power has become increasingly critical. Furthermore, improving specific fuel consumption is a crucial factor for advancing environmental sustainability. This study aims to investigate potential benefits of using nanofluids for internal combustion engine cooling, specifically focusing on reducing the critical peak temperatures of engine components by enhancing heat rejection to the engine coolant.

Literature Review

Numerous studies in the literature have explored the wide range of application areas of nanofluids such as heat pipes (Wang, et al., 2021), heat exchangers (Gupta, Verma, & Yadav, 2022), solar energy systems (Yıldırım & Yurddas, 2021), engine cooling (Jadeja, Bumataria, & Chavda, 2022) etc. Several researchers have noticed the potential of using nanofluids for cooling systems of internal combustion engines to improve thermal management efficiency. In recent computational heat transfer (CHT) studies on cylinder engine cooling using nanofluids, the heat addition from combustion has been implemented into the models as a constant heat flux imposed on the combustion chamber walls (Bøthun, 2023) (Alves & Henríquez, 2022). In the present study, a combustion analysis is performed using boundary conditions (BCs) derived from a test bench data. The results of the combustion analysis are then implemented to the model on the combustion chamber walls as heat transfer coefficients and near-wall temperatures to accurately model the heat source.

Material and Method

For potential improvement of cooling performance by using nanofluids, the present numerical study investigates the effects of inlet temperature, base fluid type, nanoparticle type and concentration on the thermal behavior of a single-cylinder natural gas engine. Previously obtained test data on the engine is gathered from a test bench archive in the Automotive Laboratory of Istanbul Technical University (ITU), Faculty of Mechanical Engineering. The research steps involve the examination of the consistency of the existing test data and its suitability for use in the analyses, construction of the computer-aided design (CAD) model of cylinder, and the conduction of combustion and conjugate heat transfer (CHT) analyses to simulate engine behavior. In the initial phase of the study, technical drawings of cylinder, spark plug and CAD data for the cylinder head were sourced from the automotive laboratory. The test data are then used to define the boundary conditions for the combustion and conjugate heat transfer analyses to ensure realistic and accurate results.

Once the computational model is constructed and validated, a series of preliminary CHT analyses are conducted in order to identify the most effective combination of nanoparticle, base fluid type and concentration and inlet temperature in obtaining lower operating temperature, and the corresponding penalty of added pressure loss. The analyses are first conducted on a pipe that is of representative length and diameter. The pipe diameter is the same as the engine's coolant inlet diameter, and analyses are performed under conditions that replicated the engine's heat flux. A total of 60 simulations were conducted to explore various combinations of AlO, CuO, carbon black (CB) nanoparticles suspended in water or ethylene glycol-based fluids. Nanoparticle concentrations of 1%, 2%, 3%, and 4%, along with coolant inlet temperatures of 25°C and 70°C, are

investigated with the aim of determining the optimal nanofluid combination that could provide the most effective heat transfer performance for the engine cooling system. Since preliminary simulations do not require significant computational resources, all environmental points were investigated to comprehensively explore the parameter space. For future studies, it is recommended to consider implementing various Design of Experiments (DoE) methodologies, such as factorial design and response surface methods, to optimize computational effort and enhance the robustness of the analysis.
Further, an in-cylinder combustion analysis was performed to evaluate the heat load within the engine during operation. This analysis provided crucial data on the heat transfer coefficients and near-wall temperatures of the combustion gases in each computational domain cell. These values were then implemented into the conjugate heat transfer simulations as convection coefficients, helping to accurately model the heat exchange between the engine components and the coolant.

Findings

The effects of nanofluid inlet temperature, type of the base fluid, type of nanoparticle and nanofluid concentration on the maximum interface temperature are shown in Figure 1.

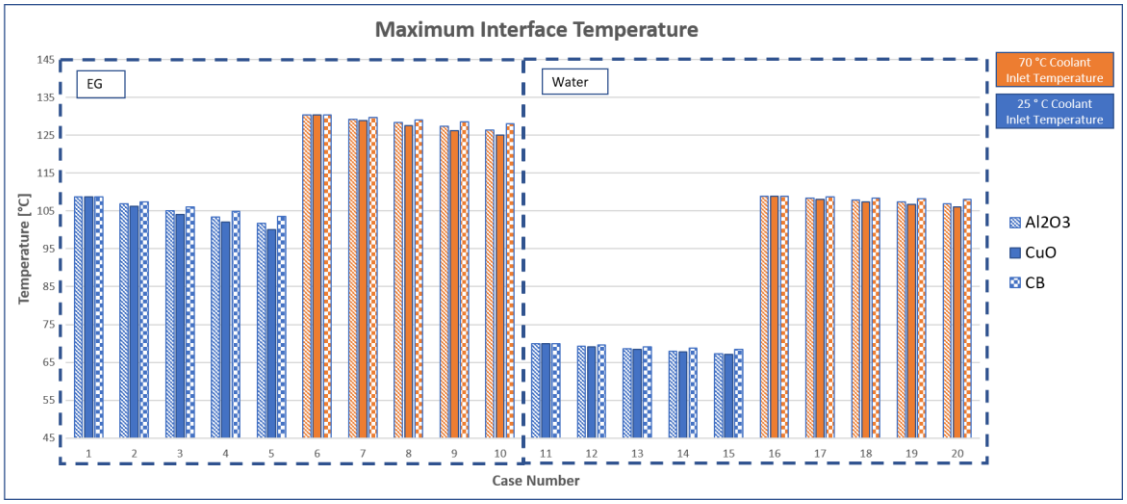

Figure 1. Maximum Interface Temperature Between Solid Pipe and Coolant.

As can be observed from Figure 1, lower inlet temperatures and nanofluids containing CuO provide lower temperatures compared to Al2O3 and CB under the same operational conditions. Due to the higher thermal conductivity of pure water compared to ethylene glycol, the temperatures are lower when pure water is used as the base fluid. As the nanoparticle concentration increases, the temperatures also decrease.

Conclusion

The research includes CHT analyses and combustion simulations to evaluate the heat load of the engine. Data from a natural gas-fueled single cylinder engine test bench were used to define realistic boundary conditions and ensure the accuracy. The results demonstrated improvements in the thermal performance of the engine when using nanofluids. The study showed that nanofluids could slightly enhance heat dissipation from critical engine components. The thermal conductivity of the coolant is enhanced by the use of nanoparticles, which positively influences heat transfer from the wall to the coolant. However, the pressure loss in the system increases due to the higher viscosity ratio compared to the condition without nanoparticles. Additionally, the use of nanofluids may contribute to a reduction in fuel consumption and thus contribute to environmental sustainability. This could potentially lower fuel consumption and contribute to environmental sustainability. In the present study, the nanofluid coolant is considered as single phase, homogeneous and the surface interactions of nanoparticles are neglected. For future research, it is recommended to explore the non-homogeneity of the nanofluid and the surface reactions of nanoparticles.

Aim

The global shift towards electric vehicles is accelerating due to the long-term economic benefits of Electrical Vehicles (EVs), the global objective of reducing greenhouse gas emissions, and the alignment with environmental policies such as the European Green Deal. For this reason, it is vital that the batteries, which are both one of the most important and most expensive components of electric vehicles, operate safely and efficiently over the long term. Heat generation and temperature distribution in the battery has an important role in battery lifetime and safety. Therefore, battery cooling systems are used to maintain the battery on the optimal operating temperatures. Generally, battery cooling systems are designed considering constant heat generation in the battery during fixed discharge conditions. However, heat generation in batteries is also affected by the state of charge (SoC) of the batteries. This study focuses on obtaining an electrochemical model of the battery to determine heat generation at different SoC levels and to obtain temperature distribution in the battery, in order to develop precise and optimized battery cooling strategies.

Material and Method

In this study, a 168 Ah NMx Li-ion prismatic battery is selected due to its high energy density and stable operating voltage range, making it particularly suitable for electric vehicle applications. The battery geometry is modeled in SolidWorks, and its dimensions are illustrated in Figure 1.

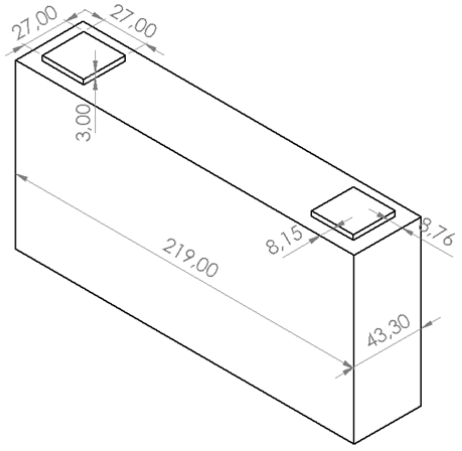

Figure 1. Battery Geometry.

Since the prismatic batteries contain layers of the cathodes, anodes, and separators, the thermochemical properties inside the battery changes with the direction. Therefore, the relevant studies are reviewed to determine specific heat and thermal conductivity of the Li-ion battery in order to obtain accurate heat generation and temperature distribution over the battery. As a result of the researches carried out by taking into account the thermochemical properties of the battery specific heat and orthotropic thermal conductivity of the battery is determined (Cheng et al., 2021; Sheng et al., 2019). The material properties which are used in our study are given in the Table 1.

Table 1. Thermochemical Properties of Materials in the Simulation.

	Density [kg/m^3]	Specific Heat [J/(kg.K)]	Thermal Conductivity In Horizontal Axis [W/(m.K)]	Thermal Conductivity In Vertical Axis [W/(m.K)]	Electrical Conductivity [S/m]
Active Zone Material	2236	1081	1.0341	21.5472	1000000
Aluminum	8978	381	387.6		58000000
Copper	2719	871	202.4		35410000

In the study, the Battery Material is identified as Active Zone Material. Positive Tab Material is identified as Copper. Negative Tab Materials is identified as Aluminum.

Since Li-ion batteries exhibit complex electrical behaviors under varying charge/discharge conditions, it is essential to develop an accurate mathematical model to represent their dynamic behavior. Equivalent Circuit Models (ECMs) are widely used for this purpose due to their balance between computational efficiency and accuracy.

Among different ECM configurations, the 2 RC model was selected in this study as it effectively captures both fast and slow transient effects during charge and discharge cycles. The model consists of internal resistance which represents instantaneous ohmic losses and two RC networks (R_1C_1 and R_2C_2) which capture short-term and long-term transient voltage responses, accounting for polarization and diffusion phenomena (Chen & Rincón-Mora, 2006).

The ECM requires test data that capture the dynamic response of the battery. To obtain the dynamic voltage and current responses across different SoC levels, the Hybrid Pulse Power Characterization (HPPC) test is adopted. A Battery Test Kit was prepared and the test was conducted following the procedure outlined below (URL-1):

1. Charge the battery to 1 SoC.
2. Rest for 1200 seconds.
3. Discharge at 1 C-rate until the desired SoC level is reached.
4. Rest for 1200 seconds.
5. Discharge at 1 C-rate for 10 seconds at the desired SoC level.
6. Rest for 1200 seconds.
7. The steps between 3 and 6 are repeated till the last desired SoC is obtained at Step 5.

Following the development of the electrical model using the ECM, the identified parameters are systematically incorporated into the Multi-Scale Multi-Domain (MSMD) model. The MSMD framework enables a comprehensive representation of electrochemical and electrical processes by integrating multiple spatial scales—ranging from the microscopic structure of electrode materials to the full cell and battery pack levels—as well as various temporal scales to ensure an accurate simulation of battery behavior under different operating conditions (Kim et al., 2011).

By employing this approach, the MSMD model provides a more detailed and physically consistent analysis of battery performance, capturing both the internal dynamics and external electrical responses with high precision. This allows for the

simultaneous evaluation of Joule heating and electrochemical heat generation, along with the resulting temperature distribution across the battery structure. Additionally, key electrical parameters such as voltage, current, and state of charge (SoC) evolution can be accurately monitored during the discharge process. These insights are critical for understanding thermal and electrical interactions within the battery system and optimizing its performance under real-world operating conditions.

Findings

To validate the simulation with experimental tests, five measurement points were selected, as shown in Figure 2, to monitor the temperature. The battery is simulated at a 100% state of charge (SoC) level, with a 0.3 C-rate, using boundary conditions where the battery wall temperature ($T_{boundary}$) is set to 22°C, and the heat transfer coefficient is 5 W/m·K for a duration of 1800 seconds.

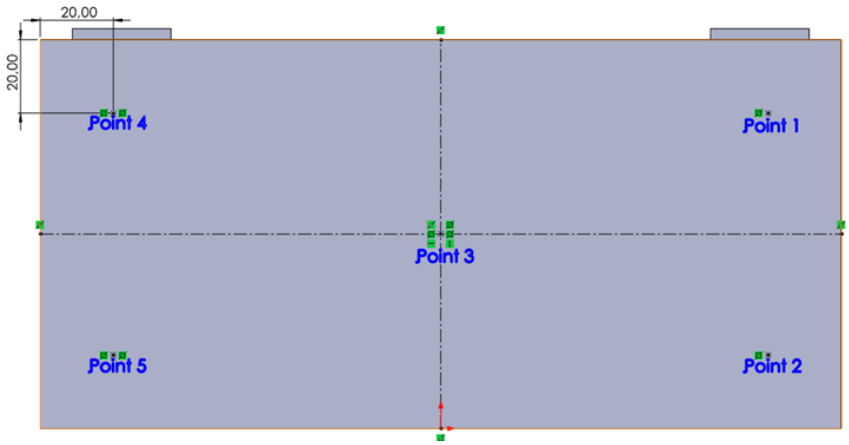

Figure 2. Temperature Measurement Points on the Battery.

After completing the simulation, Neware dataloggers are attached to the same points. The battery environment is set to 22°C, and the battery is charged to 100% state of charge (SoC). Once the battery is fully charged, it is allowed to rest until the temperature monitored by the dataloggers reaches 22°C and stabilizes. Then, the battery is discharged at a 0.3 C-rate for 1800 seconds. During the test, temperature data was obtained from the data loggers on the battery, while voltage values were recorded from the battery test system.
The temperatures obtained from both the experimental and simulation results are compared in Table 2.

Conclusion

This study provides a comprehensive experimental and numerical investigation into the thermal management of high-capacity NMx Li-ion prismatic batteries used in electric vehicle applications. By integrating electrochemical modeling, experimental validation, and computational simulations.

Key findings demonstrate that developed electrochemical and thermal model successfully predicted battery temperature distribution, with experimental validation confirming its accuracy within an acceptable margin. Although deviations were observed under the negative tab due to geometrical and material differences in the internal battery, particularly at higher discharge rates and longer test durations, the model effectively captures the heat generation characteristics and thermal behavior of the battery.

Aim

Due to climate change and restriction of the traditional energy sources, sustainability is a consequential issue. As pollutant gas emissions increase, the earth becomes more exposed to air pollution and greenhouse effect. Land transportation has almost 14% of total greenhouse gas emissions of recent years (Milovanoff et al., 2021). Hence, the modern fossil fuel land vehicles that cause emissions need to evolve the ones which use more sustainable power sourcesand produce less pollutants.Electrical vehicles are designed as one such solution. The main issue in electrical vehicles is the range and the electrical storage. Lithium-ion batteries are the preferred electrochemical storage choice in electrical vehicles (Bharti et al., 2024; Promi et al., 2024). The most significant problem in lithium-ion batteries is the increase in the cell temperature during charging and discharging. The electrochemical reaction that occurs in battery cells, the internal resistance and polarization all contribute to battery heating (Tan et al., 2023). The main parameter that affects battery temperature level and distribution are geometric and chemical structures of the batteries.
This study focuses on the effects of the different positive electrode materials on the temperature level and thermal distribution as a chemical property of batteries.

Material and Method

In this study, different cell cathode materials are compared by using an experimentally verified simulation model. Lithium Nickel Manganese Cobalt Oxide $LiNi_{0.8}Mn_{0.1}Co_{0.1}O_2$ (NMC811), $LiNi_{0.8}Co_{0.15}Al_{0.05}O_2$ (NCA) and Lithium Iron Phosphate (LFP) are the compared cathode materials. The study initially involves the electrochemical modeling in the COMSOL Multiphysics environment by utilizing charging experiments on a commercial battery with known chemical and physical properties.
In the first step of the study, the electrochemical model of the battery was created. To reduce the computational load, the cell geometry in the model was simplified to a one-dimensional environment. Experiments are caried out as charging with 0.3C current. As the electrochemical model built, measured electric potential values were compared with experimental data in Figure-1. Thus, an electrochemical-thermal model has been created. In this model, the NMC811 cathode initially used has been replaced with LFP and NCA cathodes, respectively. In the first step of the study, the electrochemical model of the battery was created. To reduce the computational load, the cell geometry in the model was simplified to a one-dimensional environment. Experiments are caried out as charging with 0.3C current. As the electrochemical model built, measured electric potential values were compared with experimental data in Figure-1. Thus, an electrochemical-thermal model has been created. In this model, the NMC811 cathode initially used has been replaced with LFP and NCA cathodes, respectively.

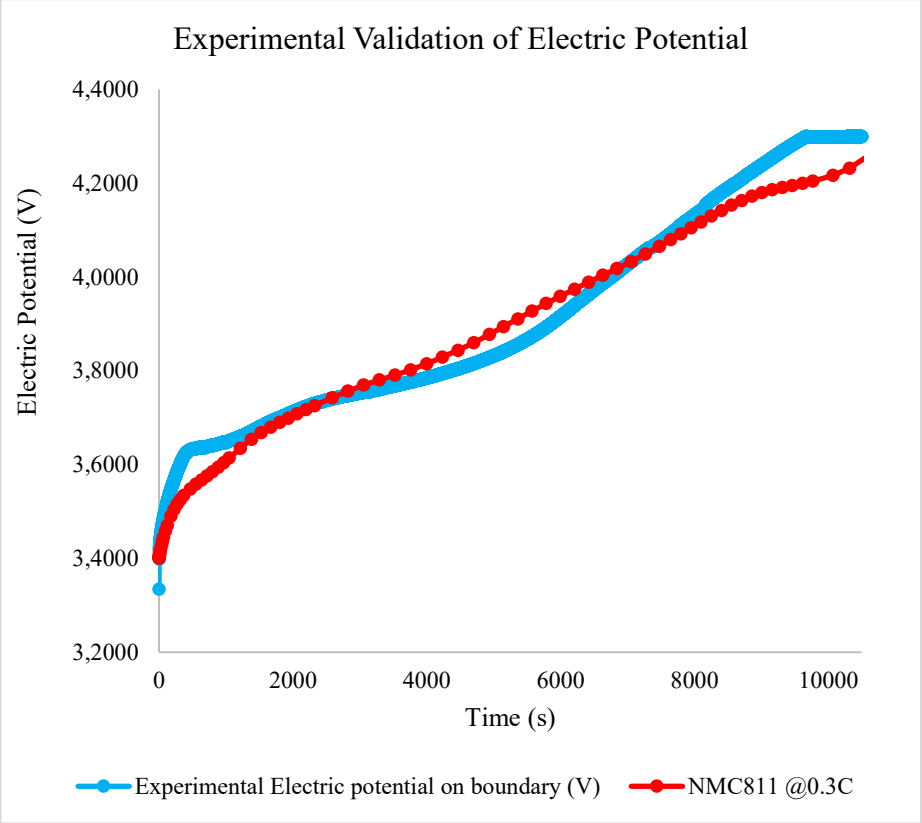

Figure 1: Experimental Validation of Electric Potential.

After validating the voltage values, the second step involved creating the three-dimensional thermal model of the battery and examining the temperature levels. Unlike the one-dimensional model, the three-dimensional thermal model was constructed at the battery pack level, including the case and terminal parts, rather than at the cell level. To simulate the thermal behavior heat transfer in solids and interface is used in 3D component. In the electrochemical model, heat sources are dynamically calculated by using time dependent electrode and electrolyte potentials. The average value of heat sources is used in time dependent thermal model. Both models are run in the same study steps.

Findings

Each cathode material has their own characteristic parameters that affects the temperature levels such as open-circuit voltage graphs, diffusion coefficients, electrical conductivity, insertion particle radius and maximum lithium host capacity. Some of the parameters were shown in Table 1. By changing and optimizing the parameters thermal and electrical behaviors simulated.

The voltage values obtained from running the electrochemical model are provided in Figure-2. Despite all cathodes has different starting voltage level, state of charge (SOC) parameters are all the same as %5.

In the 3D model, the active material of the battery is modeled in bulk, independent of the electrode-based cell structure. The time-dependent heat generation data obtained from the electrochemical model has been assigned as a heat source to the active material. The time-dependent average temperature values in the batteries are shown in Figure-3.

The thermal distribution in the 3D battery shows a relatively homogeneous distribution due to the active battery material being provided in bulk. In Figure 4, the temperature gradients of the batteries are shown by taking a cross-section from the center of the battery.

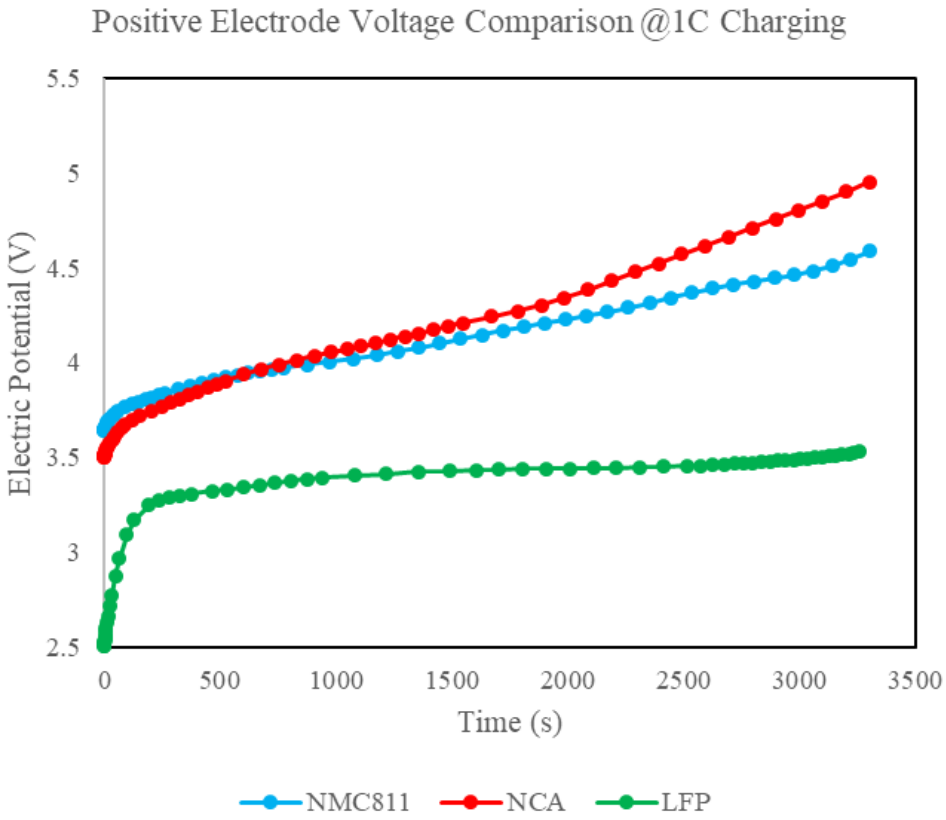

Figure 2: Electric potential values at 1C current charging.

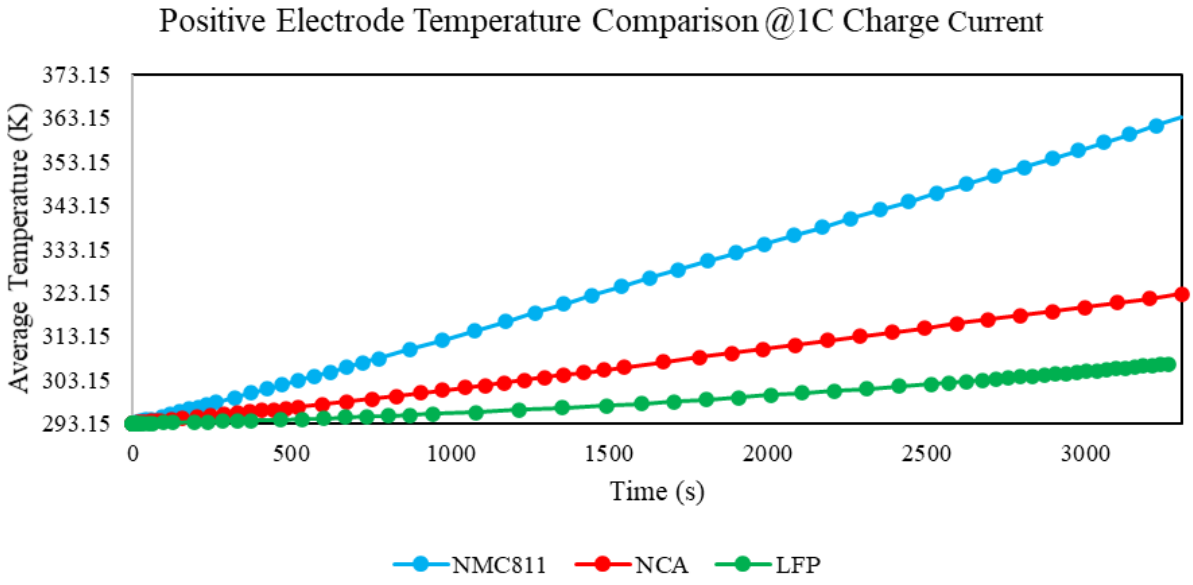

Figure 3: Average temperature levels of simulated batteries.

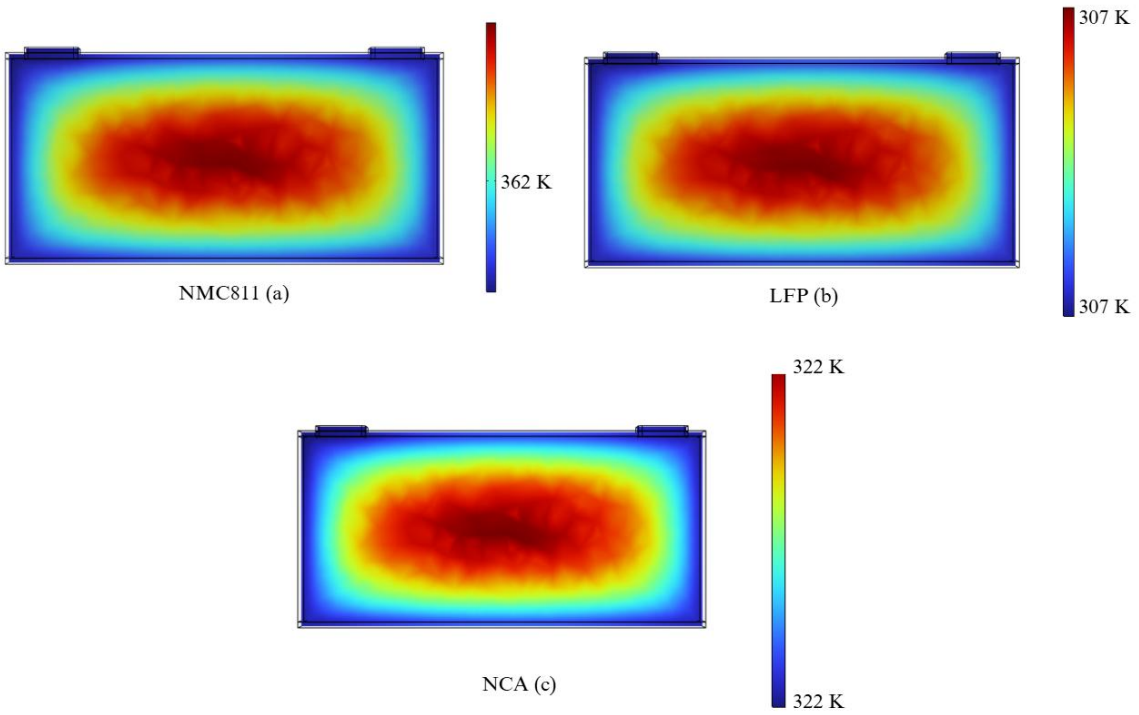

Figure 4: Temperature distirbution after 1C charging (3240s) at cross-section of the simulated batteries.

Conclusion

Three different batteries have been modeled using NMC811, NCA, and LFP as positive electrode materials. The batteries are identical in terms of open circuit voltage curves, dynamic diffusion coefficients, and geometric properties other than the values given in Table-1. Additionally, the separator, electrolyte, negative electrode, housing material, and terminals used in all batteries are identical. The batteries have been compared to examine the effect of the positive electrode's chemical characteristics on electrical potential and average temperature.

As a result of the modeling, the capacity ranking from largest to smallest is NMC811>NCA>LFP; the initial voltage ranking is NMC811>NCA>LFP; the post-charge voltage ranking is NCA>NMC811>LFP; and the temperature level ranking at the last time step is NMC811>NCA>LFP.

As given Table-1, the highest capacity belongs to NMC811 batteries because of its high lithium host capacity and OCV values. LFP has half of the capacity of NMC811, but thanks to its other parameters, shows more stable voltage profile (Figure-2), which is more favorable for battery applications.

Table 1: Characteristic parameters of the compared materials (Brown et al., 2008; Hall et al., 2016; Kasavajjula et al., 2008; Maxisch & Ceder, 2006; Sturm et al., 2019; Yang & Prakash, 2004).

	NMC811	NCA	LFP
Electrical Conductivity	0.17 S/m	91 S/m	91 S/m
Particle Radius	7 um	5 um	5 um
Maximum Ion Host Capacity	43143 mol/m^3	38482	26641
Cell Capacity	9000C	6500C	4500C

Table 2: Obtained results.

	NMC811	NCA	LFP
Start Voltage @0.05 SOC (V)	**3.6419**	3.503	2.4994
Final Voltage	4.5869	**4.9543**	3.5292
Final Temperature (K)	**363.35**	322.86	306.88

Capacity of NCA is moderate, but its high electrical conductivity brings NCA forward in after-charging voltage level. Generally, high-voltage causes high temperatures but the high ion concentration of NMC has been more effective in terms of temperature and has changed the ranking.
Considering the impact of cell temperature on safety and performance, LFP can be a good option. However, the low capacity is quite a challenging issue in land vehicle transportation. Therefore, NMC811 is preferred in some applications, but it should be accompanied by a sufficient and effective cooling system. When examining the prices for 2024, NCA cathode batteries require more cost compared to other batteries. In conclusion, the most suitable battery selection should be made by optimizing performance, safe temperature range, and cost parameters.

Keywords: Turbofan Engine, Bearing Thermal Management, Lubrication, Proportional Valve.

Aim

Effective lubrication and thermal management have become extremely important in modern turbofan engines, under extreme temperatures and high rotational speeds. The bearings in both the cold and hot sections of these engines are subjected to considerable thermal and mechanical stresses and require credible lubrication to reduce wear and avoid early failures (Rolls-Royce, 2005), (MIL-PRF-23699, 2012). Indeed, closed-loop lubrication has become the de facto industry norm in aero-engine designs as it efficiently re-circulates oil, controls heat, and removes contaminants (Winterbone & Turton, 1996). However, the biggest engineering challenge still lies in the proper optimization of oil distribution, especially across regions where there is a difference in thermal load (Hill & Peterson, 2015).
Fixed or manually adjusted components have always been a part of the traditional lubrication system. They do not adequately respond to the dynamic conditions of the engine with varying RPM and sudden thermal excursions during operation (Velásquez & Herrera, 2021).New-age systems try to overcome this limitation by adding active flow control devices like proportional valves that control oil delivery to important parts of the system in real-time (SAE International, 2019). These valves offer very precise control of oil flow, ensuring that the bearing temperatures are kept safe, which ultimately improves the durability of the engine and its operational reliability (Kerlin & Walter, 2010).

The study is directed towards the incorporation of oil flow regulation using proportional valves into a closed-loop lubrication system of a small turbofan engine, rated for approximately 4000 N of thrust . The research investigates two most vital bearings in the engine - one in the cold sector and the other in the hot sector. The bearings thermally responds appropriately to oil distribution changes under different flow scenarios. Moreover, the work contributes to the overall advancement in the aerospace arena in thermal management by showing how adaptive lubrication control could elevate efficiency and safety (Guimaraes & de Oliveira, 2017), (McLean, 2012), (Greitzer, Tan, & Lord,2007).

Material and Method

This study is about a closed-circuit lubrication system in a small-class turbofan engine that produces 4000 Newton thrust at nominal performance and reaches 44000 rpm. This lubrication subsystem consists of an oil pump, oil tank (reservoir) heat exchanger, filter, and two proportional valves separated for 2 separate bearings, cold and hot. This two-channel system provides independent control in the lubrication of each bearing group.
MIL-PRF-23699 synthetic ester oil was selected as the lubricant fluid due to its high thermal stability and low volatility properties. Due to the mentioned properties, MIL-PRF-23699 is a type of oil frequently used in aviation applications.The turbofan engine was examined by dividing it into two groups, basically cold section and hot section. While the bearing in the cold section is located in the compressor assembly where it is exposed to moderate thermal loads, the bearing in the hot section is exposed to much higher thermal loads due to its location in the turbine and combustion chamber.
To evaluate the system performance, a system architecture was designed with parametric simulations and thermal models in MATLAB. Four different valve opening ratios were determined as 25%, 50%, 75% and 100%. The oil flow rate changes

according to these opening ratios. In addition, a relationship was established between the engine speed and the pump output, and the effect of changing flow rates on bearing temperatures was examined.

Findings

Overall, this research has highlighted the importance of using proportional valve controlled lubrication system to improve the basic performance of bearings used in turbofan engines. One of the first findings is the critical relationship between valve opening ratio (%) and oil flow rate, as shown in Fig. 1. Oil flow rate (L/min) increases directly from 0 to 40 liters with valve opening from 0 to 100%. This shows the reliability of using proportional valves to control the flow of lubrication system, no matter how challenging the engine operating conditions are.

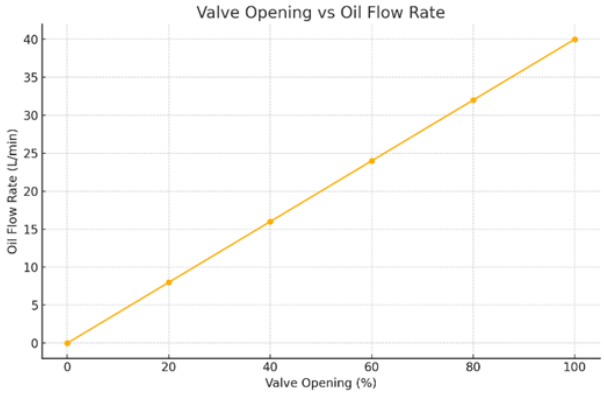

Figure 1: Valve Opening vs Oil Flow Rate.

Figure 2 shows the relationship between the pump oil output and engine speed. The pump performance starts at 10 L/min at 10,000 rpm and delivers 30 L/min at 28,000 rpm, while it delivers 40 liters of oil per minute when it reaches 44,000 rpm. This shows that engine performance and pump performance have a linear relationship under normal operating loads, and that when the maximum engine speed is approached, a regulated oil flow is provided by proportional valves.

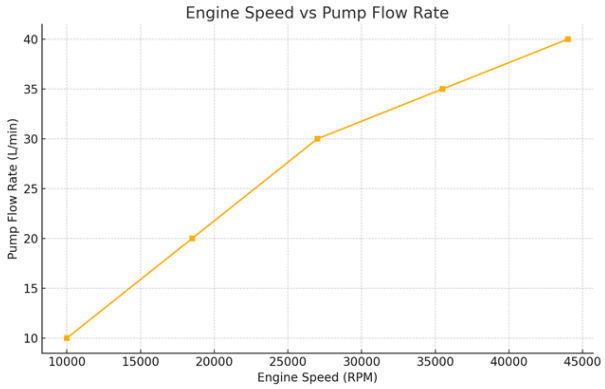

Figure 2: Engine Speed vs Pump Flow Rate.

As seen in Figure 3, the oil flow rate is of great importance in regulating the temperatures of the bearings in the cold and hot sections. The temperature of the bearing located in the cold section decreases from 55 °C to 35 °C with the increase in oil flow. In contrast, the temperature of the bearing in the hot section, which is subject to much higher thermal loads, decreases from 100 °C to 65 °C. These results emphasize the thermal gradient between the two sections and indicate that the oil supply of the system is directed more towards the areas where the cooling requirement is greater.

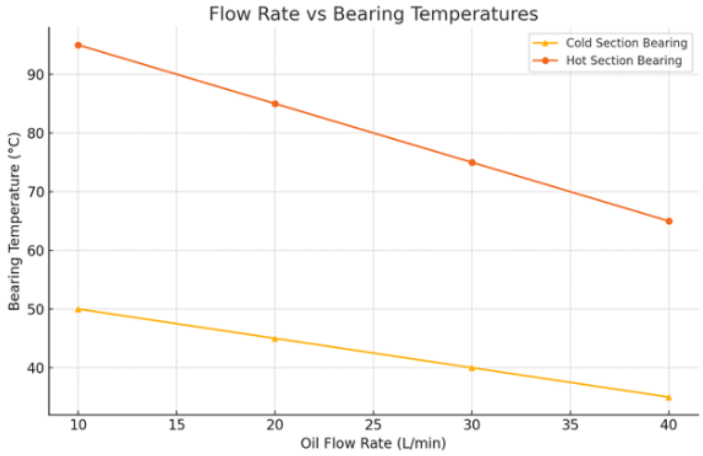

Figure 3: Flow Rate vs Bearing Temperatures.

In addition, Table 1 shows the bearing temperatures in relation to the valve openings. For example, with a 50% valve opening, the bearing temperature in the cold section is fixed at 45 °C, while the bearing temperature in the hot section is fixed at 90 °C. Therefore, these results confirm that the system is actively driven in the cooling process as determined by the local thermal requirements.

Table 1: Valve Opening & Temperature Table.

Valve Opening (%)	Cold Section Temp (°C)	Hot Section Temp (°C)
25	55	100
50	45	90
75	40	80
100	35	65

Conclusion

The results obtained from this study show that proportional valve controlled lubrication systems affect the thermal performance of bearings to a very serious extent. There is also a linear relationship between the life of the engine and the life of the bearings. Engine OEMs (Original Equipment Manufacturers) who want to produce long-life engines attach great importance to the thermal resistance of bearings in particular. Closed-loop lubrication systems create specialized thermal management systems for different performance requirements by regulating the amount of oil delivered to the bearings.

A significant result obtained is that when the oil flow rate delivered to the bearings reaches the highest levels, the bearing temperatures experience a major decrease from 55°C to 35°C in the cold section and from 100°C to 65°C in the hot section when the valve opening is compared with 25% and 100%. This cooling process reduces the thermal stress on the bearings and increases the reliability of the engine.

Moreover, this study reveals the importance of lubrication systems in reducing the energy consumption of propulsion and control systems in aviation engines. In the future, advanced 3D computational fluid dynamics analysis, testing and validation applications can optimize system performance, provide higher levels of thermal stability, and design safer lubrication systems and engines.

Sustainable GSM Base Station Energizing Using Portable Radioisotope Thermoelectric Generator (RTG) Design

Erdem Hayat[a], İskender Atilla Reyhancan[a]

[a]Istanbul Technical University, Department of Nuclear Researches, Radiation Science and Technology, Türkiye
hayat21@itu.edu.tr

Keywords: Radioisotope Thermoelectric Generator (RTG), Thermoelectric Generators (TEG), GSM Antenna, Disaster Resilience, Decentralized Energy Systems.

Aim

Conventional energy sources often struggle to provide consistent and reliable power to GSM base stations, particularly in rural and remote areas. These regions typically lack the necessary infrastructure for a stable electricity supply, and geographical challenges further complicate energy distribution. For instance, constructing power lines through dense forests and rugged terrains is not only costly but also environmentally detrimental due to deforestation and increased wildfire risks. Additionally, traditional energy sources such as diesel generators require regular maintenance and refuelling, which is often impractical in isolated locations. These challenges underscore the need for innovative and sustainable energy solutions to support remote communication infrastructure.

The primary objective of this research is to design a portable Radioisotope Thermoelectric Generator (RTG) capable of delivering uninterrupted and reliable power to GSM antennas. RTGs are particularly well-suited for this application due to their ability to provide long-term, maintenance-free power. Unlike conventional generators, RTGs lack moving parts, significantly reducing the risk of mechanical failure and ensuring continuous operation even in harsh environmental conditions. This reliability is critical for maintaining essential communication infrastructure during natural disasters or other emergencies. Furthermore, the compact and lightweight design of RTGs facilitates easy transportation and deployment in challenging environments.

Material and Method

The initial phase of RTG design involves the selection of an appropriate radioactive source and thermoelectric (TE) material. Based on the criteria outlined above, particularly the use of a beta-emitter radioisotope, Strontium-90 (^{90}Sr) was chosen as the radioactive source (Shor, 1971, May). The radiation characteristics of 90Sr and its decay product, Yttrium-90 (^{90}Y), are summarized in Table 1 (Abolhasan Khajepour, 2017). For the Radioisotope Heat Source (RHS), the strontium-based composition must exhibit high thermal conductivity, excellent chemical stability, and mechanical strength under high temperatures and pressures.

Table 1. Radiation properties of ^{90}Sr and its daughter ^{90}Y.

Nuclide	Half-life	Maximum E, MeV	Average E, MeV	Abundance, %	Specific power, W/kCi	Particles per W·s
^{90}Sr	28.90 years	0.546	0.1936	100	1.164	5.51×10^{12}
^{90}Y	64.053 hours	2.284	0.9365	100	5.551	5.51×10^{12}
		Total power			**6.715**	

*No alpha, gamma, neutron, or fission.

For the RHS, strontium titanate (SrTiO3) was selected due to its high thermal conductivity, excellent chemical stability, and mechanical strength under high temperatures and pressures. (Shigemasa Enomoto, 1975) These properties are critical for maintaining the structural integrity of the RHS and ensuring efficient heat transfer to the thermoelectric modules.

Table 2. Strontium titanate ($SrTiO_3$) properties at 25 °C.

Properties	Value
Density (g/cm^3)	5.11
Melting point (°C)	2040
Coefficient of thermal expansion ($°C^{-1}$)	12.1×10^{-6}
Specific heat (J/g·K)	0.544
[a] Specific power (W/g), 100% Sr (55%)^{90}Sr	0.247
Specific activity (Ci/g), 100% Sr (55%)^{90}Sr	36.8
Dielectric constant (ε_0)	300

a-By assuming 148.9 Ci/W (thermal), 139 Ci/g or 0.933 W/g (100% 90Sr). (Abolhasan Khajepour, 2017)

The thermoelectric modules used in RTGs rely on the Seebeck effect, which converts temperature differences into electric voltage. The performance of these modules is evaluated based on the figure of merit (ZT), which depends on the material's electrical conductivity, Seebeck coefficient, and thermal conductivity. Materials such as bismuth telluride (Bi_2Te_3) and lead telluride (PbTe) are commonly used due to their optimal ZT values at moderate temperatures. (Rowe, 2006) Recent advancements in material science have led to the development of more efficient thermoelectric materials, such as skutterudites and half-Heusler compounds, which offer higher ZT values and improved energy conversion efficiency.
The shielding design is another critical aspect of RTG development. The shielding must be robust enough to prevent the release of harmful radiation while also being lightweight to facilitate transportation and deployment. Advanced shielding techniques, such as multi-layered designs incorporating both high-Z and low-Z materials, have been developed to minimize radiation exposure and ensure the safety of personnel and the environment.

Findings

The selection of ^{90}Sr and $SrTiO_3$ as the radioactive source and RHS material, respectively, provides a robust and efficient solution for long-term energy generation. The radiation characteristics of ^{90}Sr and ^{90}Y ensure a consistent and reliable heat source, while the thermal and mechanical properties of $SrTiO_3$ enable efficient heat transfer and structural stability. The use of advanced thermoelectric materials, such as skutterudites and half-Heusler compounds, further enhances the energy conversion efficiency of the RTG system. These materials exhibit high ZT values, which are critical for maximizing the efficiency of thermoelectric modules. Additionally, the integration of segmented thermoelectric designs, where different materials are used at varying temperature zones, has shown promising results in optimizing energy conversion.
The shielding design effectively contains the beta radiation emitted by ^{90}Sr, minimizing the risk of radiation exposure. The multi-layered shielding approach, incorporating both high-Z and low-Z materials, provides an additional layer of safety, ensuring that the RTG can be safely deployed in various environments, including residential areas and nature reserves. This design not only protects personnel and the environment but also ensures compliance with international radiation safety standards.
The integration of RTGs into remote communication infrastructure offers several advantages over conventional energy sources. Unlike diesel generators, which require regular refueling and maintenance, RTGs provide a continuous and

maintenance-free power supply. This is particularly beneficial in remote and inaccessible locations where logistical support is limited. Furthermore, the silent operation of RTGs makes them suitable for use in noise-sensitive environments, such as wildlife reserves and urban areas. The absence of moving parts in RTGs significantly reduces the risk of mechanical failure, ensuring reliable operation even in harsh environmental conditions.

The portability of the designed RTG is a critical advantage, particularly in disaster scenarios. In disaster-stricken areas, energy infrastructure is often damaged or completely non-functional. In such cases, RTGs can be quickly transported to the disaster zone and provide a reliable energy source to support communication infrastructure. The silent operation of RTGs eliminates noise pollution, which is crucial for facilitating efficient communication among rescue teams. Additionally, the long energy supply duration of RTGs ensures continuous and uninterrupted power, which is essential for prolonged rescue operations. Unlike traditional energy sources, RTGs do not require personnel for maintenance or operation, making them ideal for hard-to-reach disaster areas. These features make RTGs a vital component of disaster response and recovery efforts.

Conclusion

This study demonstrates that portable RTGs provide a sustainable and reliable alternative to conventional energy sources for powering GSM base stations. The selection of ^{90}Sr as the radioactive source and $SrTiO_3$ as the RHS material provides a robust and efficient solution for long-term energy generation. The integration of advanced thermoelectric materials and shielding techniques further enhances the performance and safety of RTGs. The portability and silent operation of RTGs make them particularly valuable in disaster scenarios, where they can provide uninterrupted power without the need for frequent maintenance or personnel.

The findings of this research highlight the potential of RTGs to revolutionize energy supply in remote and disaster-prone regions. By leveraging the unique advantages of radioisotope decay and thermoelectric conversion, RTGs can provide a sustainable and reliable energy solution for a wide range of applications, including telecommunications, space exploration, and disaster management. Future research will focus on optimizing thermoelectric materials, enhancing radiation shielding techniques, and exploring hybrid energy systems that combine RTGs with renewable energy sources, such as solar and wind power. These advancements will further solidify RTGs as a cornerstone of sustainable energy solutions.

In conclusion, the development of portable RTGs represents a significant step forward in addressing the energy challenges faced by remote and disaster-affected regions. The ability of RTGs to provide reliable, maintenance-free power in the most challenging environments underscores their potential to transform the way we approach energy generation and distribution. As the world continues to grapple with the impacts of climate change and natural disasters, the importance of innovative energy solutions like RTGs cannot be overstated.

The Lifespan Comparison of an NMC811 Pouch Cell Based High Voltage Battery with Silicone and Polyurethane Foam Usage

Serhat Soyer [a]

[a] Istanbul Technical University, Department of Mechanical Engineering, Materials and Manufacturing Programme, Türkiye
soyerser@itu.edu.tr

Keywords: Battery, Foam, Pouch Cell.

Aim

The electric vehicles (EVs) increased its popularity year by year because of; improvments in its technology decreasing of battery pack costs, newly builded infrastructure and increasing level of consciousness on global warming.
So high voltage batteries are getting more and more importance since the powertrain transition of vehicle industry from internal combustion engine to electrical engines is rapidly increasing. It is a well-known fact that the most common high voltage battery cell types nowadays are mainly pouch, prismatic and cylindrical cells. Every cell type has its own advantages and disadvantages.
Cylindrical cells has high mechanical strength but also problematic thermal management systems.Prismatic cells has high energy density which represents their energy density per volume, however they have also high manufacturing cost.
Between those cell types pouch cels are one of the favourite in the vehicle cell market thanks to its high specific energy which represents energy per mass. However, pouch cells has two unignorable disadvantage that these cells has low mechanical strength and tends to swell.
Because of these reasons to prevent high swelling in lifetime and mechanical defetcs, pouch cells must be supported in battery architecture by soft materaials from its swell direction.
Due to commercial and easy applicability reasons silicone foams and polyurethane foams are two main supporter elements to cells in battery trays and selection between these two alternatives is a hot topic in high voltage battery design.
The purpose of this thesis is to prove that those two alternatives can easily be replaced instead of each other after an easy and fast compression test comparison to maintain a continuous pressure on cells to gain same level lifespans.
To understand those phenomena one polyurethane and one silicone commercial foams are selected. At first compressure deflection (CFD) curves of these two foams compared in different speeds. At the second step initial pressure of 36 cell-36 foam module stack forces are calculated from CFD curves, matched, and correlated with stack test data. At the last step the lifespan of 4 cell-4 foam battery mini-modules are tested with charge-discharge loop and their state of health which represents the condition of a cells compared to its ideal condition are measured continuously to make a final evaluation.
According to final evaluation it is proved that both foam types are suitable for use in battery cell stacks and easily replaced with each other if they have same level CFD behaviour from mechanical and lifespan point of view. For both types, the CFD curve can be used to select suitable foam option in battery modules.
The purpose of this research is to prove that two different alternative compression pad can easily be replaced instead of each other in a design after an easy and fast -shorter than a hour- compression test without performing a long and requiring resources lifecycle test.

Material and Method

Mechanically similar one silicone and one polyurethane foam products are chosen to compare. The compression deflection curves are initially compared from technical data sheets and then tested to validate accuracy. Standart test method for rubber properties is named as compression set from American Society for Testing and Materials International. Two test methods are covered as follows:

- Compression Set Under Constant Force in Air
- Compression Set Under Constant Deflection in Air

In this study compression set under constant deflection in air method is used to compare foam compression behaviour. Aufschläger at. al. (2024) shows in their study the compression ratios after 1000kPa will cause a high capacity retention for the pouch cells. In addition to that at higher compression ratios the hardening of foams will be too high unpredictably which might cause a mechanical deformation on pouch cells. Because of this reason design area of the cell stack must be selected to not exceed the 1000kPa load and the assumption of this study is on that direction as well.
Figure 1 showing that the pressure against compression is slightly higher for silicone type foam compared with polyurethane one however the pressure levels are getting closer after 70% compression ratio and almost same after %70 compression level which creating 1000kPa reaction compression.

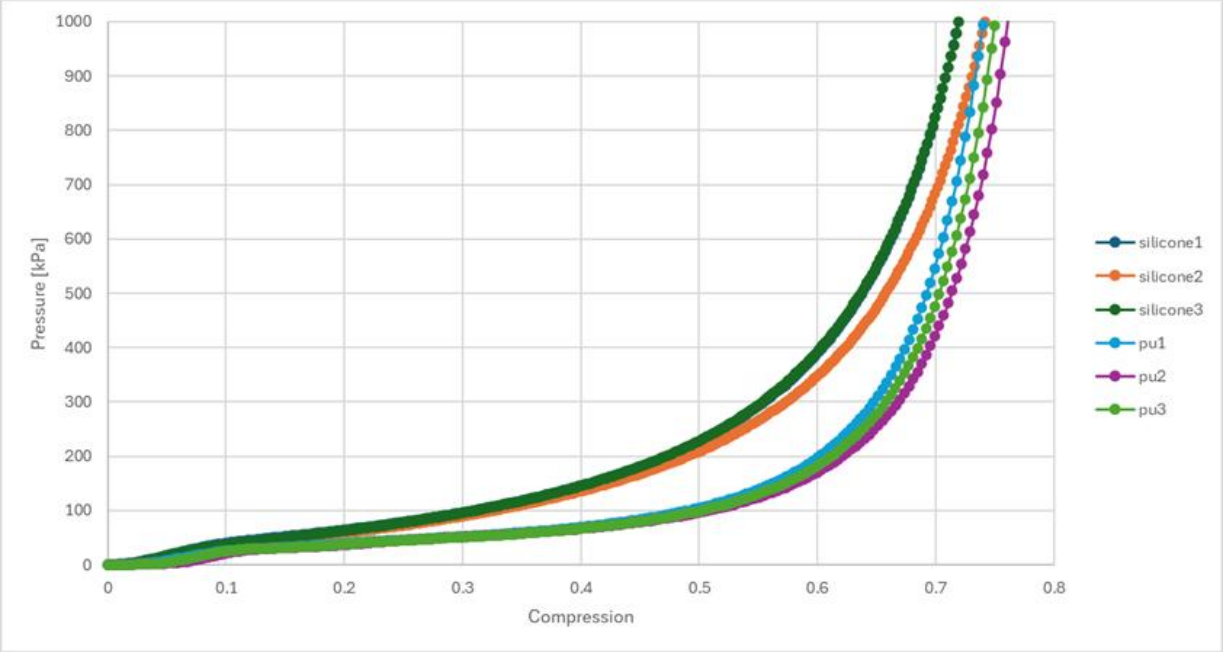

Figure 1: Compression Deflection Curve of Selected Foams.

At second step this study tested one type of module that assembled with pouch cells, compression pad foams, casettes and enclosure plates which shown in below Figure 2.

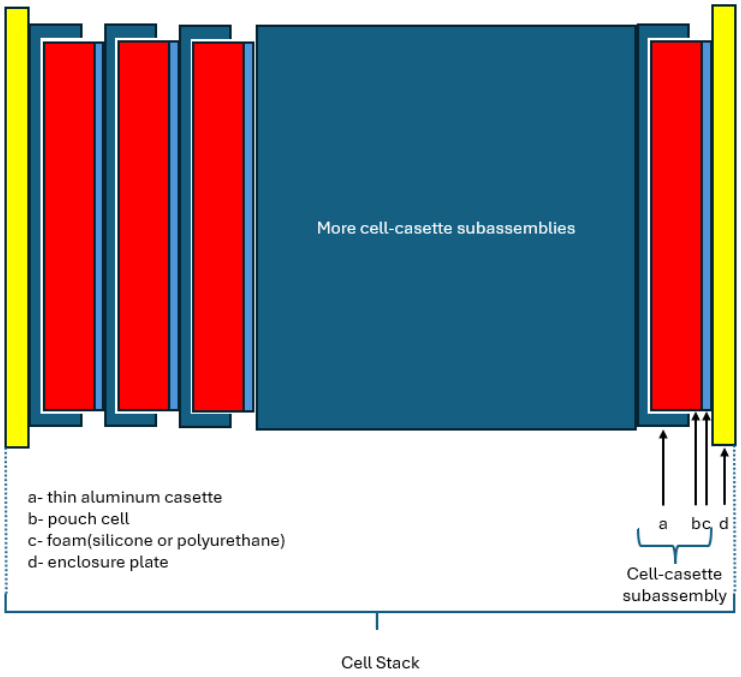

Figure 2: Schematic of Module Stack.

At the and the cycle aging is taken as the main factor to compare between two minimodule which set up with polyurethane and silicone foams.

Findings

Results clearly show that the capacity decreases between two modules which assembled with different foams are almost same in a lifetime. Below Figure 3 shows the comparison between 2 modules.
The deviation between two samples is 2 ‰ which can be negligible. In the case of different foam usage, it might be expected that the state-of-health (SOH) loss would be different because of the pressure onto cells are different. But even if the pressures are different against deformation caused by swelling for selected foams since the pressure level is lower than critical stress levels both cycle aging tests have given same capacity loss.

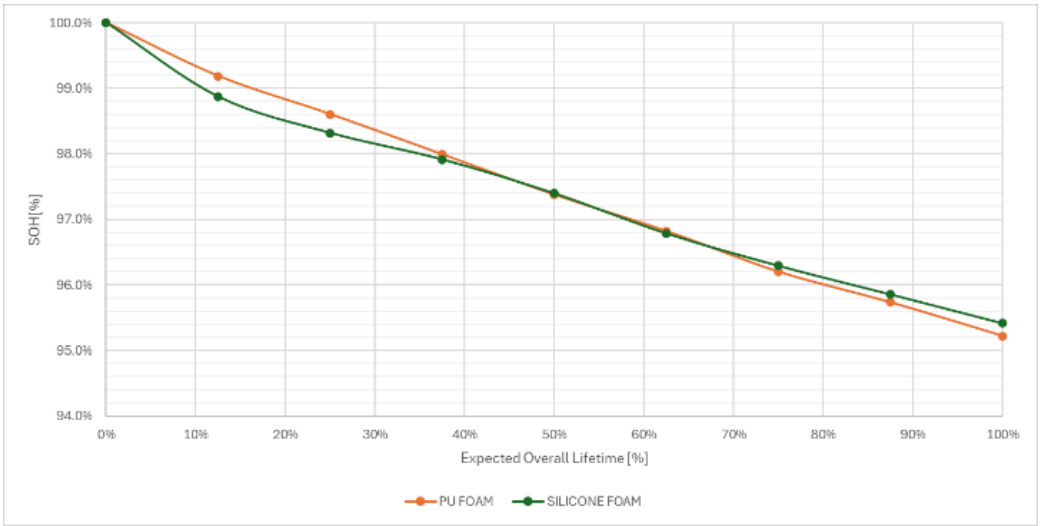

Figure 3: SOH vs. Expected Lifetime Graph.

Conclusion

This research aims to demonstrate that silicone and polyurethane foams can be substituted for one another without compromising performance, provided they exhibit similar behavior in terms of mechanical properties and lifespan. The comparison begins by evaluating the compression deflection (CFD) curves of both foam types at different compression speeds. Next, the initial pressure exerted on a 36-cell, 36-foam module stack is calculated using the CFD curves, with results matched and correlated against actual stack test data. In the final phase, the lifespan of 4-cell, 4-foam mini-modules is tested through charge-discharge cycles, and the state of health of the cells (which indicates how close the cells are to their ideal condition) is continuously monitored. The results confirm that both silicone and polyurethane foams are viable options for use in battery cell stacks. They can be interchanged as long as they exhibit similar CFD behaviors in terms of mechanical properties and lifespan. Thus, the CFD curves can be used as a reliable tool to select the most suitable foam material for battery modules.

Energy Efficiency Potential Analysis of SMEs In Türkiye's Fertilizer Sector

Sude Karabağ[a], Ebru Acuner[a]

[a]Istanbul Technical University, Energy Institute, Turkey
karabags18@itu.edu.tr

Keywords: Energy Efficiency, Fertilizer Sector, Green Transformation, SMEs, Sustainability.

Aim

Due to its high energy consumption and heavy reliance on imported raw materials, the Turkish fertilizer industry offers both potential and problems for increasing energy efficiency. The Carbon Border Adjustment Mechanism (CBAM) and the European Green Deal have increased pressure on Small and Medium Size Enterprises (SMEs) in this industry to embrace sustainable production methods. With an emphasis on their involvement in the green transition and the identification of significant challenges and opportunities, this study evaluates the energy efficiency potential of SMEs in the fertilizer sector in Turkey.

Material and Method

SMEs, which make up a sizable portion of the Turkish economy, are essential for long-term change but frequently face obstacles related to funding, access to technology, and regulatory compliance (Özdemir et al., 2007). The study examines trends in sectoral energy use, greenhouse gas emissions, and possible efficiency improvements via cutting-edge strategies including green finance and circular economy models. The results show that although some SMEs have started to adopt energy-saving practices, more industry cooperation, financial incentives, and wider regulatory support are required to hasten the process.

Assessing the energy efficiency potential of SMEs in Turkey's fertilizer industry is the aim of this study, especially in context with the European Green Deal and the Carbon Border Adjustment Mechanism (CBAM). SMEs are underrepresented in the green transition initiatives, although playing a vital role in the Turkish economy. Opportunities and difficulties unique to the fertilizer industry are addressed, with a focus on this energy-intensive and strategically significant sector for agriculture. By identifying the major factors influencing SMEs' transition to sustainable manufacturing, the study adds to the body of literature and aims to give empirical data on their energy efficiency methods.

A survey study specific to the fertilizer sector is planned in the study. This sector-based survey will determine the awareness of many SMEs in the fertilizer sector on the importance of green transformation and the differences in their approaches to sustainability. The survey includes questions to measure the awareness of SMEs in the fertilizer sector regarding CBAM; to identify the difficulties they experience in green transformation and energy efficiency studies and also includes questions necessary for data analysis. Based on the literature review, it is anticipated that certain SMEs have held energy-efficient technologies and improved resource utilization. On the other hand, some may still be reluctant because of financial limitations and insufficient support systems. The Analytical Hierarchy Process (AHP) approach is intended to be utilized to rank the challenges and opportunities highlighted in the survey. SMEs will be asked to rate different factors affecting their energy efficiency potential. This approach helps SMEs understand which aspects (financial, regulatory, technological or awareness-related) play a more important role in their decision-making processes. In this way, the aim is to evaluate the energy efficiency potentials of SMEs operating in the fertilizer sector in Türkiye using the Analytical Hierarchy Process (AHP) method.

Findings

The primary anticipated outcome of this research will be the capability of SMEs to leverage circular economy principles like waste recycling and sustainable resource utilization in their manufacturing processes. By adopting these practices, SMEs are likely to minimize their environmental impact while simultaneously enhancing their economic performance

through long-term reductions in operational expenses. However, a more widespread adoption of green practices requires a change in mindset supported by government policies and sectoral cooperation.
The gathered information will then be evaluated using Life Cycle Assessment (LCA) methods to more thoroughly examine the environmental effects for each sector. This research will act as an important reference to enhance the understanding of SMEs' roles in the transition towards sustainability and assist in setting sustainability objectives for each sector. Also, highlights that SMEs within the fertilizer industry have the capability to facilitate substantial change if provided with appropriate support and incentives. By tackling critical challenges and capitalizing on emerging opportunities, SMEs can not only minimize their environmental impact but also bolster their market position and aid Türkiye's overarching green growth strategy.

Conclusion

By adopting energy efficiency measures and sustainability-oriented policies, small and medium-sized enterprises (SMEs) in the fertilizer industry can improve their competitiveness in global markets while minimizing their environmental footprint. This research provides valuable insights into how SMEs can be assisted in their shift towards a low-carbon economy, in line with Türkiye's wider strategy for green growth.

Keywords: Conceptual Aircraft Design, Fuel Cell, Hydrogen Propulsion, Sustainable Aviation.

Aim

Since energy demand is increasing worldwide, the aviation industry is committing itself to the development of increasingly sustainable solutions and the meeting of solid emission criteria (IEA, 2023). While gas turbine engines have already been said to be very highly efficient, a completely carbon-neutral solution is impossible due to thermodynamic constraints and operational restrictions (Darecki et al., 2011; IEA, 2022). Aviation CO_2 emissions rose fastest in 2022, outpacing other modes of transport, which is likely to continue in future years (National Academies of Sciences, 2016; Roland Berger, 2020). In view of the objectives set by the European Union for 2050, alternative fuels, as well as new kinds of propulsion systems, have become an inevitable aspect of net-zero emissions flights (IEA, 2022).

To lessen this problem, sustainable aviation fuels (SAF) have been invented to curb the environmental damage associated with the burning of fossil fuels. When substituted for conventional jet fuel, SAF can cut carbon dioxide emissions by as much as 80%. For instance, as much effort may be put into making the use of burning fossil fuel neutral in carbon, it will not be attainable due to the processing and the emissions from combustion (Incer-Valverde et al., 2023). On the other hand, it is possible to use hydrogen for power generation using fuel cells and achieve almost no carbon (McKinsey and Company, 2020). Although, in theory, burning hydrogen does not produce any CO_2, this process does produce NO_x due to increased temperatures. It does have some negative impacts as well, involving excess water vapor at altitudes (Elitzur et al., 2017; Wilcox et al., 2012).

Hydrogen-powered fuel cells are hydrogen-use solutions that emit zero CO_2 and no NO_x, enabling the aviation industry to reach its net-zero targets (Noland, 2021). Most of the literature, including a few design processes for a comprehensive hydrogen and fuel cell aircraft design, is still very limited. It is noticed that ongoing studies are in the preliminary phase, and much more research is needed to carry out their transition towards an implementable full-scale application. This study aims to provide a sustainable and viable propulsion solution by evaluating the potential of hydrogen and fuel cells for use in aviation.

Material and Method

By integrating the hydrogen fuel cells into a CS-23 category aircraft and using the Dornier 228 as a reference, this study is concentrated. By weight and performance, this airplane was chosen to exhibit an ideal conversion to hydrogen cell technology.

The methodology involved assessing flight performance through constraint diagrams, analyzing flight conditions such as take-off, cruise, climb, and stall speed, and evaluating the implications of fuel cell powertrain integration. The powertrain was designed to include a fuel cell stack, a turbo-normalizing compressor, a cooling system, power management and distribution units, and electric motors. Hydrogen storage solutions were also considered, comparing liquid and gaseous hydrogen configurations for their impact on aircraft mass and aerodynamics. The wing and fuselage dimensions were adjusted to accommodate hydrogen tanks while maintaining stability and minimizing aerodynamic penalties.

By running performance simulations with MATLAB and SUAVE, the efficiency of hydrogen planes with respect to power and sustenance was compared and contrasted with that of conventional planes. The experiment established that the fuel cell efficiency of hydrogen planes is respectable and provides an appropriate flight speed without pollution. The method used

here provides a structured method for examining the incorporation of hydrogen in the improvement of aviation and offers valuable suggestions for green aviation in the future.

Findings

This study presents an extensive evaluation of hydrogen fuel cell integration into a CS-23 category aircraft, using the Dornier 228 as the reference model. The findings demonstrate significant structural and performance changes, particularly in weight distribution, energy efficiency, and operational range. One of the key results is the substantial increase in Maximum Take-Off Mass by 63.73% and Operating Empty Mass by 120.78% due to the additional weight of the fuel cell system and hydrogen storage tanks. However, despite these increases, the total fuel weight is reduced by approximately 78.42%, highlighting the superior energy density of hydrogen compared to conventional aviation fuels, as shown in Figure 1.

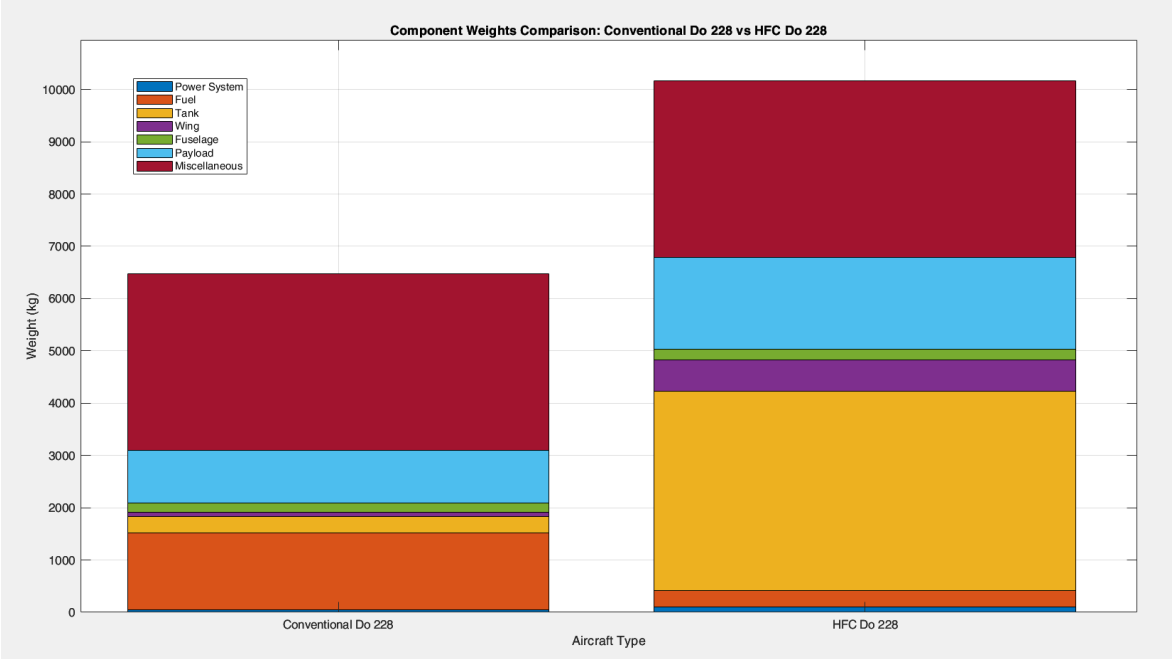

Figure 1: Weight distribution by components of the Conventional and Hydrogen Fuel Cell Dornier 228.

Analyses show that the hydrogen-powered aircraft has a lower range than the conventional version, but optimized structures, such as liquid hydrogen storage, increase operational efficiency. The effect of hydrogen on the shape of the aircraft is the requirement for a longer fuselage and larger wingspan, especially with the increase in fuel tank sizes, as can be seen from Figure 2. The fuselage length was adjusted to accommodate hydrogen tanks, reducing aerodynamic losses and maintaining aircraft stability. Renewable energy-produced hydrogen has 90% potential for sustainable aviation.

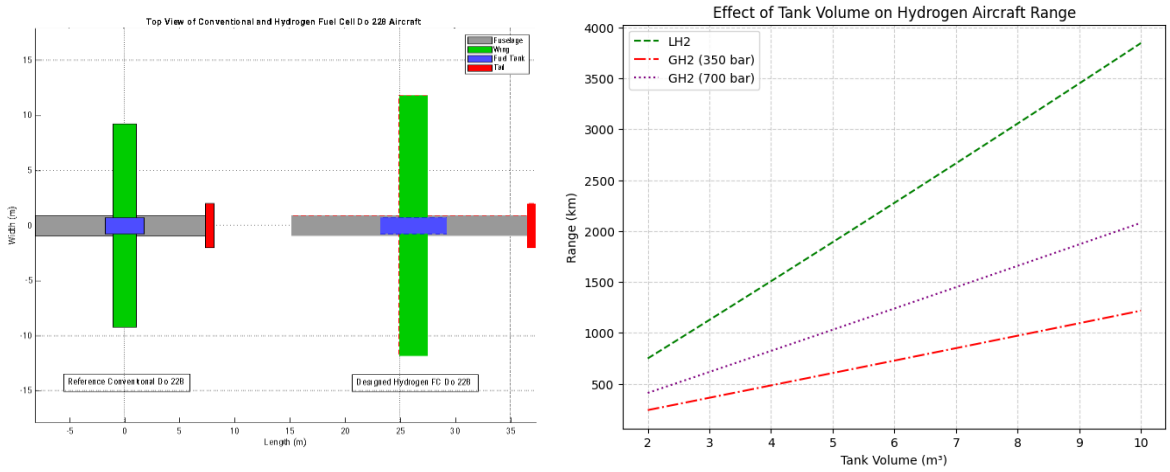

Figure 2: Comparison of Aircraft Dimensions and Range Variation with Tank Volume for the Hydrogen Fuel Cell Dornier 228.

Well-to-wing emissions are 21,995.45 kg-CO_2 for kerosene and 0 kg-CO_2 for LH_2/GH_2 if produced by renewable energy. If not, emissions rise to 366.41 kg-CO_2 for LH_2 and 368.01 kg-CO_2 for GH_2. Hydrogen still has lower emissions than kerosene due to better energy efficiency. For a 4-hour mission, the kerosene range is 1390.97 km with 1470.41 kg of fuel, and the LH_2 range is 404.40 km with 317.32 kg of fuel. When all fuel is consumed, the range increases to 3932.04 km for kerosene and 2598.53 km for hydrogen, showing hydrogen's potential for lower fuel consumption in short/medium-haul flights.

Conclusion

The integration of hydrogen fuel cells into the Dornier 228 showed a 63.73% increase in MTOM and 120.78% in OEM due to the added fuel cell system and tanks. However, fuel weight was reduced by 78.42%, highlighting hydrogen's higher energy density. Performance simulations showed a 4.86% reduction in power-to-weight ratio, with hydrogen-powered aircraft offering lower fuel consumption in short/medium-haul flights. The range for hydrogen was 2598.53 km when all fuel was consumed, compared to 3932.04 km for kerosene. Hydrogen fuel cells can reduce emissions by up to 90% with renewable energy, making them a viable, sustainable solution.

The Effect Of Seawater On The Electrodecomposition Of Hydrogen Sulfide To Hydrogen And Polysulfides

Faezeh Nazari[a], Alper Sarioglan[a], Mehmet Suha Yazici[b]

[a]Istanbul Technical University, Chemical Engineering, Turkey

[b]Istanbul Technical University, Energy Institute, Turkey

syazici@itu.edu.tr

Keywords: Hydrogen Sulfide, Hydrogen Evolution, Electrolysis, Metal-Phthalocyanine.

Aim

The effect of different types of electrolytes on hydrogen sulfide (H_2S) splitting is investigated. The coated cobalt phthalocyanine (CoPc) and nickel phthalocyanine (NiPc) on porous nickel (Ni) are selected as the catalysts for comparison. The linear sweep voltammetry (LSV) and electrochemical impedance spectroscopy (EIS) are measured to understand the behavior of the catalysts and support. NiPc on nickel in NaOH solution has the best response compared to other catalysts and electrolytes. In addition, the presence of sodium chloride decreases the rate of reaction.

The entire amount of H_2S in the Black Sea is estimated to be 4.6 billion metric tons. The anoxic conditions begin in the deeper sections of the basin (below 150-200 meters), where H_2S is believed to be created by sulfur-reducing bacteria at an approximate pace of 10,000 tons per day, which continues to reduce life in the Black Sea (Petrov et al., 2018). H_2S electrolysis involves cathodic H_2 and anodic sulfur oxidation reactions (SOR) at a low cell voltage of 0.14 V (Hakim et al., 2023). Replacing the OER with the SOR reduces the electrolysis potential from 1,23 V (H_2O electrolysis) to 0,14 V (H_2S electrolysis), resulting in significant energy savings for pure H_2 generation (Kumar and Nagaiah, 2022). In the alkali solution H_2S is desolved in the solution (Yang et al., 2019):

$$H2S + OH^- \rightarrow H2O + HS^-$$

And then in the electrolysis reaction:

$$\text{Anode}: 2HS^- \rightarrow S+H2S+2e^-$$

$$HS^- + OH^- \rightarrow S+H2O+2e^-$$

$$\text{Cathode}: 2H2O+2e^- \rightarrow H2 + 2OH^-$$

and then, sulfur rapidly dissolves in the alkaline media forming polysulfides:

$$S+HS^- + OH^- \rightarrow S2^{-2}+H2O$$

In addition, phthalocyanine (Pc) with different central metals has wonderful specifications as a catalyst such as, the ease of large-scale production, distinctive redox behavior, high efficiency, ease of separation, and recyclable nature (Yang et al., 2021).The type of metal center, substitution, support, and aggregation of Pc's are some of the critical parameters that determine the total H_2 production rate for the photo- and electrocatalytic H_2 formation processes of Pc-based catalysts

(Keshipour and Asghari, 2022). For a thorough understanding of the role of the central metal atom in a three-electrode cell electrolysis of H_2S for hydrogen production, CoPc and NiPc were selected for this study.

Material And Method

$Na_2S{\cdot}9H_2O$ (from Carlo Erba) was used as the source of H_2S for its convenience. The original pH values of the Na_2S aqueous solution were adjusted with sodium hydroxide (Riedel-DeHaen and LabKim). CoPc 96% and NiPc 98% (BLD Pharmatech GmbH) were supported on 200 micron 83% porosity nickel fiber (Bekaert).

All electrochemical measurements have done by potentiostat Gamry Instrument Interface 5000e. A conventional three-electrode cell, wherein CoPc and NiPc ($1cm^2$) on diffusion support acts as a working electrode (WE), a platinum wire as counter and 3.5M KCl Ag/AgCl as reference electrodes. The electrolyte solutions were 0.1M NaOH, 0.3M NaCl, and 0.1M NaOH+0.3 MNaCl while 0.1M Na_2S has added as the source of H_2S. The SOR activity of the catalysts was illustrated by performing LSV over a potential range of -0,5 to 0,1 V vs. SHE at scan rate 5 mV/s. The EIS measurements were performed in a frequency range of 100 kHz to 200 mHz at open circuit potential (OCP).

Findings

Electrocatalytic performance is evaluated using LSV at a scan rate of 5 mV/s (Figure 1, 2). The SOR graphs show the different catalyst performances, including NiPc on Ni and CoPc on Ni in 0.1M NaOH, 0.3M NaCl, and 0.1M NaOH+0.3M NaCl electrolyte solutions. As shown in Figure 1a, CoPc on Ni in NaOH solution produces a higher current than in other electrolytes. At 0 V (vs. SHE) in the NaOH solution, the current density is 12.7 mA/cm², while at the same voltage, the current in other electrolytes reaches 2.7 mA/cm². This pattern is also observed for NiPc on Ni. At 0 V (vs. SHE), the NaOH solution results in a current density of 9.8 mA/cm², but the currents decrease to 4.1 and 2.3 mA/cm² for NaCl and NaCl+NaOH, respectively. Moreover, comparing the catalysts CoPc and NiPc shows that in NaOH electrolyte solution, CoPc has a better response, producing 10 mA/cm² at -50 mV (vs. SHE), while NiPc reaches the same value at +37 mV (vs. SHE).z

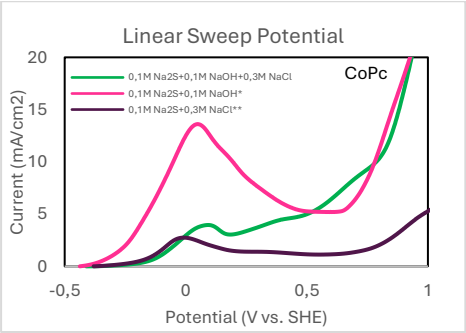

Figure 1: LSV measurement of CoPc at scan rate 5mV/s (in different electrolyte solutions).

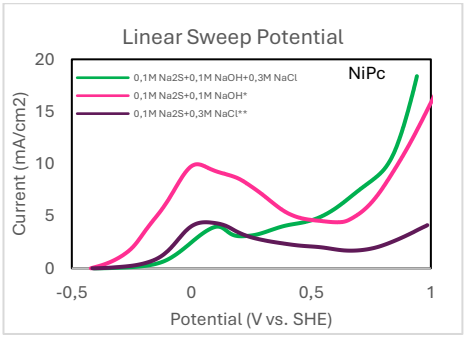

Figure 2: LSV measurement of NiPc at scan rate 5mV/s (in different electrolyte solutions).

Figure 3 reveals the impedance of different electrolytes for both catalysts, NiPc and CoPc. In NaCl and NaOH+NaCl electrolytes, the same patterns can be observed; both electrolytes exhibit lower impedance when the working electrode is CoPc. By comparing different electrolytes with NiPc, it can be concluded that NaOH+NaCl provides high resistance, which results from sluggish kinetics.

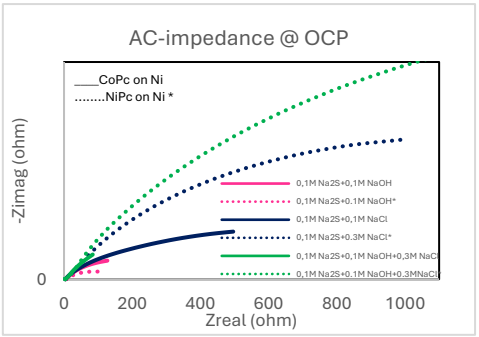

Figure 3: EIS measurement of CoPc and NiPc at OCP (in different electrolyte solutions).

Conclusion

The influence of various electrolytes on H_2S splitting is examined. The catalysts used for comparison are coated CoPc and NiPc on Ni. The LSV and EIS are used to investigate the behavior of the catalysts and support. CoPc on Ni in NaOH solution offers the best response when compared to other catalysts and electrolytes. Additionally, the presence of sodium chloride reduces the rate of reaction.

ENVIRONMENTAL ENGINEERING

Air Pollution and Control

Membrane Technologies

Effects of Air Pollutant Parameters on Respiratory Diseases in Edirne

Kutlay Özdemir[a], Burçak Kaynak[a]

[a] Istanbul Technical University, Faculty of Civil Engineering, Department of Environmental Engineering, Türkiye
ozdemirk18@itu.edu.tr, burcak.kaynak@itu.edu.tr

Keywords: Distributed Lag Non-Linear Model (DLNM), Health Effects, PM, NO2, SO2.

Aim

The association between air pollution and respiratory diseases has gained growing attention in recent years, as air pollution is recognized as one of the leading global risk factors contributing to morbidity and mortality. Increased air pollution can lead to an increase in many diseases, especially respiratory diseases. Edirne, gateway of Türkiye to Europe, with a population of over 400000, its proximity to main highways, and the number of motor vehicles up to 200000, is one of the cities with serious air pollution problems. Based on the number of hospital admissions due to respiratory diseases in Edirne between March 1, 2013 and December 31, 2017, seven different respiratory diseases (shortness of breath, cough, asthma, COPD, sinusitis, bronchitis, and upper respiratory tract infections-URTI) were examined together with the analysis of criteria air pollutants -particulate matters (PM_{10} and $PM_{2.5}$), nitrogen dioxide (NO_2), and sulfur dioxide (SO_2)- between the same dates.

The aim of this study was to evaluate the effect of each 10 μg/m³ increase in criteria air pollutants (PM_{10}, $PM_{2.5}$, NO_2, and SO_2) on respiratory diseases in Edirne/Türkiye during between March 1, 2013 and December 31, 2017. The significant effects of air pollutants on human health were investigated. At the same time, the results will enable more effective and efficient use of decision support systems.

When the relationship between them was investigated, very high levels of sulphur dioxide (SO_2) pollution occurred due to the use of poor-quality coal for residential heating in some districts of Edirne, especially in Keşan. In these years (2013-2017), Keşan was identified as the most polluted location in Türkiye in terms of SO_2. In time, with the widespread use of natural gas, SO_2 pollution has decreased to the limit values specified in the national legislation. However, despite the increase in the number of households subscribed to natural gas, a slight rise in SO_2 levels was observed in 2024. This may be attributed to the preference for cheaper and lower-quality fuels, potentially driven by the ongoing economic crisis in Türkiye.

Material and Method

In this study, the daily average concentrations of criteria air pollutants PM_{10}, $PM_{2.5}$, NO_2, and SO_2, were associated with the number of hospital admissions due to respiratory diseases in Edirne province during the study period (a total of 1767 days / 58 month). In order to investigate the health impacts of air pollutants, a time series analysis of daily hospital admissions for respiratory diseases and air pollutants at various time lags (0-9 days) was performed using a single-pollutant Poisson Generalized Linear Model (Poisson GLM). In this study, the Distributed Lag Non-Linear Model (DLNM) which is the most commonly used statistical methods to evaluate air pollution exposure on human health as a component of GLM was used to account for the delayed effect of air pollution exposure on hospital admissions (Gasparrini, et. al, 2010). This model allows the effects of pollution to be examined on the same day (lag 0), the next day (lag 1), and up to a certain number of days (in this case, 9 days).

Findings

Total hospital admissions for shortness of breath, cough, asthma, COPD, sinusitis, bronchitis and URTI in Edirne were 9625, 43547, 240787, 140539, 12091, 192080 and 1016224, respectively. PM_{10} and $PM_{2.5}$ have been found to be strongly associated with the number of hospital admissions for many respiratory diseases, both in the long term and in the short

term. The comparison of criteria air pollutants (PM_{10}, $PM_{2.5}$, NO_2, SO_2) and the number of daily hospital admissions for respiratory diseases in Edirne are given in Figure 1.

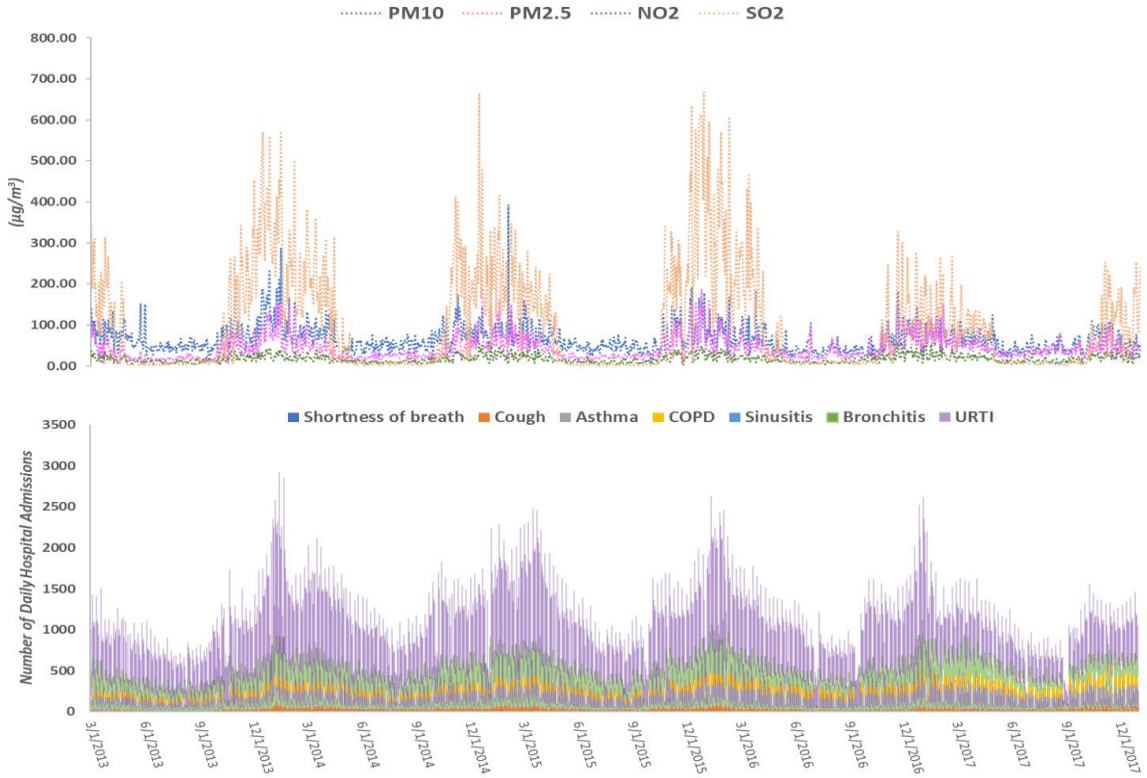

Figure 1: The Comparison of Criteria Air Pollutants (PM_{10}, $PM_{2.5}$, NO_2, SO_2) and The Number of Daily Hospital Admissions for Respiratory Diseases in Edirne between March 1, 2013, and December 31, 2017.

It was observed that hospital admissions for respiratory diseases were significantly higher during the winter months compared to the summer months. In addition to the health effects of air pollution, the air quality of Edirne province (Central and Keşan districts) was examined in detail between 2013-2024, and pollution distribution analyses were performed. Annual mean air pollutants (PM_{10}, $PM_{2.5}$, NO_2, SO_2) of 3 Air Quality Monitoring Stations (AQMSs) in Edirne province for the period between 2013-2024 and their comparison with the limit values were made. For comparison, both the limit value in the Turkish legislation (Air Quality and Assessment Management Regulation, HKDYY) and the European Union (EU) annual limit value for PM_{10} and SO_2, and the EU annual limit values for $PM_{2.5}$ and NO_2, were taken Figure 2.
When the number of natural gas subscriptions of residences in Edirne and its most large district, Keşan, was examined, and a very strong negative correlation between SO_2 pollution and natural gas subscription was observed Figure 3.

A 10 µg/m³ increase in PM_{10} (lag 0–9 days) was associated with a 16.74% [95% Confidence Interval (CI): 2.05–136.70] increase in hospital admissions for sinusitis, a 9.39% [2.63–33.57] increase for shortness of breath and a 2.16% [1.74–2.69] increase for cough. A 10 µg/m³ increase in $PM_{2.5}$ (lag 0–9 days) was associated with a 1.77% [1.29–2.42] increase in hospital admissions for sinusitis, a 1.54% [1.42–1.66] increase for URTI and a 1.45% [0.62–3.37] increase for shortness of breath. A 10 µg/m³ increase in NO_2 (lag 0–9 days) was associated with a 2.20% [1.35–3.59] increase in hospital admissions for shortness of breath, a 1.45% [1.26–1.65] increase for cough and a 1.36% [0.80–2.31] increase for sinusitis. A 10 µg/m³ increase in SO_2 (lag 0–9 days) was associated with a 1.93% [0.99–3.75] increase in hospital admissions for sinusitis, a 1.29% [1.05–1.60] increase for cough and a 1.21% [0.94–1.58] increase for shortness of breath.

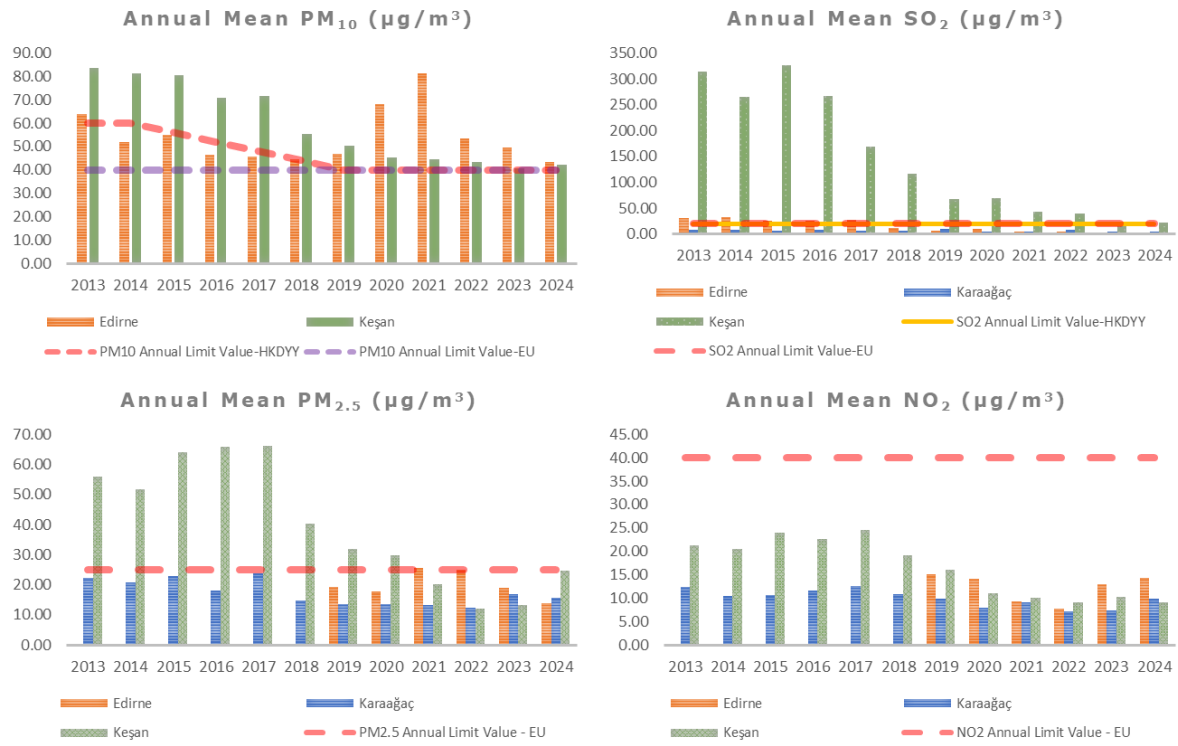

Figure 2: Annual Average Air Pollutants (PM_{10}, $PM_{2.5}$, NO_2, SO_2) of 3 AQMSs in Edirne Province for the Period between 2013-2024 and Comparison with Limit Values.

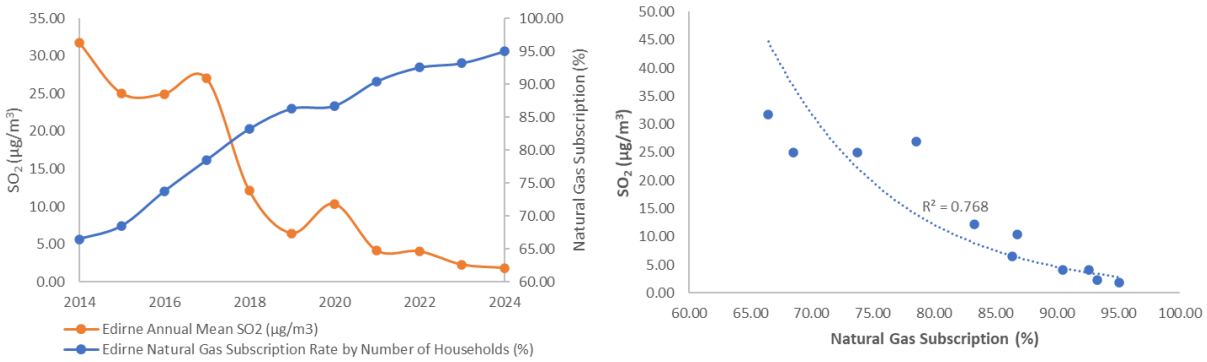

Figure 3: Relationship of SO_2 Concentrations and Natural Gas Subscription Rate by Number of Households (%) in Keşan.

When the cumulative effect was analyzed, every 10 µg/m³ increase in PM_{10} caused a significant increase, especially in sinusitis, shortness of breath and bronchitis; every 10 µg/m³ increase in $PM_{2.5}$ caused a significant increase, especially in sinusitis, cough and asthma; every 10 µg/m³ increase in NO_2 caused a significant increase, especially in shortness of breath and cough; every 10 µg/m³ increase in SO_2 caused a significant increase, especially in URTI, bronchitis and COPD. Cumulative excess relative risk (ERR, %) of hospital admissions associated with a 10 µg/m³ increase in pollutant concentrations over 10 days of lag (lag 0-9) in Edirne is shown in Table 1.

Table 1: Cumulative Excess Relative Risk (ERR, %) of Hospital Admissions Associated with a 10 μg/m³ Increase in Pollutant Concentrations Over 10 Days of Lag (lag 0-9) in Edirne.

	ERR (95% CI) (%)mean

Similarly in the literature; In Klang Valley, an industrial region near Kuala Lumpur, Malaysia's capital, the link between air pollution and acute respiratory infections in children aged 0-14 years was studied, and a significant correlation was found between acute bronchitis and high PM_{10} concentrations (Abdul Rahman et.al, 2017). PM_{10} was shown to significantly increase the risk of 13 different acute respiratory infections subtypes. Among the diseases most impacted by PM_{10} were acute bronchiolitis, acute upper respiratory infection of multiple and unspecified sites, and unspecified acute lower respiratory infection (RR = 1.07, 95% CI = 1.04–1.11 (Abdul Rahman et.al, 2017). Similarly, in a study conducted in Tasmania, Australia between 1992 and 2002, a strong association was found between daily PM_{10} concentrations and hospital admissions for shortness of breath, sinusitis, acute bronchitis and bronchiolitis, but no significant correlation was observed for acute exacerbations of asthma and COPD (Mészáros, D et.al, 2015).

Conclusion

As a result, it has been found that the air pollution parameters PM_{10}, $PM_{2.5}$, NO_2, and SO_2 were found to be closely associated with respiratory diseases, particularly sinusitis and shortness of breath, as well as cough and bronchitis in Edirne. It was found that PM_{10} is the pollutant of primary importance for shortness of breath, sinusitis, COPD, URTI, bronchitis. $PM_{2.5}$ is the pollutant of secondary importance for asthma, NO_2 is the pollutant of secondary importance for cough, SO_2 is the pollutant of secondary importance for URTI.

Although the number of natural gas subscribers has increased in Edirne, many households have been adversely affected by the ongoing economic crisis in Turkey and they have been using cheaper, lower-quality fuels. To prevent the decline in living standards and mitigate the health risks associated with increased air pollution, it is essential for the government to implement support mechanisms such as natural gas subsidies. The economic loss due to respiratory diseases will be much greater than the investments to improve air quality. Public health should be prioritized above other governmental projects or investments.

Keywords: Feed spacer geometry, Reverse osmosis, Saltwater desalination.

Aim

Reverse osmosis (RO) is a key technology for desalination, widely applied to treat saline water and provide fresh water for various industrial and domestic uses. The efficiency of RO membranes is often constrained by fouling, leading to performance degradation, increased operational costs, and reduced membrane lifespan. Addressing fouling issues requires strategies such as feed water pre-treatment (Prihasto et al., 2009), membrane surface modifications (Goh et al., 2019), operational optimization (Hoslett et al., 2018), and innovative channel designs (Koutsou et al., 2004). This study investigates the influence of feed channel geometries on RO membrane efficiency, focusing on randomly generated channel structures compared to a pre-examined sinusoidal design (Ling et al., 2021). To achieve this, three different channel designs were created by assigning Bsplines with 10, 15, and 20 random knots while maintaining the same length, allowing a systematic comparison of their impact on flow characteristics and membrane performance. Computational Fluid Dynamics (CFD) simulations were employed to analyze these flow channel configurations, aiming to enhance flow rate and improve mass transfer efficiency. Furthermore, this research will contribute to the body of knowledge by quantitatively assessing how various channel geometries affect the performance parameters of RO systems, specifically targeting enhancements in permeate flux and reduction in fouling. By integrating novel designs with practical engineering applications, the study seeks to pave the way for more sustainable and efficient RO systems.

Material and Method

Computational Fluid Dynamics Simulations

In this study, the CFD simulation was applied to investigate the influence of the feed channel geometry on the performance of RO systems. Water flow profile, membrane fouling, and clean water flow over time were calculated by CFD simulations. The CFD simulations utilize the Navier-Stokes equations to determine the velocity and pressure profiles, while the advection-diffusion equation was used to model the salt concentration distribution in the channel. Additionally, the Langmuir adsorption-desorption equation was applied to the membrane surface to quantify membrane fouling. Lastly, permeate flux equation based on Darcy's law on porous surface, was used to calculate the amount of permeate flux. These equations define the dynamics of fluid flow and the associated mass transfer phenomena within the RO process.

Feed Spacer Design and Simulation Setup

The feed channel geometry design process followed three key steps: (1) feed spacer geometries were designed using CAD software (Salome Platform version 19.4.0), (2) mesh generation was performed for CFD analysis, and (3) simulations were conducted with OpenFOAM (v2412) CFD software. pimpleFOAM solver package of openFOAM was modified to analyze flow, permeate flux, and membrane fouling for various channel geometries. Key parameters such as inflow velocity, pressure, and solute concentration were set to define the boundary conditions for the simulations. This process was repeated for each feed spacer geometry, including three randomly generated designs and one sinusoidal design. Both the randomized channels and the sinusoidal design were generated with a length of 100 mm. The randomized channels used 10, 15, and 20

knots, applying a B-spline algorithm to introduce geometric randomness. For sinusoidal design, the period is selected as 2.4 mm. From these models, the membrane performance parameters, including fouling deposition (surface fouling), fluid flow characteristics, and permeate flux were obtained.

The simulations were performed by introducing bulk concentration, surface concentration, and permeate flux as scalar quantities to pimpleFOAM solver modeling different spacer geometries, and assessing their impact on overall system performance. Residuals for flow velocity, pressure, solute concentration, and flux were set to $1\times e^{-7}$ in CFD solution package to obtain accurate results. Boundary conditions used in CFD simulations are indicated in Table 1.

Table 1. Boundary conditions used in CFD simulations: U represents the three-dimensional velocity vector(m/s), P denotes pressure (bar), C_s refers to the salt concentration on the membrane surface, C_b indicates the mass ratio of salt (1 corresponds to 0.035 kg salt/kg solution) in the solution, and J_w (Lmh) represents permeate flux.

	Input	Output	Walls	Membrane
U	0.15 m/s	dU/dt = 0	0	partial slip
P	dP/dt = 0	40 bar	dP/dt = 0	dP/dt = 0
C_s	0	0	0	$dC_s/dt = 0$
C_b	1	$dC_b/dt = 0$	$dC_b/dt = 0$	$dC_b/dt = 0$
J_w	0	0	0	$dJ_w/dt = 0$

Findings

The study comprised three random models with varying complexities, 10, 15, and 20 knots, alongside a reference model featuring a conventional flat geometry and a sinusoidal model. The comparative analysis of simulation results, as documented in Table 2, clarifies several key observations regarding the performance metrics across different channel designs including the average flux J_w, the average surface fouling C_s, and the end-to-end pressure drop. The performance metrics are independent of surface area, and they are listed in the table as additional information. Moreover, visuals showing the final fouling characteristics of all models are presented in Figure 1.

Table 2. For each channel, the average values at the membrane surface, the membrane surface area, and the calculated pressure difference between the inlet and outlet of the channel.

Models	Average J_w (Lmh) 10^{-3}	Average C_s	Pressure Drop	Models
Reference model	2.75	1.76	0.2	1.00
Random (10)	2.79	1.77	0.37	1.72
Random (15)	2.77	1.78	0.59	1.88
Random (20)	3.30	1.73	1.00	1.78
Sinusoidal	2.83	1.72	1.20	1.00

The findings indicate that all models, including those with random geometries, achieved at least comparable or superior average flux J_w values relative to the baseline established by the reference model. Notably, the Random(20) model exhibited

a significant increase in performance metrics, distinguishing itself, particularly in areas of flux enhancement. This suggests a potential correlation between the complexity of knot configurations and flux performance, although the differences between the 10, and 15 knots models were not pronounced enough to draw definitive conclusions.

In terms of pressure drop, an important factor considering hydraulic performance, the Random(20) model demonstrated advantages over the sinusoidal model, suggesting that higher knot configurations might optimize both mass transfer efficiency and hydraulic resistance. However, the results related to fouling metrics C_s did not significantly differentiate between the models, indicating that this performance aspect might be less sensitive to changes in channel geometry or might require additional experimental data for a more nuanced analysis.

Overall, the simulation outcomes underscore the promising potential of random models, particularly as the number of knots increases. These models not only challenge the traditional efficiency benchmarks set by rectangular and sinusoidal geometries but also hint at an emergent trend where increased geometrical complexity leads to performance gains. To confirm these preliminary findings and to fully figure out the impact of knots on RO system performance, further detailed experiments and analyses are warranted.

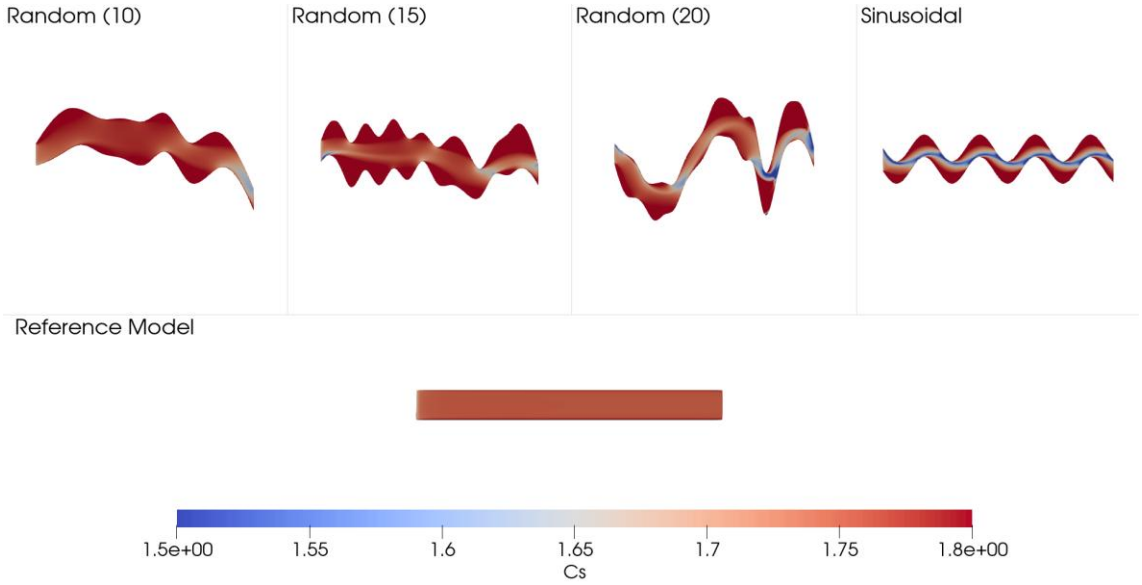

Figure 1. Membrane fouling distribution for channel geometries: 10-knots random, 15-knots random, 20-knots random, sinusoidal model, and reference model.

These insights contribute significantly to the ongoing discourse on optimizing feed spacer designs within reverse osmosis systems, highlighting the critical role of channel geometry in enhancing system efficiency and sustainability.

Conclusion

The study confirms that optimizing the geometry of the feed channel using random generation techniques and CFD simulations can pave the way to improve the performance of the RO system. These advances provide a promising pathway for designing next-generation RO systems that operate more efficiently and sustainably, offering a vital solution to global challenges in water treatment.

Keywords: Grape Pomace, Phenolic Compounds, Quercetin, Bioactive Compounds, Extraction.

Aim

In the context of functional food and bioactive compound production, the valorization of food industry by-products holds significant importance. Particularly, phenolic compounds such as polyphenols offer health-promoting effects due to their antioxidant activity, enabling the development of high value-added products. The aim of this study is to investigate the effects of sample preparation techniques, solvent concentration, and enzymatic pretreatments on extraction yield, total phenolic content (TPC), total flavonoid content (TFC), and antioxidant activity in phenolic extraction from grape pomace. In future stages of the project, the obtained extracts are intended to be evaluated for food packaging applications.

Material and Method

Extraction of bioactive compounds, primarily quercetin, was performed from red grape pomace, a by-product of wine production. Upon delivery to the laboratory, the pomace was stored at −20 °C until analysis. Prior to extraction, some samples were subjected to freeze-drying at −40 °C for 24 hours. The moisture content of pomace was calculated based on weight differences before and after drying. Fresh or dried pomace samples were ground and homogenized prior to extraction. Ethanol solutions at 50% and 80% (v/v) concentrations were used as solvents, maintaining a solid-to-solvent ratio of 1:10. Extractions were conducted at 65 °C for 1 hour in a shaking water bath.

For enzymatic pretreatments, the pH of homogenized pomace was adjusted to 5.0 using 1 M NaOH after the addition of distilled water. Then, 100 µL of Pectinex®, Celluclast®, or a 1:1 mixture of both enzymes was added per gram of pomace. The mixture was incubated at 50 °C for 2 hours with shaking. Enzymes were inactivated by heating the solution at 100 °C for 1 minute. Subsequently, solvent was added, and the conventional solvent extraction process was initiated. For control groups, all procedures were identical except for the absence of enzyme addition. After extraction, samples were centrifuged at 9000 rpm for 10 minutes, and the supernatants were stored at −4 °C until analysis.

Total phenolic content (TPC), total flavonoid content (TFC), and concentrations of specific phenolic compounds such as quercetin and resveratrol were determined. TPC was measured using the Folin–Ciocalteu method, with absorbance recorded at 765 nm and results expressed as mg gallic acid equivalent (GAE)/mL extract. TFC was determined via aluminum chloride colorimetric assay, absorbance measured at 510 nm, and results expressed as mg quercetin equivalent (QE)/mL extract. To characterize the phenolic profile, HPLC analysis was conducted using a Waters 2695 system with PDA detector. A Supelcosil LC-18 column (25 cm × 4.60 mm) was used, with the mobile phase composed of 0.1% (v/v) formic acid in water (Solvent A) and 0.1% (v/v) formic acid in acetonitrile (Solvent B). A linear gradient elution was applied with a flow rate of 1 mL/min. Chromatograms were recorded at 360 nm, and retention times and UV spectra were compared with those of authentic standards for compound identification.

Findings

Analytical results indicated that freeze-dried samples subjected to enzymatic pretreatment yielded the highest TPC (1.09 mg GAE/mL) and TFC (3.00 mg QE/mL) values. In comparison, fresh samples without pretreatment yielded a TPC of 0.58 mg GAE/mL, demonstrating the significant effect of freeze-drying on extraction efficiency. Antioxidant activity assays (DPPH and CUPRAC) also confirmed higher antioxidant potential in freeze-dried samples.

HPLC-based quantitative analysis confirmed the presence of several flavonoids, notably quercetin and kaempferol. Optimal extraction conditions for quercetin were found to be with dried pomace, without enzymatic pretreatment, and using 50% ethanol. In the following phases of the study, the application of the extract in bio-based packaging systems will be further explored and experimentally evaluated. This study aimed to extract phenolic compounds, particularly quercetin, from grape pomace—an industrial by-product of winemaking—and to enhance extraction yield using enzymatic pretreatments prior to conventional solvent extraction. The findings are consistent with previous reports in the literature. It is well-established that phenolic compounds are predominantly located in the grape seed. According to Deryaoğlu (1997), approximately 62.6% of total phenolics are found in the seed, 33% in the skin, and only 4.1% in the pulp. Therefore, the seed content of grape pomace may significantly influence the total phenolic yield obtained.

In a study by Gomez-Mejía et al. (2022), optimization of extraction parameters from grape seed pomace yielded 112 μg/g of quercetin, supporting the efficacy of similar strategies applied in this study. The use of enzymes such as Pectinex® and Celluclast® facilitates the breakdown of plant cell walls, releasing soluble phenolic compounds. This is further supported by Drevelegka and Goula (2020), who reported enhanced polyphenol extraction efficiency via enzymatic pretreatment of grape pomace. Phenolic compound content varies not only with processing parameters but also with grape cultivar, clone, geographical origin, and environmental factors. Jaworski and Lee (1987) reported considerable variability in phenolic contents among different grape varieties of Vitis labrusca and Vitis vinifera. Similarly, Roggero et al. (1986) observed notable differences in phenolic content among clones of the Syrah grape variety. In this study, enzymes were found to both enhance and reduce extraction yield depending on the sample type. The highest yield was obtained from dried pomace without enzymatic pretreatment; however, enzyme mixtures were found to be effective in fresh pomace samples. These results indicate that factors such as pomace processing (fresh vs. dried), enzymatic treatment, and solvent composition are key determinants of phenolic yield. HPLC analysis proved reliable for profiling specific phenolics in the extracts. Ultimately, the data demonstrate that grape pomace is a valuable source of bioactive compounds and that enzymatic pretreatments can significantly enhance their recovery. Further research with different grape varieties and production residues would offer more comprehensive insights.

Several studies have demonstrated the high potential of quercetin as an active compound in bio-based packaging materials due to its antioxidant, UV-blocking, and antimicrobial properties. When incorporated into biodegradable films, quercetin enhances mechanical strength, UV-barrier capacity, and oxidative stability of the film, which are all critical for food preservation (Roy & Rhim, 2021; Ezati & Rhim, 2021). For example, gelatin- or chitosan-based films doped with quercetin have been shown to significantly reduce microbial growth on perishable items like fish or fresh-cut fruits (Li et al., 2020; Tongdeesoontorn et al., 2021). Additionally, the radical scavenging ability of quercetin-loaded films contributes to the prevention of lipid oxidation in oil-containing products, thereby extending shelf life (Jakubowska et al., 2023).

In the context of this study, the quercetin-rich extract obtained from grape pomace holds considerable promise for further incorporation into biofilms. Based on literature precedents, it is anticipated that the integration of such extracts into biopolymers like gelatin, polyvinyl alcohol, or polylactic acid via electrospinning or solution casting could yield functional films with improved bioactivity. Future work will focus on optimizing the incorporation of this extract into polymer matrices and evaluating the resultant films for physicochemical, mechanical, and antimicrobial properties, aligning with sustainable packaging goals.

Conclusion

This study shows that wine industry by-products such as grape pomace can be effectively valorized for their phenolic content using enzyme-assisted extraction methods. Freeze-drying combined with appropriate enzymatic treatment yielded extracts with high antioxidant capacity and phenolic content, including elevated levels of bioactive compounds such as quercetin. These results suggest that this method may be extended and adapted for the development of functional food ingredients or active packaging materials.

Plant-Based Proteins in Instant Soups: Comparison of Sensory, Functional, and Bioactive Properties

Ceren Çakır[a], Esra Çapanoğlu Güven[a]

[a] İstanbul Technical University, Food Engineering Departmant, Master of Science Program, Türkiye
cakirce@itu.edu.tr

Keywords: Plant Protein, Instant Soup, Phenolic Content, Antioxidant Capacity, Rheology.

Aim

This study aims to develop instant soup formulations enriched with different plant proteins and to evaluate their sensory properties, bioacive properties (total phenolic content and atioxidant capacity), flowability and viscosity characteristics with explore the balance between nutritional value and consumer satisfaction. The objective is to identify plant protein sources that are both nutritionally valuable and acceptable in terms of taste and processing properties for instant soup applications. This research focuses on the potential of rice, chickpea, and pumpkin seed proteins as sustainable, plant-based ingredients in instant tomato and lentil soups. As demand for plant-based foods increases, especially among health-conscious and environmentally aware consumers, the use of novel protein sources in convenient foods such as instant soups is gaining attention (Gamal & MF Albaz, 2024).

Material and Method

Six different plant protein sources were incorporated into instant tomato and lentil soup formulations. Protein powders from different sources were supplied by industrial company. The protein powders used in this study were rice, chickpea, fava bean, pea, oat, and pumpkin seed proteins. Tomato and lentil soups were prepared in the laboratory using with industrial raw materials. Both tomato and lentil soups were prepared with 10% protein powder content (rice, pea, chickpea, fava bean, and pumpkin seed proteins). Samples without protein powder were designated as control(reference) samples. The soup mixtures containing 10% protein powder and control samples were portioned as 18 grams. They were prepared by adding 170 ml of water heated to 100°C and thoroughly mixing for 45 seconds.

Sensory analysis was conducted with 20 trained panelists aged between 22-45, evaluating attributes such as appearance, aroma, taste, mouthfeel, and aftertaste using a 6-point hedonic scale. Panelists scored the samples on a scale of 1 to 6 by comparing them to the control. Based on sensory scores, three proteins with the highest acceptability were selected for further analysis.

In vitro gastrointestinal digestion was simulated using the standardized protocol (Minekus et al., 2014), which includes oral, gastric and intestinal phases. The total phenolic content of initial and digestion samples was determined according to the method of Singleton & Rossi (1965), expressed in mg GAE/g. CUPRAC (Cupric Reducing Antioxidant Capacity) method was used to determine the antioxidant capacities of the samples according to the method proposed by Apak et al. (2009). And finally functional attributes which are flowability (ffc index) and viscosity were assessed. Flowability was expressed as the flow function coefficient (ffc), which is defined as the ratio of consolidation stress to unconfined yield strength. The viscosity of soup samples was measured using a Brookfield RV DV2T viscometer.

Findings

Tomato and lentil soups were compared with control samples in terms of appearance and color, aroma and taste, smell, aftertaste, and consistency parameters. Based on the taste test conducted with 20 panelists, samples containing pumpkin seed (P8), rice (P3), and chickpea (P4) proteins received the highest scores for taste, smell, and consistency (Figure 1). Fava bean protein (P5) altered the soups the most significantly, receiving the lowest score for taste and aroma. Oat protein also negatively affected taste and was excluded from further studies due to its low protein content and high processing costs.

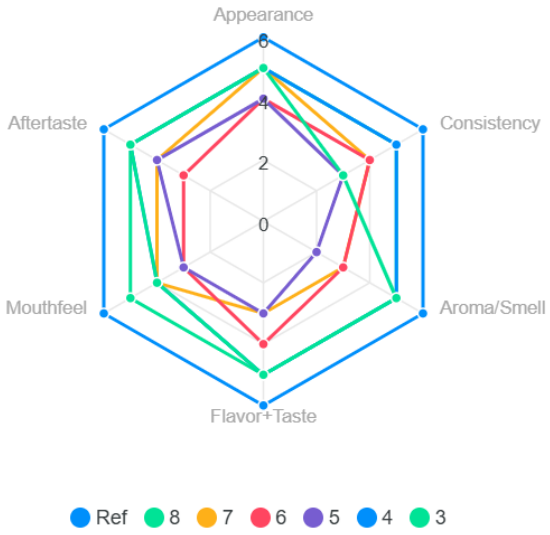

Figure 1. Sensory analysis scores.

For total phenolic content of tomato soup, the control sample showed an increase from 18.93±1.66 mg GAE/g (initial) to 25.59±3.95 mg GAE/g (gastric), but a sharp decrease to 8.18±2.61 mg GAE/g after the intestinal phase. Sample which is enriched by rice protein had the highest gastric TPC (34.25±3.24 mg GAE/g), but dropped to 7.72±1.90 mg GAE/g after intestinal digestion. Adding chickpea protein in tomato soup showed the lowest intestinal phenolic content (2.77±0.08 mg GAE/g). Tomato soup with pumpkin seed protein started with the highest initial TPC (20.50±0.85 mg GAE/g) and retained the highest TPC after intestinal digestion (23.82±3.37 mg GAE/g), suggesting strong phenolic-protein interactions that protect antioxidants during digestion. The control sample of lentil soup had the highest gastric TPC (52.43±1.44 mg GAE/g), but it dropped sharply to 6.95±1.74 mg GAE/g in the intestinal phase. When it is enriched by rice and chickpea protein maintained moderate TPC levels after intestinal digestion (17.05±0.85 and 15.40±2.15 mg GAE/g, respectively). Lentil soup with pumpkin seed protein preserved the highest TPC after intestinal digestion (22.60±5.32 mg GAE/g), outperforming other protein sources.

The antioxidant capacities of the soup samples were determined using the CUPRAC (Cupric Reducing Antioxidant Capacity) method, which measures antioxidant activity at nearly physiological pH and provides a reliable estimate of the total antioxidant potential in complex food matrices (Apak et al., 2008). The control sample of tomato soup showed an increase in antioxidant capacity from the initial (48.52±4.59) to the gastric phase (58.43±0.28), and a further increase in the intestinal phase (75.09±7.08). Among the protein-enriched samples, T+P8 (pumpkin seed protein) demonstrated a remarkable increase, reaching 160.55±8.30 after the intestinal phase. This value was notably higher than both the control and other protein-enriched samples, indicating a strong protective effect of pumpkin seed protein on antioxidant capacity during digestion. Addition rice protein and chickpea protein also maintained relatively high antioxidant capacities after the intestinal phase (63.87±6.97 and 51.82±0.50, respectively), but not as high as pumpkin seed protein. For lentil soup the control sample showed a steady increase from initial (11.14±0.88) to gastric (40.25±0.62) and intestinal phases (77.86±6.80). L+P8 (pumpkin seed protein) again stood out, with an intestinal phase value of 67.05±4.06, which was higher than other protein-enriched lentil samples. Samples which enriched by rice protein and chickpea protein had lower antioxidant capacities after the intestinal phase (38.94±5.51 and 23.37±4.13, respectively).

The viscosity and flowability results of the instant soup samples are presented in Table 2 and Table 3.

Table 1. Nutritional compositon of instant soups.

Composition	Tomato Soup	Lentil Soup
Energy	34 kcal / 143 kJ	34 kcal / 141 kJ
Fat (g)	0.6	0.5
Protein (g)	0.7	1.8
Carbohdrate (g)	6.8	4.7
Dietary fiber (g)	0.6	0.7
Salt (g)	0.5	0.5

Table 3. Ffc and Rhob values of soups with protein.

Samples	Ffc	Rhob
T	2,65±0,07	571,50±6,36
T + P3	2,35±0,07	561,50±0,73
T + P4	2,30±0,07	540,00±0,80
T + P8	2,50±0,01	477,50±0,71
L	2,03±0,11	672,00±8,48
L + P3	1,68±0,04	649,00±1,41
L + P4	1,66±0,01	633,50±0,71
L + P8	1,70±0,01	635,00±1,01

Ffc: Flow function coefficient
Rhob: Bulk density

Viscosity ranks among the most important functional properties of proteins. Therefore, understanding the flow characteristics of protein-enriched soups is vital for quality control, process design, and equipment selection. Furthermore, rheological properties of liquid foods are critically important and can directly affect sensory quality, thereby influencing consumer preference. However, these properties may be altered by various added components (Yılmaz et al., 2010). This

study evaluated how different plant proteins affected both flowability and viscosity of instant soups, providing valuable insights for industrial applications. Viscosity measurements were performed at different shear rates for both tomato and lentil soup formulations enriched with rice (P3), chickpea (P4), and pumpkin seed (P8) proteins. Tomato soup samples (T+P3, T+P4, T+P8) exhibited very low viscosity at the lowest shear rate (5 rpm), followed by a sharp increase at 10 rpm (up to 832.00 cP). The viscosity then gradually decreased at higher shear rates, indicating a shear-thinning behavior typical for semi-liquid foods. Lentil soup samples (L+P3, L+P4, L+P8) showed different flow patterns. For example, L+P8 reached the highest viscosity (900.00 cP) at 20 rpm, while L+P3 and L+P4 peaked at 50 rpm (703.20 cP and 712.00 cP, respectively). All lentil formulations showed a decrease in viscosity at the highest shear rate (100 rpm).

Maintaining component functionality stability from powder mixing to packaging is critical in industrial production of instant soups. These products consist of various ingredients (salt, flour, starch, oils) that differ in particle size, distribution, and density, resulting in diverse flow properties. Determining these properties is essential to prevent major issues such as agglomeration or poor flow during processing. Flowability, measured by the flow function coefficient (ffc), represents plastic deformation under specific stress and serves as an excellent metric for characterizing powder behavior-higher ffc values indicate better flowability. According to industry standards, powders are classified as non-flowing (ffc<1), very cohesive (1<ffc<2), cohesive (2<ffc<4), flowing (4<ffc<10), or free-flowing (ffc>10) (Schulze, 2008). Ffc values indicated that tomato-based soups had better flowability (Ffc: 2.65–2.50) compared to lentil-based soups (Ffc: 2.03–1.66). Among the protein-enriched samples, the addition of pumpkin seed protein (P8) resulted in the least reduction in flowability for both soup types. Bulk density (Rhob) was higher in lentil-based soups (672.00–633.50 g/L) than in tomato-based soups (571.50–477.50 g/L). Protein addition generally increased the density of tomato soups, while it slightly decreased the density in lentil soups. There was a clear negative relationship between viscosity and flowability, samples with higher viscosity tended to have lower flowability, making them harder to process and serve.

Conclusion

In summary, the results of this study demonstrate that the type of plant protein added to instant soup formulations has a significant impact on sensory properties, flowability, viscosity, total phenolic content, and antioxidant capacity. Among the tested proteins, pumpkin seed protein consistently provided the highest antioxidant retention and total phenolic content after digestion, as well as favorable flow and viscosity characteristics, making it a promising ingredient for functional instant soups. These findings highlight the importance of selecting appropriate protein sources not only for improving nutritional value but also for optimizing technological and sensory qualities in instant soup production. As protein content and functional properties such as water-holding capacity, emulsification, and gelation are critical for product quality and consumer acceptance, further studies will continue to investigate these functional attributes in detail (Zhang et al., 2021).

Keywords: Aquafaba, Legume, Food Waste, Emulsion, Foam.

Aim

Today, one of the leading global problems is malnutrition, and one of the ways to prevent this is to utilize nutrient-rich agricultural products without loss and to recycle by-products for sustainability. In terms of sustainability in the food sector, there is a need to develop innovative, nutritious, healthy and low-cost products and to utilize waste within circular economy system. Due to problems such as lactose intolerance and milk protein allergy worldwide, the increasing cost of animal production and its effects on the environment, a decrease in animal-based foods and an increase in plant-based foods and proteins are predicted. Legumes such as beans, chickpeas, broad beans, lentils and peas, which contain 20-30% protein, are being investigated as an alternative to animal-based foods. Legumes are among the most important food sources that benefit the sector and sustainable production and consumption due to their nutritional richness, formation of multiple by-products in the process stages, functional and technological properties, and diversity of use in foods. The evaluation of a by-product released from the production of canned legumes is important in terms of the economical use of natural resources, the reduction of waste and the creation of a circular economy system in which waste is evaluated. Soaking and boiling pulses in water before selling them as canned or frozen are processes that use a significant amount of water in the industry. Canning process includes soaking, boiling (85°C for 30 minutes), cooling, filling and adding filling liquid to the can and finally sterilization stages. The remaining process water after boiling is called as aquafaba, which is a significant nutritionally valuable waste and this waste liquid is obtained not only from chickpeas, but also from lentils, peas and different types of beans. Legume process water varies according to the legume type, legume:soaking and boiling water ratio, temperature, pH, time and pressure and has a content of carbohydrates, proteins, phytochemicals, vitamins and minerals. Legume process water has recently been investigated as a structuring additive in plant-based food production studies due to its functional properties such as foaming, emulsification, thickening and gelation. There are very few products that commercial process water is used for. The demand for plant-based products is constantly increasing. The fact that process water is both plant-based and contains surfactants shows that it has high potential. In this study, composition and functional properties of process waters obtained from different local legume species (İspir bean, red lentil, mung bean, grass pea, pigeon pea) were investigated.

Material and Method

Legumes were soaked in distilled water at 25°C for 12 hours with a 1:4 (w/w) legume:water ratio to ensure hydration. Then, the soaking water was separated from the legumes and water was added at a 1:1 (w/w) legumes:water ratio and heated at 85°C for 30 minutes. The resulting mixture was filtered through coarse filter paper to obtain process water samples. The obtained process waters were analyzed for dry matter, ash, protein and carbonhydrate content using standard analytical methods (e.g., Lowry method for soluble protein, gravimetric analysis for dry matter, ash and carbonhydrate). Functional properties such as foaming and emulsion capacity and stability were evaluated by measuring foam overrun and emulsion phase separation over time.

Findings

Process water samples from local legumes contained 2.93–5.69% total solids, 0.33–0.73% ash, 0.27-1.52% protein and 1.60–3.44% carbonhydrate. The lower total solids content compared to the literature is due to the process waters not being cooked for a short duration and under pressure. The composition of process water depended on legume type, cell wall composition and structure. Among the legumes analyzed, mungbean had the highest dry matter, protein, ash and carbonhydrate content and this is probably due to the small size of this legume. Because high surface area increases the extraction efficiency and enables more soluble solid compounds into the process water. Grass pea, ispir bean, pigeon pea and red lentil followed mungbean in terms of dry matter content. The foaming capacity and stability ranged between 54.17 to 145.83% and 31.37 to 63.27%, respectively. Among the process water samples, İspir, red lentil and pigeon pea showed good foaming capacity with overrun values greater than 100%. Red lentil process water was determined to have the highest foaming activity and stability. This is mainly due to high soluble protein content and polysaccharides. Less foaming activity of mung bean with the highest protein content compared to red lentil can be explained by low molecular weight proteins (albumin) and saponin content. Low molecular weight proteins are well-known foaming and surface-active attributes. Pigeon pea, ispir bean, grass pea and mung bean followed red lentil in terms of foaming capasity. The emulsion capacity and stability ranged between 71.88 to 76.39% and 73.61 to 75.35%, respectively. Similar results were observed in terms of emulsion activity and stability among the samples. İspir bean process water was determined to have the highest emulsion activity and stability. Red Lentil, mung bean, grass pea and pigeonpea followed ispir bean in terms of emulsion capasity and stability. The emulsifying properties of aquafaba are attributed to its protein, oligosaccharide, polysaccharide, phenolic, saponin contents, protein- polysaccharide complex and hydrophilic to hydrophobic groups of proteins with emulsifying properties.

Conclusion

In conclusion, it was determined that process waters from local legumes had a nutrient-rich composition with significant foaming and emulsifying activity and stability. While studies on chickpea aquafaba are prevalent in the literature, this study compares the functional properties of process waters obtained from different legumes, including İspir bean, red lentil, mung bean, grass pea, and pigeon pea. Additionally, the industrial potential of these local species is evaluated. The study highlights a substantial potential for the development of novel products, which could contribute to the advancements in the field. In addition, studies on local legumes for our country will pave the way for the production of this low-cost waste by-product as an additive in both liquid and powder form. Future studies could investigate the effects of different cooking temperatures and durations on the functional properties of process water. Additionally, a detailed molecular-level analysis of specific components that enhance foam and emulsion stability could be conducted.

Effects of Audible-Range Sound Treatment on the Microbiological Quality of Strawberry During Post-Harvest Storage

Deniz Çavdar[a], Gürbüz Güneş[a]

cavdard18@itu.edu.tr

Keywords: Frequency, Fruits and Vegetables, Microbiology, Postharvest, Sound Treatment.

Aim

Plants continuously interact with the external environment. They utilize various external factors for growth and development, striving to maintain optimal conditions for survival. However, exposure to factors that disrupt these optimal conditions, stress factors, can make survival more challenging. Stress factors are generally categorized into two types: biotic (e.g., plants, microorganisms, animals, and anthropogenic effects) and abiotic (e.g., temperature, water, sound, minerals, light, chemicals, radiation, etc.) (Levitt, 1980; Lichtenthaler, 1996). To survive, plants develop physiological and metabolic responses to these stress factors (Korkmaz & Durmaz, 2017). It has been suggested that when stress levels are mild, instead of causing harm, they may lead to beneficial changes in plants (Ozkurt & Altuntas, 2018). In response to stress, the secondary metabolites, which play a crucial role in plant defense mechanisms, accumulate, and are influenced by factors including temperature, humidity, light intensity, and mineral availability (Akula & Ravishankar, 2011).

Sound stress, an abiotic stress factor, is a form of mechanical stress that originates from sound waves generated by various sources (Ozkurt & Altuntas, 2018). Sound waves are classified into three main spectral ranges based on their frequency: infrasound (<20 Hz), audible sound (20 Hz-20 kHz), and ultrasound (>20 kHz) (Dikilitaş et al., 2016). The application of sound waves has been studied as non-thermal postharvest preservation method. Although most research in this field has focused on high-frequency "ultrasound" waves, research on audible sound waves has demonstrated their potential effects on plant growth and metabolism. For instance, the application of "green music" consisting of classical music and natural sounds (e.g. birds, water, and insects), for three hours during two growth stages (seedling and mature) of Chinese cabbage was found to increase polyamine levels and oxygen uptake compared to the control group (Qin et al., 2003). Furthermore, sound wave exposure has been suggested to enhance plant resilience to abiotic stresses (Jung et al., 2018). Plant Acoustic Frequency Technology (PAFT) has been reported to stimulate plant growth, improve photosynthesis efficiency, enhance yield and quality, strengthen the immune system, and extend the postharvest shelf life of agricultural products (Hendrawan, 2020).

Some postharvest studies on audible sound waves suggest their potential for preserving fruit and vegetable quality and shelf life. Audible sound treatments have been shown to delay tomato ripening and extend shelf life (Kim et al., 2015), while also preserving the color and texture of broccoli (Asuncion et al., 2020) and white oyster mushrooms (Paclibare Ceejay et al., 2019). However, research on the postharvest effects of audible sound waves on fresh produce remains scarce. Most studies in the literature focus on preharvest applications or ornamental plants. Despite this, the potential impact of audible sound on postharvest preservation should not be overlooked, and further studies are needed to better understand its effects on fruits and vegetables.

The aim of this study is to investigate the use of audible-range sound waves during the postharvest storage of fruits to retard microbial growth and extend their shelf life. In the literature, the use of audible sound waves during the pre-harvest period has been reported; however, there is limited information on their post-harvest applications. This study will contribute to the use of audible sound waves as a food preservation method after harvest.

Material and Method

The effects of sound waves on microbial growth in strawberries were investigated. Fresh strawberries were purchased from a local market and rinsed with water before the sound treatment. The strawberries were stored at 4°C in a cooling unit for 12 days, where sound treatment was conducted at frequency of 250 Hz for 12 hours per day. Analyses were performed on predetermined storage days (0, 3, 5, 7, 10 and 12). Microbiological analyses included total mesophilic aerobic bacteria and mold/yeast counts. Casein-pepton Soymeal-peptone (CASO) Agar was used for total viable bacterial analysis, while Czapek-Dox Sabouraud Dextrose Agar (C-SDA) was utilized for mold and yeast analyses. 10 g of strawberry samples were blended and homogenized with 90 mL of Physiological Saline Solution (PSS), and further dilutions were prepared. While total viable bacterial plates were incubated at 37°C for 48 h, mold/yeast plates were incubated at 30°C for 72 h. Each analysis was conducted in triplicate using three parallel samples. All experimental data were statistically analyzed using Minitab 21.

Findings

The total aerobic mesophilic bacteria count results are presented in Figure 1. Initially, bacterial counts were similar across all groups (~2.69 log CFU/g). However, distinct trends emerged during storage. In the control group, bacterial counts increased to 3.75 log CFU/g by day 12. The 250 Hz treated samples exhibited fluctuations, decreasing to 2.3 log CFU/g on day 10 before slightly rising to 2.75 log CFU/g by day 12. Statistical analyses confirmed significantly lower bacterial counts in the 250 Hz group on days 10 and 12, compared to the control ($p<0.05$).

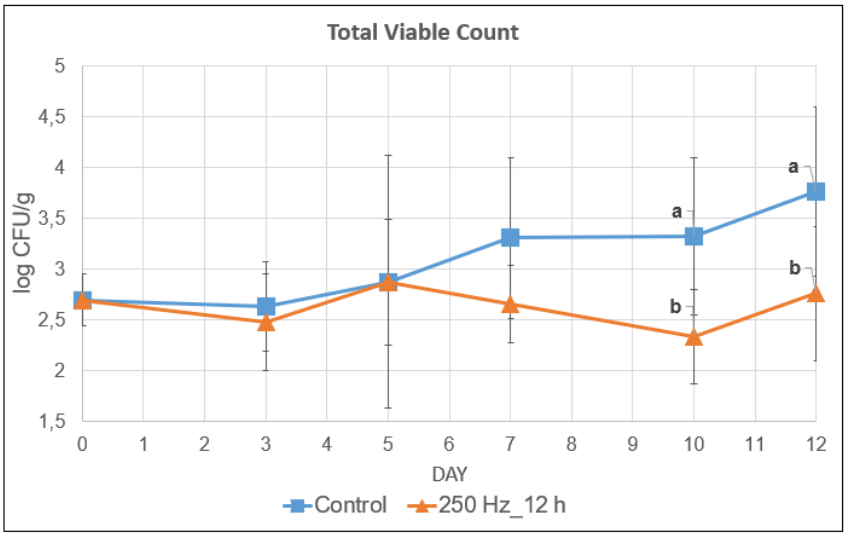

Figure 1. Changes in the total aerobic mesophilic bacterial count in strawberry samples (log CFU/g). Values marked with different letters on the same day are statistically different ($p<0.05$)

Mold and yeast growth results are shown in Figure 2. Unlike bacterial inhibition, the effect of sound treatment on mold and yeast was more limited. Initial counts (~3.18 log CFU/g) were similar across both control and treated samples, and gradually increased throughout storage. By day 12, mold and yeast loads reached 3.91 log CFU/g in the control group, 3.88 log CFU/g in the 250 Hz group. However, no statistically significant differences were observed between groups ($p>0.05$), suggesting that mold and yeast exhibit greater resistance to sound waves compared to bacteria.

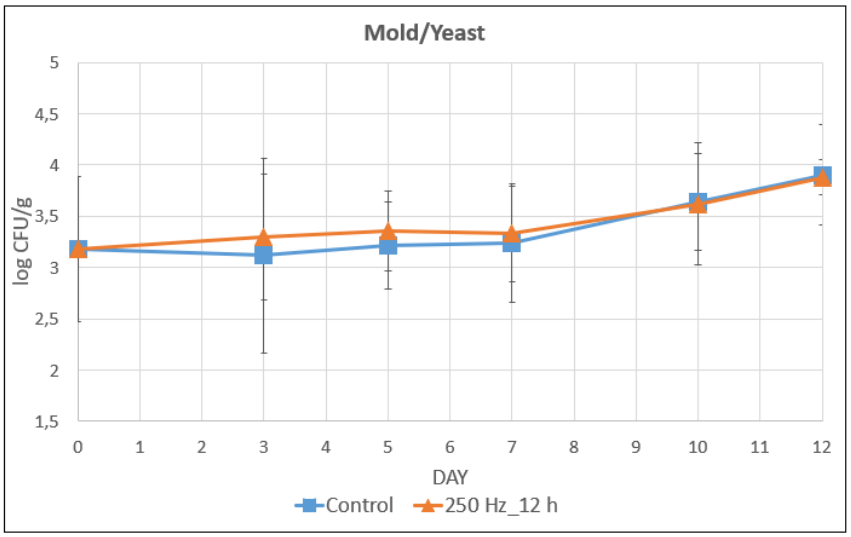

Figure 2. Changes in total mold/yeast count in strawberry samples (log CFU/g). No statistically significant differences were found between values on the same day ($p>0.05$).

Razavizadeh et al. (2024) investigated the effects of sound waves on certain molds that cause food spoilage, including *Aspergillus niger*, *Aspergillus flavus*, *Aspergillus parasiticus*, and *Botrytis cinerea*. Molds inoculated on Potato Dextrose Agar (PDA) medium were exposed to 250 Hz sound at 25°C for 24 hours, and the growth was recorded as colony diameter. The 250 Hz sound application showed an inhibitory activity on different *Aspergillus* species. While the effect was the least on *A. flavus*, the inhibition was the most against *A. niger* by 20.02% compared to the control group. In the case of *B. cinerea*, no significant growth difference was observed compared to the control group ($p > 0.05$). The underlying reason for the lack of the antifungal effect observed in our study can be explained by the fact that different mold species showed different resistance to sound treatment in the study conducted by Razavizadeh et al. (2024). Our study included the natural microbiota of strawberries, rather than specific mold inoculation. The dominant mold species of the natural microbiota may be resistant to sound treatment; however, the antifungal activity may be further investigated by spot or spray inoculation of selected yeasts and molds, and under varied frequencies.

Conclusion

The findings show that sound waves exhibit different effects on microbial growth. The results indicate that sound application within specific frequency ranges can have an inhibitory effect on total viable bacterial load. However, a similar effect was not observed in mold and yeast populations. It is suggested that molds are more resistant due to the durability provided by their spore structures, and the applied sound treatments were not sufficient to suppress these microorganisms effectively. These findings suggest that audible sound frequencies could be considered as an alternative method for food preservation. However, to enhance the effectiveness of sound waves and to better understand their impact on shelf life, it is necessary to optimize different frequencies and treatment durations. In the future, integrating this method with other preservation techniques for industrial applications could be a promising research area for extending shelf life of fruit and vegetables by retarding microbial growth and preserving their freshness.

Development and Characterization of Biodegradable Films Enriched with Protein Extracted from Agro-Industrial Pea Waste and By-Products

Nihal Sultan Bayar[a], Neşe Şahin Yeşilçubuk[a], Hande Yenipazar[a], Ayşe Saygün[a]

[a]Istanbul Technical University, Faculty of Chemical and Metallurgical Engineering, Food Engineering, Türkiye
sultan@itu.edu.tr

Keywords: Alkali Extraction, Biodegradable Film, Pea Pod Protein, Ultrasound Pre-Treatment, Valorization.

Aim

Agricultural and agro-industrial production generate substantial volumes of waste and by-products each year. A recent review indicates that the fruit and vegetable industry contributes to around 14.5% of total waste (Pérez-Marroquín et al., 2023). Notably, certain vegetable components like hulls, seeds, stems, leaves, and bagasse are often discarded due to their undesirable taste or texture (Lau et al., 2021). Peas are among the most widely consumed seasonal legumes, available in fresh, frozen, or shelled forms in supermarkets. The pea industry generates approximately 30%–40% of waste from pea pods during processing (Çam et al., 2022). Recently, food scientists have shown increasing interest in utilization of pea pod by-products as functional food ingredients, as they are rich in dietary fiber, carbohydrates, crude proteins, minerals, and bioactive compounds (Nasir et al., 2023). Especially, pea pods have 13% crude protein content (Karabulut et al., 2023). Efficient utilization and valorization of these by-products are essential for environmental sustainability and economic viability.

The objective of this study is to valorize pea by-products for the extraction of pea pod protein and to evaluate its potential in the formation of biodegradable films. In this context, the study aims to characterize the biodegradable films formulated with pea pod protein and to assess its suitability as a film-forming material. By conducting a comprehensive analysis, this research seeks to demonstrate the feasibility of utilizing pea pod protein in biodegradable film production, thereby contributing to the valorization of agricultural by-products and the development of sustainable packaging alternatives.

The study comprised of four steps: preparation of pea pods for protein extraction, extraction of protein, development of biodegradable films incorporating pea-pod protein, and characterization of the films.

Material and Method

Green peas supplied from a local market in Istanbul were separated from their seeds. The remaining parts especially pods were washed, dried and grounded into fine powder for performing alkali extraction. Pea pod protein was extracted from pea pod powder by ultrasound-pretreated alkali extraction method, which is known to enhance protein recovery efficiency (Kumar et al., 2021). Following the extraction process, the obtained protein was subjected to freeze drying procedure to form a uniform powder, ensuring consistency for the subsequent preparation of biodegradable films and further analyses. In order to determine the extraction efficiency, the protein content of both pea pod powder and extracted protein was quantitatively analyzed. Total nitrogen content was analyzed by the Kjeldahl procedure (AOAC Method No. 920.87, 1995). The conversion factor of 6.25 was used to transform nitrogen into protein (Mateos et al., 2010) In order to investigate the film-forming capability of pea pod protein in combination with different materials, various film forming materials were investigated. Agar, fish gelatin and chitosan were determined as main film forming materials which are widely recognized for their structural and functional properties in film development. Following this preliminary assessment, film forming solutions were prepared and development of biodegradable films were carried out using these materials.

Five different film samples that successfully formed films were selected for further analysis. Three of these films contained pea protein, while the other two were selected as controls. These formulations included A (agar-based film), AP (agar-pea pod protein-based film), AGP (agar-gelatin-pea pod protein-based film), C (chitosan-based film), and CP (chitosan-pea pod protein-based film), each representing different combinations of film-forming materials. The agar containing film samples were prepared according to the method specified by Ozhan (2022), while chitosan based film were prepared by Nan et al.

(2022) with some modifications. The production of edible films was conducted utilizing the solvent casting method. Biodegradable films were obtained after drying at 55°C for 24 hours.
For the characterization of the film samples, thickness, transmittance, opacity, moisture content, swelling behavior, color attributes, and antimicrobial activity assays were conducted. A range of instruments was utilized to conduct experimental measurements, including an electronic digital micrometer for film thickness determination, a Nano spectrophotometer for transmittance and opacity measurements, a Chroma meter for color analysis. The antimicrobial activities of all films were investigated for their inhibitory effects towards Gram-positive *S. aureus*, Gram-negative *E. coli* and fungus *A. niger* using the agar disc diffusion method. Statistical analysis was conducted with the use of Minitab Statistical Software.

Findings

Protein extraction was conducted with ultrasound-assisted alkali extraction method. Based on the findings obtained from protein content analysis, the efficiency of the protein extraction process was determined to be 13.20%, indicating the proportion of protein successfully recovered from the original raw material. Karabulut et al. (2023) studied different protein extraction methods from pea pods to maximize protein yield and evaluate the effects of ultrasound and enzyme pretreatments on extraction. Their findings showed that ultrasound-pretreated alkaline extraction achieved the highest protein recovery, 21.1%, which is comparable to the extraction efficiency observed in the current study.
After obtaining the protein, biodegradable film samples were prepared using the selected film formulations. Visual appearances of biodegradable film samples are shown in Figure 1.

Figure 1. Visual appearance of the film samples.

a: A (agar-based film), b: AP (agar-pea pod protein-based film), c: AGP (agar-gelatin-pea pod protein-based film), d: C (chitosan-based film), e: CP (chitosan-pea pod protein-based film)

The developed films were systematically characterized through a series of tests to assess their physical and functional properties. Thickness, transmittance, opacity, moisture content and swelling values of the film samples are shown as in Table 1.

Table 1. Thickness (mm), transmittance (%), opacity (%), moisture content (%) and swelling (%) values of the film samples.

Sample	Thickness (mm)	Transmittance (%)	Opacity (%)	Moisture content (%)	Swelling in water (%)
A	0.041±0.0020^{c}	0.84±0.014^{ab}	4.46±0.535^{a}	20.65±0.275^{b}	761.01±11.812^{b}
AP	0.031±0.0052^{c}	0.88±0.020^{a}	4.25±1.008^{a}	11.77±2.546^{c}	201.26±20.449^{d}
AGP	0.039±0.0039^{c}	0.85±0.026^{ab}	4.08±0.904^{a}	9.30±1.371^{c}	2223.68±37.500^{a}
C	0.132±0.0165^{a}	0.78±0.040^{b}	1.87±0.39^{b}	28.57±3.046^{a}	287.97±14.998^{c}
CP	0.213±0.0165^{b}	0.62±0.105^{c}	2.27±0.776^{b}	28.30±4.036^{a}	169.20±16.478^{d}

A: Agar based film, AP: Agar-protein based film, AGP: Agar-gelatin-protein based film, C: Chitosan based film, CP: Chitosan-protein based film. Results are given as average ± standard deviation. Means within a column followed by different lowercase superscripts (a–d) are significantly different (p<0.05).

Based on the thickness findings, no significant differences were observed among the agar-containing films. (p<0.05) However, the thickness of chitosan-containing films showed a significant difference when compared to agar-containing films (p<0.05). Films containing chitosan were found to be thicker compared to those containing agar. Additionally, CP was measured as the thickest, with a thickness of 0.21±0.02 mm.

The opacity values of the chitosan containing films are significantly different from agar containing films. (p<0.05). Moreover, the transmittance of the agar containing films are not significantly different from each other, while CP which has the lowest transmittance value (0.62±0.11%), is significantly different from the other films. (p<0.05). CP had also the lowest opacity value (2.27±0.78 UA/mm) among protein containing films.

While chitosan films have the highest and similar moisture content, films containing both agar and pea protein have the lowest and similar moisture content (p<0.05). Agar film is significantly different from the other films (p<0.05).

Swelling measurements of the film samples revealed that the addition of pea pod protein reduced the swelling values. While CP exhibited similar moisture content to the control, its swelling value (169.20 ± 16.478) was nearly half that of the control (287.97 ± 14.998). Similarly, the swelling value of AP (201.26 ± 20.449) was lower than that of A (761.01 ± 11.812). In contrast, AGP (2223.68 ± 37.500) showed a significantly higher swelling value compared to AP, indicating the effect of gelatin's hydrophilicity (Ramos, 2016).

According to the color results of the biodegradable films shown in Table 2, in terms of L* values which represents light coefficient, AP is significantly different from all other films and the other films show similarities with each other (p<0.05). b* value of CP is significantly different from AP and AGP through protein containing films. (p<0.05) CP had the highest b* value (4.02±1.247) that indicates dark yellow color is significantly different from the other protein containing films (p<0.05).

Table 2. Color values of the film samples.

Sample	Color parameters		
	L*	a*	b*
A	45.53±1.046[a]	4.27±0.059[a]	-3.18±0.108[c]
AP	38.16±0.567[b]	2.33±0.136[d]	-0.74±0.426[b]
AGP	45.76±2.529[a]	3.45±0.379[b]	-1.01±0.274[b]
C	45.31±1.373[a]	3.60±0.068[b]	-0.32±0.454[b]
CP	43.97±0.554[a]	2.98±0.299[c]	4.02±1.247[a]

A: Agar-based film, AP: Agar-protein-based film, AGP: Agar-gelatin-protein-based film, C: Chitosan-based film, CP: Chitosan-protein-based film. Results are given as average ± standard deviation. Means within a column followed by different lowercase superscripts (a–d) are significantly different (p<0.05).

For antimicrobial activity, the largest inhibition zones (0.39±0.005 mm against *E.coli*, 0.46±0.005 mm against *S.aureus* and 0.72±0.008 mm agains *A. Niger*) were observed in CP among the protein-containing films, likely due to the antibacterial and antifungal properties of chitosan (Manigandan et al., 2018). The results also indicate that pea pod protein reduced the antimicrobial effect of chitosan, though CP films still exhibited promising activity compared to other protein films.

Conclusion

The results demonstrated that pea pod protein-enriched films positively impacted film properties, underscoring their potential as nutritious food packaging alternatives. Furthermore, the findings highlight the role of pea pod protein in reducing agricultural waste while enhancing the sustainability and functionality of edible films in the food industry. No significant adverse effects of pea pod protein were observed, suggesting its suitability for biodegradable film formation. This study recommends further research on the application of these films to selected food products to evaluate their practical use in food packaging.

A Comparative Study For Analyzing LLM Performance in Bluff-Based Card Games

İrem Şalk[a], Sanem Sarıel[b]

[a]Istanbul Technical University, Game and Interaction Technologies Program, Türkiye
[b]Istanbul Technical University, Artificial Intelligence and Data Engineering Program, Türkiye

Keywords : Artificial Intelligence, Card Game, Game-Playing Agent, Imperfect Information, Probabilistic Problem.

Aim

The aim of this study is to investigate and compare the decision-making performance of multiple agent strategies in a modified bluff-based card game under imperfect information. The study focuses on whether a large language model (LLM) that is prompted through in-context learning (ICL), can generate effective action recommendations when compared to other agents that use traditional rule-based strategies and reinforcement learning in a game where deception plays a critical role. The central hypothesis is that reasoning-driven agents using LLM, can adaptively recommend successful bluff or challenge actions by interpreting structured sets of information despite having no training on game-specific reward signals. Our research question is "Can LLM-driven strategy suggest optimal actions by making predictions and inferences about opponents in a bluff based card game?".

Material and Method

Several studies on AI decision-making have examined the use of Large Language Models (LLMs), reinforcement learning, and Monte Carlo methods in strategic games (Cowling et al., 2015; Duan et al., 2025; Huang et al., 2024; Wu et al., 2024). Zeek and Ben (2025) developed an LLM-based assistant for the game Diplomacy, which has a deceptive game environment, combining language reasoning with computational tools for strategic guidance. An instruction-driven poker engine that provides players a new gameplay experience by generating the whole process of the defined games was created by Wu et al. (2024). A study conducted by Luo and Tan (2023) improved the decision-making process of the game DouDiZhu which is a gambling game popular in China, by combining reinforcement learning with a reward-shaping algorithm. Also, Guo et. al. (2024) conducted a study where they introduced GPT-4 with Theory of Mind (ToM) abilities to predict beliefs, intentions, and strategies of opponents, since these quantities are important for bluffing scenarios in real-life gameplay. They focused on single-move decision-making, where the model predicts opponents' behavior by evaluating their behavior and detecting possible deception using GPT-4 with modular prompts and human-like planning.

This study will contribute to growing research on the application of LLMs in real-time decision-making domains by analyzing the performance of the agents in terms of success rate of actions and win. To do that, the evaluation focuses on the model's ability to reason over game states, player histories, and probabilistic cues to select actions in a bluff-based setting.

The game environment is a modified version of the traditional Bluff (also known as Cheat or BS) card game. The modified version of Bluff game uses a special 24-cards deck which consists of 6 suits and 4 and played by three players (agents). At the start of the game, cards are evenly distributed among all players, the first player is chosen randomly and turns continue with clockwise direction in each game. Players keep their cards hidden from others during the game. A fixed table rank is used throughout the game. During the gameplay, players can perform two actions: challenge and move. When players make a move, they pile face down in the middle and claim to play a certain amount of cards with the table rank and rank value. This feature allows players to bluff their opponents. A bluff move includes at least one card not matching the declared rank while a truthful move in which all cards match the declared rank. To simplify the action selection we limit the challenge phase to one player, as only the next-moving player may perform challenge action. Therefore, a player may challenge the previous move if they believe it does not match the required rank. If the last played move was bluff then the previous player

takes all cards in the pile, otherwise the player who performs the challenge takes all cards in the pile. The first player who discards all the cards in their hand is the winner of the game. The game proceeds in turns until one player wins.
To create a game simulation framework, we first model the gameplay and rules mathematically by using set notation based on our game design. Then, we derive frequency of action selections along with their corresponding outcomes, define dynamic reward-penalty for each action and game conclusion. Next, we model the game which is played by five different agents. Each agent selects actions based on its internal strategy logic, and rewards are distributed based on the success of bluffs and challenges. In this methodology, five distinct agents are implemented:

1. Random Agent: Selects actions uniformly at random without considering game context. Serves as a performance baseline.
2. State Dependent Agent: Uses handcrafted rules based on the current state, such as pile size, card distribution. We modelled the agent with minimal logic and contextual awareness as calculating the probability of occurrence of the matching cards in the opponent's hand.
3. Bayesian Agent: Employs hierarchical priors from historical game data and current game state to evaluate best action for bluffing and challenging. Adapts action preferences based on prior success rates.
4. DQN Agent: A deep reinforcement learning model trained to maximize long-term reward. It maps observed states to derive optimal actions using Q-learning, updating its policy across turns in episodes. To support reinforcement learning, we defined both episode-level rewards (e.g., winning or losing the game) and turn-based rewards for each action type (move and challenge) to guide the learning process of the agent effectively.
5. ICL Agent: A GPT-based language model (GPT-4o) receives a structured prompt describing the rules and instructions, current state, past behaviours, and probabilistic game summaries such as winning rate. In addition, we represented a simple chain of thoughts by instructions and strategy guidelines to analyze opponents behaviors, predict possible outcomes of possible action scenarios and evaluate risk-reward to select an action. It reasons step-by-step internally but outputs only the final action as JSON.

At this stage, we compared the win rate by simulating different player combinations. The most successful player in the baseline strategies was Bayesian Agent. In 900 games,The Bayesian Agent achieved a 42% win rate, followed by the State Dependent Agent with 38%, and the Random Agent with 19%. When we compared the performance of the two most successful players in the baseline strategies with the DQN Agent over 900 games, we observed that ability to adapt through reinforcement learning of the DQN agent proved highly effective with a 74% win rate when we compared the other agents' win rate which are 16% for Bayesian and 10% for State-dependent. As a result of these simulations, learning-based and inference-driven agents show stronger performance trends than rule-based or random strategies.

Findings

Simulation results will be used to analyse different strategy types. The analysis will focus on success in bluffing and challenging decisions, and consistency across repeated trials. Metrics such as win rate and cumulative performance will be used to compare static strategies (Random, State-dependent, Bayesian), learning-based agent (DQN) and reasoning-based agent (LLM). The findings will aim to show how adaptive decision-making contributes to success in environments that involve uncertainty, deception, and player modeling. Findings will provide a comparative analysis of action success rates, adaptability, and overall win rates across all agent types and allow evaluation of performance of LLM-driven strategy.

Conclusion

In conclusion, by comparing the action decisions made by the LLM with those generated by other strategies, the study aims to determine the effectiveness of LLM-driven actions and will assess the relative effectiveness of LLM-driven recommendations. By designing this framework, the study contributes to understanding of how LLMs perform in strategic decision-making in games where uncertainty and deceptiveness are the primary objective.

Preliminary Study on the Feasibility of Neural Network-Based Generative AI Models in Video Game Music Production

Ülkü Nur Nar [a], Ozan Sarıer[b]

[a] Istanbul Technical University, Department of Game and Interaction Technologies, Game and Interaction Technologies Program, Turkey
[b] Istanbul Technical University, Department of Turkish Music State Conservatory, Music Technologies Program, Turkey
naru17@itu.edu.tr

Keywords: Generative AI, Video Game Music, Ludomusicology.

Aim

Music is not just a background element for games but also plays a central role in increasing the depth of the narrative, directing the emotional experience of the player, and strengthening the player's engagement (Collins, 2008). With an understanding of the role and importance of music in games, the importance given to game music has increased both in academia and in the game industry as a creative production area.

Kamp, Summers, and Sweeney (2016) stated that video game music studies have developed rapidly in the last half decade. However, they stated that this field addressed basic research questions. In the same study, they mentioned that the concept of "ludomusicology," which is formed by combining the terms "ludology" and "musicology" and refers to video game music research, was proposed by Guillaume Laroche and Roger Moseley in 2013.

The aim of this paper is to present a preliminary study that evaluates the feasibility and possibilities of integrating generative artificial intelligence models into game music workflows. In particular, it aims to make a meaningful contribution to both the ludomusicology sub-discipline and the game industry by providing a theoretical basis for understanding the potential of neural-network-based music production tools in game development.

Material and Method

This study was designed as a preliminary qualitative and theoretical research. Within the scope of this method, the literature and documentation of generative artificial intelligence models were examined, and an observational analysis was conducted on prompts created according to the selected game types and sample outputs obtained from these tools.

The focus of this study is to evaluate the extent to which neural network-based music production tools can meet the creative and technical requirements of game development processes in terms of efficiency, adaptability, and artistic expression and to investigate which functions of these models can be used practically in the game development process.

Traditional AI music production tools are generally parameter based. They request musical input from the user to guide and structure the music production process. Neural networks and deep learning models that emerge later have the potential to produce higher-quality music and resolve more complex relationships within music (Zhu et al., 2023; Herremans et al., 2017).

The nonlinear nature of games is the most important problem faced by game music composers (Collins, 2008). The fact that games are based on complex interactions indicates that such systems have the potential to offer more compatible solutions for game music production.

Based on this potential, only neural network-based generative AI music models were evaluated in this study. Sample music outputs were obtained from the Suno.AI model and Udio neural network-based systems, which provide music and sound production from text, are based on advanced artificial intelligence models and have the ability to produce realistic and expressive musical content (Nugroho & Manggala, 2024).

Three game types were determined within the scope of observational analysis: puzzle, action adventure, and horror. Based on Collins' (2008) statement that "different genres have different types of recording needs," each game type's unique

musical needs were taken into consideration and special prompts were created in line with the in-game atmosphere and musical function.

Puzzle games generally do not contain dialogue; music usually plays a background role that supports concentration, and minimal ambient music is preferred in this genre (Collins, 2008). The prompt for the puzzle game: "Minimal ambient background music for a puzzle level that supports focus and calm thinking."

In most action-adventure games, the music may be soft and calm in areas where there is no conflict, but when conflict begins it may become faster and more energetic, encouraging the player to adventure (Nieves, 2021). The prompt for the action-adventure game: "Fast-paced action music with percussive elements and dramatic tension."

In horror games, the psychological state of the player can be reflected in the music with dissonant tones to increase the tension and make the player tense (Munday, 2007). The prompt for the horror game: "Dark orchestral theme with dissonant harmonies and ambient textures to build suspense and tension."

Findings

Udio (Free) generated Silent Clarity and Quiet Reflections, both with durations of 32 seconds for the puzzle genre. Silent Clarity features a modal tonality, static harmonic progression, minimal melodic content with soft pads, and no discernible rhythm. It creates a calm and meditative atmosphere, and it is not loopable. Quiet Reflections is set in a minor key with subtle harmonic shifts, sparse melodic material, and very low rhythmic density. It conveys a melancholic and introspective tone, and it is not loopable.

It generated *Rising Storm* and *Rushing Shadows*, both with durations of 32 seconds for the action-adventure genre. *Rising Storm* features a minor, electronic tonality, a repetitive and stable harmonic progression, strong percussive patterns. Its lead synth motifs, creates an energetic and tense atmosphere, and it is not loopable. *Rushing Shadows* is also in a minor key, with limited harmonic complexity, prominent percussion, and rapid electronic beats. It layers synth textures, conveying an intense and suspenseful tone, and it is not loopable.

It generated Veil of Shadows 1 and Veil of Shadows 2, both with durations of 32 seconds for the horror genre. Veil of Shadows 1 features a minor tonality, mostly consonant harmonic progression with slight background dissonance and minimal ambient pulses and pads. It creates a dark and atmospheric tone, and it is not loopable. Veil of Shadows 2 also uses a minor key with slightly richer harmonic layering and subtle dissonant touches, very low rhythmic activity. Its ambient flow conveys a dark and slightly tense atmosphere, and it is not loopable.

Suno.AI (Free) generated Puzzle Whisper 1 and Puzzle Whisper 2, both with durations of approximately 2 minutes for the puzzle genre. Puzzle Whisper 1 features a modal tonality, static harmonic progression and soft ambient textures with piano. Its low rhythmic density creates a calm and reflective atmosphere, and it is not loopable. Puzzle Whisper 2 is set in a minor key with gradual harmonic shifts, sparse piano figures, gentle pulses, and light percussive movement. It conveys a calm yet slightly melancholic tone, and it is not loopable.

It generated Action Adventure 1 and Action Adventure 2, both with durations of approximately 2 minutes for the puzzle genre. Action Adventure 1 features a minor tonality, repetitive and stable harmonic progression, strong percussive foundation, metal guitar-like riffs. It creates an energetic and adventurous atmosphere, and it is not loopable. Action Adventure 2 also uses a minor key with a repetitive harmonic structure, percussive drive, electronic pulse, aggressive guitar, and synths. It conveys an intense and dramatic tone, and it is not loopable.

It generated Horror 1 and Horror 2, both with durations of 4 minutes for the horror genre. Horror 1 features a minor tonality with layered dissonant textures, sustained tension, minimal rhythmic activity and ambient noise. It creates a tense and suspenseful atmosphere, and it is not loopable. Horror 2 also uses a minor key with chromatic and slow-moving dissonance, and very low rhythmic activity. Atmospheric layers convey a dark and unsettling tone, and it is not loopable.

Suno.AI (Premium) generated Puzzle 1 and Puzzle 2 for the puzzle genre, with durations of 4 minutes and 1 minute 45 seconds. Puzzle 1 features a modal tonality with static harmonic progression and low rhythmic density. Subtle pulses, piano motifs, and layered ambient pads create a calm and reflective atmosphere. It is partially loopable. Puzzle 2 is set in a minor key with gradual harmonic evolution, soft percussive and piano arpeggios. Ambient textures, and light synth layers convey a calm yet slightly melancholic tone. It is also partially loopable.

It generated Action Adventure 1 and Action Adventure 2 for the action-adventure genre, with durations approximately 3 minutes. Action Adventure 1 features a minor tonality with repetitive, stable progressions, strong percussive drive, metal guitar riffs, orchestral bursts, and synthetic leads. It creates an energetic and dramatic atmosphere. It is partially loopable. Action Adventure 2 also uses a minor key with cyclical, stable progressions and occasional harmonic shifts, fast-paced percussion, layered guitar lines, synth textures, and dynamic orchestral hits. It conveys an intense and suspenseful tone. It is not loopable.

It generated Horror 1 and Horror 2 for the horror genre, both with durations of 4 minutes. Horror 1 features a minor tonality with chromatic dissonance, dissonant layers, slow-moving harmonic tension, minimal rhythm, eerie ambient swells, and dark textures. It creates a tense and unsettling atmosphere. It is not loopable. Horror 2 also employs a minor key with dissonant clusters, a highly unstable harmonic field, and very low rhythmic density. Its layered dissonances, and evolving textures convey a dark, anxiety-inducing tone. It is loopable due to smooth transitions.

Conclusion

In this study, the generated outputs were analyzed for their musical structure and adaptability to game environments in terms of genre suitability.

For the puzzle genre, most outputs, particularly from Udio (Free) and Suno.AI (Free), met the minimum ambient background music requirement to support calmness but were not conducive to concentration. Suno.AI Premium outputs, while partially loopable, introduced more harmonic complexity and movement. They offered richer textures that could have been distracting to players in a typical puzzle environment.

For the action-adventure genre, the outputs, especially in the Suno.AI Premium tracks, effectively captured the fast-paced, percussive, and energetic qualities expected during combat scenes. However, some free-to-play outputs fell short in terms of dramatic tension and orchestral or cinematic depth. In terms of loopability, the AI tools examined did not provide sufficient performance for the game music requirements.

In the horror genre, AI models consistently delivered dark, tense, and dissonant textures. Suno.AI outputs generally showed more layering and atmospheric complexity than Udio, closely matching player expectations for increased tension and excitement. While all models demonstrated a basic capacity to meet genre demands, Suno.AI Premium emerged as the most consistent model in delivering outputs that reflected both the emotional and structural demands outlined in the literature. It was moderately successful in terms of loopability.

Although the outputs are not yet ready for direct integration into game workflows without manual editing, they hold clear value for prototyping and experimentation. Continued research and development will be crucial to improving their use in real-time game music production.

Optimizing Level Production in Hidden Object Games Using YOLO Object Detection

Ekin Demircan[a], Sema Alaçam[b]

[a] Istanbul Technical University, Department of Game and Interaction Technologies
[b] Istanbul Technical University, Faculty of Architecture, Department of Architecture
demircanek@itu.edu.tr

Keywords: Hidden Object Games, Level Design Optimization, Level Generation, Object Detection.

Aim

Hidden object games (HOGs) are a widely recognized subgenre of casual games, characterized by their extensive level-based content. The primary challenge in developing these games lies in optimizing level design while maintaining quality and efficiency. The traditional level production process is a very time-consuming process when done manually. Marking the locations and names of the objects that are desired to be found in the game, which is necessary for tracking the success condition, is a repetitive and time-consuming action for the level designer. This study proposes a level production model, that optimizes the location marking and naming part of the level production process with an object recognition algorithm, YOLO. The main focus of this study is to optimize the level production pipeline, which will be achieved through the training of the YOLO object detection algorithm.

Material and Method

The proposed production model will be tested as a small-scale prototype to test its applicability to the hidden object game. The Level production process for HOG is grouped under four main topics, and the production model's steps are determined accordingly. (1) deciding a game concept and style, (2) placing objects in an environment to create a level composition, (3) marking object positions for possible success conditions, and (4) selecting target objects as objectives of a level to finalize the level.

The production model has been structured to create a sample level. To maintain visual harmony across all level compositions, a photocopy filter will be applied during the concept definition phase. (Figure 1.) Following this, the selected objects will be placed within different environments to construct the level layout, establishing the foundation for object placement. (Figure 2.) In the third step, the Yolo algorithm is utilized for object recognition. The Yolo algorithm contributes to the estimation of the bounding box enclosing an object and determines its location based on its coordinates. (Do,2021, p.11) The YOLO algorithm will be run to detect the positions and labels of objects that can be assigned as tasks within these created compositions. (Figure 3.) In the fourth step, the marked objects will be selected as the level objectives, and the finalized level will be prepared accordingly.

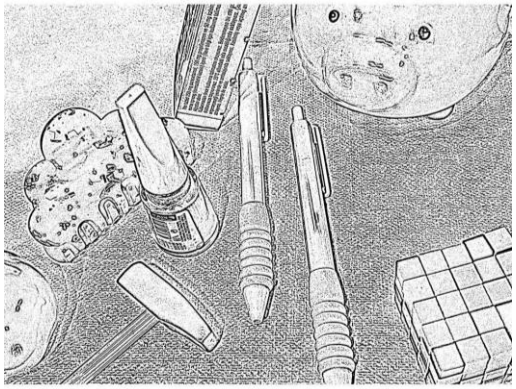

Figure 1.

Figure 2.

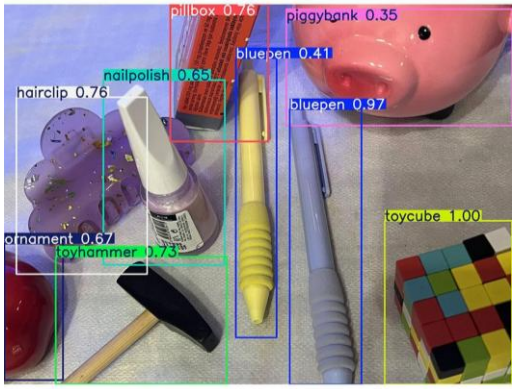

Figure 3.

In the scope of this study, a hidden object game titled June's Journey is utilized for the testing process. June's Journey, one of the most popular mobile games, surpassed 60 million downloads in 2022 (Long, 2022). Its level progression has been taken as a reference, as it serves as a significant example for understanding this widely preferred game structure, making it a suitable choice for this study. In June's Journey, which has been selected as a reference, the early game levels include a hidden object search task with 8 to 10 objects per level. The level progression is designed in a way that presents three words (objects) at a time as tasks to the player. Once an object is found, the next object to be discovered appears in its place. Based on this structure, 10 objects will be selected for a single level, and the model will be initially tested using these objects.
In the context of data collection, a total of 200 photos were taken of 10 selected objects from different angles. These objects were chosen with attention to their distinguishable forms to ensure they could be differentiated from one another. The selected objects are: a piggy bank, ballpoint pen, colorful toy cube, fork, medicine box, toy hammer, decorative pomegranate figurine, nail polish bottle, and decorative elephant figurine. The dataset was annotated and augmented with the use of Roboflow. The augmentation process involved rotating, scaling, and altering the lighting conditions of the objects to create a more robust dataset capable of handling real-world variations. The training process will be conducted using Google Colab, leveraging GPU acceleration to enhance model performance. The dataset was divided into training, validation, and test sets to train the algorithm. Various training epochs, batch sizes, and learning rates will be tested to determine the optimal balance between accuracy and computational efficiency.

Findings

Multiple test environments will be created to validate the model's applicability to the hidden object game. These scenarios will feature backgrounds with varying levels of simplicity and complexity. Model performance will be measured based on how accurately the YOLO-trained algorithm identifies objects within these diverse setups. If the model exhibits low accuracy, the dataset will be expanded, and the factors affecting accuracy will be further examined.

Conclusion

In conclusion, this study aims to present a scalable model that optimizes the level design process by testing a proof of concept. By integrating the object detection algorithm into the proposed model, the goal is to automate one of the stages of the process, eliminating manual workload and improving efficiency. To support scalability, future work should involve expanding and diversifying the dataset. Furthermore, designers should be included in the testing phase to gather feedback on usability and integration into hidden object games. The aim is for this generation model to recognize objects accurately under various lighting and rotation conditions, and across different scenarios, ultimately optimizing the level generation process. The model's scalability will be evaluated based on its detection accuracy. In future stages, designers will be included in the process to evaluate the model's efficiency in generating levels, aiming to reduce the time spent on manual creation. As the number of examples increases, the object recognition algorithm is expected to improve its accuracy. Accordingly, more object images will be added to the dataset based on test results.

A Systematic Approach to Ludonarrative Harmony: Methods for Aligning Interactive Gameplay and Storytelling

Cem Çelik[a], Ayşegül Akçay Kavakoğlu[b]

[a] Istanbul Technical University, Institute of Science and Technology, Department of Game and Interaction Technologies, Turkey
[b] Istanbul Technical University, Faculty of Architecture, Department of Landscape Architecture/Architectural Design Computing, Turkey
celikc15@itu.edu.tr

Keywords: Ludonarrative Harmony, Game Design, Player Agency, Narrative Coherence, Interactive Storytelling.

Aim

Ludonarrative harmony in game design enhances the cohesiveness and enjoyment of the gameplay experience. This work is motivated by a fascination with how interactive gameplay can enhance narrative impact and by a desire to contribute to the development of interactive art. It ensures that the narrative and gameplay elements of a game are effectively integrated. This enhances the game's emotional impact and engages players effectively. Ludonarrative dissonance occurs when gameplay mechanics and narrative elements in video games are incongruent, resulting in a diminished immersive experience and thematic coherence.

This work presents a multi-dimensional evaluation method whereby ludonarrative harmony is seen as a continuum rather than as a binary concept. The proposed paradigm defines three basic dimensions: mechanics-narrative synchronization, player agency and narrative coherence, and systematic storytelling integration, thereby evaluating the degree of coherence between gameplay and narrative. Game designers might use a choice matrix as a theoretical tool to carefully assess and improve ludonarrative alignment in their works.

By taking a methodical approach to comprehending and utilizing ludonarrative harmony, this work seeks to enhance scholarly debate and useful game design techniques. This study combines theoretical frameworks with real-world game development techniques to build a foundation for interactive experiences that are immersive, story-driven, and emotionally powerful.

Material and Method

To create a systematic framework for assessing ludonarrative harmony, this study employs a qualitative research technique. A methodical approach to looking at how gameplay and story interact is shown in this study, which uses a comparative case study analysis and well-known theoretical models.

The technique consists of four primary components:

Literature Review and Theoretical Synthesis

The study starts with a full review of the literature on basic game design theories. Works like The Art of Game Design (Schell, 2008), Ludonarrative Dissonance: Is Storytelling About Reaching Harmony? (Seraphine, 2016), and The Quest for Ludonarrative (Donoghue, 2021) are included. This review lays out the theoretical basis of ludonarrative harmony, showing how it differs from dissonance and pointing out important design issues.

Development of the Ludonarrative Harmony Framework

Drawing from existing research, the study constructs a multi-dimensional evaluation framework that positions ludonarrative harmony on a continuum rather than a binary scale. Three core dimensions are defined to analyze the level of integration between narrative and mechanics:

Mechanics-Narrative Synchronization (MNS): Evaluates whether core gameplay mechanics reinforce or contradict the game's narrative themes.

Player Agency and Narrative Coherence (PANC): Measures the extent to which player choices align with narrative constraints, preventing thematic inconsistencies.

Systemic Storytelling Integration (SSI): Evaluates the impact of environmental and systemic design components on storytelling, eschewing passive exposition.

These criteria are intended to offer a systematic yet adaptable framework for assessing ludonarrative design. This framework does not provide fixed ratings but presents a reproducible process for qualitative evaluation.

Dimension	Definition	Evaluation Criteria	Example
Mechanics-Narrative Synchronization (MNS)	Measures how well gameplay mechanics reinforce narrative themes.	- Do mechanics embody or contradict the game's themes? - Is player interaction aligned with intended emotional responses?	Celeste (gameplay mirrors protagonist's struggle)
Player Agency and Narrative Coherence (PANC)	Assesses the balance between player freedom and narrative integrity.	- Does increased agency disrupt or enhance narrative coherence?	Brothers: A Tale of Two Sons (control scheme reinforces emotional themes)
Systemic Storytelling Integration (SSI)	Evaluates how environmental and systemic design elements contribute to storytelling.	- Does the game world convey narrative meaning through interaction?	Hollow Knight (worldbuilding and lore integrated into exploration)

Table 1. Ludonarrative Harmony Framework.

Comparative Case Study Analysis

A case study analysis was performed to evaluate the applicability of the framework on games demonstrating differing levels of ludonarrative harmony. Titles like Celeste and Brothers: A Tale of Two Sons were scrutinized for their robust integration of gameplay and narrative, whereas Bioshock was evaluated for its thematic contradictions. Each scenario was evaluated utilizing the proposed paradigm, offering specific instances of how mechanics, player agency, and systemic storytelling affect ludonarrative cohesiveness.

Decision Matrix Development

Based on the case study findings, a decision matrix was proposed as a theoretical tool for categorizing games along the ludonarrative harmony spectrum.This matrix serves as a systematic evaluation tool, assisting developers in recognizing possible design discrepancies and enhancing narrative-gameplay cohesion.Despite the lack of quantification in this work, the matrix offers a systematic basis for iterative design methods and future investigations.
This methodology connects academic research with practical application, providing game makers a systematic technique to assess and enhance ludonarrative coherence in interactive games.

Findings

This study introduces a comprehensive evaluation framework that transcends subjective interpretations, providing a systematic approach for assessing ludonarrative harmony and dissonance. The research identifies three key factors influencing ludonarrative cohesiveness.

Mechanics-Narrative Synchronization (MNS): The extent to which game mechanics align with or oppose narrative themes. This evaluation involves analyzing the ways in which core gameplay interactions contribute to the intended narrative experience, referencing texts such as The Art of Game Design (Schell, 2008) and Ludonarrative Dissonance: Is Storytelling About Reaching Harmony? (Seraphine, 2016).

Player Agency and Narrative Coherence (PANC): refers to the equilibrium between player autonomy and the integrity of the narrative. This examines the influence of interactive choices on narrative development, citing research on emergent storytelling (Greenwood, 2022) and structured narrative constraints (Donoghue, 2021).

Systemic Storytelling Integration (SSI): refers to the extent to which environmental design and systemic mechanics enhance narrative meaning independently of non-interactive exposition. This is consistent with studies on diegetic storytelling and structured experience frameworks (Winn, 2008).

A comparative case study analysis was conducted to implement this paradigm, categorizing games along a harmony-dissonance continuum based on these principles. The findings suggest that games with strong alignment between mechanics and narrative themes tend to improve player immersion and emotional engagement, whereas those characterized by mechanical-narrative dissonance often experience a deficiency in thematic coherence.
A choice matrix was created as a theoretical framework to categorize games along the ludonarrative harmony continuum according to these dimensions. This framework is not an empirical scoring system; instead, it is a systematic approach for evaluating narrative-mechanical integration in game design, facilitating further study and iterative game creation. This analytical framework enables a systematic evaluation of ludonarrative integration, providing developers with an organized method to enhance the interaction between narrative and gameplay.

Conclusion

This study demonstrates that ludonarrative harmony is a concrete design principle, rather than an abstract or subjective notion, which can be methodically studied and applied. This research establishes a basis for evaluating and enhancing the interaction between gameplay and narrative by identifying essential dimensions: mechanics-narrative synchronization, structured player agency, and systemic storytelling integration.
The results show that games with good ludonarrative integration make players more immersed and keep the theme consistent. On the other hand, games with mechanical-narrative dissonance may not have the effect they wanted on the story. This paper introduces a choice matrix as a theoretical tool that gives game designers a way to measure ludonarrative harmony that goes beyond subjective assessments. A key contribution of this study is a qualitative, adaptable framework for evaluating ludonarrative harmony in both existing and in-development games. This framework provides practical guidance for designers to align gameplay with narrative, while also serving as a structured method of scholarly inquiry that respects the artistic nature of game design.

Impossible Spaces in Games: Using Anamorphic Projection in Space Interactions to Explore Possibilities of New Game Mechanics

İrem Aydındoğan[a], Sema Alaçam[a]

[a] Istanbul Technical University/Graduate School, Department of Game and Interaction Technologies, Game and Interaction Technologies Program, Türkiye
aydindogan@itu.edu.tr

Keywords: Anamorphosis, Non-Euclidean, Optical Illusion, Perspective.

Aim

This study aims to explore Impossible Spaces in games and the potential of anamorphic projection as a spatial game mechanic to create perceptual illusions and exciting level designs. The central research question is: How can anamorphic projection be used to redefine spatial interactions in game environments to challenge the conventional notions of reality and navigation?

Impossible spaces are environments that cannot be experienced within the physical rules of the real world. These spaces feature impossible geometries that are beyond human visualization and consist of spatial configurations that defy the rules of gravity, time, perception and Euclidean geometry. According to Thiering and Mittelberg (2022), game environments of impossible worlds play with players' knowledge and expectations of logic. Using digital tools, it is possible to visualize such spaces, and they are commonly used in movies, games and other digital media. Games can be considered the ideal place to explore such spaces because they offer a unique advantage of being interactive. While movies only allow for observation, games enable true engagement. There is a symbiotic relationship between games and impossible spaces: as digital game environments make them possible to be experienced, these spaces open up new possibilities for exciting game mechanics that enrich game design. Many designers experiment with the creation of surreal and mind-bending game worlds. Often inspired by the works of M.C. Escher, as noted by Orbons and Ruttkay (2008), artists research in the area to create paradoxical and mathematical scenes in virtual 3D environments.

It is evident that games have used a variety of techniques to challenge rules of physics to present new mechanics and experiences, using different impossible spaces as their environments. Broadly speaking, these games can be categorized into two groups. The first group includes games that take place in fundamentally Euclidean spaces but use non-Euclidean manipulations to create the illusion of impossibility. These game spaces include portals, gravity shifts, perspective manipulations, optical illusions, warping and spatial discontinuities that break players' spatial expectations. According to Osudin et al. (2024), these types of games are known as non-Euclidean by the players but those games only appear impossible because they use pieces of Euclidean manifolds combined in a novel way to create these illusions. The second group includes games that take place in truly non-Euclidean spaces, where the geometry of space is redefined and mathematically curved into hyperbolic and spherical worlds.

To better understand the different approaches to the concept of impossible spaces, it is helpful to examine existing games that use a variety of different techniques to represent those worlds. Table 1 provides a comparative overview by categorizing selected games based on whether they take place in Euclidean or non-Euclidean space, their core spatial and perceptual mechanics and the type of game world representation (2D or 3D) they employ. What these have in common is that they challenge the players' intuitive understanding of space through diverse approaches to perception- and space-based mechanics, such as visual illusions, dimensional transformations and time manipulations.

This paper focuses on anamorphic projection as a technique to experiment with possibilities of level design and game mechanic ideas.

Table 1. Comparative Overview of Games Using Impossible Spaces.

Game Title	Publishing Year	Dimension	Game Space Category	Core Mechanic/ Technique
Portal	2007	3D	Spatial Illusion	Portal-based teleportation
Echochrome	2008	2.5 D	Spatial Illusion	Optical illusion, perspective dependent paths
Braid	2008	2D	Time Manipulation	Time reversal, object-time independence
HyperRogue	2011	2D	Non-Euclidean Geometry	Hyperbolic tiling, infinite procedural world
Fez	2012	2.5 D	Dimensional Shift	Rotation between 2D planes in 3D space
Antichamber	2013	3D	Spatial Illusion	Illusions, space rearrangements
Monument Valley	2014	2.5 D	Spatial Illusion	Escher-like illusion, perspective based architectural puzzles
Life is Strange	2015	3D	Time Manipulation	Narrative time manipulation
Fragments of Euclid	2017	3D	Spatial Illusion	Escher-like environment, perspective portals
Superliminal	2019	3D	Spatial Illusion	Forced perspective object scaling
Manifold Garden	2019	3D	Spatial Illusion	Gravity shift, infinite space
Hyperbolica	2022	3D	Non-Euclidean Geometry	Hyperbolic geometry
Viewfinder	2023	3D	Spatial Illusion	Photographic teleportation

Anamorphosis is a term used to describe a distorted or skewed image that appears in its intended form only when observed from a specific angle, or through a reflective surface placed in a correct position and orientation. Araújo (2017) points out that a common way to create surface anamorphosis is by projecting objects onto a plane. Anamorphic projection is a technique that uses geometry and perspective to distort and project the subject onto a surface, creating the illusion of anamorphosis. According to Di Paola et al. (2014), first uses of anamorphosis can be found in art pieces like Pala di Brera by Piero della Francesca (1472) and Hans Holbein's painting The Ambassadors (1533). The Ambassadors painting includes a distorted skull that only becomes visible when viewed from a specific perspective. During the Renaissance, anamorphosis

was often used in murals and ceiling paintings to surprise viewers' perceptions, becoming a tool for exploring perspectives, illusions, and hidden meanings.

In contemporary art, artists use the technique with large-scale pavement drawings that appear three-dimensional when viewed from a precise angle. In architecture, anamorphic projections are used to create spatial illusions that reveal the artwork not only as a visual trick but also as a form of spatial storytelling. Digital installations take this one step further by employing digital tools and projections onto surfaces to boost the effect of the illusion. While anamorphic projection techniques are being used in games, there is still significant untapped potential for their implementation. Unlike static media, games allow anamorphic illusions to become dynamic and interactive.

Material and Method

This paper adopts a research-through design methodology to explore the potential of anamorphic projection in level design to experiment with novel game mechanics that allow players to experience and interact with the environment in non-traditional ways. The core concept of suggested mechanics is to treat the game levels as projected objects, fragments of space that can only be discovered and accessed when the player finds the correct viewpoint. In this environment, perception becomes access: the alignment of the player's perspective acts as a key to solve the puzzles and progress through the game. The project explores the notion that in digital games, perception can be more than a means of observing reality; it can become a mechanism for shaping it. The illusion becomes the structure, what is seen becomes real. Perception shapes reality, acting both as subject and as the primary design tool.

A framework is proposed for implementing anamorphic projection as a spatial mechanic. The method involves the use of portal planes and projection cameras. Two visually connected portal surfaces are placed in two different 3D environments. Portal 1 is located at the entrance of Level 1, and Portal 2 is at the entrance of Level 2. Since the portals are connected, Portal 2 displays a view of Level 1 and Portal 1 displays a view of Level 2. A projection camera is positioned in front of Portal 2, capturing the view of Level 1 through Portal 1. This view is then projected on the surface of Level 2. At the beginning of the game, the player can see the projection, but the object being projected remains hidden. The player's task is to explore the space and find the exact viewpoint that matches the position and orientation of the projection camera. When the correct location and rotation are found, the hidden portal becomes visible and active, allowing the player to pass through into the next level. Figure 1illustrates the logic of the system.

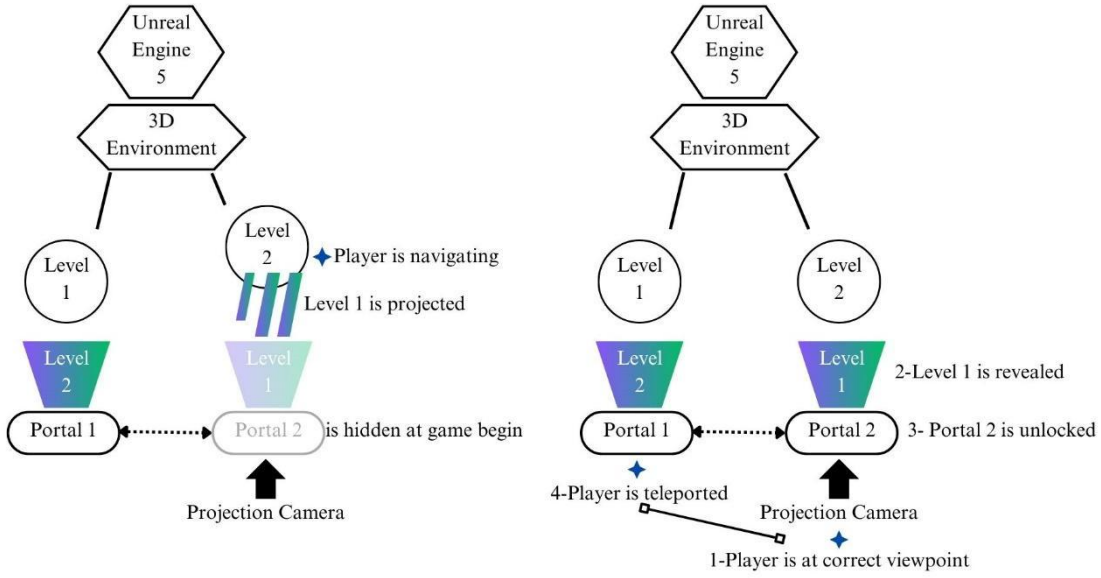

Figure 1. Portal/Projection Setup Diagram.

Using this system a game prototype is developed using Unreal Engine 5. In this prototype, three game levels were created, and the portal/projection systems were implemented within each level. The player's objective is to progress through levels by finding the correct viewpoint. Figure 2 shows the implementation in Unreal Engine 5.

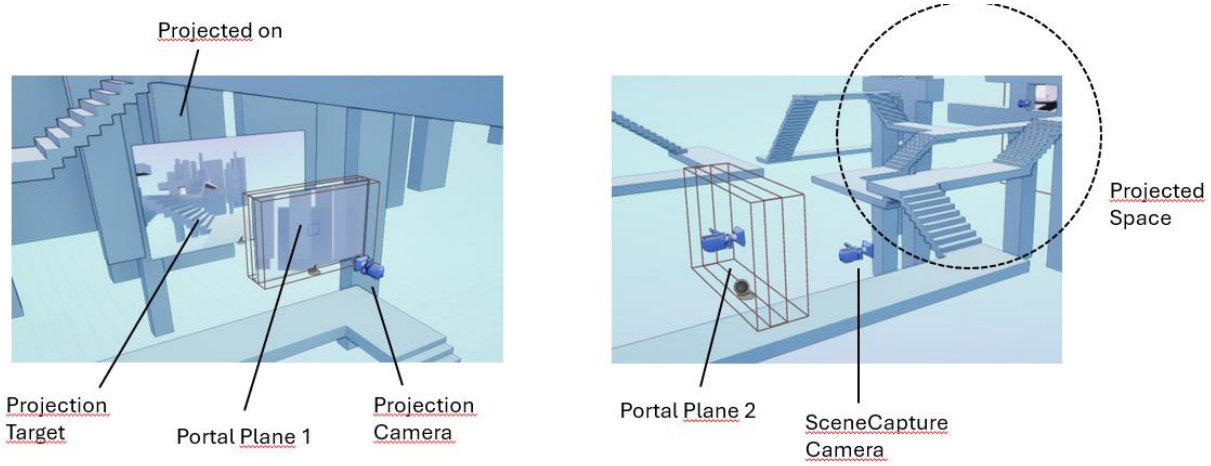

Figure 2. Prototype Implementation of Portal/Projection Logic in Unreal Engine 5.

To evaluate the usability and experiential impact of the mechanic, the study employed the Player Experience Inventory (PXI), developed by Vanden Abeele et al. (2020), to measure both functional and psychosocial consequences of gameplay. Since the aim was to assess both the effectiveness and emotional response, examining functional aspects (Ease of Control, Progress feedback, Audovisual appeal, Goals and Rules, Challenge) as well as psychosocial constructs (Mastery, Curiosity, Immersion, Autonomy, Meaning), the PXI was a valid choice for this study.

A total of 33 participants played the prototype and completed a survey that uses questions from the PXI tool, using a 7-point Likert scale. Six out of ten constructs were selected as they were most relevant to the mechanic: Ease of Control, Goals and Rules, Challenge, Mastery, Curiosity, and Immersion. Most of the participants were familiar with games, as shown in Figure 3., 57.6% play games every day and 30.3% percent play games several times a week.

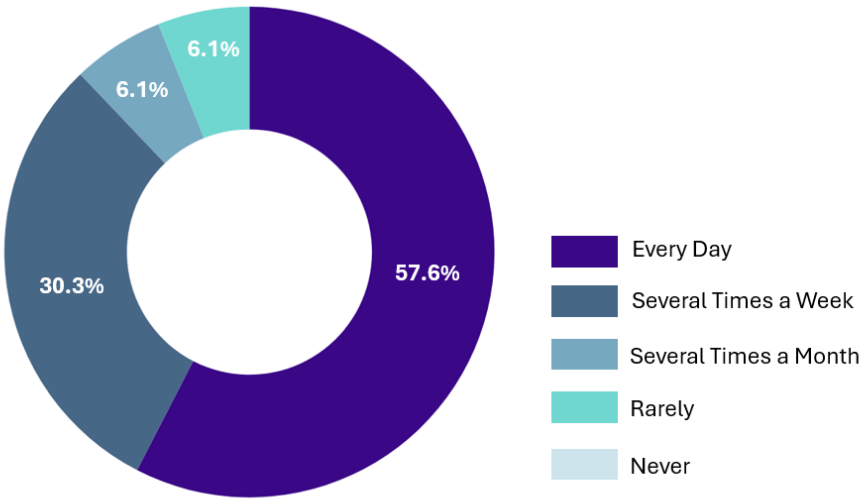

Figure 3. Distribution of Participants by Game Playing Frequency.

Findings

The average scores indicate a consistently positive reception of the mechanic. As shown in Figure 4, Mastery received the highest average score (5.97). This suggests that the players felt successful while interacting with the mechanic. Goals and Rules received the second highest score (5.57), suggesting that the players did not have a problem understanding the objective of the mechanic and the goal was clear. Ease of Control scored the third highest (5.47) which indicated that the controls were manageable. The Curiosity, Challenge and Immersion constructs received a slightly lower score (5.14, 5.09 and 5.06, respectively), which although being lower still indicates a good level of cognitive engagement. One possible reason for this is that the prototype consisted of only three levels designed primarily to introduce the mechanic, and the players did not have the opportunity to apply their understanding in more complex scenarios.

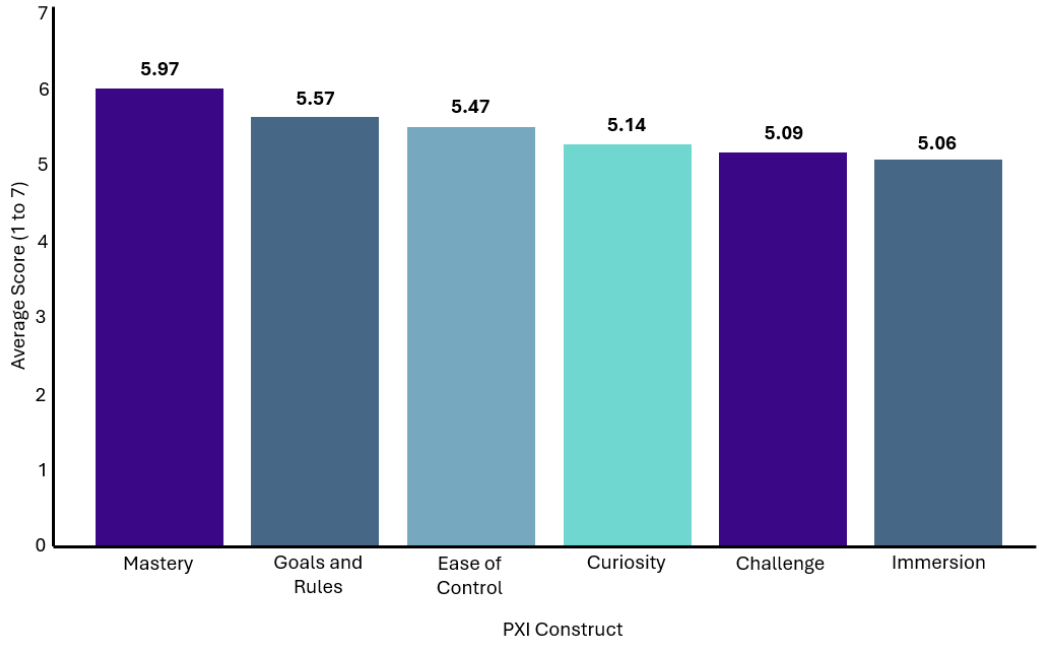

Figure 4. Average PXI Scores for Selected Constructs.

Conclusion

This study explored the use of anamorphic projection as a game mechanic by turning perspective into a key for unlocking new levels. Through the development of a design framework and a prototype to test the system, the findings from the PXI-based evaluation reveal that the players responded positively to the mechanic. The results suggest that the perception can be used as a design tool in games and the mechanic holds foundational potential for future iterations that focus on more emotionally engaging environments.

Understanding Player Behavior: The Role of Intrinsic and Extrinsic Motivations in Bartle Player Types

Muhammet Sinan Çavdar[a], Derya Güleç Özer[b], Hüseyin Kutay Tinç[c]

[b] Istanbul Technical University, Faculty of Architecture, Department of Informatics Architectural Design Computing, Türkiye
[c] MEF University, Faculty of Art, Design and Architecture, Department of Digital Game Design, Türkiye
cavdarm17@itu.edu.tr

Keywords: Core Gameplay Loop, Motivation, Player Typologies, Reward.

Aim

Player engagement is a fundamental aspect of game design, ensuring player continuity, satisfaction and loyalty. What pleases players and what connects them to the game has always been one of the biggest study and research topics in game design. While some players are interested in competition or achievement, others seek exploration, social connection or simply relaxation. To analyze and address the diverse expectations of players, they have been categorized into various typologies over the years.

Richard Bartle's player type model (1996), one of the most well-known typologies, divides players into four main categories, as shown on Chart 1, based on their expectations and desires from games: achievers, explorers, killers, and socializers. According to Bartle, the player typology framework is based on two dimensions: action versus interaction and player orientation versus world orientation.

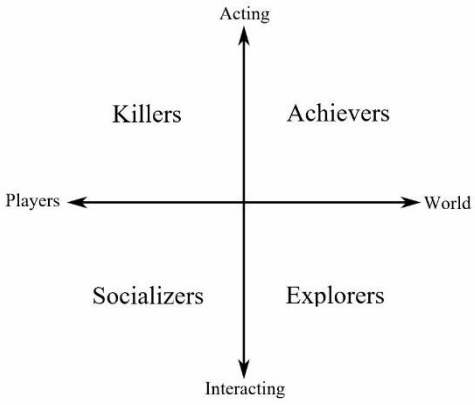

Chart 1. The Bartle taxonomy of player types (Bartle, 1996).

The most important component to meet players different expectations is core gameplay loop. According to Brazie (2023), the structure of a significant majority of core gameplay loops contains three important elements: challenge, actions, and reward. Creating a core gameplay loop that keeps the player engaged and satisfied is a huge challenge. According to Guardiola (2016), the primary goal in game design and game analysis is to define the basic gameplay of a game as a cycle (pp. 2-3). This involves identifying the set of actions that players repeat most often and linking them to certain winning or losing outcomes.

Meaningful play describes the experiences in which players perform actions for a specific purpose and have fun. For gameplay to be meaningful, every action taken by the player must be meaningful and no action must occur without a reason or consequence. As Tekinbas and Zimmerman (2003) explain, for an action to be meaningful, it must be both discernible and integrated. A discernible action allows the player to understand that their actions have consequences. Integrated action

ensures that the consequences are visible and truly effective, sometimes immediately and sometimes as the game experience progresses (p. 12).

In game loops, elements that give feedback to the player about their progress are needed so that they can understand that they are experiencing certain developments. These elements can be called progression mechanics. Butler et al. (2015) highlighted that what keeps players engaged and interesting is not the rules of the game or the interactions they have in the game, but how they combine them in progression in increasingly complex ways. There are many combinations to mix basic concepts, but creating progression while making the game experience engaging and interesting is an enormous challenge (p. 2407).

Player motivation examined under two main headings. These are intrinsic motivation and extrinsic motivation. Intrinsic motivation is the motivation that expresses the situations in which the action they do is interesting to the player and the player enjoys doing this action internally. Extrinsic motivation is the motivation that expresses the situation in which the player does the action entirely for the reward they will receive afterwards, and continues what they do with the desire to receive great items and awards. According to Zubek (2020), intrinsic motivation is hard to analyze and manage, whereas extrinsic motivation is easier to handle, because the player can be satisfied by simply increasing the outcome. However, over time, extrinsic motivation may begin to feel more like a job for the player (pp. 136-137).

The aim of this study is to provide a deep understanding of Bartle's player types, their intrinsic and extrinsic motivations, their expectations and preferences regarding the reward system within the core gameplay loops. The study aims to reveal whether different player types show significant differences in their preferences in the game and their satisfaction levels in terms of whether their expectations are met. By analyzing player behavior through a developed game, this study aims to reveal how much the characteristics of the player types that players define themselves as are truly reflected in the game.

Material and Method

The developed game for this research is designed to include core gameplay loops, decision mechanisms, and reward systems compatible with intrinsic and extrinsic motivations. Players' in-game data is collected based on their preferences, decisions in certain situations, and satisfaction levels for each level.

Players answer certain questions about themselves at the beginning of the game, as seen on Image 1 and Image 2, and they are categorized based on Bartle's player types in line with their own choices.

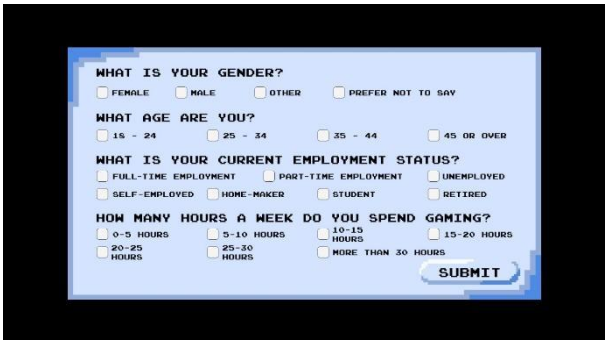

Image 1. Data collected to separate players into categories.

Image 2. Categorizing players by Bartle player types.

During the game, data is collected about players' interactions, preferences, and performances. At the end of each level, a general satisfaction score is obtained from the players. This satisfaction evaluation can be seen on Image 3.

Image 3. Players' overall satisfaction rating within the levels.

When the game is completed, the data sent allows a comparison and analysis between the player types they report and their actual in-game behaviors. According to certain situations, many comparative statistical methods are used to standardize and compare player preferences among different player types.

Findings

The findings of this study provide insights into how different types of players identified by Bartle respond to intrinsic and extrinsic reward systems within core gameplay loops.

A study was conducted with 80 people on the developed game, and players were asked for personal information about themselves in order to conduct a detailed analysis. Information was obtained on which Bartle player type they thought they were suitable for.

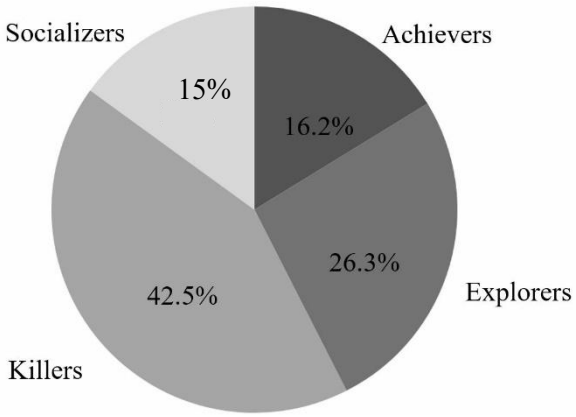

Chart 2. Distribution of 80 participants according to Bartle's player types.

As shown in the Chart 2, 16.2% of the participants identified as achievers, 26.3% as explorers, 42.5% as killers, and 15% as socializers. Before the players played the game, they were told that there would be two separate leaderboards, which would be published publicly for everyone to examine, based on a 'Lost Souls' counter that is kept according to the number of deaths in the game but can be reduced with certain choices, and the time it takes to complete the game. The elements that would motivate players with extrinsic motivation priorities were notified to them in advance.

The game begins with our main character learning that he can bring back a friend who has already died with the help of a portal and thinking that he will go to this portal no matter what. There are 3 sections in the game where players can explore different areas and complete achievements by helping a side character. Players can choose to help these side characters and play, discover new levels and witness different stories. However, when they choose not to play, their 'Lost Souls' number decreases by 5, and since they do not play extra levels, they have a chance to rise in both leaderboards.

Table 1. Correlation between death counts and satisfaction scores at level ends, compared across normal and side levels, based on Bartle's player types.

	Normal Levels	Side Levels	All Levels
Achievers	-0,055	-0,084	-0,058
Explorers	-0,315	-0,421	-0,340
Killers	-0,379	-0,243	-0,357
Socializers	0,088	-0,065	0,056
All Players	-0,202	-0,181	-0,198

According to the data analysis shown on Table 1, it is seen that the satisfaction levels of achievers and socializers are not affected much by dying. The satisfaction levels of explorers and killers are negatively affected due to more deaths. It can be said that explorers aim to gain new experiences by playing without dying and killers are negatively affected by dying in order to rise in the competitive leaderboard. It can also be seen that explorers, unlike killers, are more negatively affected by dying in side levels.

When the portal is reached at the end of the game, our main character learns that if he saves his friend, his 'Lost Souls' number will increase by 20, and therefore they will fall on the leaderboard. Accordingly, the player is asked to make a decision, 'Save the friend of the main character whom they have struggled with throughout the game and fall behind on the leaderboard or leave them as they are and stay where they are on the leaderboard?'.

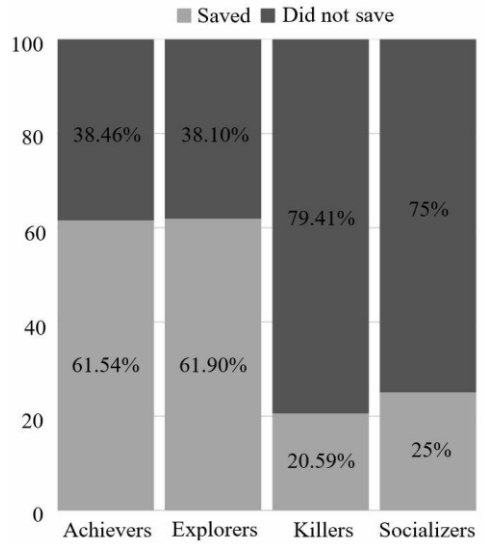

Chart 3. Percentage of players saving the main character's friend at the end of the game by Bartle's player types.

Again, according to the data analysis shown on Chart 3, 61.54% of the achiever players, 61.90% of the explorer players, 20.59% of the killer players and 25% of the socializer players chose to save the main character's friend. The fact that the characters rescue, which is the reward for the effort given throughout the game, is accepted by the achievers at a high rate, and rejected by the killers at a high rate, at the cost of the 'Lost Souls' number increasing by 20 and falling behind on the leaderboard, is exactly the expected data from the player types. The absence of discovery, and it being only a result of the struggle given throughout the game makes it meaningful for the explorer players to make such a decision. Socializer players are clearly interested in climbing the leaderboard and being able to talk about it with their friends.

Conclusion

In conclusion, 80 different people who played the game were expected to make different choices according to their own motivations and expectations during the game, and these preferences were analyzed according to Bartle's player types. Achiever players are more focused on certain achievements and completing different tasks, and they stand out with intrinsic motivation. Explorer players were completely satisfied with the discovery of stories, and their expectations were in this direction, so they focused on completing side missions as much as possible and seeing new and different levels. Killer players were clearly not satisfied with the side missions and focused on finishing the game quickly and climbing the leaderboard as much as possible. Acting in a way that met the expectations of their extrinsic motivation, very few of them eventually saved the main character's friend. Finally, socializers, generally acting similarly to killers, did not focus much on side missions, acting with the insight of climbing the leaderboard, sharing this with their friends, and proving themselves to their friends and few saved the main character's friend at the end of the game. Significant differences have been identified in the intrinsic and extrinsic motivations of various player types, as well as in the types of rewards that effectively satisfy them.

In the future, the findings of this research will offer game developers valuable insights into how to effectively satisfy players of different types by addressing their expectations in terms of intrinsic and extrinsic motivations.

Keywords: Game Audio Design, Audio Programming, RNBO, Interactive Sound.

Aim

Audio is a critical component of games that greatly contributes to player experience. While the visuals shape the game world, audio design enhances immersion by engaging players emotionally and reinforces the game's narrative and gameplay. Commonly, modern game audio relies on middleware tools such as Wwise or FMOD to create interactive soundscapes. Popular and recently released games that use Wwise include Silent Hill 2, Alan Wake 2 and Baldur's Gate 3 (Audiokinetic, n.d.). Some of the popular games that use FMOD are Celeste, Silence of the Lambs, and Sekiro: Shadows Die Twice. Big studios like Activision, Bethesda and Rockstar are also known to use FMOD (FMOD, n.d.). Both AAA and independent studios widely use FMOD and Wwise in their games. Audio middleware tools are powerful audio engines that provide seamless integrations to popular game engines like Unity and Unreal Engine. These middleware tools allow audio designers to create immersive audio environments without scripting, and overall having much more control over the game. However, these software tools mainly rely on pre-recorded samples and pre-configured effects, which limits their interactive responses.

Game audio designers would benefit from a flexible, real-time sound synthesis tool to create dynamic and interactive soundscapes. Unreal Engine has released MetaSound which is a high-performance audio system. MetaSound provides sound designers control over Digital Signal Processor which allows them to generate sound sources. It is a node-based system where sound designers can create audio behaviors with visual scripting. It can be easily integrated with game data and player interactions, creating an immersive experience (Epic Games, n.d.).

Max is a visual programming language for creating music, interactive audio, and multimedia applications. It is used in real-time sound synthesis, sound design, and interactive applications. It allows the sound designer to manipulate samples, or design their own custom synthesizer (Cycling '74, n.d.). RNBO is a patching environment for exporting software made in Max. This allows the user to turn audio patches into standalone plugins, C++ code, or web applications. It's designed for real-time cross platform audio processing and is very useful in interactive applications (Cycling '74, n.d.).

Unlike middleware tools, RNBO provides dynamic sound generation using Digital Signal Processing (DSP). DSP mathematically manipulates audio signals in real-time, enabling features such as live sound synthesis, adaptive effects, and procedural audio generation. By processing audio live, DSP allows the game audio to be in sync with players actions, creates interactive soundscapes and improves immersion.

RNBO has multiple export formats, but none can be directly imported into game engines with ease, limiting its use for sound designers who lack coding experience. Many audio designers are experienced with Max and RNBO, but they don't have the technical background needed to integrate it to game engines, consequently, this limits their ability to take advantage of procedural audio.

This research focuses on developing a tool, using RNBO exports, that enables sound designers to create and implement real-time audio processing in Unity. Creating a native audio plugin for sound designers would give them the freedom to use their skills in a familiar environment like Max and then easily integrate it into game engines. It is expected that this would result in a more dynamic and immersive audio experience by expanding the creative possibilities of in-game sound.

Material and Method

The study begins by researching, analyzing and understanding RNBO's capabilities, focusing on its functionality, real-time audio processing potential, and its integration capabilities with game engines. RNBO works as a visual patching environment inside Max. It allows users to design digital signal processing (DSP) algorithms through a node-based interface. Unlike commonly used sample-based methods, RNBO enables procedural sound synthesis, real-time signal manipulation and effects, making it a perfect tool for interactive game audio.

RNBO provides various export formats, each format was examined to determine if it is suited for game development. This examination was done by looking for factors such as performance, flexibility, and ease of integration to the game engines. The C++ export was prioritized as it offers the most efficient path leading to a low-latency digital signal processing within a game engine. However, since Unity does not support RNBO's output formats natively, additional interface is required. The study identified technical struggles of connecting Unity and RNBO, such as compatibility constraints, performance issues and the need for structured workflow to create smooth integration.

After analyzing various integration methods, it was determined that the JUCE framework provides the most efficient and flexible solution for incorporating RNBO into Unity. JUCE is an open-source C++ framework, which is generally used in audio application and plug-in development. It provides a broad set of tools for building custom digital signal processing (DSP) modules, standalone applications, and audio plug-ins. One of its key advantages is, its ability to export a number of formats such as, VST, AU and AAX, making it a popular choice (JUCE, n.d.). JUCE also integrates well with popular game engines such as Unity.

JUCE serves as an important network for linking RNBO and popular game engines like Unity, enabling seamless integrations for real-time audio processing inside interactive environments. Since RNBO's C++ export provides a raw DSP unit, JUCE can be used to process the DSP code into a native audio plugin for Unity, whether as a VST3, AU, or a custom DSP module. The process begins with designing and exporting a RNBO project which can range from being a procedural sound generator to an interactive effects unit. The RNBO generated code is then integrated into JUCE AudioProcessor, allowing it to operate within a real-time audio environment. Using JUCE Projucer to ensure cross-platform compatibility, the project can be compiled into different formats including plugins compatible with Unity. Once integrated into Unity, these plugins can directly be controlled by C# scripts, enabling adaptive and interactive soundscapes in game environments, enhancing player immersion.

To ensure a smooth integration of RNBO into game engines, this study primarily relies on the official documentation of Unity, JUCE, Max and RNBO. The Unity Engine documentation provides important insights into the game engines native audio system and its support for custom audio plug-ins. To understand how to develop cross-platform audio applications and wrap RNBO exports into formats compatible with Unity, JUCE's extensive documentation is essential. Additionally, Max and RNBO documentations play an important role in understanding the capabilities of RNBO patches, their export options, and how they can be adapted for real-time game audio. With the help of these materials, a roadmap for making a RNBO audio plugin for Unity can be create.

Findings

The research led to several key findings about integrating RNBO into Unity. First, the analysis of RNBO's capabilities confirmed it is a powerful environment for digital audio processing in real time. An essential component of RNBO is its ability to export projects as C++ code, which is a vital step in the tool's development. Second, the analysis of Unity's native audio system showed its support for custom audio plugins, creating a pathway for integration. Nonetheless, Unity's lack of native support for RNBO export format created challenges during initial considerations. This made it clear that an intermediary solution was required. JUCE was found to be a practical and effective way to connect the two. The ability of JUCE to compile C++ code into various plugin formats showed a clear path for creating a RNBO plugin that works with Unity.

At this point, a simple RNBO patch has been successfully exported and compiled within a JUCE plugin structure. Frequency and gain were the two parameters defined in Max/RNBO, which were preserved in the exported code and mapped within

the JUCE processor. This confirms that the C++ export from RNBO can be adapted for real-time DSP inside JUCE. While Unity integration is still in progress, the early tests show that the proposed workflow is technically feasible.

Conclusion

In conclusion, this study aims to provide a practical and user-friendly tool for integrating RNBO into game development environments. By using JUCE to turn RNBO's C++ exports into plugins compatible with Unity, this approach lets sound designers implement real-time procedural audio without needing to write complex codes. The goal is to combine creative audio design and technical implementation, helping to create more dynamic and immersive soundscapes in video games and interactive media. With the early stages of development, the project has strong potential to offer sound artists a better control over the game audio. Future work will involve completing the plugin prototype, examining its performance in a real game setting, and optimizing the workflow.

Procedural Entity Generation For Simulated Ecosystems

Gazi Muhammet Canbolat[a], Selçuk Sümengen[a], Sema Alaçam[a]

[a] Istanbul Technical University, Faculty of Computer and Informatics Engineering, Game and Interaction Technologies, Turkey
canbolat24@itu.edu.tr

Keywords: Computer Graphics, Ecosystem Simulation, Gamification, Procedural Content Generation, Procedural Modeling.

Aim

Procedural Content Generation (PCG) is a common technique in game development and simulations to create dynamic and diverse environments. It allows for the automatic generation of game levels, textures, and characters, reducing manual effort while maintaining variety. Our study demonstrates how procedural modeling approaches can be used to simulate biological ecosystems by dynamically generating entities and their interactions in a structured 3D simulation environment. We enable procedural content generation in our scalable and adaptable simulation environment, resulting in a rich and dynamic simulation that does not require pre-modeled elements. Our 3D simulation utilizes computer graphics principles to enhance visualization and realism, ensuring an immersive experience. As a proof of concept, the presented framework enables the investigation of how procedural modeling might be used to simulate an ecosystem.

Material and Method

Related Work

Procedural modeling plays a crucial role in content generation, allowing for the dynamic construction of objects based on predefined rules. Unlike traditional modeling, where assets are manually designed, procedural modeling enables the algorithmic creation of complex structures with minimal user intervention. PCG is commonly utilized in game development to enhance content diversity and reduce manual workload. It provides a structured approach to content creation, allowing developers to generate interactive environments efficiently.

Hendrikx et al. (2013) propose a six-layered taxonomy for PCG, categorizing it into game bits, game space, game systems, game scenarios, game design, and derived content. From low-level materials like textures and models to high-level game mechanics and narrative frameworks, each of these layers represents a distinct degree of content abstraction.

PCG techniques can also be classified according to their generation process. Togelius et al. (2011) describe three main approaches: constructive, generate-and-test, and search-based. Constructive approaches generate content in a single pass using predetermined rules, providing immediate usability but limiting flexibility. Generate-and-test methods iterate over generated content without structured optimization, whereas search-based techniques refine content over multiple iterations using evaluation functions.

In the realm of game development, procedural techniques have also been successfully integrated into various games. For instance, Spore (Maxis, 2008) and No Man's Sky (Hello Games, 2016) utilize procedural methods to create vast and highly detailed game worlds. By using algorithmic approaches to generate complex environments, these methods enhance scalability and diversity while minimizing the need for manual design effort. No Man's Sky employs procedural methods to generate planets and ecosystems, whereas Spore concentrates on evolutionary simulations and species development. Procedural content generation in Spore and No Man's Sky highlights how PCG enhances adaptability and scalability in interactive simulations.

Simulated Ecosystem

We used procedural modeling to generate biological entities that vary in shape, size, and behavioral characteristics based on predefined rules. The creatures in our simulation environment are divided into three groups depending on their eating habits: producers, herbivores, and carnivores. These classifications align with the ecological structuring described by Schoener et al. (1989), forming the foundation of procedural entity generation.
The entity attributes are classified into three broad categories. The first category contains static physical attributes, including body structure and limb count. The second category contains dynamic features that alter over time, such as entity growth caused by consuming food. The final category contains hereditary traits that carry across generations, impacting how children adjust to environmental limits.
The food chain regulates resource distribution, ensuring that producers sustain herbivores, which in turn support carnivores. When an entity dies from starvation, its remains enrich the soil, allowing new producers to grow and contributing to the ecosystem's nutrient cycle. In our simulation, procedural rules govern how entities consume resources, grow, reproduce, and interact with one another, ensuring that ecosystem balance emerges naturally.

Implementation

In this study, PCG is primarily used for game space and game systems, where interactions and environmental conditions are generated dynamically. The presented simulation framework utilizes a hybrid procedural generation approach. Initial procedural entity creation follows constructive principles, ensuring structural consistency. However, inherited traits introduce indirect selection over generations, allowing for emergent ecological adaptations without the need for explicit optimization. The hybrid approach that we used during entity generation balances structured procedural generation with dynamic environmental interactions, resulting in a self-regulating ecosystem model.
Our simulation environment offers an interactive and customizable framework, incorporating elements of gamification to enhance user engagement and experimentation. Users configure initial population parameters and adjust environmental variables to observe how species adapt over time. Before running the simulation, users can specify the initial number of entities for each species, as well as define value ranges for procedurally assigned attributes such as movement speed, body size, reproduction rate, and energy consumption. As the simulation progresses, new entities inherit certain parameters from their parents, with slight adjustments made by randomization processes. The given parameters have an impact on how entities interact in the environment, including population dynamics and resource competition. Through controlled experimentation, users can analyze the effects of procedural constraints such as energy consumption, predator-prey relationships, and reproduction rates on ecosystem stability. This interactive aspect introduces a gamification element, making the simulation applicable as both a research tool and a procedural game design framework.

Findings

The presented study advances procedural modeling by illustrating how PCG may be used to generate an artificial ecosystem in which elements interact dynamically. Furthermore, our approach lays the groundwork for game developers to incorporate similar procedural entity generation techniques into their projects. Such an approach enhances versatility and scalability in gaming environments.
In our simulation environment:

- A scene graph is used to efficiently handle scene objects, permitting optimized transformations and the effective display of procedural entities.

- PCG eliminates reliance on pre-modeled assets, allowing for dynamic ecosystem generation while significantly reducing data storage requirements.

- The structured procedural generation method uses predefined rules to regulate entity behaviors while allowing for variable ecological interactions, resulting in a scalable and adaptable simulation framework.

Conclusion

As a proof of concept, our simulation framework demonstrates how procedural approaches go beyond traditional game development, giving a systematic foundation for ecological simulations and artificial life studies. The methodology used in our research may be applied to investigate population dynamics by modeling how species interactions and resource availability affect long-term ecosystem stability. By applying procedural modeling principles, our system enables a continuously adapting environment, facilitating in-depth studies of ecological dynamics and providing an engaging framework for interactive applications.

Future Work

Future research may focus on expanding procedural interactions and increasing species diversity. Additional ecosystem categories could introduce more complex ecological relationships. The simulation framework could also be extended to support multiple ecosystems, each with unique environmental conditions and interactions. Further advancements may explore integrating deep learning techniques into the reproduction process, refining trait inheritance, and enhancing biologically inspired adaptation mechanisms. These improvements could elevate procedural modeling applications in artificial life research and game design, contributing to more intricate and realistic ecosystem simulations.

Naval History Reconstruction Through 3D Modeling and Simulation

Deniz Çakır[a], Gökdeniz Neşer[a]

[a] Dokuz Eylül University, Institute of Marine Sciences and Technology, Naval Architecture, Türkiye
deniztcakir@gmail.com

Keywords: 3D Modeling, Naval Architecture, Naval History, Realistic Texturing, Warship Visualization.

Aim

The aim of this study is to digitally reconstruct historical and unrealized warships through a visually accurate and technically grounded 3D modeling workflow. This reconstruction supports academic research by providing precise visualizations based on archival documentation, aids in digital preservation of naval heritage, and enhances public engagement by making historically significant vessels accessible in virtual environments. Such digital twins serve as invaluable tools to bridge the gap between historical records and modern audiences, preserving maritime culture in an interactive and immersive way.

Material and Method

This study employs a systematic and structured 3D modeling workflow founded on extensive archival research and careful blueprint analysis. The process begins with collecting primary and secondary source materials, including detailed ship plans, archival photographs, written technical documentation, and where possible, first-hand testimonies or museum records. These materials provide the foundational data for creating geometrically accurate digital models.

The initial modeling phase utilizes polygonal modeling techniques in professional 3D software, where the hull, superstructure, and key components of the ship are recreated with high fidelity. A novel aspect of the workflow is the application of a grid-based topology method during the modeling phase. This approach organizes the mesh into uniform, logically arranged quads that facilitate subsequent UV unwrapping processes. The consistent topology improves texel density distribution, reducing texture stretching and wasted UV space, which is critical when working with high-resolution textures.

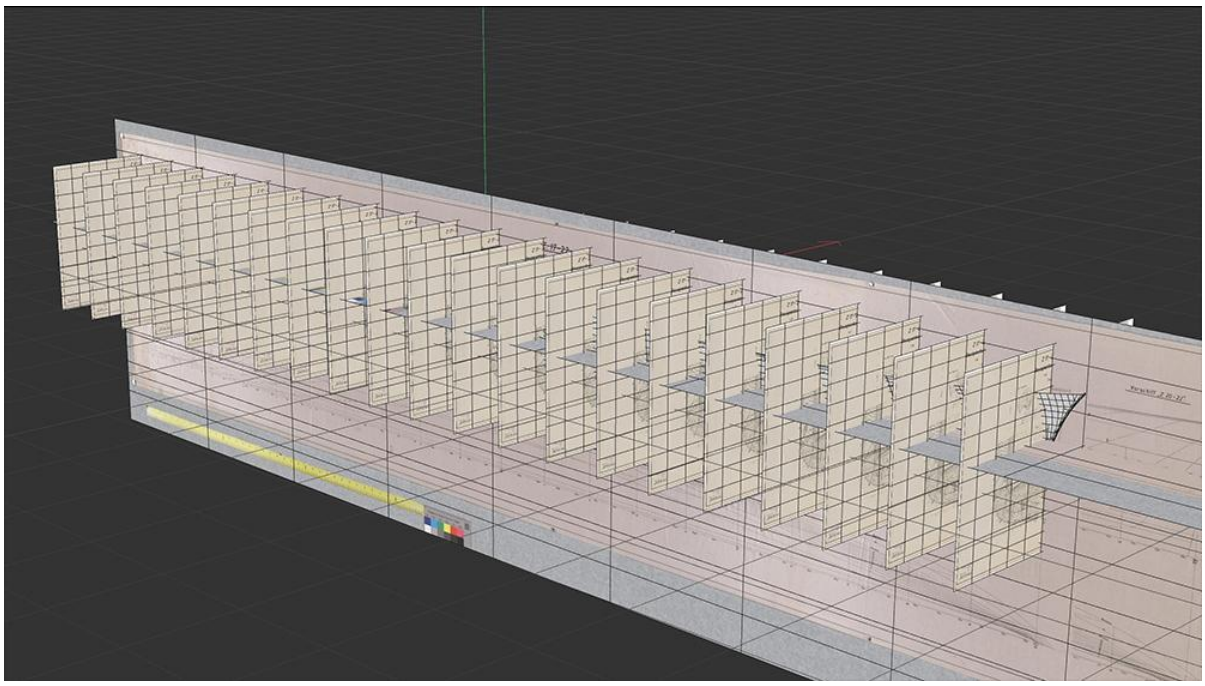

Figure 1. Reference to 3D Model Stage.

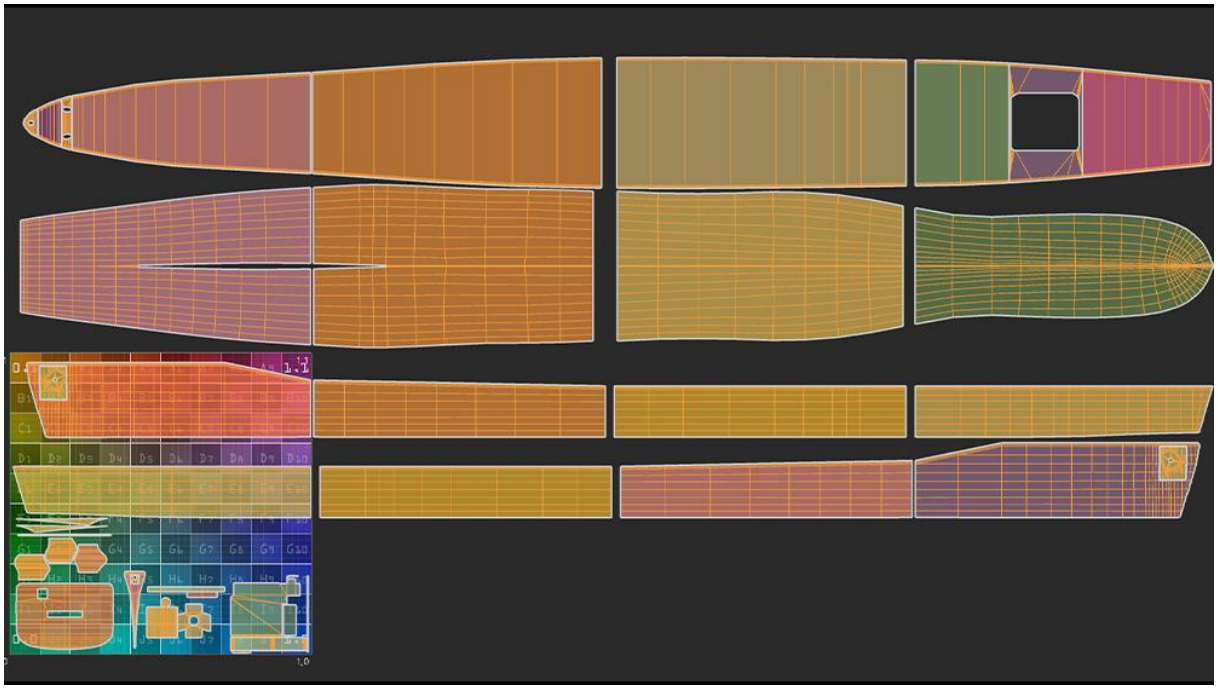

Figure 2. UV Islands.

Texturing is performed using Physically Based Rendering (PBR) techniques in software such as Substance Painter. This approach allows for the realistic simulation of materials under various lighting conditions by accurately replicating physical properties like metalness, roughness, and reflectivity. Surface details such as micro-wear, manufacturing tool marks, environmental weathering effects (e.g., rust, paint chipping), and asymmetries are intentionally integrated. These imperfections enhance visual authenticity, conveying the vessel's history and usage over time.

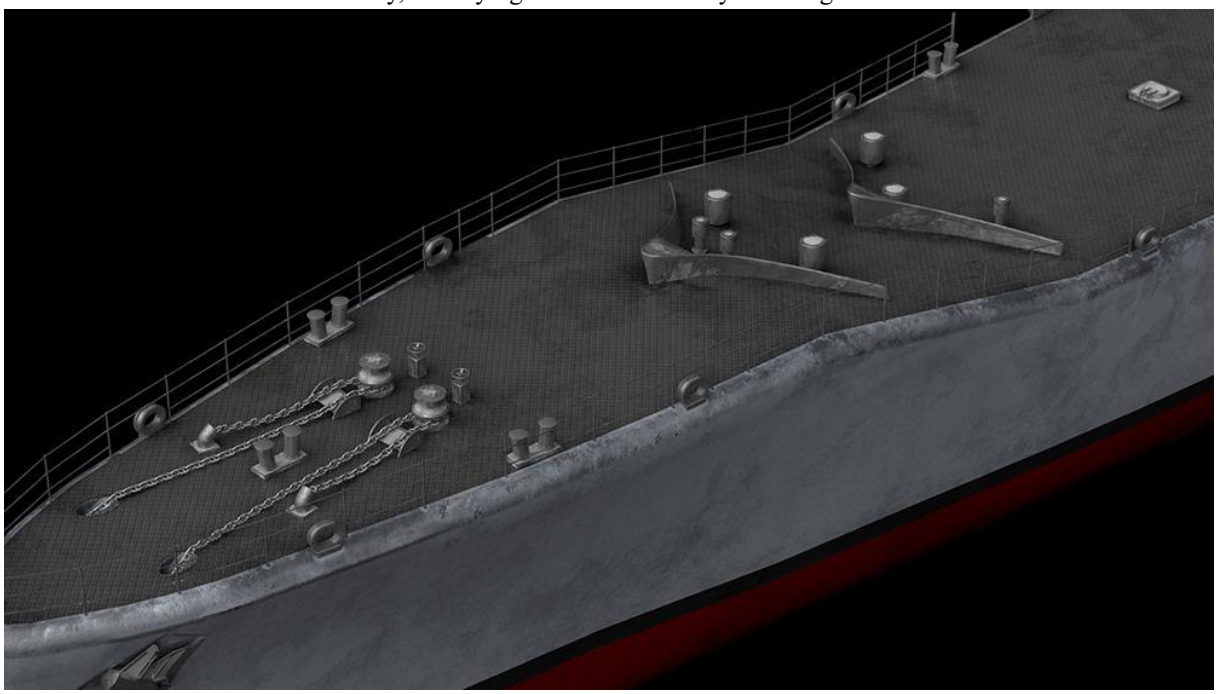

Figure 3. Realistic texturing.

To simulate dynamic elements, Houdini is employed to generate realistic ship wake effects. Using the ship's 3D geometry as input, fluid and particle simulations produce volumetric wake data that can be exported as VDB files. Final composition includes realistic lighting setups, ocean surfaces, and atmospheric effects, with post-processing touch-ups done in Photoshop to enhance color grading and contrast.

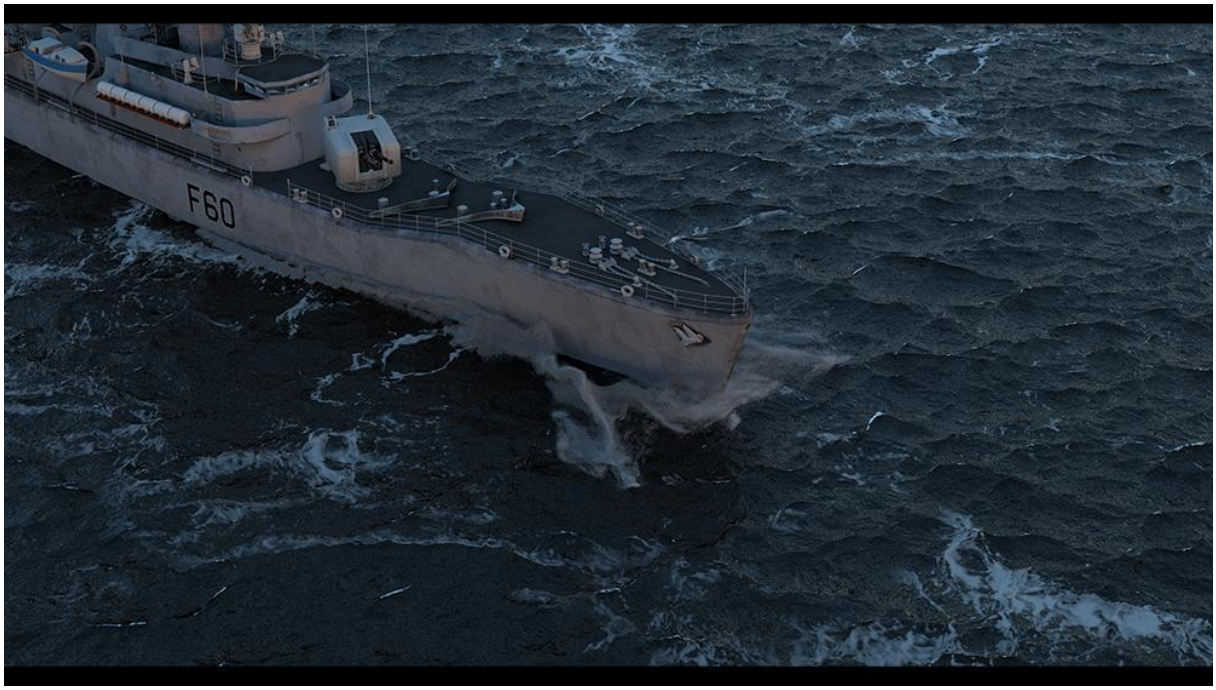

Figure 4. Volumetric Data Wake Imported into Scene.

Importantly, this workflow is versatile enough to digitally realize "never-built" warships from historical plans that were either canceled or remained conceptual, such as the German H-44 class battleships or the Soviet Stalingrad class heavy cruisers. This aspect allows historians and researchers to visualize theoretical designs and assess their feasibility and appearance in ways previously impossible.

Figure 5. Final Scene Render.

One key challenge in this workflow is ensuring the balance between geometric accuracy and computational efficiency. High polygon counts increase detail but can hinder real-time rendering performance, especially for interactive applications such as virtual museums or VR experiences. Thus, strategic use of grid-based topology and texture optimization is critical. The choice of industry-standard software such as Houdini for fluid simulations and Substance Painter for PBR texturing reflects the need for robust tools that can handle complex data while maintaining artistic flexibility.

Additionally, the ability to simulate environmental effects like corrosion, dirt accumulation, and wear patterns allows for more authentic reconstructions that go beyond mere geometric modeling. These effects are essential for conveying the lived history of the vessels, enabling viewers to understand their operational context and aging process.

Findings

The implementation of the grid-based topology method yields significant improvements in UV layout efficiency. Uniform polygon distribution enables optimized use of texture space, preventing common issues like pixel density imbalance and texture distortion. This optimization allows for higher detail levels on critical visual areas without increasing overall texture memory requirements, a crucial factor for real-time visualization and digital exhibitions.

Physically based texturing combined with carefully modeled imperfections results in models with a high degree of visual realism and narrative authenticity. These subtle surface details help viewers subconsciously associate the models with tangible, historical artifacts, increasing immersion and credibility. The integration of realistic wake effects generated through Houdini simulations further enhances dynamic realism, making the scenes more engaging and lifelike.

The final models and scenes are well-suited for use in various contexts such as academic research presentations, digital museum exhibits, educational virtual reality environments, and even entertainment or documentary production. By balancing technical accuracy with artistic detail, the workflow successfully bridges the gap between scientific fidelity and visual storytelling.

Conclusion

This research demonstrates how advanced visual effects tools and techniques traditionally used in the entertainment industry can be effectively adapted to serve the field of naval historical research. The presented workflow offers a reliable and

repeatable method for visualizing both existing and unrealized warships within digital environments. This approach fills a crucial gap in public access to naval heritage, providing detailed and immersive representations that support both academic documentation and popular engagement.

Furthermore, by balancing fidelity, modularity, and realism, the method ensures that digital reconstructions are not only visually compelling but also technically sound, facilitating their integration into a range of applications from virtual museums to interactive simulations. As digital technology evolves, such workflows will become increasingly vital in preserving and reinterpreting maritime history for future generations.

As digital preservation and visualization technologies continue to evolve, workflows like the one presented here will play an increasingly vital role in safeguarding maritime cultural heritage. By making naval history accessible and engaging to a broad audience, these digital reconstructions help foster appreciation and understanding of the past, informing present and future maritime research and conservation efforts.

Mechanics To Design Virtual Reality Cognitive Training Games

Evrim Kabadayı[a], Leman Figen Gül[b]

[a] Istanbul Technical University, Institute of Science and Technology, Department of Game and Interaction Technologies
[b] Istanbul Technical University, Faculty of Architecture, Department of Informatics Architectural Design Computing
kabadayie21@itu.edu.tr

Keywords: Cognitive Training, Virtual Reality, Game Mechanics, Game Design, Serious Games.

Aim

The capacity of humans for cognitive abilities is their best "x-factor" for differentiating themselves from other animals. These skills play an important role not only in managing large-scale actions but also in doing everyday tasks. Cognitive training denotes a systematic array of activities aimed at improving, sustaining, or rehabilitating cognitive processes including memory, attention, problem-solving, and executive functions. These programs are constructed according to neuroscientific and psychological principles, with the objective of enhancing brain pathways and optimizing cognitive efficiency.

Cognitive training is employed in various contexts, including clinical applications for rehabilitating patients with neurodegenerative diseases, brain injuries, or cognitive impairments, as well as non-clinical settings that promote healthy aging, academic achievement, and professional skill enhancement. Traditional cognitive training methods, such as pen-and-paper exercises, have been used for decades to measure, preserve, and enhance these cognitive functions. While cognitive training creates a multibillion-dollar market (Ahuja, 2019), the healthcare industry explores new mediums to find more adaptive methods.

Virtual Reality is seen as a promising alternative, giving immersive and interactive environments for cognitive training for players (Damaševičius et al., 2023). Since then, an increasing number of medical fields have seen the potential of VR for data collection, treatment, and training. (Pawassar & Tiberius, 2021). Unlike conventional training methods, VR enables users to actively participate in exercises that challenge their cognitive functions in a dynamic and responsive setting.

Khaleghi (2021) emphasized that most gamified cognitive tasks are developed by cognitive psychologists rather than professional serious game designers. As a result, researchers tend to prioritize the clinical effectiveness of these tasks while paying less attention to creating engaging and well-structured game design outputs. If clinical outcomes are prioritized over the user experience process -where data is collected, or progress is assessed- the product will lack durability and genuine efficacy.

The extent to which these two methodologies are equilibrated dictates the project's definition. The project may serve as a gamified cognitive task – a replication that disregards new patterns that could be uncovered by technological advancements. Also, it can be a cognitive-based serious game which is produced and refined in the light of the behavioral traces that people give during the content they are exposed to. This highlights the need for collaboration between serious game experts and cognitive scientists to better understand the tension between studied cognitive functions and related game features (Lumsden et al., 2016).

This study aims to explore the game mechanics that contribute to the effectiveness of cognitive training games in VR. By analyzing existing virtual reality cognitive training games, the research seeks to identify common design patterns that have an impact on user experience. This study intends to understand the mechanics of current VRCTs. The main issue of research is how VR cognitive training games use design aspects to improve cognitive functions and what important factors influence their efficacy.

Material and Method

To effectively evaluate the design features of cognitive training games in VR, the Elemental Tetrad (Schell, 2008) framework proves to be a valuable tool. By categorizing design elements into technology, story, mechanics, and aesthetics, this framework provides a structured way to analyze how these components interact within a virtual reality cognitive training environment. Technology plays a significant role in immersion and accessibility, while mechanics determine the effectiveness of cognitive engagement. Story elements, even in minimalistic forms, contribute to motivation and goal setting, whereas aesthetics influence user experience and emotional connection. The framework is used to evaluate the hypothesis that accessible cognitive training games are not engaging and user-friendly, but also functional, addressing critical factors such as usability, interaction, and immersion that are essential for cognitive development process. This study will focus solely on the 'Mechanics' section of the four headings of the framework.

Priority was given to commercial VRTCs during the game selection process over the ones with academic purposes. These games were selected based on their accessibility, focus on cognitive training, and relevance to the study's objectives. A keyword-based search was carried out using the terms "cognitive," "training," and "health" inside the Meta Quest and Steam VR stores to guarantee the selection of pertinent titles.

The only product that appeared in both platforms' search results was Enhance VR. In addition to Enhance VR, other products were found for case analysis: NeuroBoostVR, Optics Trainer, Oroi Cognitive, Mastermind Cognitive Training, XRHealth Physical & Cognitive Space, and REAKT Performance Trainer. Although the usability of these games was determined during the study, some of them was excluded from the study as it could not be accessed through the Meta Store during the process. The selected virtual reality cognitive training games are NeuroBoostVR, Optics Trainer and REAKT Performance Trainer. Following the selection process, playtest sessions are conducted for each of the four VRCTs. The products were analyzed through a comparative analysis under the 'Mechanics' sections, including Game Mechanics, Difficulty Curve, Game Balance, Feedback, Locomotion, and Interaction.

Findings

Players can navigate through menu in Optics Trainer and REAKT Performance Trainer, unlike in NeuroBoostVR. Task objective differ across platforms: NeuroBoostVR provides generic cognitive exercises, Optics Trainer focuses on visual domain-specific tasks, and REAKT Performance Trainer incorporates both cognitive and motor domain-specific components.

In terms of feedback modalities, NeuroBoostVR utilizes auditory and visual cues, whereas both Optics Trainer and REAKT Performance Trainer integrate auditory, visual, and haptic feedback, offering multimodal sensory engagement. A training overview screen is available exclusively in REAKT Performance Trainer.

Structured training systems are absent in NeuroBoostVR, integrated with prescription logic in Optics Trainer, and comprehensively implemented in REAKT Performance Trainer. Competitive mechanics are included only in REAKT Performance Trainer, enabling social comparison and performance benchmarking.

Difficulty settings are not available in NeuroBoostVR, are limited to three levels in Optics Trainer, and consist of ten gradations in REAKT Performance Trainer. Interaction styles remain unspecified for both NeuroBoostVR and REAKT Performance Trainer, and require clarification in Optics Trainer. Session duration control is open-ended in NeuroBoostVR, pre-defined in Optics Trainer, and user-adjustable in REAKT. Spatial orientation is reportedly more difficult to navigate in NeuroBoostVR, whereas Optics Trainer and REAKT provide structured orientation environments.

Conclusion

This study highlights the necessity of connecting academic research with practical game design in VR-based cognitive training. Cognitive training games, although primarily designed with a clinical emphasis, must also prioritize engagement and structured design to enhance their long-term effectiveness and usability.

The development of a common terminology between cognitive scientists and game designers facilitates the creation of advanced, user-focused cognitive training experiences that integrate clinical efficacy with engaging gameplay.

This study provides a foundation for future research and development in the field, offering insights that may inform subsequent iterations of virtual reality cognitive training games. The ongoing evolution of these technologies necessitates a collaboration to fully realize their potential in enhancing and preserving cognitive skills.

An Analysis of Gaming Behavior Through Bartle's Player Model & Human Psychology

Asena Ersoy[a], Leman Figen Gül[b]

[a] Istanbul Technical University/Graduate School, Department of Game and Interaction Technologies, Game and Interaction Technologies Program, Turkey
[b] Istanbul Technical University/Faculty of Architecture, Department of Architecture, Architectural Design Computing Program, Turkey
ersoya16@itu.edu.tr

Keywords: Game Psychology, Bartle Player Types, Virtuality and Identity, Gaming Motivations.

Aim

The aim of this research is to understand the effects of personalities and demographic groups on player motivations. In other words, it is aimed to discover which characteristics of individuals shape their in- game behaviours. Thus, by examining how individuals' real-life characteristics shape their behaviours and motivations in games, it is aimed to show the opportunities that games offer to people. This study, which focuses not only on personality traits but also on the demographic structure of individuals, aims to create an important data source for a better understanding of the reasons for playing games. Players' personality, such as anyone, has a significant impact on how they act or think under certain conditions, suggesting that in-game behaviour is influenced by personality (Quwaider, Alabed&Duwairi, 2019). For this reason, some studies examine and categorize players' personalities and motivations. Bartle (1996), in his study of Multi-User Dungeon players, divided player types into four on a coordinate system: achiever, killer, socializer, and explorer. Also, personalities can be classified according to different models. One of the most broadly used and inclusive classifications of personality types is The Five Factor Model. Divides personalities into five categories: Extraversion, Agreeableness, Conscientiousness, Emotional Stability and Openness (Liu et. al., 2024).

Material and Method

In this study, a questionnaire is used to measure personalities and player types. Validated and tested Turkish questionnaires from different sources are used to determine personality and player types. The personality assessment was based on the model proposed by Tatar (2017), while the player type classification was adopted from the model developed by Hamutoğlu, Topal, Samur, Gezgin, and Griffiths (2020). The questionnaire included demographic questions and two different models: one is used to analyse player types and the other is used to analyse personality traits. Bartle model is preferred for the analysis of player types and Five Factor Model is preferred for the analysis of personality traits. The Bartle model has a simple and widely accepted structure that divides players into four basic groups according to their in-game behaviours. The fact that this model has similar characteristics with the Five Factor Model used for personality analysis enables the examination of the relationships between the two models. Also, the Five Factor Model is a widely studied model with high validity and reliability values. Its measurement of continuous variables enables in-depth analyses of personality traits, while questionnaires of different lengths provide flexibility. Observing the similarities between the personality dimensions in the Bartle model and the Five Factor Model provides an important basis for analysing the relationships between player types and personality traits.

The questionnaire is delivered to the participants online via Google Forms. The questionnaire is delivered to the participants by snowball sampling and it is therefore prepared in Turkish. The questionnaire distribution process lasted for six weeks, and it is important that the participants in the research are gamers and even massive multiplayer online role-playing game players. Therefore, when the questionnaire was to be distributed, massive multiplayer online role-playing game players were first asked to complete the questionnaire and forward it to their communities. Then, academics and students working in the field of Digital Game Design are asked to participate and spread this survey. Likewise, the survey was sent to the

Game Development student communities of schools via WhatsApp. To ensure that the entire sample does not consist of similar demographic groups, the questionnaire is sent to people of different ages, professions and genders. As a result of the survey, a total of 417 people are reached. The majority of the participants are between the ages of 18-30 and most of them are university graduates. Approximately two-thirds of the participants identified themselves as male and the rest as female or other. When the gaming habits of the participants are analysed, there are very few participants who do not play games. Specifically, the number of people who answered the question of how many hours they played a massive multiplayer online role-playing game in total is less than half of the data. The participants in the survey are mostly gamers. When the data are analysed, 6 incorrect entries are detected and these are removed. The analysis is made over 411 data. The data collected from the survey are statistically analyzed and visualized in Python. Correlation analysis, ANOVA test and Tuckey's Honestly Significant Difference tests are applied respectively.

Findings

The findings of the study show that there are significant relationships between individuals' personality traits and their preferences in games. In particular, it is observed that individuals with high openness to experience display an exploration-oriented approach in games and show less interest in tasks and collecting points. When gender differences are examined, it is observed that women who prefer socializing in games are more responsible and disciplined individuals in real life, while men who prefer socializing in games stand out with a compatible and helpful personality structure. This situation can be interpreted as that women consider games as a space to get away from the responsibilities of daily life, while men behave more parallel to their real-life tendencies in in-game social dynamics.

When analyzed in terms of age groups, it is found that emotionally stable young individuals tended to explore the game world, whereas older individuals who were open to experience are more distant from in-game goals and achievement-oriented mechanics. This suggests that emotionally stable younger individuals tend to view games as a way to stimulate a sense of exploration, whereas older individuals may tend to perceive games as an extension of real life. The findings may indicate that in-game behaviours are shaped not only by individual personality traits but also by the developmental dynamics of individuals.

In the analysis in terms of educational level, no significant results are obtained for the group above the university level since the majority of the participants are university graduates. When high school and university level participants are analyzed, similar results are observed with the age analysis. In addition, a negative relationship is found between the personality traits associated with agreeableness, helpfulness and the player type representing competitive and aggressive play style. This finding suggests that compliant individuals tend to avoid causing difficulties to other players in the game. A comprehensive comparison could not be made due to insufficient data on other education levels.

Conclusion

In conclusion, by helping to better understand player motivations and behaviours in the game world, the outputs of this research can help game designers create more effective content that appeals to different demographic groups. The results of this research help us understand how games reflect social structures by revealing how individuals' demographic identities and their roles in the game world overlap or diverge. Furthermore, how games shape how individuals express themselves can be better understood. This study contributes to understanding how games function as part of social identities, rather than simply as a means of entertainment.

Current Challenges in Port Management and Common Approaches from Geographic Information Technologies (GIT)

Cemre Fazilet Aldoğan[a], Hande Demirel[b]

[a] Istanbul Technical University/Informatics Institute, Department of Informatics Applications, Geographic Information Technologies, Türkiye
[b] Istanbul Technical University/Faculty of Civil Engineering, Department of Geomatics Engineering, Türkiye
aldogan17@itu.edu.tr

Keywords: GIT, Maritime Transportation, Port Management.

Ports are key transportation centres for global trade, and they face challenges as the number of ships continues to increase. Efficiency problems in cargo handling, vulnerability of ports to illicit activities such as illegal fishing, terrorism, and trafficking, and pollution from ships are some of the human-induced problems still requiring effective measures. On the other hand, natural disasters as a result of climate change are a serious threat to port security, besides anthropogenic interventions. The infrastructure of ports is prone to being affected by floods and earthquakes, followed by their adverse effects on the economy. A review of methods and solutions regarding these challenges is necessary for identifying gaps for future studies. Thus, this paper aims to discuss common approaches that Geographic Information Technologies (GIT) provide, along with a review of these challenges regarding port management. Aerial, remote sensing, and ground-based instruments as part of GIT offer large volumes of geospatial data to gain insights for potential solutions. Optical and radar remote sensing images supported by computer vision technology facilitate automated surveillance of ports, vessels, and containers. Ship detection in port areas helps authorities to track unauthorized entrances, enabling a more secure environment. Detection of oil spills, clutter, and other types of pollution in ports and open seas is one of the other approaches that GIT reflects for helping form environmental measures. For addressing challenges related to port operations, proprietary and open-source GIS software launch frameworks are used to decrease congestion and support better management of traffic flow. In addition, these maritime frameworks integrated with Automatic Identification System (AIS) act as an adept tool to respond to vulnerability caused by natural and man-made disasters with map visualizations. This paper intends to assess the sufficiency of the aforementioned methods and findings from a critical perspective. It is anticipated that this study will inform researchers about the future directions and contribute to the conduct of further studies.

Aim

Ports serve as critical transportation points where more than 80% of global trade is handled (UNCTAD, 2024). Due to pressure caused by increased shipping activities, a myriad of issues related to port management have emerged, such as congestion in marine environments, disruption in cargo operations, and inadequacy in maintaining port security due to the impracticality of inspecting the conditions of containers. Security is a major concern, especially in large container ports. Since marine environments by nature are difficult to manage, this leaves large container ports vulnerable to terror attacks (Widodo et al. 2024). Moreover, the infrastructure of ports is affected by extreme weather events such as high winds, heavy rainfall, tectonic activities, and tsunamis. Geographic information systems (GIS) tailor solutions to the problems above by collecting, integrating, and analyzing a variety of geospatial data. Therefore, the main aim of this review is to explore what these geospatial solutions are in the current research agenda. In this review, a short body of literature was synthesized to deliver up-to-date approaches.

Material and Method

For a systematic and concise literature review, journal articles featuring port management and GIS technology with a query "Port Management AND GIS" were searched in databases of Web of Science and Scopus. A year filter limitation was applied to each database search to obtain the articles between 2020 and 2025. 165 and 68 articles in total were retrieved from Web of Science and Scopus databases, respectively. After retrieving articles from each database, they were filtered

manually by focusing on specific maritime keywords such as port operations, port infrastructure, environmental risks, and maritime traffic management. Final selection of the articles was completed in this order, following the aim of this paper. As a result, 21 articles were distilled from the entire search. The usage purposes of GIS in these articles are multifaceted. However, many commonalities exist, such as overlaying data sources, multi-criteria decision making, and thematic mapping. Vulnerability and risk assessment studies were observed to share this order in methodology. The articles in which natural disasters and their impact on the functionality of port operations are dominant since nowadays the destructive effects of climate change are distinct (Allen, McLeod, ve Hutt, 2021; Alshareef vd. 2024; Abdelaziz vd. 2024). On the other hand, GIS was observed to be utilized as an auxiliary tool to help design digital twin (DT) and building information modeling (BIM), besides being utilized as a decision support system (Agostinelli vd. 2022).

Findings

It has been revealed that the articles are centered around three research problems such as the health of port infrastructure, shipping traffic, and natural disasters. Infrastructural problems can be summarized as energy efficiency (Agostinelli vd. 2022; Wang vd. 2024), risk of construction damage due to chemical explosions (Lee, Ham ve Jeong, 2022) and aging of port infrastructure (Tsaimou, Sartampakos ve Tsoukala, 2023). As for the problems related to shipping traffic, only a small minority of papers focused on delivering a solution regarding the traffic flow of ships or accidents in general. Because ports are primary places having a high probability of being affected by water-related disasters, the number of papers covering environmental risk assessment for coastal areas is higher.

Conclusion

In this paper, a short body of literature was analyzed to reveal the most recent issues and geospatial practices related to ports. The statements and observations were made to guide the target audience of this paper on corresponding research directions. A future study can be implemented to cover a large body of literature about these issues to discuss them in more detail. An alternative study idea can be based on the comparative advantages and disadvantages of proprietary or open source GIS software regarding the contributions they made to resolving the aforementioned issues. Lastly, a future study can be conducted by applying frequently used spatial analysis techniques to address problems related to shipping traffic as a case study.

Tactile Map Production Processes And Application Areas For Visually Impaired

Ayça Eraslan[a]

[a] Istanbul Technical University, Applied Informatics, Geographical Information Technologies, Turkiye
eraslana@itu.edu.tr

Keywords: Visually Impaired, Tactile Maps, Accessibility, 3D Printing, Spatial Awareness.

Aim

Visually impaired individuals face significant difficulties in terms of spatial awareness and independent mobility. According to research, 56% of visually impaired individuals state that they have various difficulties in independent mobility (Bahram, 2013). This situation directly affects the social and professional lives of individuals and increases the risk of social exclusion. Therefore, accessible geographic maps play a critical role in ensuring understanding of the city and neighborhood structure and enabling safe and independent mobility.

Traditionally, embossed maps and Braille texts have been used for visually impaired individuals (Brock et al., 2012). However, such tactile maps can provide limited spatial information and are insufficient to include detailed data. In addition, there is an increasing demand for map systems that can be customized according to individual needs (Kern, 2016).

Tactile maps appeal to two main user groups: mobility trainers who create maps and train users, and visually impaired individuals who use these maps to find their way and provide spatial awareness (Rowell & Ungar, 2016). Considering the limitations presented by traditional map designs, the development of new generation tactile maps that offer more accessible and inclusive solutions is of great importance.

In order for visually impaired individuals to use tactile maps effectively, certain design criteria must be taken into consideration. Factors such as the arrangement of the spaces between the signs, material selection, interactive elements and inclusive design directly affect the ease of use of maps. Research shows that visually impaired individuals prefer rough-surfaced papers and Braille-compatible plastic surfaces (Ungar et al., 2005). While voice guidance systems increase the understandability of maps, interactive screens and mobile applications stand out as innovative solutions that support accessibility. In addition, the ability of individuals with or without visual impairments to use the same map offers a more inclusive approach in education and social life.

Increasing automation in the map design process and shortening the production time provide significant advantages in terms of accessibility (Koch, 2012). Increasing the production speed, especially in maps developed for visually impaired individuals, enables faster responses to individual needs. In this context, interactive interfaces and multimodal technologies – such as voice guidance systems, touch screens and mobile applications – offer revolutionary innovations in terms of map design and user experience.

At the same time, the proliferation of large-scale web map systems has made open source data available to wider audiences, which has contributed to the increased adoption of automated cartography solutions (Brock et al., 2015). Thus, it has become possible to produce maps specific to different user groups in a short time and to present these maps in formats that appeal to multiple sensory organs.

Different printing techniques are used in the production of tactile maps. Studies based on user experiences show that rough paper and microcapsule paper are preferred more by visually impaired individuals (Ungar et al., 2005). In addition, voice feedback and mobile applications are considered as key components that increase the accessibility and ease of use of tactile maps.

This study aims to analyze the impact of tactile maps on accessibility and to provide suggestions for the development of existing systems and the implementation of new technologies. In the study, different techniques such as relief maps, 3D printing technologies, thermal expansion method and digital tactile maps were examined and their advantages and limitations were discussed. In addition, innovative applications such as TEKNOFEST "Talking Maps" project and London

Tactile City Map were evaluated and the effects of voice feedback and multimodal interactions on accessibility were discussed.

Material and Method

Accessible solutions such as tactile tube maps and embossed bus station maps are being developed to enable visually impaired individuals to move independently in public transportation and city planning processes. The London Tactile Tube Map is produced by embossing on plastic material and includes various surface textures to distinguish different tube lines. In this study, the methods used in tactile map production and the advantages of these maps in terms of accessibility are analyzed and how they can be made more effective for visually impaired individuals in different application areas are examined. In this context, different types such as embossed maps, maps produced with 3D printing technology, maps prepared with the thermal expansion method and digital tactile maps were evaluated.
Inclusion Criteria: The case study must feature a significant technological advancement in tactile map design, such as 3D printing, digital tactile maps, or integration with voice-guided systems The case studies must be derived from various geographical regions, ensuring a diverse perspective on the use of tactile maps in different cultural and urban environments. The case studies should involve active participation from visually impaired users in the development or testing phase, ensuring the maps are designed with user needs in mind. The case studies must demonstrate how tactile maps improve accessibility in public spaces, transportation systems, or educational environments for visually impaired individuals
Exclusion Criteria: Maps that are purely static and do not offer any form of interactivity, voice guidance, or multi-modal features will be excluded. Case studies that do not include feedback or testing from visually impaired users will be excluded from this analysis, as user-centered design is crucial for assessing the effectiveness of these maps Case studies limited to private use or small-scale applications (e.g., personal devices) that do not address broader societal accessibility needs will be excluded.

Findings

The findings of the study show that smart city applications and automatic map production systems have the potential to increase the spatial awareness of visually impaired individuals. In this context, the integration of new technologies is important to make accessible maps more inclusive and effective. In addition, the dissemination of accessible maps in education, transportation and daily life areas will contribute to the independent movement of visually impaired individuals.

Conclusion

The development of tactile maps that can be customized according to demand will provide solutions that are suitable for individual needs. Digital and voice guidance systems should be made more widespread, mobile applications and smart maps should be made accessible for visually impaired individuals. The use of tactile maps in education should be increased. In order to develop spatial skills of visually impaired students, relief maps and interactive educational materials should be made widespread. Public and private sector collaboration should be encouraged, and municipalities, transportation companies and tourism sectors should be directed to develop accessible map solutions for the visually impaired. In the future, the integration of tactile maps with interactive and smart technologies will provide more accessible and user-friendly solutions for visually impaired individuals.

Analysis of Customer Complaints in Mobile Communication Networks with GIS

Merve Tanur[a], Rahmi Nurhan Çelik[a]

[a] Istanbul Technical University/Graduate School, Department of Geomatics Engineering, Geomatics Engineering PhD Program, Türkiye
korkutanm@itu.edu.tr

Keywords: Big Spatial Data, GIS Applications, Mobile Communication Networks, Spatial Decision Support Systems, Spatial Planning.

Aim

In the telecommunications sector, the correct management of customer complaints, which helps to bring a product or process to higher quality, is seen as one of the biggest criteria of success. The main reason for complaints indicating the existence of deficiencies or malfunctions resulting from many reasons is that the service provided does not satisfy the customer. In order to resolve customer complaints quickly and accurately, the tools and methods used must be sufficient and appropriate to take rapid and accurate actions (Alabay, 2012). Since mobile communication networks have a dynamic and spatial structure, it is important that complaint management, which will be discussed within this scope, is also examined in a dynamic and spatial dimension (Zhu et al, 2019). The increasing market volume day by day brings with it increasing customer complaints. Considering the total number of mobile subscribers, including machine-to-machine communication (M2M) subscribers, reaching 94.5 million, corresponding to a penetration rate of 110.7% by the end of the third quarter of 2024 in Türkiye, the volume that can arise when each subscriber creates at least one complaint record reveals the importance of proper complaint management. The total number of subscribers to UMTS technology, which was launched in July 2009, reached 65.9 million by the end of March 2016. With the LTE technology that was put into service in April 2016, there was a transition period from UMTS subscription to LTE subscription. At the end of the third quarter of 2024, the number of UMTS subscribers was 4.6 million, while the number of LTE subscribers reached 87.5 million. When we consider the number of complaints submitted through the Online Consumer Complaint System of Information and Communication Technologies Authority in Türkiye on a quarterly basis, we see that among the consumer complaints made within the scope of mobile access at the end of the third quarter of 2024, the ratio of complaints regarding coverage area/service quality to total complaints was 21.2%. In addition, three mobile operators in Türkiye made investments of ₺6.1 million, ₺7.1 million, and ₺17.2 million respectively in 2023, reaching a total mobile investment value of approximately ₺30.5 million (BTK, 2024). In order for customer complaints to be resolved as quickly and correctly as possible, it is essential that every stage of complaint management is carried out meticulously. In this context, complaints must be understood correctly, categorized correctly, directed to the right places, and workflows must be adapted accordingly. In a dynamic mobile network structure, using customer complaints as a dynamic system input is very valuable in terms of planning and investment. Proper mobile network planning means making the right mobile investment. The fact that investment is being made in the right places in an effective, demand-driven mobile network planning process is an indicator of the effective use of mobile investment costs. New base stations installed to provide maximum benefit with minimum quantity are a powerful weapon in increasing customer satisfaction and reducing complaints, as well as increasing customer loyalty and increasing mobile market share. Customer loyalty, which is an important factor for companies to achieve a sustainable competitive advantage, is one of the keys to both company performance and growth (Kim et al, 2004).

Material and Method

This study will present an approach to analyze the complaints about mobile communication network design in GIS (Geographic Information Systems) environment and use these complaints as an input for future mobile communication network planning. Within the scope of the study, it will be analyzed from which perspective and how customer complaints obtained through different channels are evaluated in mobile network planning with UMTS (Universal Mobile

Telecommunications System) and LTE (Long-Term Evolution) technology. The spatial data subject to the study does not belong to any telecommunications company and consists of sample datasets produced entirely for academic purposes. This preference was intended to increase the objectivity and reliability of the scientific study. In this context, many different datasets such as customer complaint dataset for a one-year period, Türkiye province map, Türkiye geographical regions map, UMTS coverage map, LTE coverage map, land use map and settlement map were used. It is aimed to produce a comprehensive and rapid solution for this large spatial data by using GIS tools and methods. Due to the need to confirm the locational accuracy of customer complaint data obtained through different channels, data cleaning was performed by first eliminating data that was not located within the administrative borders of Türkiye. Complaints submitted for different reasons were classified according to the reason for which they were received and it was decided from which perspective the problem should be addressed. In this framework, questions such as which base station the customer complaint locations should be associated with in the GIS environment, in which time period the complaints increased the most, in which provinces and regions the most problems were experienced, in which land use areas the most problems were experienced, whether the location subject to the complaint was inside or outside the settlements were analyzed in detail. In addition, UMTS and LTE coverage maps were used to obtain signal levels at complaint locations separately for each technology. For both technologies, signal levels were divided into three different classes as good, medium and bad, and it was determined which level had more coverage complaints. After all the analyses, it was decided that the problems declared by the customer should be used as input in the next mobile planning phase as a result of matching the same problems on the technical side.

Findings

Within the scope of the study, two hundred thousand customer complaints collected from different channels within a one-year period were analyzed. It was observed that the rate of records falling outside the administrative borders of Türkiye was 1% after the process of removing records containing incorrect coordinate information from the data set for various reasons. The complaint type was divided into two classes as call and internet. Call type complaints had a distribution of 28%, while internet type complaints had a distribution of 72%. The sub-details of the problem types were divided into eight different groups. The problem detail with the highest rate was the lack of indoor coverage with a rate of 58%. The month in which the highest complaint occurred was January, while the city with the highest complaint was Istanbul with a rate of 15%. The region with the highest complaint rate among the seven geographical regions was the Marmara Region with a rate of 25%. The main cluster with the highest complaint was dense urban with a rate of 38%, while the sub-cluster was the city center with a rate of 65%. By looking at the distance of the existing base station near the place where the complaints occurred, the problem was tried to be addressed to one of the existing base stations. In this context, it was seen that the presence of an existing base station 150 meters or closer to the location of the problem was 15%. On the other hand, the rate of the place subject to the complaint being located within a settlement is 83%. Considering the presence of technology-based coverage in the complaint locations, the rates for UMTS outdoor, UMTS indoor, LTE outdoor, LTE indoor are 96.5%, 91.2%, 99.9, 99.5%, respectively. As can be understood from these results, the places subject to the complaint mostly indicate UMTS indoor coverage problems. According to the signal levels divided into three classes as good, medium, and bad, it was seen that 93% of the complaints came from places with good coverage, 5% from places with medium coverage, and 2% from places with poor coverage.

Conclusion

The impact of the solutions produced within the scope of this study on the sector will be of great benefit both technically and commercially. The fact that the benefits provided can be felt by both telecommunications companies and customers increases the importance of the study. It is important for companies to be able to analyse customer complaints at a spatial level in order to correctly identify the source of the complaint, take the right action and identify areas for improvement (Tanur et al, 2024). On the other hand, responses to complaints that are satisfactory and understandable to the customer, as well as feedback such as providing an estimated time for resolution, increase the sense of trust in the customer and positively support customer loyalty. The approach of this study on how to analyze customer complaints, which is one of the spatial inputs in mobile communication network planning in the telecommunications sector, with GIS is framed only with UMTS

and LTE technology since 5G technology is not yet available in Türkiye. Once 5G technology starts to be used actively in Türkiye, it will be necessary to examine similar processes from different perspectives. One of the things that is essential to ensure rapid adaptation to the 5G ecosystem is to create a scalable and sustainable infrastructure (Deloitte, 2022). In this regard, more base stations will be needed to achieve the desired level of 5G performance and effectiveness. Thus, the prediction that future complaints about the coverage and capacity of 5G technology will be greater than current complaints will further reveal the need for rapid action to be taken with GIS tools and methods of large spatial data. Since the customer satisfaction indicators of 5G technology (higher speed, lower latency, etc.) will be higher than the current UMTS and LTE technologies, it will be necessary and beneficial for different academic researchers to further enrich the scope of this study for 5G technology.

Keywords: LIDAR Technology, 3D City Model, Urban Transformation, Point Cloud, Urban Analysis.

Aim

In the past, with the migration of people living in the east of the country to Istanbul in the hope of finding work, the need for housing close to the areas where the migrants would work emerged. With the number of residential buildings in Istanbul being low compared to the incoming population, housing production came to the agenda. As a result of the rapid migration to the city and the fact that the people coming to the city for work purposes mostly belonged to low or middle-income households in terms of economic status, the way for the process of shantytowns was paved in order to meet the need for housing. With this wave of migration, some districts in Istanbul received more migration than other districts. Zeytinburnu district was one of the districts with the highest population in Istanbul during the period when migration from east to west began. It was observed that the number of houses produced as a result of shantytowns in the district after the wave of migration was quite high. When the existing building stock in the district is examined, it is concluded that there are quite a few illegal constructions in the buildings built in that period, and that buildings that are in need of transformation in terms of urban transformation and that carry earthquake risk should be subject to transformation.
Urban transformation works in the district are increasing day by day in order to increase the quality of life in the district and to create qualified and healthy housing structures. Urban transformation projects are implemented with the aim of both making existing structures safe and creating more livable areas. These transformation projects are carried out with the support of the public and private sectors, and a series of analysis and evaluation studies are required within the scope of the preparation processes in these processes. The transformation preparation processes are carried out by the relevant persons, institutions or organizations before the demolition and renovation processes of these structures, which are transformed by both the persons authorized to build by the parcel owners and the authorized institutions and organizations. The preliminary preparation processes in urban transformation are basically grouped under two headings: urban analyses that will include analyses regarding the existing building stock in the transformation area and cost calculations to be created together with these analyses. In line with these headings, studies should be carried out within the scope of the phase specified as the preliminary preparation phase, where all the analysis, research and calculation data needed are evaluated. In order to obtain the mentioned data at this stage, it is seen that it needs to be accelerated due to reasons such as the high number of relevant institutions and organizations from which data requests will be made through applications, the time-consuming processes of processing the obtained data and obtaining a feasibility study by making an evaluation. Within the scope of the study, it is aimed to accelerate the processes of obtaining these stages and to develop more reliable data collection by feeding with technological developments.

Material and Method

When urban transformation processes are examined in detail, it is seen that the stage that needs to be accelerated in urban transformation preliminary preparation processes is the collection of data obtained through field research, not obtained from relevant institutions, and this stage takes too much time, causing time loss in urban transformation studies. Trying technological methods that will minimize this time loss and being able to obtain preliminary preparation processes with less time, cost and damage is an important step for the acceleration of urban transformation. It is foreseen that by facilitating the collection of data in a short time without performing one-to-one measurements and photography on the relevant land

where urban transformation will be carried out, the loss of time will be prevented and healthier studies will be carried out as a result of providing fast and reliable data for the necessary urban analysis and feasibility studies in the preliminary preparation phase If we are to talk about the device, the measurements were made using a drone, which is an unmanned aerial vehicle, and this device is equipped with a LIDAR sensor.

Findings

An urban transformation area declared as a risk area in the district has been determined as a study area. It is thought that by measuring with a drone containing advanced laser scanning technology and producing 3D point cloud data and using this data in the production of a 3D city model, the resulting model and point cloud cluster will be used in the preliminary preparation studies to obtain information such as current area size, function, number of floors, urban voids, illegal construction, type and material information, and to produce base studies such as the current situation, thus providing direct savings in the number of personnel to be assigned in the field and time, and the margin of error in the obtained data will be less than collecting one-to-one data in the field, except for the margin of error obtained as a result of the measurement. In order to evaluate the quantitative accuracy of the studies, laser scanning technology is used to send laser beams to urban surfaces in the area determined within the scope of the study and to obtain a point cloud cluster with the X, Y, Z values obtained from the data reflected from this energy and to compare the obtained point cloud data with the current application project data and to investigate its statistical accuracy. By conducting ground-based measurements at four points around a randomly selected area, the obtained coordinates were matched with their corresponding points within the 3D point cloud data in the 3D Survey software, and error margin calculations were performed. Upon examining the results, it was determined that the error margin for the point cloud data corresponding to these four points was less than one.With this comparison study, the results regarding how close the measurements made with LIDAR technology are to the truth have been revealed. In particular, it is very important to determine the margin of error rate and prove the reliability of the study in estimation studies such as the distribution of the construction to the rightful owners and the approximate size of the construction area to be built. For this reason, the error rate in the study conducted using LIDAR technology was determined by considering the margin of error in the current application studies.

Conclusion

As a result, the time spent while carrying out urban transformation works in cities with earthquake risk such as Istanbul is of vital importance. It is seen that minimizing the time spent in implementing urban transformation works in the most healthy way is quite important when the multitude of structures in need of urban transformation are taken into consideration. For this reason, in order for these projects to be successful, technological methods should be used more effectively and data collection processes should be accelerated. In this study, important solutions are presented for accelerating the urban transformation pre-preparation processes of the construction areas that will be subject to urban transformation where risky structures are dense in order for urban transformation to be carried out successfully. In summary, the study demonstrates that with low cost and minimal manpower, it is possible to access up-to-date information with a low margin of error. It is anticipated that studies like this one will contribute to future research, regardless of changes in the location of the study area. Determining the ways of using the dataset obtained as a result of the study in a way that will contribute to urban transformation and design processes by creating a solid model, presenting the program and determining which urban analyzes that will guide urban transformation pre-preparation works together with this study as a final product will have a significant impact on the institutions and organizations responsible for accelerating urban transformation processes. This structure created to accelerate urban transformation pre-preparation works is an important step in terms of providing development in the field of urban transformation and improving time and economy management.

Mitigating Urban Heat Island Effects through Nature-Based Solutions: The Case of Istanbul

Gizem Baydı[a], Prof. Fatih Terzi[b]

Keywords: Urban Heat Island, Nature-Based Solutions, Urban Resilience, Istanbul

Climate change has become one of the most important environmental problems affecting cities on a global scale. Temperature increases caused by climate change have started to be felt more intensely in cities. The urban heat island effect (UHI) is a phenomenon that occurs as a result of urbanization and causes higher average temperatures in cities than in rural areas (Oke, 1982; Howard, 1818). UHI was first described by Howard (1818), who recorded that cities were warmer than rural areas. Later, in modern climatology, the UHI effect was systematically explained by Oke (1982) and reached its current definition. UHI is becoming an increasing problem, especially due to increasing surface permeability, decreasing green areas and thermal properties of building materials (Voogt & Oke, 1997).

The urbanization process exacerbates the urban heat island effect, leading to increased energy consumption, more frequent extreme heat events and increased public health risks (IPCC, 2014). According to a study conducted in a densely built metropolis such as Istanbul in Türkiye, increasing building density and decreasing amount of green space complicate thermal comfort conditions and increase the severity of the UHI effect (Okumuş & Terzi, 2021).

Although solutions have been developed to mitigate the UHI impact, traditional engineering-based approaches, such as highly reflective materials or cooling coatings, cannot ensure ecosystem services and environmental sustainability in the long term (Gill et al., 2007; Santamouris, 2015). To overcome these limitations, the concept of Nature-Based Solutions (NBS) has come to the fore. NBS was first proposed by the World Bank in 2008 as nature-based solutions to environmental problems. It was then conceptualized by IUCN (2009) and defined as a multifunctional strategy to strengthen the climate adaptation and resilience of cities in the European Commission's 2015 documents (MacKinnon et al., 2008; IUCN, 2009; European Commission, 2015).

When evaluated in the context of urban planning, according to studies, NBS provide many benefits such as regulating the microclimate, increasing thermal comfort and reducing carbon emissions by making ecological contributions. In this context, green roofs, vertical gardens and permeable surfaces are prominent practices to reduce the impact of UHI (Eggermont et al., 2015; Benedict & McMahon, 2002). However, questions such as how effective these practices are in different cities, in different morphological structures, and under which microclimatic conditions they work best are still under investigation. In particular, there are gaps in the literature on how effective NBS strategies are in densely built urban textures (Depietri & McPhearson, 2017).

Aim

The main objective of this study is to examine the role of nature-based solutions in mitigating the impact of UHI in the light of existing studies in the literature and to determine the most effective solution alternatives by comparatively analysing NBS applications on different surfaces (ground, roof and vertical) in a densely built-up area of Istanbul. For this purpose, microclimate simulations are performed using Ladybug software in the selected area and the cooling potentials of NBS applications are evaluated and analysed based on parameters such as surface and air temperature.

The research aims to contribute to the development of climate change adaptation strategies for urban planners, local governments and other decision makers in metropolises such as Istanbul.

Material and Method

In this study, microclimate simulations were conducted in a densely built-up area of Istanbul to assess the cooling potential of nature-based solutions (NBS) on the urban heat island (UHI) effect. The study is structured with a quantitative approach that allows for comparative analysis of different NBS scenarios.

Study Area Selection

Yenigün Neighbourhood in Bağcılar district of Istanbul was selected as the study area. This area was selected for case study due to its high building density, insufficient urban green space ratio, a texture in which different urban functions are intertwined, and limited natural factors affecting the microclimate (e.g. marine influences).
Furthermore, in the study conducted by Okumuş and Terzi (2021), the region including Yenigün Neighbourhood was identified as one of the areas with the highest surface urban heat island effect (SUHI) in Istanbul. In this context, the fact that the area offers a sample of areas with pronounced UHI impacts creates a suitable space to test the potential of nature-based interventions.
The simulations are conducted over an urban area of approximately 250x250 meters, allowing for a detailed assessment of the impacts at the local level. This scale is considered appropriate for both comparability of intervention scenarios and modelling detail and corresponds to the 200–300-meter range recommended in Emmanuel & Krüger (2012) for micro-scale urban climate modelling (Emmanuel & Krüger, 2012).

Data Sets and Analysis

The simulation studies were carried out using the Ladybug Tools plugin running in the Rhino + Grasshopper environment. Ladybug is an open-source environmental design tool that enables environmental analysis based on climate data and geometry. In this study, Ladybug Tools was used to calculate radiation load on surfaces of study area and simulated scenarios. (Roudsari & Pak, 2013).

The simulation process includes the following stages:

- Climate Data Integration – Climate data in EPW format for İstanbul was imported to Grasshopper-Ladybug environment. Direct and diffuse radiation values were used for cumulative sky matrix based on Perez Sky Model (Perez et al., 1990).
- 3D Spatial Modelling and Urban Geometry –The study area was modelled in 3D using Rhino. Buildings, roads and open spaces were recreated and assigned different surface categories (roof, ground, facade) to allow scenario-specific simulations.
- Radiation Analysis – Using Cumulative Radiation Analysis in Ladybug, the annual incident solar radiation (kWh/m²) on each surface and each scenario was calculated.

Simulation Scenarios

After analysing the current situation of the site, a total of three scenarios were defined:

- Scenario 1 - Ground Planting: Covering open areas and roadsides with grass and trees.
- Scenario 2 - Green Roofs: Planting scenario for all flat roofs.
- Scenario 3 - Vertical Gardens: Vertical gardens were applied to the south and west facades, which are most exposed to solar radiation. This choice was based on the expectation that these facades experience high levels of heat gain during the day and that the greening intervention would have the highest impact on thermal comfort (Perini et al., 2011; Wong et al., 2010).

Analysing the microclimate regulating effects of NBS in urban areas through simulations has been suggested in numerous studies (Gill et al., 2007; Norton et al., 2015). Open-source simulation tools such as Ladybug allow for rapid and comparative testing of different scenarios, making it possible to generate concrete data for planning decisions.

Findings

In this study, the effects of three different nature-based solution scenarios applied in urban area context on microclimate were evaluated through radiation analysis. The analyses were carried out on the basis of annual cumulative solar radiation (kWh/m²) and the extent to which each scenario reduces the energy accumulation on the surfaces was comparatively analysed.

The current situation, while most of the surfaces receive high radiation, green interventions on the ground and facades significantly reduced the radiation value. The ground green application scenario, despite having the smallest application area, provided the highest radiation reduction per m² (250 kWh/ m²) and was the most efficient scenario. Vertical green surfaces are the interventions that provide the highest radiation reduction in total (approximately 318.500 kWh). The green roof scenario was applied to a larger area but had more limited effect per m².

Table 1. Quantitative Findings of Simulation Analysis.

Scenario	Surface Area (m²)	Radiation Reduction (kWh)	kWh/m² Reduction	Cooling Potential per m² (°C)
SC1 - Green Ground	22686.54	58.500	2.57	0.01
SC2 - Green Roof	650.0	162.500	250.0	0.94
SC3 - Vertical Garden	22844.97	318.500	13.94	0.05

The results show that the effect of nature-based solutions vary not only according to the size of the application area, but also according to the orientation, location and urban context of the surface.

Conclusion

In the study, the microscale cooling potential of nature-based solutions applied in a dense built urban area with simulation based scenarios. Within the scope of the study three different nature-based solution application scenarios were modelled and the effects of these applications on solar radiation accumulation on surfaces were calculated and analysed. Radiation analysis conducted by Ladybug Tools plug in allows each scenario to be compared on annual basis based on energy load (kWh/m²).

According to the results, each nature-based solution intervention scenario provides different advantages in the spatial context. Vertical green surfaces provided the highest reduction in total radiation load. This was related with the size of the green facade areas and their orientation to the South-west in the scenario. On the other hand, ground green area scenario achieved the most efficient application for radiation load reduction. Despite it has the smallest application area, the radiation reduction per m². Green roofs, have a strong potential for generalizability throughout the urban areas despite having a lower unit effect.

From methodological aspect, Ladybug Tools enables rapid scenario generation with its open-source structure, however software limitations and detailed data cause some restrictions. In addition, since radiation analysis does not provide direct thermal data, it should be considered that this study provides a preliminary assessment framework.

As the result, it has been observed that even small nature-based solution interventions have positive effects in densely built urban areas, and this observation supports NBS applications in different scales in urban areas.

GEOLOGICAL ENGINEERING

Rock Mechanics

Detachments Induced By Thermal Cycling At Grain Boundaries of Fine Grained Marble

Dilek Karapınar[a], Yılmaz Mahmutoğlu[a], Orhan Apaydın[b],

[a] İstanbul Technical University, Faculty of Mining, Geology Engineering, Türkiye
[b] İstanbul Technical University, Faculty of Mining, Geophysics Engineering, Türkiye
dilekkarapinar@itu.edu.tr

Keywords: Afyon Sugar Marble, Sugaring, Grain Boundary, Thermal Cycling, Image Processing.

Aim

Marble is the most widely used type of stone in the construction of architectural elements in the historical period. However, it is sensitive to atmospheric factors and has limited durability. Factors such as rain, snow, cycling temperature changes, wind and pollutants have negative effects on the structural strength and appearance of such building blocks. Temperature can affect the rate of degradation and the pattern of salt migration in the stone. High temperature causes an increase in the rate of chemical change, low temperature causes freeze-thaw problem, and sudden temperature change causes internal stress due to different expansion (Mahmutoğlu, 2017).

The thermal expansion coefficient of the calcite mineral that forms the marble shows significant anisotropy. Heat-induced elongation along the c-axis, shortening in the a-axis direction and expansion in the opposite direction due to cooling occurs from the crystal axes. Dolomite mineral expands thermally in different amounts in each direction and shows elongation and shortening behaviour depending on heating and cooling. Therefore, this mineral is more resistant to degradation than calcite (Ruedrich et al., 2013; Shushakova et al., 2013). Due to the anisotropy in the thermal expansion coefficients of both minerals, permanent stresses develop at the grain joints due to temperature change. Kessler (1919) pointed out the permanent change in the internal structure of the material due to repeated heat treatment. Battaglia et al. (1993) showed that in heat-treated marble, even low temperature fluctuations can lead to irreversible permanent deformations that may result in failure and weakening. Siegesmund et al., (1999, 2000, 2008), Zeisig et al., (2002), Koch and Siegesmund, (2004), Luque et al., (2011) found that repeated heat treatment leads to a size change of about 1 mm/m and cohesion along grain boundaries is lost.

Due to its mineral composition, the periodic change in atmospheric temperature is of great importance in the disease of marbles. Although there are many different causes, the general view is that thermal cyclical is the main source of the event. Due to the thermal effect, sugaring problems occur in marbles.

The candied of marble, which is usually seen in the exterior elements of ancient and modern buildings, is one such degradation event. This term is derived from the transformation of calcite grains into sugar-like powder as a result of the dispersion of marble grains (Carfagni, 1999; Sassoni & Franzoni, 2014). Darot & Reuschle´* (2000), Mahmutoğlu (1998,2006), Ferrero and Marini (2001), Siegesmund et al., (2000b), Zeisig et al., (2002), Bandini and Berry (2013), Ghobadi & Babazadeh (2015), Khanlari & Abdilor (2015). Depending on the number of heat treatment periods, it was determined that the deterioration and opening between the calcite grains increased, and the cohesion along the grain boundaries of the material was partially lost (Mahmutoğlu 2006).

For this reason, in this paper, the tissue damage caused by the increasing and growing grain boundaries between the calcite grains due to heat treatment in Afyon (Sugar) marble, which is also widely used in our country, has been revealed by imaging the changing grain borders. This study aims to contribute to the literature in defining the behavior of Afyon Marble, which is used as a monument and decorative material, against thermal effect.

Material and Method

Material (Afyon Sugar Marble)

Marble, which is called finely crystalline Afyon Sugar, which is operated in the Afyon region, which has homogeneous and isotropic properties, was selected as the experimental material. Generally, the smooth-shaped grains are straight and slightly curvature, and the rock has a homoblastic texture. In the sections examined under the microscope, it was determined that the grain size generally varied between 0.5-2 mm (Figure 1a). According to the results of XRD analyzes performed to reveal the chemical content of marbles; It contains 96% calcite, about 2% dolomite and trace amounts of quartz. TG-DTA analyzes (Figure 1b) were performed on the marble sample in order to determine the thermal and gravimetric changes that occur in the material with the increase in temperature. According to the results of the analysis, the critical temperature values of the sample were seen as 900-950ºC.

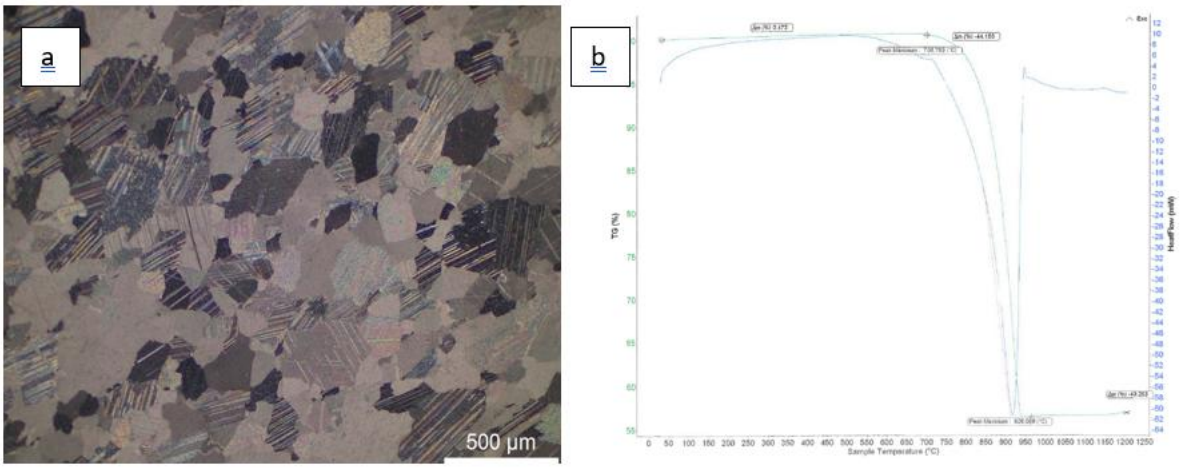

Figure 1. Optical microscope image of Afyon (Sugar) Marble (a), TG-DTA analysis (b).

Sample Preparation and Heat Cycling

The homogeneous and isotropic fine crystalline marble called Afyon Sugar, which is operated in Afyon region, was selected as the experimental material. Generally, the grains are straight and slightly curved and the rock has a homoblastic texture. It was determined that the grain size generally varied between 0.5-2 mm in the sections examined under microscope (Figure 1a). According to the results of XRD analyses performed to reveal the chemical content of the marbles; it contains 96% calcite, approximately 2% dolomite and trace amounts of quartz. TG-DTA analyses (Figure 1b) were performed on the marble sample in order to determine the thermal and gravimetric changes that occur in the material with increasing temperature. According to the results of the analysis, the critical temperature values of the sample were 900-950ºC. In other words, it is predicted that no endothermic reaction will occur as long as this material does not reach this temperature.

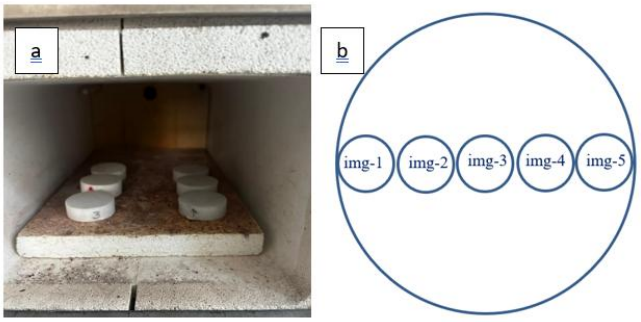

Figure 2. Marble samples subjected to heat treatment (a) and representative locations of photographic locations taken from sections (b).

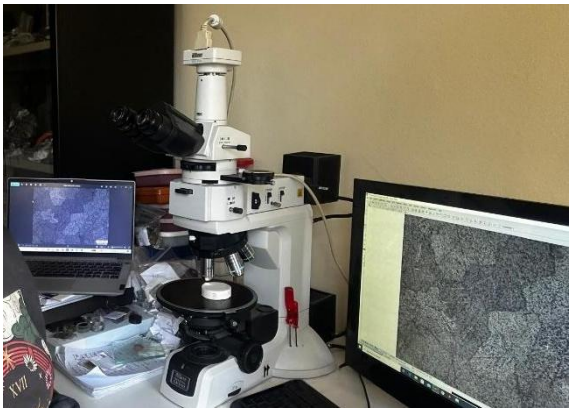

Figure 3. Photographing polished sections.

Processing of Images

The sample images were imaged and processed using the Matlab programme. The images were read in the programme in grayscale (0-255) and then a histogram of the pixel values of the image was drawn (Figure 5b). Grain boundaries appear dark (black). Pixel values below the threshold value (65) determined from the histogram were considered to correspond to this darkness. In addition to these dark colours, grain boundaries and discontinuities, it is seen that the heat interactions are negligible as a result of the follow-up of the sample from its original state. The regions below the determined threshold values were visualised with white colour (Figure 5c). Then the ratio of the area below this threshold value to the whole image was calculated (Figure 5d).

Findings

The photographed area in the A0 sample was re-imaged as the A4 sample after 4 times heat treatment. A certain area of both images was magnified and examined in detail (Figure 4a,b). In these regions, the images were processed (Figure 5) and it was observed that the grain boundaries of the same sample, which was subjected to heat treatment 4 times, grew and new borders were formed.

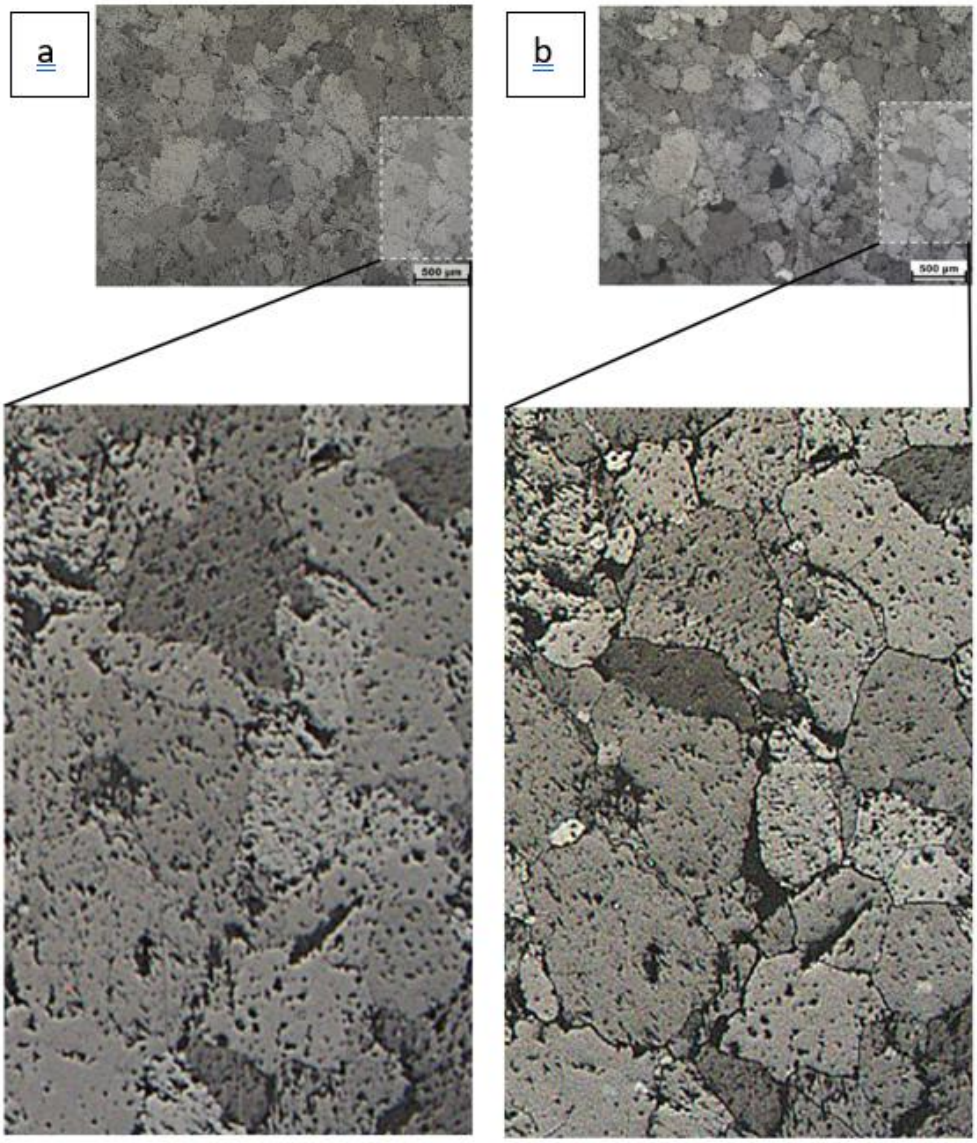

Figure 4. Detailed image of the A0 sample and its specific region (a), A4 sample and its detailed image of the specific region (b).

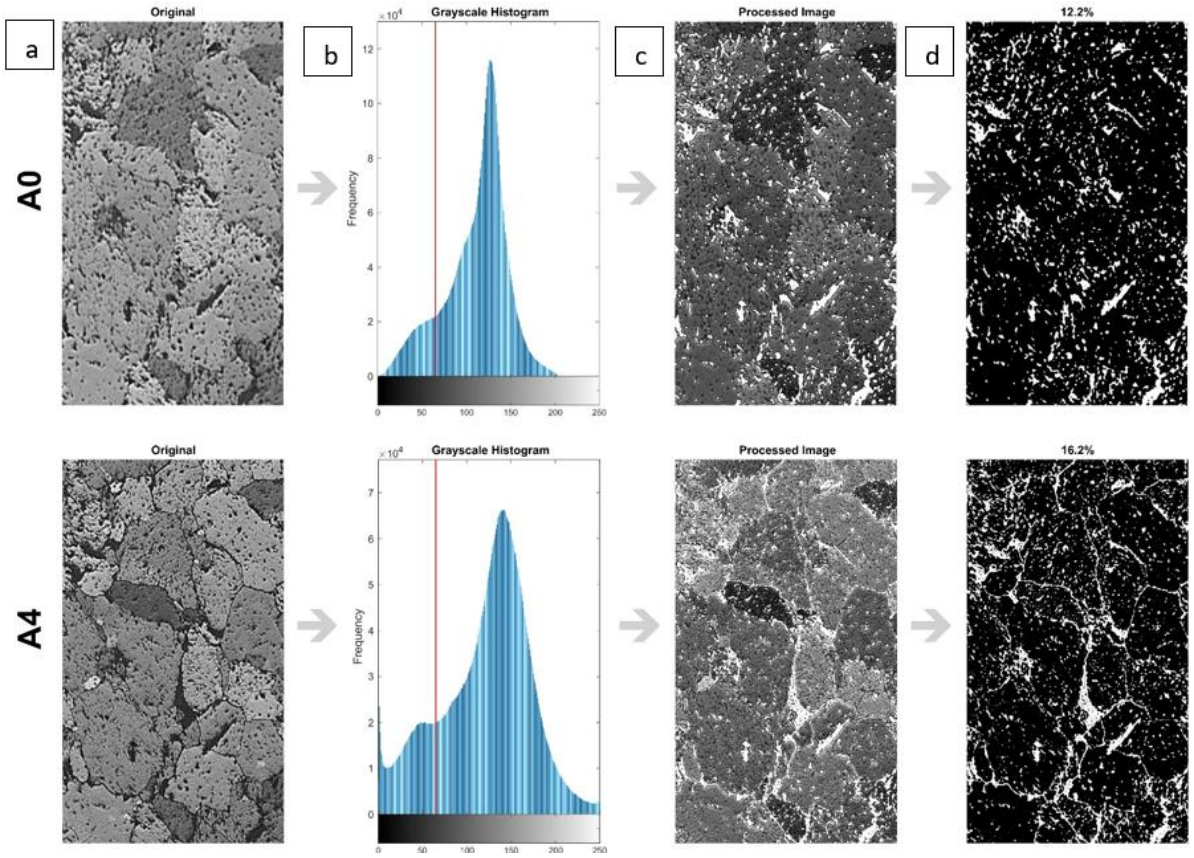

Figure 5. (a) Image of the original (A0) and heat-treated (A4) regions of the same sample, (b) grayscale histogram of the images, (c) representation of places below the threshold, (d) representation of varying grain boundaries.

Conclusion

The region determined in the original Afyon Marble, which was not heat treated, was photographed after heat treatment 4 times and the ratio of the black regions of the picture determined as the threshold value to the total area of the picture was calculated. This ratio was calculated as 12.2% in the A0 sample and 16.2% in the A4 sample. It was observed that the darkest black regions seen in the photographs are also seen in the natural state of some minerals along with the grain boundaries. In the calculation made by neglecting the effect of heat treatment on the black areas outside the grain boundaries, the relative areal increase in the grain boundaries caused by heat treatment in the examined region was calculated as 4%.

On the Role of Earth Observations and Geodetic Data in Environmental and Climate Change

Solmaz Farnad[a*], Bihter Erol[a]

[a] Istanbul Technical University, Geomatics Engineering Department, Türkiye
farnads22@itu.edu.tr

Keywords : Climate Change Impact, Geodetic Data Integration, Groundwater Depletion Monitoring, Satellite Earth Observation, Sustainable Water Management.

Aim

1. Environmental Challenges and the Need for Monitoring

The Earth is facing numerous environmental challenges that are increasingly jeopardizing natural ecosystems and human welfare. Climate change, resource depletion, and rising human activity are intensifying these threats. One of the most urgent concerns is the depletion of groundwater resources, which are essential for agricultural production, industry, and human consumption. Groundwater is a critical resource in many parts of the world, particularly in regions with limited access to surface water, such as arid and semi-arid zones (Kala and Kumar, 2022).

In Türkiye, as in other countries, the depletion of groundwater is becoming a growing problem. Regions that rely heavily on groundwater for irrigation and drinking purposes are experiencing heightened water stress (Baykal et al., 2024), driven by both unsustainable water extraction and shifting climate patterns. This highlights the need for reliable and sustained monitoring of groundwater to inform resource management policies. However, widespread monitoring remains difficult due to the challenges of obtaining comprehensive in-situ data and the complexity of hydrological dynamics.

Satellite-based Earth observation systems are vital in addressing these challenges, enabling the tracking of environmental changes across large areas and over extended periods (Müller and Pail, 2022). These systems detect shifts in Earth's gravitational field, which correlate with changes in mass distribution, such as groundwater depletion or replenishment. As changing precipitation patterns and increased water scarcity worsen, these satellite datasets provide invaluable insights into groundwater dynamics, enabling early detection of resource loss and improved management strategies (Li et al., 2022).

2. Aim and Objectives of the Research

The goal of this research is to demonstrate how satellite-derived geodetic data, specifically from GRACE (Gravity Recovery and Climate Experiment) and GRACE-FO (GRACE Follow-On), can be used to monitor and analyze environmental changes, with a particular focus on groundwater depletion in Türkiye. Groundwater scarcity is a growing global issue, especially in areas where climate change and poor water management practices exacerbate water shortages. This study presents a novel approach by providing a detailed, region-specific assessment of groundwater fluctuations in Türkiye, contributing to global efforts to tackle this pressing issue. By analyzing GRACE and GRACE-FO satellite data from 2013 to 2025, this research will assess the effects of climate change on groundwater resources and provide valuable insights into trends in water availability.

The primary objective is to use GRACE and GRACE-FO data to track groundwater depletion and pinpoint areas in Türkiye that are experiencing increasing water scarcity. By integrating these satellite-based data with climate models, the research will help predict the future trajectory of groundwater resources, offering a new perspective on areas at risk of significant depletion and providing guidance for future water management strategies.

Additionally, this research will refine the application of GRACE and GRACE-FO data in areas where traditional ground-based monitoring methods are limited, contributing to the development of a global groundwater monitoring system that can be applied universally, advancing the field of environmental monitoring in innovative ways.

Material and Method

1. The Role of Earth Observations and Geodetic Data

Geodetic methods, particularly those relying on satellite observations, have transformed our capacity to track Earth's hydrological activities (Müller and Pail, 2022). The GRACE and GRACE-FO missions represent major advancements in this field, measuring subtle changes in Earth's gravitational pull caused by mass redistribution, such as the movement of water between land, oceans, and ice. These missions offer essential data on fluctuations in groundwater over time and space, providing precise estimates of groundwater availability and assessing the influence of climate change on this vital resource.

The GRACE mission, launched in 2002, revolutionized our understanding of water storage shifts, particularly in areas dependent on groundwater. GRACE-FO, launched in 2018, builds on this work by offering greater accuracy and precision in tracking these changes. The GRACE-FO mission uses cutting-edge technologies to monitor gravity variations, which enhances our ability to track groundwater resources and better understand the effects of climate change on water availability (Xiang et al., 2023).

The data from GRACE and GRACE-FO satellites is indispensable because it provides a global perspective on groundwater depletion, significantly extending monitoring beyond traditional ground-based methods. By integrating this data with local climate models, researchers can obtain more comprehensive insights into the ways climate change and alterations in land use influence groundwater resources. This integration allows for the analysis of critical parameters like precipitation patterns, temperature shifts, and evapotranspiration, helping to predict future water availability trends and enabling more informed water management decisions.

Moreover, GRACE and GRACE-FO are essential for studying the interactions between groundwater, surface water, and atmospheric factors. For instance, changes in groundwater storage can affect river systems, wetland environments, and agricultural output. Tracking these interactions provides insights into how climate change may alter regional water cycles and the overall availability of water resources (Li et al., 2024a).

2. International Collaboration and the GGOS

Given the global scope of environmental challenges such as groundwater depletion and climate change, international cooperation is indispensable for tackling these issues effectively. The Global Geodetic Observing System (GGOS) plays a pivotal role in fostering international collaboration in Earth observation (Plag and Pearlman, 2009). GGOS facilitates worldwide cooperation to collect and distribute geodetic data, ensuring that measurements of the Earth's physical properties, such as its shape, gravitational field, and rotational dynamics, are precise and consistent across different regions and time periods (Sehnal et al., 2024b).

By synthesizing data from various satellite missions, GGOS helps create global geodetic reference frames, which are vital for better analyzing and understanding Earth dynamic processes. These reference frames are used to monitor shifts in water storage, sea-level rise, land subsidence, and other phenomena affected by climate change. Observing Earth's hydrological systems and tracking changes water budgets come in front of the studies which require a unified geodetic infrastructure and data with global coverage. The fusion of geodetic data with climate models further refines predictions about future water availability and strengthens efforts to develop sustainable water management strategies.

The collaboration facilitated by GGOS is particularly critical for monitoring groundwater depletion, as it ensures that data gathered from different satellite missions and countries can be integrated into a unified framework. This enables researchers to track groundwater changes on a global scale, offering insights into areas where groundwater depletion is most severe, and helping policymakers to prioritize water management strategies accordingly (Sehnal et al., 2024a)

Findings

The findings from this research will significantly enhance our understanding of groundwater depletion in Türkiye and provide valuable insights for local water management strategies. By integrating GRACE and GRACE-FO satellite data with climate models, this study will improve our comprehension of how climate change influences groundwater resources, offering predictions that can guide future water management practices.

Conclusion

This research provides a comprehensive overview to the contribution of Earth observations and geodetic data to the studies on environmental and climate change, with a case study of groundwater budget analysis. The methodology developed in this research provides a structured approach for future studies in the case study area. It presents a systematic method for monitoring groundwater changes, which can be adapted to regions facing similar water scarcity challenges. This work will contribute to sustainable water management and climate change adaptation, offering a solid foundation for emerging researchers and future investigations on both local and global scales.

Keywords : Spatial Issues, Hospital Campuses, GIS.

Aim

One of the important application areas of Spatial Information Systems (SIS) is health-related research, planning and administrative processes using Geographical Information Systems (GIS) Technologies (Pandery ve Karnatak, 2025). GIS technologies significantly increase the quality and efficiency of health research by establishing the link between public health and geographic location (Nykiforuk ve Flaman, 2011). GIS applications provide the opportunity to make data contribution and analyses on many basic health issues such as regional development and spread of diseases, development of disease prevention and control approaches, analysis of disease risk factors and planning of health screening services (Biu vd., 2024). One of the most important application areas of GIS is health-related research, planning and administrative processes (Mitropoulos vd., 2006). Thus, the use of GIS enables managers to make informed decisions on issues such as facility location selection and optimizing resource allocation. With each passing day, the role of GIS applications in the strategic planning and management of healthcare facilities is increasing due to demands for more efficient and higher quality healthcare services (Neutens, 2015). GIS contributes to determining the level of accessibility to health services of different populations and creating solutions thanks to spatial data such as transportation times, transportation networks and geographical barriers (Khashoggi ve Murad, 2020).

In this study, the difficulties in reaching the hospital campus area and the health units within the campus, spatial inadequacies and spatial data quality were investigated specifically for three large hospitals with campus structures. The aim of this study is to determine approaches that will contribute to more efficient use of resources in state and private health institutions and to the most efficient and easy access of patients to hospital services, through the correct spatial analysis method.

Material and Method

While creating the sample, care was taken to ensure that the selected hospital campuses included all branches of medicine and differed in terms of establishment date and financial possibilities. In accordance with this purpose, a faculty of medicine affiliated to a state university with a campus structure in Istanbul (Istanbul Faculty of Medicine), a faculty of medicine affiliated to a foundation university (Koç University Faculty of Medicine) and a city hospital with a campus structure (Başakşehir Çam and Sakura City Hospital) were selected.

Interviews were conducted with people who worked in managerial positions (deputy chief physicians) in these hospital campuses, and the current status of the campuses and spatial problems were questioned. In addition, spatial data such as the establishment year of the campuses, settlement area, distance to main roads, earthquake effect, reconstruction process and student education were obtained from publicly available sources. In the light of the existing data, the spatial adequacy status of the campuses, ease of access to health units and inadequacies in spatial data infrastructure were discussed in light of the literature and solution suggestions were presented.

Findings

When the adequacy level of the spaces, ease of transportation and finding units and SIS were questioned regarding the Istanbul Faculty of Medicine (IFM), Koç University Faculty of Medicine (KUFM) and Başakşehir Çam and Sakura City Hospital (BÇSCH) campuses (Table 1).

It was stated that larger areas were needed in the IFM and KUFM campuses, while the areas in the BÇSCH campus were sufficient for now. When hospital administrators were asked whether patients and their relatives had difficulty finding the areas they were looking for on the campus, it was stated that they had difficulty for the IFM and KUFM campuses, while it was stated that there was a good directional sign system for the BÇSCH campus and there were colored directions on the roads. While it was stated that there was no SIS in which the spatial coordinates of the units were registered for the IFM and KUFM, it was stated that the SIS integrated with the Turkish national geographic information system for the BÇSCH was available and updated, and that a navigation system was established for employees and citizens where settlement coordinates could be seen, but it was not active. While a negative response was received to the question of whether spatial changes were recorded in SIS for the IFM campus, it was stated that spatial changes were recorded in SIS for the KUFM and BÇSCH campuses. It was stated that important spatial information such as emergency exits and fire extinguishing instructions for the IFM, KUFM and BÇSCH campuses are posted in visible places and recorded in SIS.

Table 1. Questions and answers regarding the spatial structuring and spatial information system (SIS)

Interview questions	Istanbul Faculty of Medicine Campus	Koç University Faculty of Medicine Campus	Başakşehir Çam and Sakura City Hospital Campus
Are the existing areas and spaces on the hospital campus sufficient? Is there a need for new areas?	There is a need for larger areas for clinics. There is a need for sports fields, green areas, sitting areas and parking areas.	It is not enough, new areas are needed.	Since hospitals are dynamic structures, new areas may be needed over time, but for now it is sufficient.
Are hospital staff and/or patients having difficulty finding the places they are looking for?	Yes, they are struggling. That's why we put consultants on the ground floor of many buildings.	In hospital corridors, we often encounter patients looking for a department.	There is a good signage system. There are also colored directions on the roads.
Is there a SIS in which spatial settlements are registered?	No, it does not exist.	No, it does not exist.	There is but it is not active
Are the units spatial coordinates available? Is it integrated with the Turkish national geographic information system? How often is SIS updated online?	No, it does not exist.	No, it does not exist.	It is registered and updated in the national information system.
Is there a SIS available to employees where location coordinates can be viewed?	No, it does not exist.	No, it does not exist.	There is a navigation system for employees and citizens, but it is not active.
How are spatial changes monitored? Are spatial changes recorded in SIS?	It is known where the sections were moved to, but the detailed layout is unknown.	Spatial changes are regularly recorded in their own systems and announced internally.	When changes are made, they are recorded in the system.

Is important spatial information, such as emergency exits and firefighting instructions, recorded in visible locations and in the SIS?	There is a system that works very well.	There is a record in the fire automation system, and there are also emergency escape sketches on the floors and walls of common areas.	Yes, it is mandatory according to our quality system.	of hospital

campuses.

Spatial data such as the establishment year, area (m²), distance to main roads and earthquake impact and reconstruction process obtained through literature review regarding the IFM, KUFM and BÇSCH campuses are given in Table 2.

Table 2. Spatial data for three hospital campuses.

Spatial data	Istanbul Faculty of Medicine Campus	Koç University Faculty of Medicine Campus	Başakşehir Çam and Sakura City Hospital Campus
Year of foundation	1944 and following years	2014	2020
Campus land area	Campus area:110.000 m²	Campus area:214.000 m²	Land area: 789.031 m²
Distance to main roads	- E5 (D100): 3-4 km - TEM (E80): 5-6 km - Metro 900 m - Tram line 200 m	- E5 (D100): 1-3 km - TEM (E80):7-9 km	-European Motorway: 4 Km -Istanbul Airport: 30 km -To the Anatolian Side:25 km - Metro line passes under the hospital.
Earthquake impact and reconstruction process	After the 1999 Gölcük Earthquake, some campus buildings suffered serious damage. For this reason, reconstruction was initiated as of the beginning of 2020.	Earthquake resistant structures were built using earthquake isolators and modern engineering technologies.	The buildings are constructed to be earthquake resistant.
Student education on hospital campus (2024)	- Faculty of Medicine (360 Students)	- Faculty of Medicine (41 Student) - Faculty of Nursing (41 Student)	No undergraduate education

Conclusion

The increasing number of patients observed every passing day, technological developments creating a need for new areas, and requirements such as parking, green areas and social facilities cause the existing campus areas to become insufficient over time. When choosing a location for hospital campuses, many factors such as short-term and long-term regional needs, financial opportunities, suitable land selection, and equal and accessible service provision gain importance. When the construction process of IFM is examined, it is seen that its establishment dates back to the Second World War (Url-2). In 1967, Cerrahpaşa Faculty of Medicine was separated as a separate faculty and the remaining part on the Capa campus continued its services under the name of IFM. The buildings of the Faculty of Dentistry, which continued its education on the Capa campus, were completely separated from the Capa campus in 2019 due to severe damage due to earthquakes. Since it was established on a limited land of 110 acres, the Çapa campus area is insufficient to meet today's needs (Table 2). Due to the old campus buildings and the negative effects of the earthquake, a reconstruction process has been initiated in IFM, which has negatively affected education, healthcare services, spatial services, access to units and SIS. On the other hand, the KUFM campus, which was completed in 2014, and the BÇSCH campus, which was completed in 2020, were established on larger areas (Url-1; Url-3). While it was stated that new areas were needed for the KUFM campus, it was emphasized that the existing area for the BÇSCH campus was sufficient for now, but since hospitals are dynamic structures, new areas may be needed over time (Tablo 1). Proximity to main roads is considered a positive variable for all three campus locations (Table 2).

GIS plays an active role in solving fundamental problems such as patient access and effective healthcare delivery by facilitating the planning of healthcare services (Shaw, 2017). Experience with three hospital campuses demonstrates the importance of GIS in selecting an optimum location with equal accessibility for patients that can meet healthcare expectations and educational needs.

Statement

This paper constitutes a part of the doctoral thesis titled Researching Spatial Data Quality and Attributes for Spatial Analysis and Testing on a Project (Mekansal Veri Kalitesi ve Niteliklerinin Araştırılması ve Bir Proje Üzerinde Test Edilmesi), which is currently underway at Istanbul Technical University, Graduate School, Geomatics Engineering Doctoral Program.

Social Vulnerability Analysis of the Cities Affected by the February 6 Turkey Earthquake

Hilal Akın[a], Himmet Karaman[a]

[a] Istanbul Technical University, Graduate Institute, Geomatics Engineering Program, Türkiye
[a] Istanbul Technical University, Faculty of Civil Engineering, Department of Geomatics Engineering, Türkiye
akinh22@itu.edu.tr

Keywords : Social Vulnerability, February 6 Earthquake, Spatial Statistic.

Aim

Since the first years of human existence on earth, earthquakes have been one of the most destructive disasters causing irreversible material and moral damages. Located on the Alpine- Himalayan tectonic belt and under the influence of active tectonic movements, Türkiye has faced many devastating earthquakes throughout its history. The second largest earthquake that happened in Turkey in the last 100 years was the 7.7 and 7.5 magnitude earthquake that occurred in Pazarcık district of Kahramanmaraş province on February 6, 2023. The aim of this study is to determine the level of vulnerability of local governments and the public to disasters through data such as demographic, socio-economic, cultural, and humanitarian attitudes, to conduct disaster preparedness studies with the analysis of the results obtained, and to conduct social vulnerability analysis, which is used to create more resilient societies to disasters, in 11 provinces affected by this earthquake. The study will not only determine the social vulnerability after the earthquake, but will also examine the solution methods applied in the subsequent processes and the material and moral damage repair works.

Material and Method

Through social vulnerability studies using Geographic Information Systems (GIS), a tool of geomatics, social vulnerability can be analysed, mapped and visualized, and different assessment methods can be proposed. In this study, the news prepared and published by Anadolu Agency and Cumhuriyet Newspaper from February 6, 2023, the date of the earthquake, until February 6, 2024, were first collected to obtain raw data, and 3824 news items were analyzed to study the long-term effects of the earthquake. The news content was then categorized into 24 sub-headings to see the socio-economic, demographic and other impacts on society. In the rest of the study, numerical data will be obtained using the Statistical Package for the Social Sciences (SPSS) program, which is used in many fields from health to engineering for analysis, visualization and evaluation. The extrapolation method, which allows comments and predictions to be made about the future using existing data, examines factors such as migration and urbanisation, housing and infrastructure, social support programmes, the impact of education and employment policies. However, it should be borne in mind that there may be calculation errors due to the uncertainty factor and insufficient data. In order to visualize the data, the data shared by the state was transferred to the ArcGIS program via Excel files. Then, the migration data was integrated by coordinating them onto the provincial administration border data shared by the General Directorate of Mapping of Türkiye. The map was colored according to the number of migrants and figure 2 was created.

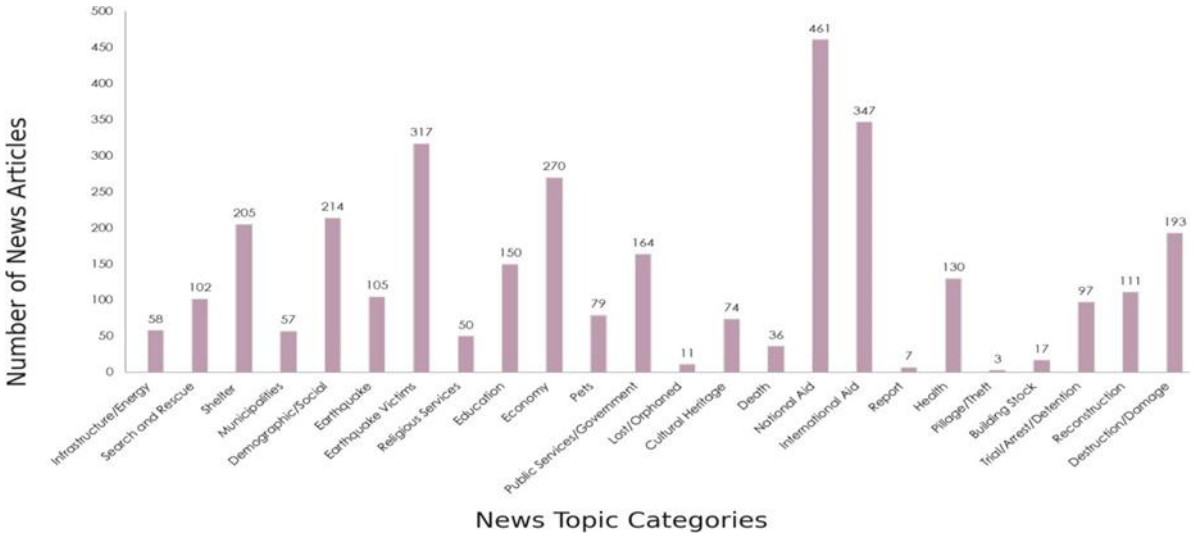

Figure 1. Distribution graph of earthquake-related news into 24 subcategories.

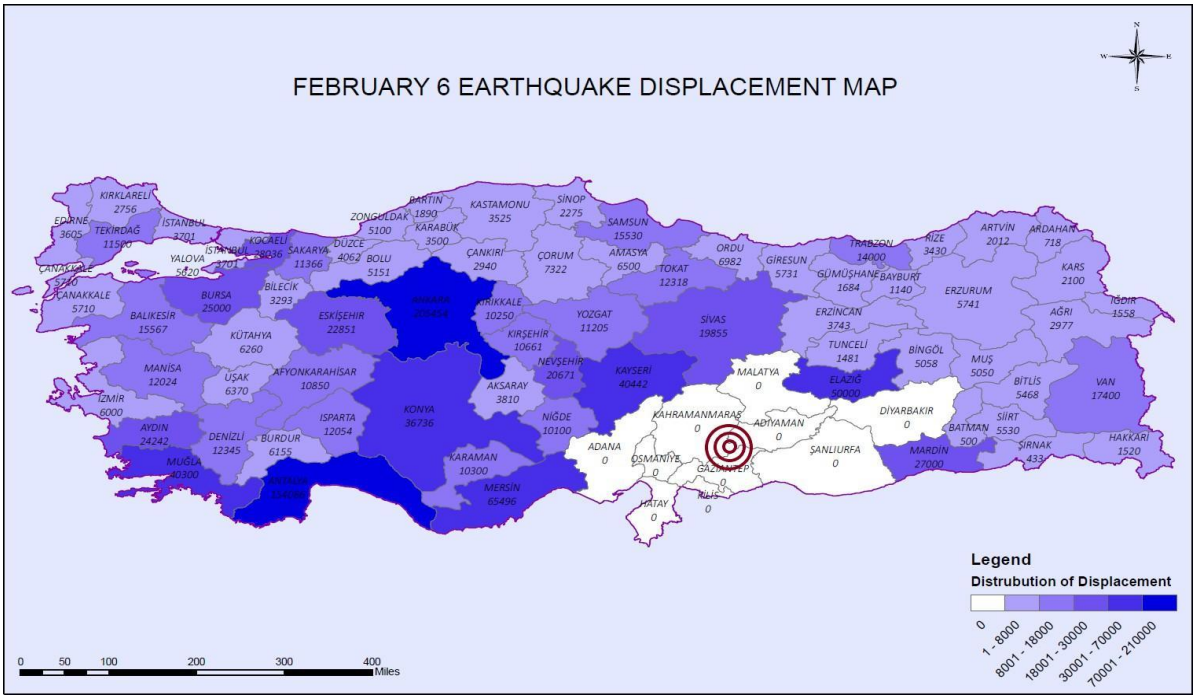

Figure 2. Map showing the migration of people displaced by the earthquake.

Findings

In the literature review, Armaş and Gavriş (2013) conducted a social vulnerability study of Bucharest, Romania, which has the highest earthquake risk in Europe. Factors such as elderly population density, income distribution, housing quality and living conditions were identified for the analysis. SoVI (Social Vulnerability Index) and SEVI (Spatial Multi-Criteria Social Vulnerability Index) were used as multi-criteria measurement methods. The results show that the most vulnerable regions are concentrated in the central and outer areas. As a policy recommendation for local governments, the importance of working on disadvantaged regions is emphasized.

In his study, Fekete (2019) started with a case study of social vulnerability in Germany and reviewed a total of 63 different scientific articles. In his study, he emphasised the importance of using common parameters for more reliable assessments, even if the results of social vulnerability analysis are close to reality and accurate. He concluded that the focus should not be on the results of the analysis, but rather on developing systems for understanding vulnerability analysis by administrations and the public, and for integrating it into everyday life.

On the basis of the information obtained, the study seeks to answer questions such as whether kinship relations have an impact on the spread of evacuations from the earthquake zone to the rest of the cities in the country, which districts are chosen for settlement, what are the reasons for moving, what is the rate of unemployment in the abandoned earthquake cities, whether there is a return, where the aid areas are concentrated, how long it takes for the aid to arrive, how many different institutions and organisations provide aid, and whether the migration areas are also aid areas.

For example after the news was separated according to cities, it was seen that the migration was not only from the earthquake zone to other cities of the country, but also from villages to cities within the city borders, from apartment buildings to state dormitories, among the cities in the earthquake zone for a certain period of time due to the teams and volunteers who came for aid.

Conclusion

Turkey is a country that has a high probability of facing many disasters due to its geological structure and geographical location. Although earthquake safety, precautions, strategic plans and public awareness activities have been accelerated as a result of major earthquakes, the February 6 earthquake with a magnitude of 7.7 and 7.5 centered in the Kahramanmaraş Pazarcık district has shown that the local government and the public still have a long way to go in terms of combating disasters. This study aimed to analyze the regions most affected by the February 6, 2023 earthquake in terms of social, physical, administrative components and economic factors, which are sub-classes of social vulnerability. For instance as a result of the statistical data obtained from the migration numbers, it was observed that there were almost equal numbers of incoming benevolent to those who left the region on the day of the earthquake. The remainder of the study will continue to show such results. The main findings obtained as a result of examining 3824 earthquake news items that constitute the study materials are that the people in the earthquake region are not aware of the extent of the devastating effects of disasters and that individuals in the construction sector have not worked with sufficient seriousness and responsibility and have only developed structures built on concrete and brick.

Spatial Analysis and Optimization of E-Commerce Company's Parcel Collection Operations: The Case of Esenyurt, Istanbul

Fatma Reyyan Sarıkaya[a], Adalet Dervişoğlu[b]

[a] Istanbul Technical University, Geomatics Engineering Program, Türkiye

[b] Istanbul Technical University, Civil Engineering Faculty, Department of Geomatics Engineering, Türkiye

sarikaya22@itu.edu.tr

Keywords : Spatial Analysis, E-Commerce Logistics, Geographic Information Systems (GIS), Network Analysis, Multi-Criteria Decision Making (MCDM).

Aim

The rapid and continuous expansion of the e-commerce sector has significantly increased the complexity and sophistication of logistics operations. Thus, it is necessary to develop highly adaptable management strategies to meet both efficiency and changing consumer expectations.The e-commerce supply chain consists of several stages, including order processing, parcel collection, sorting at branch offices, and last-mile delivery (Figure 1). Among these, both parcel collection and last-mile delivery are critical processes that directly influence customer satisfaction and overall operational performance. While last-mile delivery has received considerable attention in academic and industry research, parcel collection — the first operational phase in the logistics chain — remains relatively underexplored despite its foundational importance.

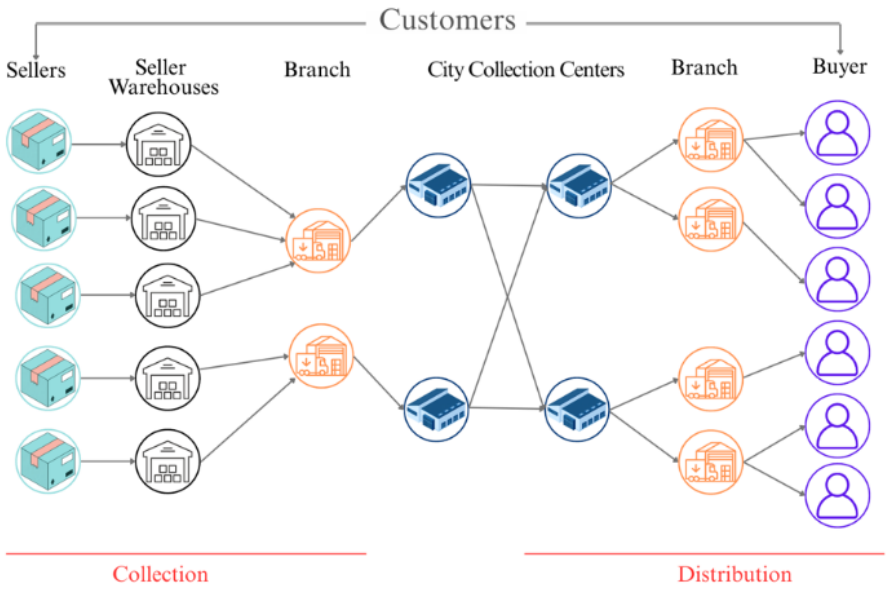

Figure 1. E-Commerce Logistics

Parcel collection operations in rapidly growing and densely populated metropolitan areas, such as Istanbul, face a range of challenges. These include heavy traffic congestion, limited road accessibility, growing shipment volumes, and restrictions on vehicle capacity and fleet availability. Logistics companies must transport parcels efficiently from a wide range of geographically dispersed collection points to their associated branch offices. This task becomes even more complex when companies aim to optimize route planning, manage fleet operations, and meet strict time constraints simultaneously.

This study specifically focuses on the spatial analysis of parcel collection operations in Esenyurt, a high-density urban district on the European side of Istanbul. Esenyurt is known for its significant residential population and fast-growing e-commerce activity, making it a critical area for urban logistics research. This research aims to assess the spatial distribution of collection points, evaluate the capacity and configuration of vehicle fleets, and examine the efficiency of parcel transportation from the field to branch-level facilities. By identifying both spatial and operational inefficiencies, the study intends to offer data-driven recommendations for improving logistics strategies in complex urban environments.

Material and Method

This study was based on logistics data from the day with the highest shipment volume to comprehensively evaluate the parcel collection system. The study area is Esenyurt, one of the most densely populated and logistically active districts on the European side of Istanbul. The analysis focuses on the peak period in November, specifically on 29 November 2024, which was identified as the busiest day in terms of shipment volume, with a total of 104,508 parcels processed. Figure 2 illustrates all parcel collection points along with the locations of the two branch offices.

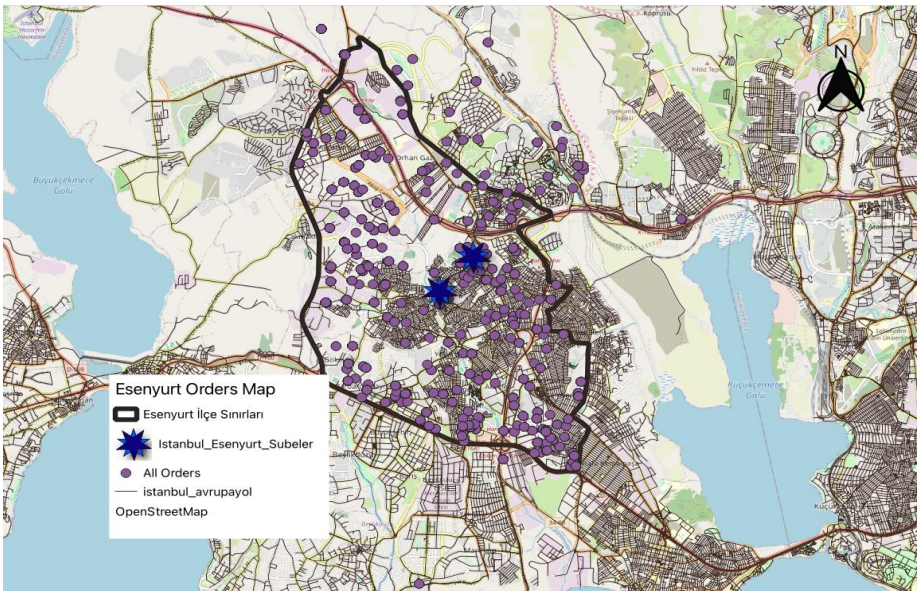

Figure 2. Esenyurt Orders Map.

This high volume was distributed between two main branches operating in the district: Esenyurt and Haramidere. The Esenyurt branch was allocated 9 vehicles, while the Haramidere branch was assigned 8 vehicles. Each vehicle had a capacity of 15,000 desi, defining a significant operational framework for daily parcel collection. As a result of field operations, 65,993 orders were successfully collected, whereas 38,515 orders remained uncollected, indicating that the system's available resources were insufficient to meet the full demand and that operational capacity limits were exceeded.

Analyzing operations on this peak day provided important insights into systemic bottlenecks, network capacity, and operational stress points within the existing infrastructure. The dataset includes detailed information such as the geographic coordinates of collection points, parcel dimensional weights (in desi), daily shipment volumes handled by each branch, and the time-dependent flow of orders throughout the day. All routing and accessibility analyses were conducted using road network data specific to the European side of Istanbul. Considering traffic density and spatial distribution is essential when evaluating operational data in large cities (Allen, Piecyk, & Piotrowska, 2018).

The methodological framework of the study is grounded in Geographic Information Systems (GIS) and network-based analysis techniques. GIS is a powerful tool for modeling, analyzing, and planning spatial relationships in urban logistics systems. In urban freight research, the use of such spatial tools is considered essential for addressing issues related to access

and infrastructure constraints (Dablanc, 2007). Accordingly, ArcGIS-based analyses were used to assess connectivity between collection points and branch facilities, travel times, and general accessibility.

To analyze the spatial distribution of parcel clusters, Kernel Density Estimation (KDE) was applied based on the desi values of parcels. This technique is commonly used to visualize shipment concentration patterns and understand delivery challenges within high-density areas (Lin, Chen, & Kawamura, 2016).

For route optimization, the Vehicle Routing Problem (VRP) was implemented, incorporating realistic constraints such as traffic intensity, vehicle capacity, service time per order, and driver break schedules. In the context of city logistics modeling, such optimization frameworks are key to improving route planning and resource efficiency (Anand, van Duin, Quak, & Tavasszy, 2015).

In addition, Multi-Criteria Decision-Making (MCDM) techniques were applied to evaluate various performance criteria simultaneously. These included vehicle load balance, route length, parcel volume, and time windows. MCDM provides a structured and comprehensive evaluation framework, particularly useful in transport planning where multiple objectives must be reconciled (Macharis & Bernardini, 2015).

In summary, the study integrates GIS, KDE, VRP, and MCDM approaches to build a multi-layered analytical framework. This enables the development of more efficient, flexible, and sustainable parcel collection strategies tailored to dense and complex urban settings like Esenyurt.

Findings

This study analyzed parcel collection processes in Esenyurt from both operational and spatial perspectives, revealing key issues affecting overall efficiency. One of the most prominent problems identified is the imbalance in vehicle capacity utilization. While some vehicles operate at full capacity during peak hours, others run with low occupancy rates, leading to route delays and increased fuel consumption. As illustrated in Figure 3, the desi-based kernel density heatmap visualizes the spatial distribution of parcel clusters and highlights the geographical factors contributing to this imbalance.

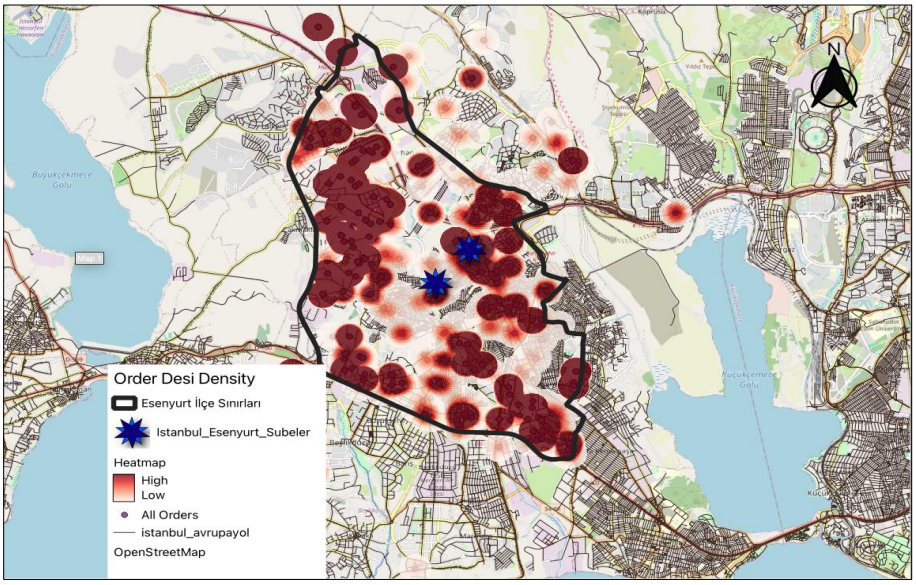

Figure 3. Kernel Density Heatmap Based on Parcel Volume (Desi).

A GIS-based Vehicle Routing Problem (VRP) analysis was conducted in the study, incorporating constraints such as average traffic intensity, vehicle capacity, and service duration. While the traditional method required 17 vehicles to complete daily collection operations, the optimized VRP solution successfully fulfilled the same task using only 7 vehicles. This corresponds to approximately a 59% reduction in vehicle usage, indicating that the system had been operating with significant excess capacity. However, it is important to note that this result is based on average traffic conditions during working hours, and actual performance may vary under real-world circumstances. The optimized routes for successfully collected orders are shown in Figure 4, and a summary of related statistics is presented in Table 1.

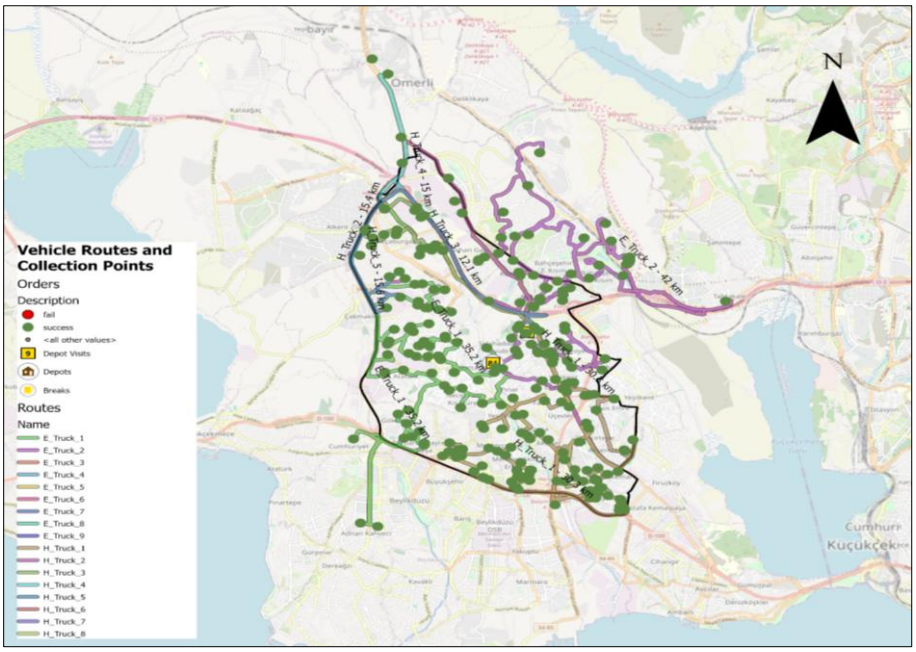

Figure 4. VRP Optimization Based on Successfully Collected Orders.

Table 1. Summary of Successfully Collected Orders.

Truck Name	Start Depot Name	End Depot Name	Capacity (desi)	Max Total Time (min)	Order Count	Total Time (min)	Travel Time (min)	Distance(km)
E_Truck_1	Esenyurt	Esenyurt	15000	600	70	144,1	251,2	35,18
E_Truck_2	Esenyurt	Esenyurt	15000	600	79	458,9	335,1	41,98
H_Truck_1	Haramidere	Haramidere	15000	600	96	194,8	171,1	30,32
H_Truck_2	Haramidere	Haramidere	15000	600	7	63,5	44,6	15,43
H_Truck_3	Haramidere	Haramidere	15000	600	23	93,7	79,8	12,08
H_Truck_4	Haramidere	Haramidere	15000	600	2	36,4	29,9	14,99
H_Truck_5	Haramidere	Haramidere	15000	600	4	68,1	52,2	15,64

Additionally, a full-demand scenario, which included all planned orders, was analyzed. The optimized routes for this scenario are presented in Figure 5, while route-based performance metrics are detailed in Table 2. This full-demand scenario offers critical insights into how the system would perform under maximum load conditions and emphasizes the need for additional resources during peak periods.

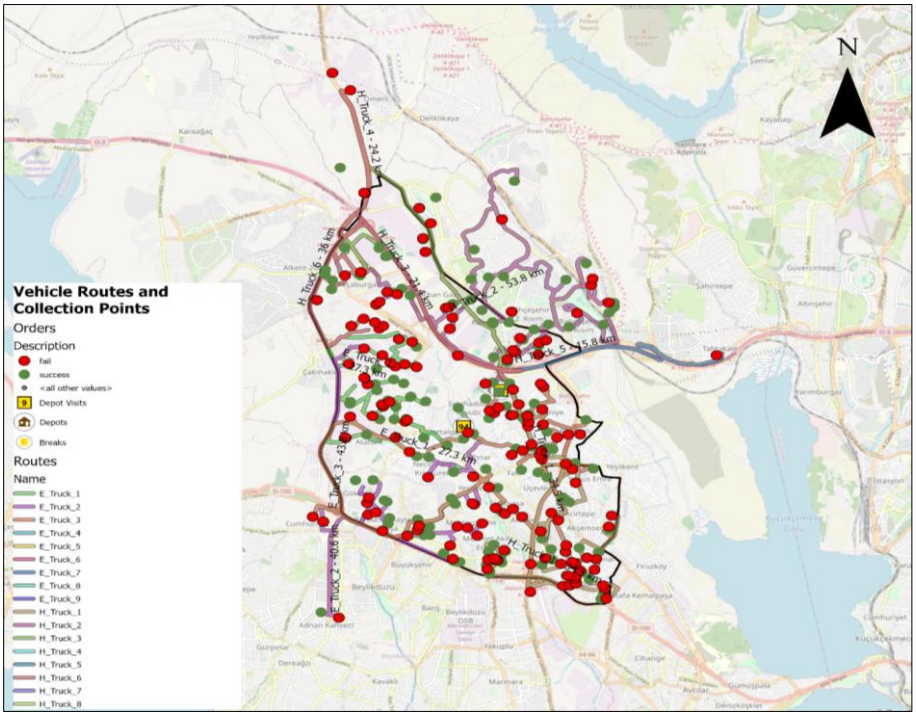

Figure 5. VRP Optimization Based on All Planned Orders.

Table 2. Summary of Routes from Full Demand VRP Scenario.

Truck Name	Start Depot Name	End Depot Name	Capacity (desi)	Max Total Time (min)	Order Count	Total Time (min)	Travel Time (min)	Distance (km)
E_Truck_1	Esenyurt	Esenyurt	15000	600	74	150,3	141,8	27,3
E_Truck_2	Esenyurt	Esenyurt	15000	600	57	116,3	138,6	40,5
E_Truck_3	Esenyurt	Esenyurt	15000	600	92	186,5	151,1	43,8
H_Truck_1	Haramidere	Haramidere	15000	600	99	199,9	119,2	34,4
H_Truck_2	Haramidere	Haramidere	15000	600	75	155,1	304,4	53,7
H_Truck_3	Haramidere	Haramidere	15000	600	18	96,9	56,3	21,3
H_Truck_4	Haramidere	Haramidere	15000	600	5	52,3	29,9	24,1
H_Truck_5	Haramidere	Haramidere	15000	600	2	56,4	28,1	15,8
H_Truck_6	Haramidere	Haramidere	15000	600	15	94,3	76,28	36,0

Seasonal fluctuations also impose considerable pressure on the collection system. Parcel volumes rise significantly during promotional campaigns or holiday seasons, causing already strained systems to become increasingly inefficient. Without a flexible and scalable strategy, delays, missed pickups, and customer dissatisfaction become inevitable in such periods.

All these findings clearly demonstrate the potential of GIS-based analysis and optimization techniques to enhance the efficiency of urban parcel collection processes while minimizing resource use.

Conclusion

This study presents a comprehensive spatial and operational analysis of parcel collection logistics in Esenyurt, Istanbul. Through the integration of GIS mapping, Multi-Criteria Decision-Making (MCDM) techniques, and Vehicle Routing Problem (VRP) solutions, the research identifies inefficiencies, constraints, and potential improvements within the urban logistics system. While traditional operational methods often result in inefficiencies due to high vehicle requirements and fragmented routing strategies, the optimization results obtained in this study represent a significant improvement.

By adopting a holistic approach to routing, the number of vehicles needed for daily operations was significantly reduced, leading to decreased field workload and lower logistical costs. Incorporating operational parameters—such as service time per order and scheduled driver breaks—ensured that the models remained grounded in real-world conditions. This not only

enhanced spatial efficiency but also supported more sustainable practices in terms of time management and workforce planning.

However, GIS-based VRP solutions (e.g., ArcGIS Network Analyst) can be time-consuming, particularly when working with large datasets. Therefore, in the later stages of the study, alternative optimization tools such as Google OR-Tools were employed. These tools offered improved computational speed, greater flexibility in scenario testing, and better scalability in solution generation.

Although this study's findings are specific to Esenyurt, the methodology provides a robust framework for optimizing logistics in other high-density urban areas. As e-commerce continues to expand globally, urban centers will face increasing pressure to streamline logistics while maintaining service quality. Future research could explore the integration of AI-powered demand forecasting, autonomous delivery systems, and IoT-enabled fleet monitoring to enhance urban logistics performance further.

In conclusion, spatial analysis and data-driven optimization techniques are powerful tools for modern urban logistics. This study demonstrates how geospatial data and multi-criteria evaluation can reveal hidden inefficiencies and guide smarter, more strategic decision-making in e-commerce parcel collection operations.

Transformation of Solid Waste Management in Baku: A GIS-Based MCDM Approach to Landfill Site Selection Beyond Balakhani

Kanan Alakbarlı[a], Dursun Zafer Seker[b]

[a] Istanbul Technical University, Graduate School, Geomatics Engineering Program, Türkiye
[b] Istanbul Technical University, Department of Geomatics Engineering, Türkiye
alakbarli17@itu.edu.tr

Keywords : Solid Waste Management, GIS, MCDM, AHP, Landfill Site Selection.

Aim

Baku, Azerbaijan's rapidly growing capital, faces mounting pressure on its solid-waste infrastructure. With a current population of 2.3 million—projected to nearly double in the metropolitan area—the city generates roughly 1.8 million tons of waste yearly (World Bank, 2018). Historically, inefficient waste disposal practices, exemplified by the pre-rehabilitation Balakhani landfill, have led to significant environmental degradation, including groundwater contamination and air pollution. Supported by international initiatives, such as the World Bank's Integrated Solid Waste Management Project, completed in 2016 and managed by Tamiz Shahar, Azerbaijan's waste authority, Balakhani was transformed into a sanitary landfill and industrial park, processing over 500,000 tons of waste annually through waste-to-energy incineration, recycling, and landfill gas capture (World Bank, 2021). Despite these advancements, urban sprawl has reduced the buffer zone between Balakhani and residential areas to less than 2 kilometers, raising concerns about odor, health risks, and capacity limits, projected to be exhausted within a decade given a 3% annual waste growth rate (Huseynova, 2023). This situation underscores the urgent need to identify alternative sanitary landfill sites to sustain and build upon SWM progress in the city.

This study aimed to evaluate the transformation of solid waste management in Baku, specifically focusing on the Balakhani case, and to develop a spatially optimized framework for selecting alternative landfill sites using Geographic Information Systems (GIS) and multi-criteria decision-making (MCDM) techniques. The primary objective is to propose viable landfill locations beyond Balakhani that minimize the environmental impact, ensure social acceptability, and maintain economic feasibility, thereby supporting Baku's long-term waste management strategy. Landfill site selection is a complex decision-making process that requires the integration of environmental, social, and economic factors. Traditional methods often lack spatial precision and stakeholder consensus, necessitating advanced tools such as Geographic Information Systems (GIS) combined with Multi-Criteria Decision-Making (MCDM) techniques such as the Analytic Hierarchy Process (AHP). This study aims to develop an optimized landfill site selection framework for Baku by leveraging GIS-MCDM and AHP to identify sustainable locations that minimize environmental impact and address urban growth pressures. Drawing on international case studies (Khan & Samadder, 2021; Nas et al., 2010; Younes et al., 2021) and local data (Tamiz Shahar, n.d.), this study evaluates the success and limitations of the Balakhani transformation and proposes a scalable model for Azerbaijan's waste management future. This study also seeks to contribute to the global SWM literature by demonstrating the application of GIS-based MCDM in a rapidly developing urban context.

Material and Method

The methodology integrates GIS technology with the Analytic Hierarchy Process (AHP), a widely used MCDM method, implemented using ArcGIS Pro software to assess potential landfill sites in Baku, which is depicted in Figure 1 step by step. Regarding criteria identification, specific criteria under different categories, such as environmental, social, and economic, were selected based on literature review and local context, considering the availability of the necessary dataset as well: distance from residential areas, proximity to transportation networks (roads), groundwater depth (to avoid contamination), slope, elevation, land use type, surface water proximity, fault line proximity, distance from sensitive areas such as protected areas and airstrips.These align with Azerbaijan's environmental regulations and international standards

(Islamic Development Bank, 2020). Spatial data were sourced from multiple platforms, including the Humanitarian Data Exchange for administrative boundaries, OpenStreetMap for environmental and infrastructure-related geospatial information, and print-based maps published in the atlas that were digitized afterward in a GIS environment. Waste statistics were derived from the World Bank (2021) and Tamiz Shahar (n.d.) and supplemented by field observations near Balakhani. Using ArcGIS Pro, the dataset was processed, and spatial layers were created for each criterion. The Boolean overlay excluded unsuitable areas (such as residential zones and water bodies), whereas the weighted overlay analysis ranked suitable sites. Based on the threshold values, the raster maps were reclassified on a 1-5 suitability scale (1 = least suitable, 5 = most suitable). AHP Implementation: AHP assigned weights to criteria, reflecting their relative importance and considering stakeholder priorities. Pairwise comparison matrices were constructed with input from waste management experts and local authorities, following a 1-9 scale and consistency ratios, ensuring reliability by validating the weighting process. Environmental factors received the highest weight by considering the groundwater depth and topographical factors, reflecting regulatory priorities and Balakhani's lessons on groundwater protection, followed by combined technical and socioeconomic factors. Weighted scores were integrated into GIS to produce a final suitability map using ArcGIS Pro's Weighted Overlay tool, combining the thematic layers into a final suitability map, validated against Balakhani's current location and projected waste volumes (1.8 million tons/year growing at 3%). The map classified the study area into five suitability zones: highly suitable, suitable, moderately suitable, less suitable, and unsuitable. This hybrid approach mirrors successful applications in diverse contexts, such as Konya, Turkey (Nas et al., 2010) and Srinagar, India (Khan & Samadder, 2021), adapted to Baku's unique urban and environmental profile. Considering the availability of data used for map generation regarding site selection analysis presented on the Table 1, limitations generally cover the lack of open-source data regarding the geological structure of country and complexity regarding for finding digitally available groundwater data. To overcome these difficulties, hard-copy or paper-based sources like atlas depicting the ecological situation of Azerbaijan, including groundwater depth was used. For this purpose, the digitization was applied by transforming the paper-based atlas to digital form in corresponding coordinate system via GIS tools for using groundwater factor in the analysis.

a

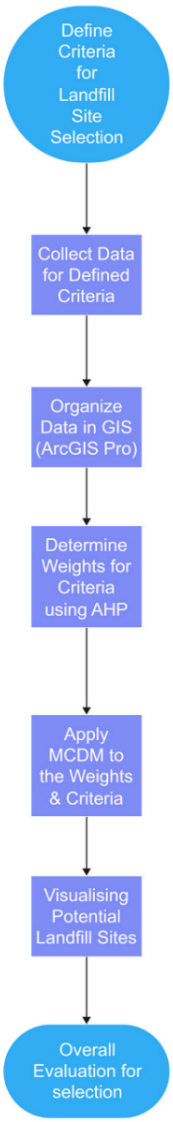

Figure 1. Overall Flowchart of Suitability Analysis.

Table 1. Factors and their relevant dataset sources.

Factors	Used Dataset

LULC	Sentinel-2 10m
Faults (Seismic)	Global Earthquake Model Active Faults Database

Findings

As a result of the GIS-MCDM analysis, the suitability map depicted on the Figure 2 identified high-potential zones, with the most promising locations with the green color in peri-urban areas in the east and southwest of Baku, each exceeding 20 ha and meeting key criteria. These sites scored highly because of their distance from water bodies, flat terrain, and access to major roads, which reduced transportation costs. While the current sanitary landfill site,Balakhani, still locates on the suitable area according to generated suitability map, the other most suitable areas for new landfill sites offer greater isolation from populated areas and capacity for at least 25 years of waste disposal based on projected volumes. Balakhani's transformation reduced groundwater contamination risks by 60% post-2016 through liner systems and leachate management (World Bank, 2021); however, its proximity to urban expansion—now within 1.8 km of new housing—compromises long-term viability. With a capacity of 7 million cubic meters, it processes 500,000 tons annually but faces exhaustion by 2035 at current growth rates (Tamiz Shahar, n.d.). The proposed sites, with capacities exceeding 10 million cubic meters, could extend operational lifespans by 15-20 years by incorporating technologies such as landfill gas-to-energy, which currently recovers 10 MW at Balakhani (Islamic Development Bank, 2020). The framework's strengths lie in its spatial precision and adaptability, contrasting with Balakhani's ad-hoc siting in the 1980s. Limitations include data resolution specifically regarding the geological structure and lack of digitally available information about the location of groundwater throughout the country and exclusion of climate change impacts, such as rising precipitation affecting leachate volumes, warranting future research. Considering the CR (Consistency Ratio) value of applied AHP method in this study compared to the existing literature, the calculated value of 0.14 slightly exceeds generally accepted threshold value of 0.1, while value till to 0.15 is still considered as acceptable.

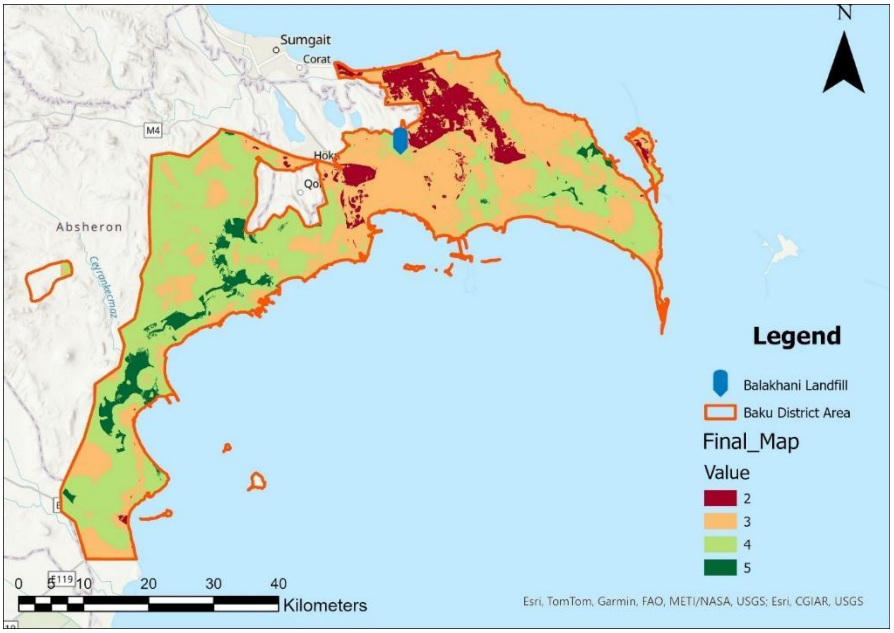

Figure 2. Generated Suitability Map for Landfill Site Selection in Baku.

Conclusion

While Balakhani's rehabilitation marks progress in Baku's waste management, the city must urgently identify new landfill sites to accommodate future waste volumes and prevent renewed environmental risks by integrating GIS with AHP while supporting Azerbaijan's sustainable waste management goals. The identified sites enhance environmental protection and operational efficiency, critical as Baku's waste generation nears 2 million tons annually. Limitations include potential data gaps (e.g., incomplete geological surveys) and the need for field validation, which could refine the suitability scores. Recommendations include conducting detailed environmental impact assessments (EIAs) for top-ranked sites, engaging local communities to ensure social acceptance, and exploring waste-to-energy integration to enhance sustainability. Future research could extend this methodology to other Azerbaijani cities or incorporate real-time waste-generation data for dynamic planning.

Flood Risk Analysis with Geospatial Artificial Intelligence Techniques

Miraç Taha Derman[a], Muhammed Oğuzhan Mete[a]

[a] İstanbul Technical University, Geomatics Engineering Department, Geomatics Engineering Program, Türkiye
derman17@itu.edu.tr

Keywords : Flood, Hazard, Machine learning, Python, Vulnerability.

Aim

In recent years, extreme precipitation events, rapid build-up in urbanization, and irregular land use have significantly increased flood risk. In order to mitigate risks and increase urban resilience, there is a need for the integration of innovative approaches to classical disaster management methods. In this context, Geographic Information Systems (GIS) offer robust spatial analysis workflow and data processing for efficient decision-making capability. In addition, desktop GIS software has some limitations in processing large volumes of datasets. This study uses geospatial artificial intelligence (GeoAI) methods to develop a flood risk analysis model in an open-source Python environment. The proposed methodology is applied in the Marmara Region of Türkiye as a case study highlighting flood risk. The Marmara Region is one of the most critical regions in Türkiye in terms of economic and socio-cultural aspects. The region includes the provinces that connect the European and Asian continents. In addition to its geographical location, the abundance of development and job opportunities in the region has made it the country's most populous area. On the other hand, the Marmara Region is at high risk of disaster due to its climate diversity. Thus, it has become possible to build a high-resolution, automated, and repeatable analysis process with large data sets that were not feasible using traditional methods. In this regard, spatial data processing, modeling and analysis are carried out in an integrated manner through open-source libraries. The vulnerability of the Marmara Region in this context, with its potential to work in harmony with machine learning algorithms, positively affects flood management and offers an innovative perspective. In this context, the flood risk map of the Marmara Region is produced for eleven cities using open-source and governmental data gathered from official institutions to serve as an accessible guide for decision-makers.

This study aims to estimate the flood and inundation risk in the Marmara Region using Python-based multi-criteria analysis methods which is Analytic Hierarchy Process (AHP) and machine learning algorithms. It is aimed to obtain a holistic high-resolution flood and inundation risk map by combining hazard and vulnerability evaluations. While evaluating the criteria affecting flood and inundation in the Marmara Region, Hazard and Vulnerability parameters are taken as references from studies in the literature. With the Python-based methods used, the dependency on GIS tools is reduced and an automatable analysis process is presented.

A comprehensive flood risk estimation was carried out in the Marmara Region by creating maps using a machine learning-based method in the production of flood vulnerability maps and integrating these maps using the Python-based AHP method in the production of flood hazard maps. Hydrological data was integrated with spatial analysis. Historical disaster data and real-time meteorological parameters were associated using artificial intelligence algorithms. This comprehensive approach aims to develop strategies for the early detection of flood events that may occur in the Marmara Region by revealing how both Hazard and Vulnerability elements complement each other.

Material and Method

Within the scope of this study, hazard and vulnerability maps were produced to estimate the risk of flood and inundation disasters. The raw data used in the production of these maps were obtained from open-source and official institutions (Table 1). In this study, the authors' previously published studies (Demir & Keskin, 2022) and (Ghosh et al., 2022) were examined to determine the source data sets of flood and inundation analyses. Building, road, waterways, and water bodies data belonging to the study area were obtained from the Overturemaps web platform, which is an open-source data provider. In addition, Marmara Region study area polygon data was obtained from OpenStreetMap; ESRI open data within the scope

of land use; Digital Elevation Model (DEM) data with 25-meter resolution was obtained from USGS data portal; and population data was obtained from TUIK open-source data portal. The data obtained from official institutions were 40 years of daily precipitation data from the General Directorate of Meteorology (MGM); and flood and inundation inventory data from the General Directorate of State Hydraulic Works (DSİ) in the Marmara Region in the past 50 years. The study of Aydın and Birincioğlu (2022) was taken as a reference while creating the hazard map, especially on narrowing down map creation parameters. In this context, the criteria based on the Analytical Hierarchy Process (AHP) were applied with raster analyses in Python. Slope, aspect, elevation, flow direction, flow accumulation, waterways proximity, waterbodies proximity and precipitation analysis were performed. These data were divided into risk classes in parallel with the study of Aydın and Birincioğlu (2022) by processing the 30-meter resolution raster analyses performed in Python with libraries such as rasterio and geopandas. Each raster data obtained was weighted with AHP and the final hazard map was obtained. In this process, instead of GIS, a completely Python-based analysis process was carried out.

Table 1. Flood risk criteria and data sources.

Data Name	Data Source
Building	Overturemaps
Road	Overturemaps
LULC	ESRI
Work Area Polygon	OSM
Digital Elevation Model (DEM)	USGS
Waterways	Overturemaps
Waterbodies	Overturemaps
Precipitation	MGM
Population	TUIK
Flood Inventory	DSİ

While creating the vulnerability map, XGBoost and Random Forest (RF) models, which are machine learning models, were preferred based on the study of Koyuncu & Ekmekçioğlu (2024). In this context, elevation, aspect, plan curvature, profile curvature, drainage density, distance to drainage network, curve number, precipitation, Topographic Wetness Index (TWI), Topographic Roughness Index (TRI), Stream Power Index (SPI), population and land use classification analyses were performed using open-source Python libraries. Flood inventory data were processed and used with these analyses. Training and test data sets with 13 parameters and the flood inventory of the past 50 years; a raster stack was created in the data pre-processing steps. According to the obtained test set results, flooded and non-flooded regions were obtained on a point basis (with coordinates) as 1 and 0, respectively, due to the binary classification logic. Then, the flood susceptibility map was produced based on the Marmara Region borders by interpolating the 1 and 0 points with the Kriging method, which is one of the widely used methods in the literature (Koyuncu & Ekmekcioğlu, 2024). Class imbalance was eliminated by Random Under Sampling (RUS) and RUS was used for feature scaling. Thus, a flood vulnerability map was produced for the Marmara Region. Model performance was evaluated with F1-Score and AUROC metrics. Then, the results of XGBOOST and RandomForest (RF) machine learning models were compared.

Hazard and vulnerability maps were combined with libraries such as rasterio and geopandas used for raster calculation libraries in Python to create the final risk map. While small-scale and province-based studies are widely used for flood risk, this study used large-scale data to study the Marmara Region in a comprehensive manner. The big data was processed using open source python and machine learning algorithms.

Findings

It is not newly discovered that floods and inundations are one of the major natural disasters that frequently occur in nature and cause loss of life and property. Nevertheless, there are parameters that increase the risk of this disaster. Many factors, especially rainfall regime, river density and distance to these waterways, population density in the region, topographic structure of the land, water flow direction and accumulation affect the risk of floods and inundations. In this multi-parameter compound, determining flood and inundation risks in the region is essential for effective disaster management.

As a result of the analyses carried out in the Python environment, the areas with high flood risk in the Marmara Region are presented in the integration of the criteria determined for the hazard map. Proximity to waterways, high flow accumulation and precipitation, and low slope criteria stood out as determining factors in the increase in risk. The results obtained showed a risk distribution compatible with the flood inventory (Figure 1).

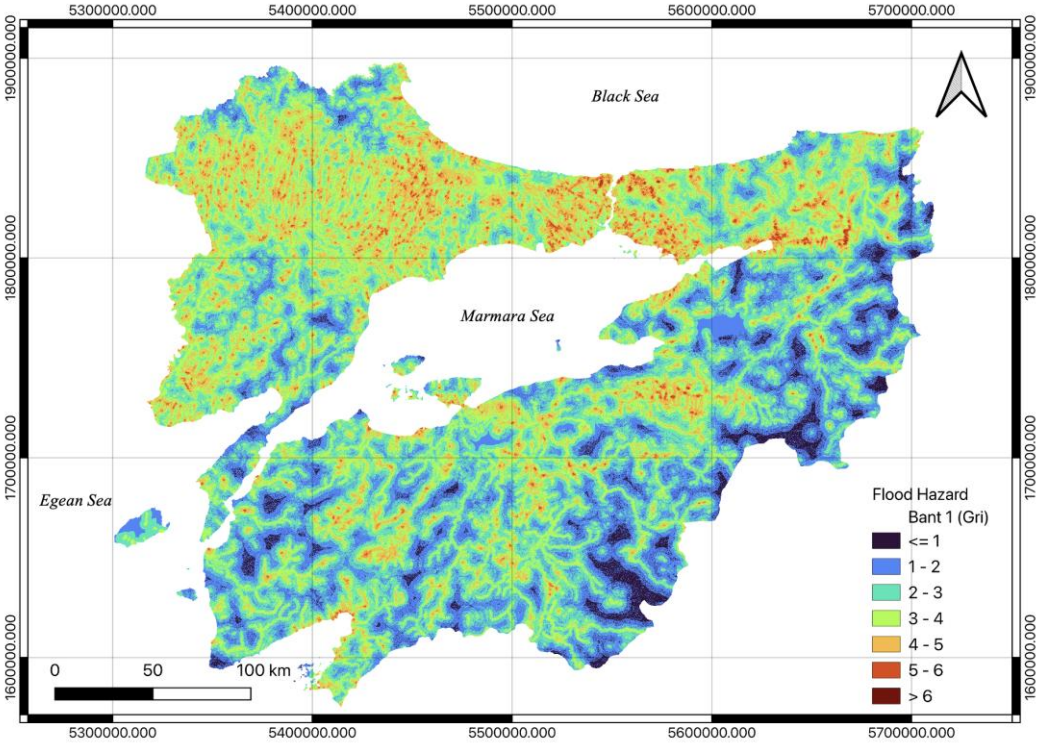

Figure 1. Marmara Region flood hazard map.

In the hazard map, it was observed that the northwestern and northern regions, where the density of rivers is high and the rainfall is high, are exposed to higher flood risk. This risk parameter is limited by the regions with high land slopes. According to the vulnerability results, the precipitation factor was found to be the most important variable in flood vulnerability mapping. This factor was respectively followed by the distance to the drainage network, the curve number and the Topographic Roughness Index (TRI). The results of XGBoost and RF methods were used to obtain the flood vulnerability map of the Marmara Region.

Conclusion

Floods and inundations, which are some of the natural disasters mostly affected by the realities of global warming and climate change happening today, cause many losses of life and property. When the human factor is added to the changing climate and weather conditions, floods are considered as a natural disaster that negatively affects human life. In order to prevent these disasters or reduce their effects, it is necessary to determine the region where the event may occur and to what extent it may be affected. In this study, the flood and inundation risk in the Marmara Region was evaluated through Python-based multi-criteria analysis methods (AHP) and machine learning algorithms. The final output of the study shows that hazard with Python-based analysis methods; vulnerability with machine learning algorithms; and flood risk maps created by the integration of these two maps provide high accuracy and efficiency in determining flood and inundation risks in the Marmara Region. Python-based analyses have offered significant advantages in terms of automating the dynamic process in flood risk assessment, repeatability and obtaining high-performance analysis output. In line with these advantages, a dynamic and continual framework for risk management has been proposed to regional and local governments.

In future studies, it is possible to include more parameters and criteria in model estimates on flood and inundation risk to expand the scope of the studies. Currently, the model and maps produced within the scope of this study provide a basis for being prepared for possible disasters in the future and are offered to be used by official institutions. With the potential regulation of the proposed model and maps, regional and local governments would be able to consider the disaster planning and therefore contribute to the reduction of losses and flood and inundation effects.

Seismic Hazard Assessment of Kahramanmaraş Region: Analysis of Earthquake Sources and Probabilistic Seismic Risk

Sajjad Alghezi[a], Abdullah Zülfikar[b]

[a] Istanbul Technical University, Graduate School, Geomatics Engineering Program, Türkiye
[b] Istanbul Technical University, Disaster Management Institute, Earthquake Engineering Program, Türkiye
alghezi22@itu.edu.tr

Keywords : Seismic Hazard, East Anatolian Fault Zone, Probabilistic Seismic Risk, Kahramanmaraş.

Aim

This study aims to assess the seismic hazard of the Kahramanmaraş region, located in southeastern Turkey, by applying a probabilistic seismic hazard analysis (PSHA) approach to both pre- and post-earthquake data spanning from 1980 to 2023. The research focuses on identifying and characterizing seismic sources within the region, i.e., the East Anatolian Fault Zone (EAFZ) Main Segment, its splays, and the influence of the Bitlis-Zagros Fold and Thrust Belt. By applying the frequency–magnitude distribution of earthquake ground motions from seismically recorded earthquakes and calculating Gutenberg-Richter parameters (a and b values), the study estimates exceedance probabilities for various magnitudes of earthquakes and calculates corresponding recurrence periods. The results provide critical data to quantify seismic hazard and support data to guide seismic design requirements, risk reduction, and urban resilience planning in one of Turkey's most seismically active regions.

Material and Method

This part accounts for the method used to evaluate the seismic hazard and risk in Kahramanmaraş. The study sought to evaluate earthquake data collected before and after the destructive February 6, 2023, earthquakes, including a magnitude Mw7.7 earthquake in Pazarcık and an aftershock Mw7.6 earthquake in Ekinozu as illustrated in the preliminary report by Garini and Gazetas (2023), the earthquakes spread through over 500 km of fault segments. The approach involves seismic source characterization, Gutenberg-Richter law-based frequency-magnitude distribution, and seismic risk estimation through probabilistic seismic hazard analysis (PSHA). Recent regional applications of probabilistic seismic hazard analysis in Turkey, such as those integrated into catastrophe modeling platforms (Akkar et al, 2022), have further demonstrated the critical role of PSHA in informing risk-based design and reinsurance frameworks.

The study area spans latitudes 36°00'N to 38°00'N and longitudes 35°00'E to 39°00'E (Figure 1). The study area encompasses the Kahramanmaraş region and its surroundings, located at the intersection of the Anatolian, Arabian, and African tectonic plates, a simplified tectonic map illustrating the fault systems is presented in Figure 2. The region is seismically active and primarily influenced by the East Anatolian Fault Zone (EAFZ), which accommodates the westward escape of the Anatolian Plate. Three key seismic source zones have been identified:

- Source Zone 1 – EAFZ Main Segment: A major left-lateral strike-slip fault that has generated multiple large earthquakes, including the Mw 7.7 event on 6 February 2023.
- Source Zone 2 – EAFZ Splays: Secondary fault branches off the main EAFZ, contributing to the distributed seismicity in the region.
- Source Zone 3 – Bitlis-Zagros Influence: A compressional regime linked to the Bitlis-Zagros Suture Zone, contributing thrust-related seismic activity.

Figure 1. Black box show the study area.

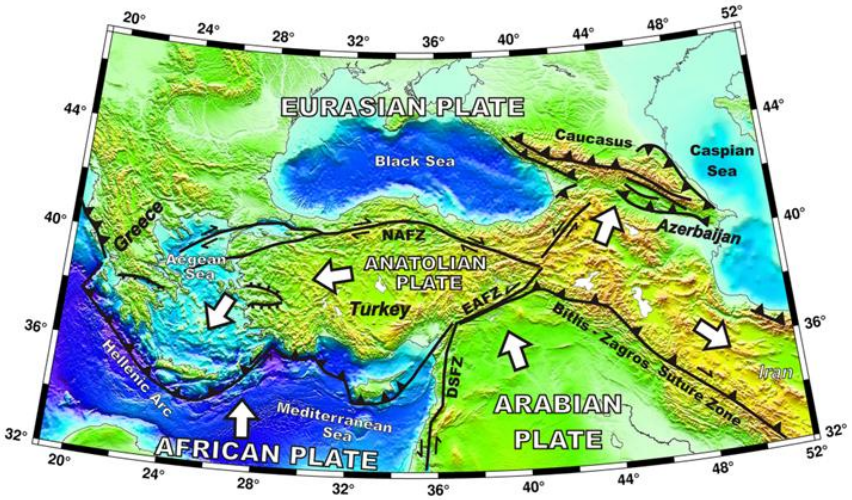

Figure 2. Simplified tectonic map of Turkey and its surroundings (Tan, O.2021).

Earthquake data were sourced from the Disaster and Emergency Management Presidency (AFAD) of Turkey. The dataset comprises: Pre-event period: January 1980 – 5 February 2023 and Post-event period: 6 February 2023 – December 2023. The dataset includes both earthquake event parameters (epicenter coordinates, magnitude, and depth) and associated ground motion recordings (Peak Ground Acceleration – PGA, and hypocentral distance). The total dataset consists of Pre-earthquake: 32 events, 1198 recordings and Post-earthquake: 44 events, 4034 recordings. This comprehensive dataset allowed us to analyze seismicity patterns both before and after the major 2023 earthquakes, figure 3 (Magnitude vs. Distance) showing data distribution.

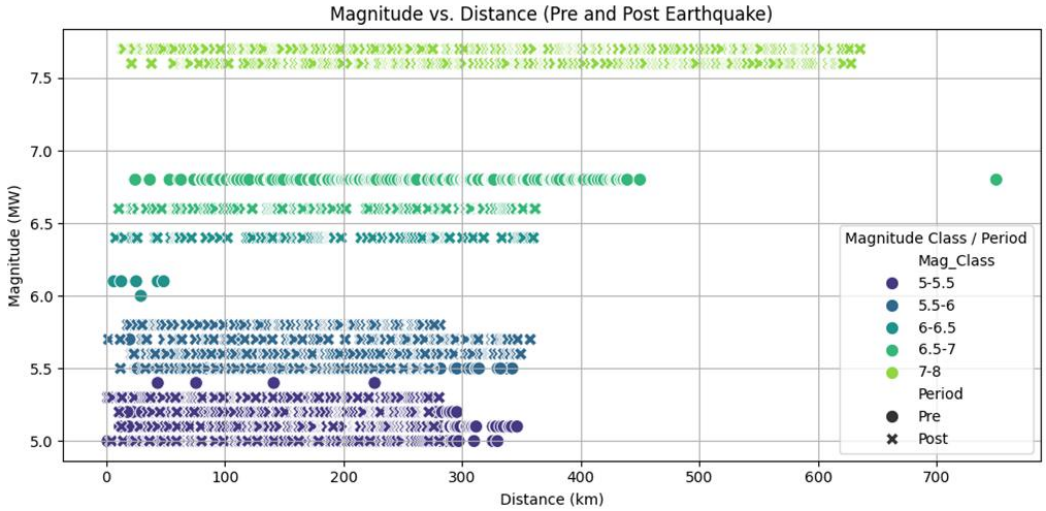

Figure 3. Magnitudes vs. Distance.

The frequency of earthquake events was computed in 0.5 magnitude unit bins ranging from Mw 5.0 to Mw 8.0. The cumulative frequency was also calculated to assess the recurrence characteristics. This distribution is summarized in Table 1.

Table 1. Magnitudes and cumulative frequency values at 0.5 unit intervals.

Magnitude	Frequency (N)	Cumulative Frequency (Ni)
5.0 - 5.4	51	72
5.5 - 5.9	14	21
6.0 - 6.4	3	7
6.5 - 6.9	2	4
7.0 - 7.4	0	2
7.5 - 8.0	2	2

The magnitude–frequency distribution was modeled using the Gutenberg–Richter law (Gutenberg & Richter, 1954).

$$\log 10N(M) = a - b\,M \qquad \textbf{(Equation1)}$$

where:

- $N(M)$: Cumulative number of earthquakes with magnitude M or greater,
- a: Measure of seismicity level in the region,
- b: Slope of the frequency-magnitude curve, indicative of the relative occurrence rates of small versus large earthquakes.

The least squares method (LSM) was employed to calculate the *a* and *b* values for the study area. This approach ensures robust parameter estimation by minimizing the residuals between observed and predicted values. The b-value was found to be approximately 0.63, suggesting a relatively higher frequency of smaller magnitude earthquakes, consistent with active strike-slip faulting. Figure 4 illustrates the magnitude-frequency relationship derived from the earthquake data.

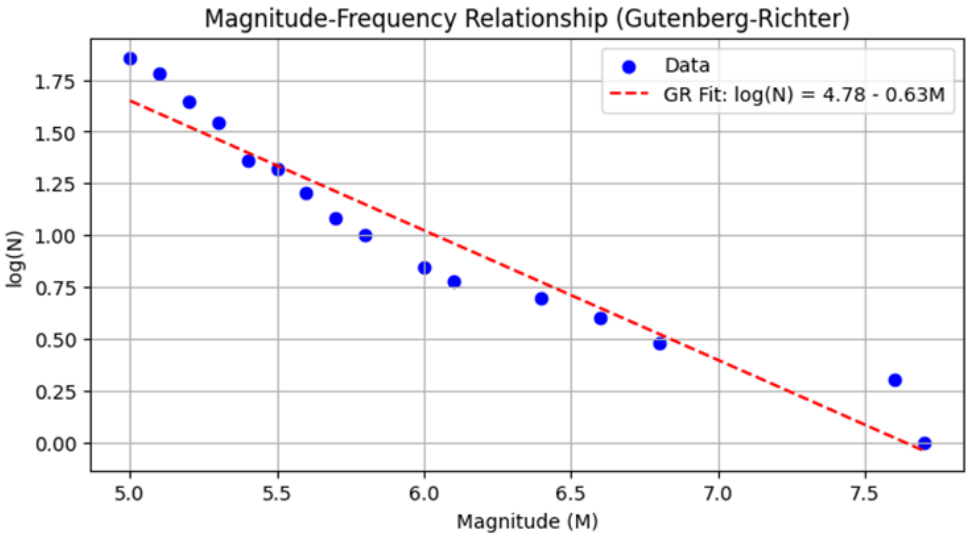

Figure 4. Magnitude-frequency relationship.

Using the combined event data over a 44-year period, the annual rate of occurrence $n(M)$ for earthquakes exceeding magnitude M was computed. The exceedance probability for a time interval T is modeled by the Poisson formulation (Baker, 2013).

$$P(M,T) = 1 - e - n(M) \cdot T \qquad \textbf{(Equation 2)}$$

where:

- $P(M,T)$: Probability of exceeding magnitude M in T years.
- $n(M)$: Annual rate of occurrence of earthquakes with magnitude $\geq M$.
- T: Time interval (years).

Recurrence periods Q (in years) are calculated as:

$$Q = 1 / n(M) \qquad \textbf{(3)}$$

Table 2 summarizes the probabilities of exceeding various magnitudes and their corresponding recurrence periods. Figures 5 and 6 visualize these results, providing insights into the temporal and spatial characteristics of seismic hazard in the region.

Table 2. Probabilities of exceeding magnitudes and recurrence periods over 10–100 year intervals.

M	10	20	30	40	50	60	70	80	90	100	Q(years)
5.00	100%	100%	100%	100%	100%	100%	100%	100%	100%	100%	0.58
5.23	100%	100%	100%	100%	100%	100%	100%	100%	100%	100%	1.26
5.45	99%	100%	100%	100%	100%	100%	100%	100%	100%	100%	2.1
5.68	95%	100%	100%	100%	100%	100%	100%	100%	100%	100%	3.67
5.90	88%	99%	100%	100%	100%	100%	100%	100%	100%	100%	6.29
6.13	74%	95%	100%	100%	100%	100%	100%	100%	100%	100%	8.8
6.35	60%	89%	98%	100%	100%	100%	100%	100%	100%	100%	11
6.58	45%	79%	95%	98%	100%	100%	100%	100%	100%	100%	14.67
6.80	32%	65%	85%	93%	98%	100%	100%	100%	100%	100%	22
7.00	20%	49%	72%	82%	91%	98%	99%	100%	100%	100%	44
7.25	13%	35%	55%	68%	80%	91%	95%	98%	99%	100%	66
7.47	8%	24%	40%	51%	64%	77%	86%	92%	95%	98%	88
7.70	5%	15%	26%	35%	47%	59%	70%	80%	86%	90%	110

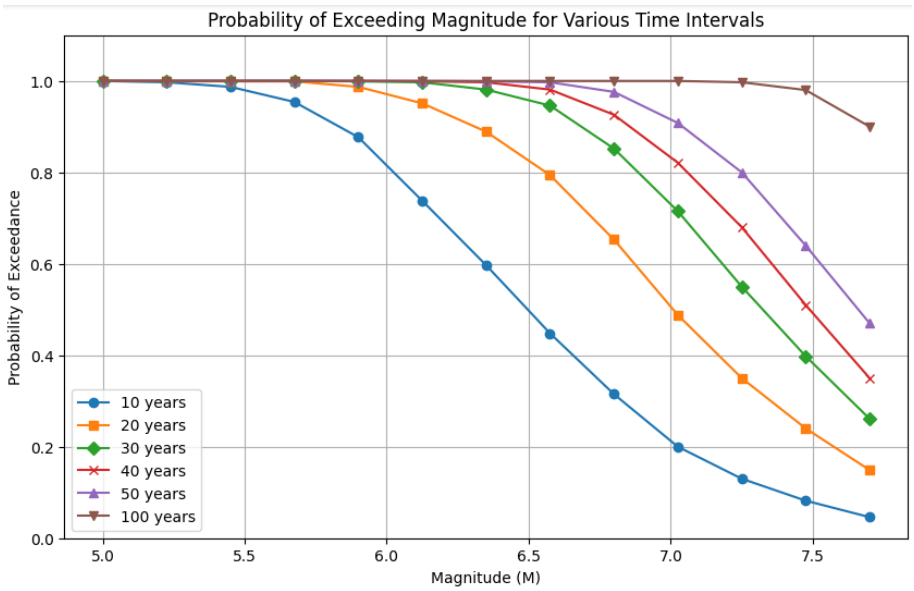

Figure 5. Probabilities of exceeding various magnitudes.

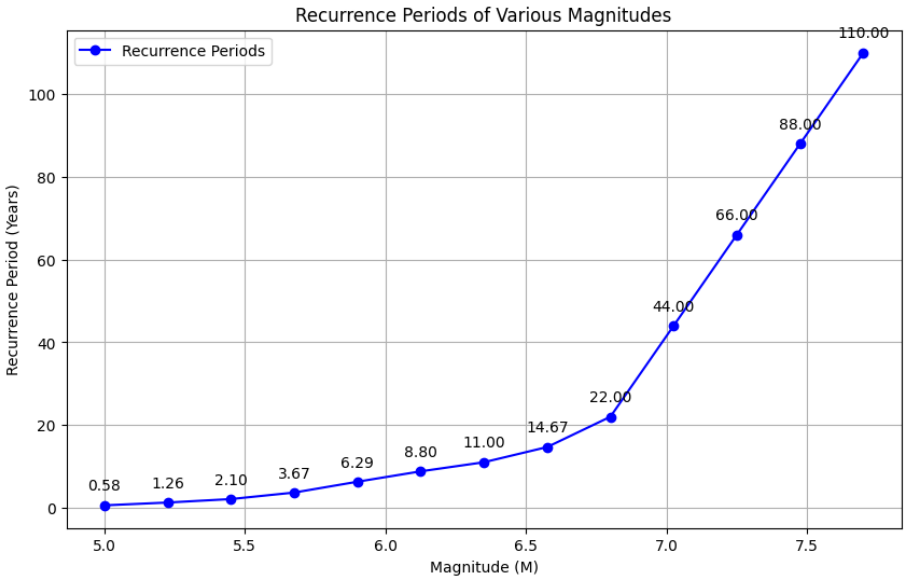

Figure 6. Recurrence periods of various magnitudes.

Findings

The seismic hazard assessment for the Kahramanmaraş region revealed critical insights into the tectonic activity and earthquake recurrence characteristics of this highly active zone. Analysis of the combined dataset from 1980 to 2023, which includes both pre- and post-earthquake data surrounding the Mw 7.7 and Mw 7.6 events of February 6, 2023, demonstrated the region's exposure to frequent moderate earthquakes and occasional large-magnitude events.

The magnitude–frequency distribution, as shown in Table 1, illustrates that the majority of events on record are within the range Mw 5.0–5.9, with significantly fewer events at magnitudes above Mw 6.5. While less common, the potential for damage for the larger events remains high due to the high population density and exposure of infrastructure in the region.

The Gutenberg–Richter relationship, fitted to the cumulative frequency data, yielded an a-value of 4.78 and a b-value of 0.63 (Figure 4). This b-value reflects a moderate slope, indicating a relatively high proportion of smaller to medium earthquakes, consistent with other seismically active strike-slip regions. The frequency–magnitude plot (Figure 4) confirms the reliability of this fit across the studied magnitude range.

The probabilistic risk analysis applied a Poisson model to estimate the probability of exceeding various magnitude thresholds over future time intervals. Results show that for a 100-year period, the probability of experiencing an earthquake of at least Mw 5.0 is effectively 100%, while the probability of a Mw 7.7 event is approximately 90% (Figure 5). The analysis also shows that events with Mw 6.5 have an estimated recurrence period of approximately 14.67 years, while Mw 7.7 earthquakes are expected approximately every 110 years (Figure 6 and Table 2).

These findings highlight a key duality in the seismic hazard profile of the region: frequent low-magnitude events pose persistent risks to non-engineered structures, while infrequent high-magnitude events can produce catastrophic damage across broad areas. In terms of structural safety, this means both frequent service-level ground shaking and rare design-level or collapse-level shaking must be considered in engineering practice. Given that the design life of most buildings is about 50 years, the exceedance probabilities associated with magnitudes above Mw 6.0 suggest a substantial seismic risk over the typical building lifespan.

From a geotechnical perspective, these results support the prioritization of seismic retrofitting in older or vulnerable structures, especially those located near known fault traces or on soft soils. Integration of local ground conditions into future hazard models would further improve accuracy.

Conclusion

This study provides a probabilistic seismic hazard assessment for the Kahramanmaraş region, utilizing earthquake data observed in a 44-year period including the major February 6, 2023, earthquakes. Seismic source zones, including the East Anatolian Fault Zone (main segment and splays) and the Bitlis-Zagros effect, were determined as the regional seismicity's major sources by the analysis.

Magnitude–frequency distribution follows Gutenberg–Richter relation with a b-value of 0.63, indicating moderate seismic regime dominated by small to medium earthquakes. However, probabilistic risk modeling also supports non-negligible probability of large-magnitude events (e.g., $Mw \geq 7.0$) on a 50 to 100-year return period. Notably, recurrence time for a Mw 7.7 event is around 110 years, while events with smaller magnitude like Mw 6.0–6.5 recur with a recurrence time of 10–15 years.

These results emphasize the importance of long-term planning for seismic resilience in the Kahramanmaraş region. Structural design criteria, urban planning initiatives, and emergency response measures must consider both the high frequency of small earthquakes and the low but significant hazard of large earthquakes. Site-specific soil properties, recent ground motion models, and building vulnerability analyses must be considered in future research to increase the validity and applicability of hazard estimates.

Remote Sensing

Generating a High-Definition Map (HD Map) via YOLO (You Only Look Once) Deep Learning-Based Object Detection Model

Yasin Memi[a], Hande Demirel[b]

[a] Istanbul Technical University, Graduate School, Department of Geomatics Engineering, Türkiye
[b] Istanbul Technical University, Faculty of Civil Engineering, Department of Geomatics Engineering, Türkiye
memi16@itu.edu.tr

Keywords : Object Detection; Panoramic Camera; LiDAR; Sensor Fusion.

Aim

Autonomous driving systems, High-Definition Maps and smart tracking technologies require advanced detection methods to increase environmental awareness and maximise object detection accuracy. Traditional object detection methods are usually based on a single sensor, but using only camera or only LIDAR (Laser Imaging Detection and Ranging) has several limitations. For example, cameras may be inadequate in low-light areas such as tunnels and underpasses, while LIDAR sensors cannot provide colour and texture information. This paper proposes a system that improves real-time object detection capability by combining 360° panoramic camera, LIDAR and GPS (Global Positioning System) data. The main objective of the study is to provide the highest detection and identification accuracy, reduce false positives, and determine the positions of objects in three dimensions with high precision with this sensor fusion approach.

Material and Method

The proposed system consists of three main components: 360° panoramic camera with Inertial Measurement Unit (IMU) integration, LIDAR sensor and GPS module. In addition, YOLO (You Only Look Once) deep learning-based object detection model and Python coding language are used. The 360° camera provides a complete view of the surroundings, avoiding blind spots in detection. The IMU used in conjunction with the camera measures the vehicle's rotation, acceleration and speed, enabling more precise image processing. The LIDAR sensor generates a high-precision 3D point cloud of the environment, providing distance and position information of objects. The GPS module is used to integrate the detected objects into the world coordinate system by georeferencing the point cloud created with 360° panoramic camera images and LIDAR sensor.

YOLO (You Only Look Once) deep learning-based object detection model performs real-time object detection by processing panoramic images. The YOLO model has high processing speed and accuracy with its single-pass detection architecture. OpenCV, PyTorch and NumPy libraries are used in the system developed using Python language. The sensor fusion module synchronises the data received from the camera and LIDAR to precisely determine the position of the objects.

Findings

The application was made with the data obtained by scanning the Ayazağa campus of Istanbul Technical University with the vehicle with the sensors used. Within the scope of the application, images taken at different points of the campus were evaluated in test scenarios. As a result of the experiments carried out on the roads, car parks and controlled test areas within the campus, it was observed that the number of photographs used in model training and the number of these photographs belonging to different locations significantly increased the detection accuracy. fter the false object detections in Image 1, more accurate results were obtained as in Image 2 as a result of the model developed by increasing the test images. Compared to the YOLO model where the camera is used alone, sensor fusion has increased the detection success. Object detection accuracy for vehicles, pedestrians, signposts and other objects has increased significantly. False positives were reduced due to LiDAR integration. In low light conditions such as tunnels, the camera-only YOLO model struggled to detect objects, while the system was able to produce more reliable results thanks to the LIDAR depth information.

Image 1

Image 2

Conclusion

This study presents an innovative 360° detection system that integrates panoramic imaging, LIDAR depth mapping and deep learning-based object detection. The results show that multi-sensor fusion improves object detection reliability and accuracy. Sensor fusion improves detection accuracy, reduces false detections and enables the system to operate more reliably in low light conditions. Thanks to the depth information provided by LIDAR, distance estimation has become more accurate, and the misclassification rate of detected objects has decreased with the labelling made with 360-degree panoramic camera images. However, there are some aspects of the system that need to be improved. First of all, it is of great importance to calibrate the camera and LIDAR accurately. Small calibration errors can lead to deviations in depth estimation. In future studies, it is suggested to investigate the effect of weather conditions on the detection performance, to increase the stability of the system by adding additional sensors such as radar, and to optimise the processing efficiency of the system by developing lighter, faster models.

Keywords : Ramsar Site, Manyas Lake, Remote Sensing, Anthropogenic Impact, Geographic Information Systems.

Aim

Water is fundamental to life's existence and sustainability. In terrestrial ecosystems, water bodies serve as critical habitats that support a wide range of organisms. Any negative alterations in these environments can directly and significantly impact biodiversity. In particular, the increasing influence of industrialization and human activities over time has posed substantial threats to these ecosystems, leading to potential disruptions in ecological balance and habitat integrity. Especially, the increased industrialization and human activities can threaten these regions from the past to the present. In fact, in the last half century, even in the Mediterranean ecosystems, whose surrounding lands have been cultivated for thousands of years, there has been a comprehensive and rapid change that has never been seen in history (Gülçin, 2021). Various national and international efforts are being made to protect freshwater resources, which also host many migratory bird species. There are 14 Ramsar Sites of international importance in Türkiye, and because of this Intergovernmental Convention, they must be protected. These areas are recognized for their essential values for humanity and are protected for conservation and sustainable use. One of these areas is the Manyas Bird Paradise and Lake Conservation Area, located within the borders of Balıkesir province. The region is vital for the 270 birds, 118 plants, and 23 fish species in Manyas Lake and the various reptile species it hosts (Url-1). The study aims to use remote sensing data and methods to determine changes in the water surface area of Manyas Lake, assess changes in land use/land cover (LU/LC) in the lake protection area, and analyze the changes using demographic and meteorological data.

Material and Method

Manyas Lake, also known as Lake Kuş (Bird Lake), is located in the Marmara Region of northwestern Türkiye, within the boundaries of Balıkesir Province. Covering an approximate surface area of 160 square kilometers, the lake lies at an elevation of around 18 meters above sea level. The lake has a width of 20 km in the east-west direction, 14 km in the north-south direction, an average depth of 3 m, and has constantly turbid and abundant nutrient (eutrophic) properties due to the colloidal clay it contains (Url-1). Due to its shallow waters, the lake is highly sensitive to seasonal and anthropogenic changes. The important streams feeding the lake are the Sığırcı Stream, coming from the north, and Manyas Stream and Kara Stream, reaching the lake from the south (Figure 1).

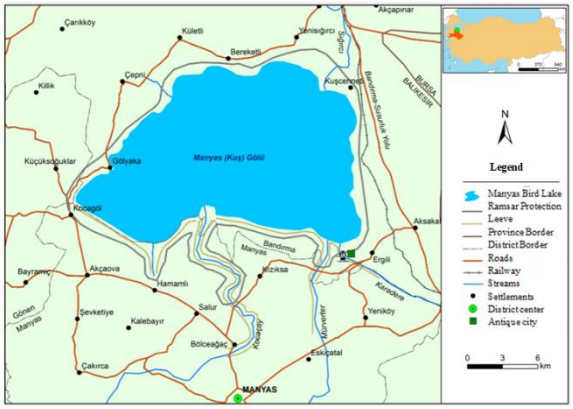

Figure 1: Manyas Lake and Surroundings (Url-2).

The important human settlements within the area are Kocagöl, Çepni, Kuşcenneti, Gölyaka, Bereketli, Yenisığırcı, Doğa, Ergili, Kızıksa, Akçakova and Salur neighborhoods.

Manyas Lake is internationally recognized for its ecological importance, particularly as a critical habitat for waterbirds. The Kuşcenneti (Bird Paradise) National Park, established in 1959, is situated on the northeastern shore of the lake and is designated as a Ramsar Site due to its significance for bird biodiversity. Over 270 bird species have been recorded in the area, including pelicans, herons, storks, and many migratory species.

The vector data used in the study (Buffer zone, Core protection zone, and Ecological impact limit) were obtained from the Ministry of Agriculture and Forestry (Figure 2). The buffer zone boundary is defined to reduce human pressure around the protected wetland. In the strictly/core protected area, human activity is completely prohibited. Ecological impact boundary refers to the spatial limit beyond which human activities, such as construction, agriculture, or resource extraction, are expected to have significant, measurable, or irreversible effects on an ecosystem's structure, function, or biodiversity.

Figure 2. Buffer zone boundary (red), Core protection zone (blue), Ecological impact boundary (yellow).

The population data of the settlements were obtained from the Turkish Statistical Institute (TUIK). Meteorological data were obtained from the General Directorate of Meteorology.

Sentinel-2 images were utilized both to monitor changes in the lake's water surface area and to assess alterations within the protected areas, owing to their accessibility as free remote sensing data sources, their adequate spatial resolution (10 m), and their high temporal resolution (5 days).

The most widely used Normalized Difference Water Index (NDWI) in the literature was used to determine the change in the lake surface area. This index enhances the presence of water while suppressing vegetation and soil features. NDWI is calculated using the near-infrared (NIR) and green bands of satellite imagery with the formula:

$$NDWI = (Green - NIR) / (Green + NIR)$$

High NDWI values indicate open water, low or negative values represent vegetation, soil, or built-up areas. It's commonly used in environmental monitoring, agriculture, and water resource management.

In addition, seasonal water surface area changes between 1985 and 2020 was determined by applying NDWI to spring and autumn Landsat satellite images. While Sentinel 2 images have been available since 2015, Landsat satellite images have been available since 1972, but their spatial resolution is lower than Sentinel 2's (30m).

A supervised random forest algorithm was used to determine land use/land cover (LU/LC) change in the area within the buffer zone boundaries, and images belonging to the years 2015, 2017, 2019, 2021, and 2023 were classified. The Random Forest algorithm is a supervised learning method widely used in machine learning. It is an ensemble-based algorithm that works with high accuracy in classification and regression problems. In the classification, four classes (water bodies, artificial area/bare soil, weak vegetation/shrubs and vegetation) were selected to determine the changes, and images from July and August were used.

Findings

Figure 3 shows the NDWI results applied within the protected area boundaries from the 2015-2023 Sentinel 2 images.

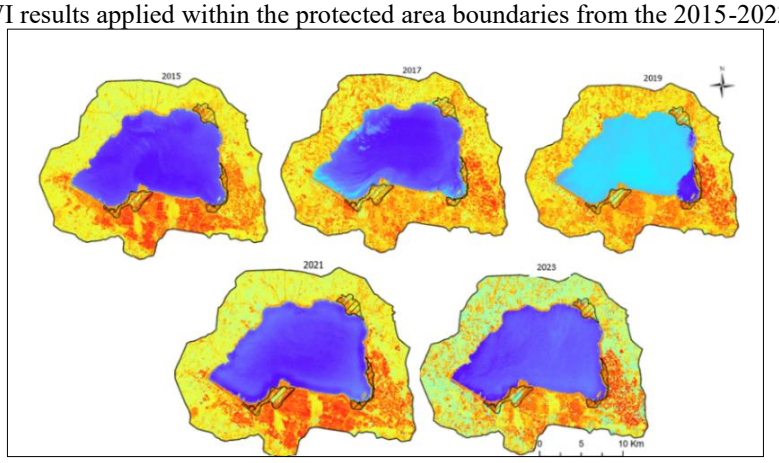

Figure 3: NDWI maps for years 2015, 2017, 2019, 2021, and 2023.

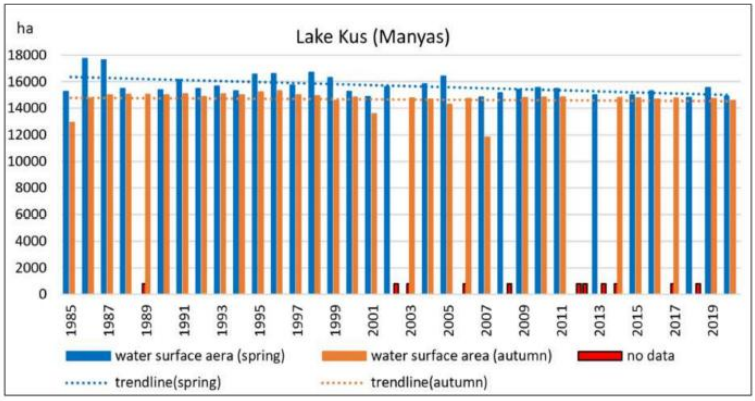
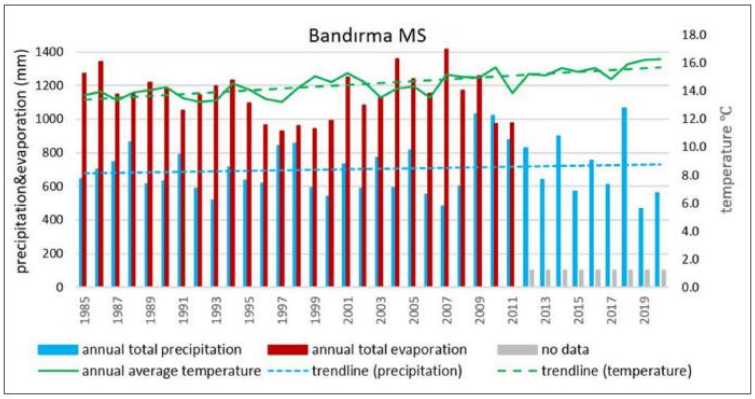
According to the NDWI results applied to five Sentinel 2 images from 2015 to 2023, the water surface area has fluctuated over the observed period. It was determined to be less than 150 km² in 2015. Later, it significantly increased by expanding to 155.9 km² in 2019. However, this trend reversed, and the area shrank to less than 150 km² in 2021. These changes in surface area can be attributed to annual rainfall fluctuations, which can significantly affect water levels in such ecosystems. This pattern highlights the dynamic nature of the water body and its sensitivity to climatic factors and the remarkable rainfall variability.

Figure 4a shows the water surface areas obtained according to the NDWI results applied to Landsat Satellite images in hectare units. The closest meteorological station to Manyas Lake is Bandırma station, and the data from this station were used to interpret these results (Figure 4b).



a)



b)

Figure 4. a)1985-2020 Fall and spring water surface area changes and change trends (Dervisoglu, 2021).
b) Annual total precipitation, evaporation and average temperature, and their trendlines (Dervisoglu,2021).

When the graph showing the annual water surface areas in Figure 4 a is examined, it can be seen that there was a decrease in the spring, and the trend did not change much in the autumn months. When the meteorological data were examined an increase in the annual total precipitation trend and temperature was found. The average precipitation (35 years) was 704.16 mm and the average evaporation (27 years) was 1141.87 mm, indicating that evaporation was about 1.62 times more than precipitation. While the lake had a water surface area of 15,269.35 ha in 1985, it decreased to 14,919.41 ha with a 2.3% loss in 2020. The main reason for the high-water level difference in the spring and autumn months is the withdrawal of water from the lake for agricultural activities.

Random Forest image classification was applied to five Sentinel 2 images between 2015 and 2023 to assess potential land use/land cover (LU/LC) changes in the study area (Figure 5a). The analysis revealed fluctuations among different land cover classes over the years; however, these changes did not follow a unidirectional trend but exhibited oscillatory patterns. The graph in Figure 5b shows the results obtained from the classification made in the buffer area.

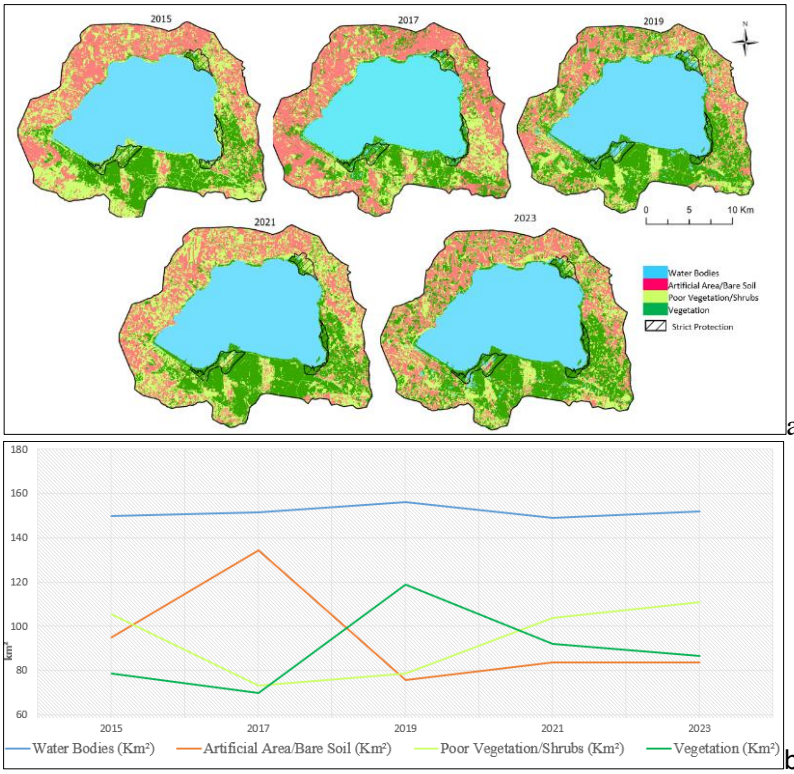


Figure 5: a) LU/LC Classification of the Lake protection area for years 2015, 2017, 2019, 2021, and 2023. b) LU/LC changes in buffer zone area (km²).

When Figure 5b is examined, although there are small fluctuations in the water surface area between 2015 and 2023, the general trend is stable (around 150 km²). Artificial Area/Bare Soil areas were around 100 km² in 2015, and peaked with a significant increase in 2017 (around 130 km²). A sudden decrease is observed in 2019, and its area decreased to approximately 80 km² as of 2023. This change can be interpreted as a decrease in artificial surfaces or re-covering bare lands with vegetation. The vegetation area, approximately 90 km² in 2015, peaked with a significant increase in 2019 (around 120 km²). It then showed a decreasing trend; it decreased to 80 km² levels again as of 2023. This situation may suggest a temporary improvement in vegetation and then deterioration, and harvesting agricultural areas may have been effective in the change.

The neighborhoods and towns around Manyas Lake are in close contact with the lake ecosystem and the surrounding natural life. When their populations were analyzed, it was determined that they tended to decrease. The population of the Manyas district showed a general decreasing trend between 2015 and 2024. The population, which was 20,154 in 2015, declined to 17,890 in 2024.

Conclusion

This study used Sentinel-2 and Landsat images and remote sensing techniques to analyze the LU/LC and water surface area changes in Manyas Lake. Although water surface areas occasionally show an increase or decrease, no significant change can be mentioned.

No specific one-directional change trend has been observed in the field. This can be explained by the fact that a large part of the land consists of agricultural areas and the study's short temporal range. The dominance of the vegetation class is noticeable in the strictly protected areas. Since the region consists mainly of agricultural land, the land cover constantly changes, making it difficult to reach a definitive conclusion about classification. Data spread over a more extended period and field exploration research will increase the accuracy. Agricultural activities around Manyas Lake have changed

significantly over the years. A considerable increase has been observed in paddy (rice) cultivation areas, especially south of the lake. This situation indicates the transition from traditional subsistence farming to commercial farming (Url-3).

In addition, when the lake waters recede in the summer months, vegetable farming is carried out in the emerging areas (Url-4). However, increased agricultural activities negatively affect the lake water quality and the lake ecosystem because of the fertilizers and pesticides used. For this reason, agricultural practices should be carried out with sustainable and environmentally friendly methods.

Various measures must be implemented in Ramsar protected areas to ensure sustainability and biodiversity conservation. In this context, the natural hydrological structure of wetlands should be preserved, and destructive activities such as drainage and landfilling must be avoided. Pollution, especially from agricultural and industrial sources, should be strictly controlled. Regular monitoring, scientific data collection, and public awareness are critical. Remote sensing images and methods are very effective tools for monitoring these areas regularly.

Aircraft Contrails Detection with Deep Learning Methods on Remote Sensing Images

Çağatay Yıldırım[a], Hande Demirel[a]

[a] İstanbul Technical University, Graduate Institute, Geomatics Engineering Department, Geomatics Engineering Phd. Program, Türkiye
cagatay.yildirim@itu.edu.tr

Keywords : Contrail Detection, Satellite Imagery, Deep Learning, Infrared Bands, Environmental Monitoring.

Aim

Aircraft contrails contribute to climate change by affecting Earth's radiation balance. Detecting and analyzing contrails is crucial for understanding their environmental impact. In this study, a deep learning-based approach is developed to identify contrails using satellite imagery. Due to the limited temporal resolution of Sentinel-2, GOES-16 satellite data is utilized for more frequent observations.

By analyzing the top-performing models in the Google Open Contrails competition, it is observed that processed satellite images, such as Ash Color and IR False Color composites, provide better contrail detection accuracy. Various deep learning architectures, including EfficientNet V2, CoAtNet, and MaxVit, are evaluated, with MaxVit emerging as the most effective model due to its ability to capture both local and global features. Additionally, loss functions like Dice Loss, Focal Loss, and Lovasz-softmax improve segmentation accuracy.

The study identifies that bands 11, 14, and 15 (infrared bands) are most effective for contrail detection, while band 16 may provide further insights into high-altitude contrails. Large datasets are processed efficiently using the HDF5 format, and data augmentation techniques are applied to enhance model performance.

While this research focuses on 2D imagery, contrail altitude remains a critical factor for accurate detection. Future work can integrate altitude data to refine contrail identification. This study highlights the potential of deep learning for contrail detection, contributing to aviation regulations and sustainable air traffic management.

This study aims to develop and evaluate advanced deep learning models for detecting aviation-induced contrails using satellite imagery. The primary objective is to improve the accuracy and efficiency of contrail detection in order to support environmental monitoring and reduce aviation's impact on climate change. By comparing multiple state-of-the-art models, the research focuses on identifying the most effective approach for robust contrail identification under varying atmospheric conditions.

Material and Method

The dataset used in this study is sourced from GOES-16 satellite imagery, with a focus on infrared bands 11, 14, 15, and 16. These bands were selected to enhance contrail visibility through Ash Color and IR False Color composite generation. Data were stored in HDF5 format and augmented with flipping, rotation, and brightness adjustments.

Three deep learning architectures—EfficientNetV2, CoAtNet, and MaxViT—were selected for evaluation. Among them, MaxViT was identified as the most effective due to its ability to capture both local and global features. Training was performed with an 80–20 training-validation split using the Adam optimizer and learning rate scheduling. Focal Loss, Dice Loss, and Lovász-Softmax were applied to address class imbalance. Model performance was evaluated using metrics such as mIoU, precision, recall, and Dice coefficient.

Findings

The experimental results demonstrated that MaxViT outperformed other models with a high segmentation accuracy (mIoU ≈ 87%) and fast inference speed. Infrared bands significantly enhanced contrail visibility, particularly during nighttime observations. Composite imagery further aided manual and automated detection. The use of Focal Loss and Lovász-Softmax improved detection of thin and hard-to-identify contrails. Data augmentation contributed to better generalization across varied atmospheric conditions. The low inference latency of MaxViT supports potential real-time deployment in operational monitoring systems.

Conclusion

This research highlights the effectiveness of deep learning, particularly MaxViT, in identifying contrails from GOES-16 satellite data. The integration of infrared bands and optimized training strategies enhanced detection accuracy and model robustness. While current results are promising, limitations remain, including the lack of altitude data. Future work should focus on incorporating 3D spatial information and validating the model on datasets from other satellite platforms. The outcomes of this study support ongoing efforts in aviation climate impact assessment and real-time environmental monitoring systems.

Enhancing Sentinel-1 SAR Geolocation Accuracy: The Impact of DEM on Orthorectification Performance

Sena Oğuzhanoğlu[a], Filiz Sunar[b]

[a] Istanbul Technical University, Graduate School, Geomatics Engineering Program, Turkey
[b] Istanbul Technical University, Faculty of Civil Engineering, Department of Geomatics Engineering, Turkey
oguzhanoglu17@itu.edu.tr, fsunar@itu.edu.tr

Keywords : DEM, Orthorectification, SAR Geolocation Accuracy, Sentinel-1.

Aim

Spaceborne Synthetic Aperture Radar (SAR) is a critical Earth Observation technology that monitors local and global environmental conditions. Unlike optical sensors, it operates day and night in all weather conditions. It actively transmits and receives microwave signals to generate images. Amplitude and phase components of SAR imagery enable applications such as surface deformation analysis and land cover classification. SAR imagery uses phase differences to accurately represent surface features, with side-looking geometry providing distinct range measurements based on signal travel time and Doppler effects (Gisinger, 2020). However, this side-looking geometry introduces geometric distortions - foreshortening, layover, and shadowing - that cause pixel shifts in range and azimuth directions (i.e., affect terrain representation) and require geometric corrections.

In addition, terrain elevation, orbit, and atmospheric errors affect the accuracy of SAR geolocation. Although technological advances by satellites such as TerraSAR-X and Sentinel-1 have significantly improved orbital accuracy, reducing elevation-related errors is still challenging (Li and Zeng, 2024). Early work in SAR remote sensing identified the need for precise orthorectification to reduce geometric distortions, improve the geolocation accuracy of SAR images, and provide reliable spatial analysis. Therefore, methods were developed that integrated Digital Elevation Models (DEMs) and precise orbital parameters.

The effectiveness of orthorectification depends on the resolution and accuracy of the DEM used, since errors in elevation data (dz) proportional to the angle of incidence (θ) can lead to position shifts (dx) (i.e., planimetric errors), as shown in Figure 1 (Shimada, 2010). Global DEMs, such as the Shuttle Radar Topography Mission (SRTM), and more recent high-resolution data sets, such as WorldDEM, significantly improve the geolocation accuracy. Higher resolution DEMs provide a more accurate terrain representation, especially in regions with complex topography, thereby improving SAR-based environmental monitoring and GIS applications. Evaluating the performance of different DEMs in SAR orthorectification is crucial to optimize geolocation accuracy and ensure the integrity of the derived spatial information.

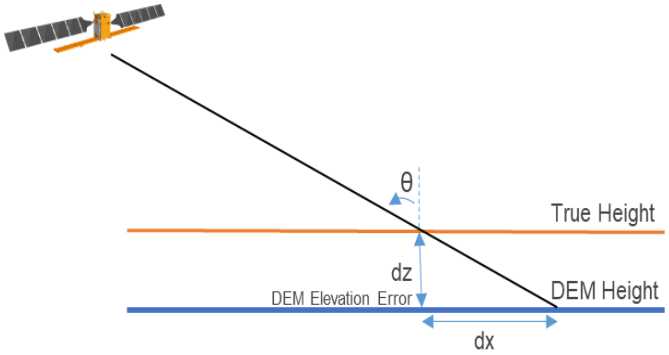

Figure 1. Effect of DEM errors on planimetric accuracy of the orthorectification.

For this purpose, this study assesses the impact of different DEMs on SAR geolocation accuracy using Sentinel-1 satellite images. Several DEMs, including SRTM 1 Arc-Second 30 m (DTED Level 2) and SRTM 3 Arc-Second 90 m (DTED Level 1), and a DEM generated from Sentinel-1 satellite imagery are used for orthorectification in the study area of Gölbaşı, Ankara. Their performance is evaluated using ground control points and quantified by metrics such as Root Mean Square Error (RMSE) and Circular Error at 90% Confidence Level (CE-90).

Material and Method

Gölbaşı, located in Ankara province, Turkey, was selected as the study area because of its relatively homogeneous land cover. The region consists mainly of open areas with minimal forest and shrub cover, which minimizes volume scattering effects in SAR imagery (Figure 2).

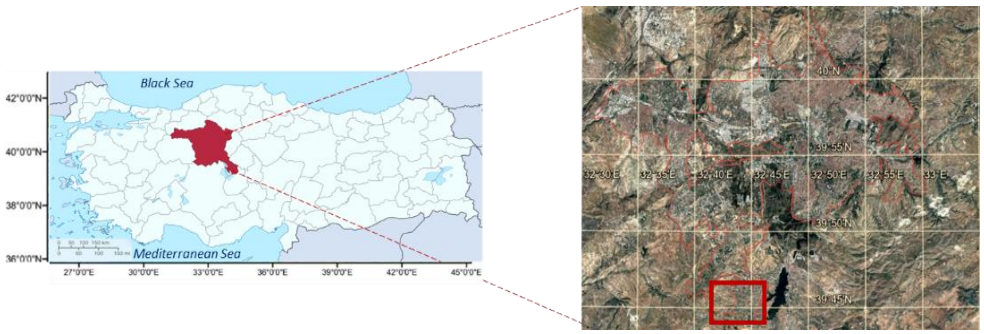

Figure 2. Satellite image of test areas in Ankara – Gölbaşı (red box) (©2020, Google Earth).

For the geolocation accuracy analysis, selected DEMs were applied to Sentinel-1 GRD (Ground Range Detected) satellite imagery in VV polarization. VV polarization was chosen because it provides higher backscatter contrast between different surface types, which improves feature discrimination, especially in open areas with minimal vegetation cover. Also, DEM generated from Sentinel-1 SLC (Single look Complex) satellite images. Sentinel-1 operates in C-band and the acquisition parameters of Sentinel-1 Interferometric Wide (IW) mode data used in this study are presented in Table 1.

Table 1. Sentinel-1 Interferometric Wide properties.

Characteristics	Value
Centre frequency	5.405 GHz (~5.55 cm)
Bandwidth	0-100 MHz
Polarization	Dual HH+HV, VV+VH Single HH, VV
Pulse Repetition Frequency	1 000 - 3 000 Hz
Sampling	10 bits
Swath	250 km
Incidence angle	29.1° - 46.0°
Sub-swaths	3
Maximum NESZ	-22 dB

The first step in this study is to generate a Digital Elevation Model (DEM) from Sentinel-1 SAR data using Interferometric Synthetic Aperture Radar (InSAR) techniques. This process uses Sentinel-1 Single Look Complex (SLC) images to derive

topographic information by exploiting phase differences between SAR acquisitions. The interferometric workflow includes co-registration of master and slave images to ensure precise alignment, followed by interferogram generation to capture phase variations associated with terrain elevation. Coherence estimation is performed to assess the quality of the interferometric fringes to ensure reliable phase unwrapping. Then, Goldstein phase filtering improves phase continuity, phase unwrapping is applied to resolve phase ambiguities and retrieve accurate elevation information. The unwrapped phase is then converted to elevation values using a phase-to-elevation transformation (Osmanoğlu et al., 2016) Finally, the generated DEM is validated against reference dataset before being used in the orthorectification process.

Once the interferometric DEM is generated, it is incorporated into the orthorectification process along with existing DEMs, including SRTM 30 m and SRTM 90 m. Orthorectification is performed using Sentinel-1 Ground Range Detected (GRD) products, applying Range Doppler Terrain Correction (RDTC) techniques within SNAP ESA's Sentinel-1 Toolbox. The RDTC method uses orbit state vectors, radar timing annotations and DEM inputs to correct for geometric distortions. This method allows Sentinel-1 SAR data to be projected into a uniform map coordinate system (UTM) (Bayanudin and Jatmiko, 2016). The orthorectification results obtained from different DEMs are then compared to evaluate the influence of the DEM on the geolocation accuracy.

To evaluate the accuracy of the orthorectified images, ground control points (GCPs) are used to measure the residual displacement between the reference and corrected SAR images. The assessment is performed using quantitative metrics, including Root Mean Square Error (RMSE) and Circular Error at the 90% Confidence Level (CE-90), according to the National Standard for Spatial Data Accuracy (NSSDA). The final accuracy assessment provides insight into the optimal DEM selection for Sentinel-1 SAR geolocation correction, ensuring accurate spatial alignment for further geospatial applications.

Findings

The geolocation accuracy evaluation showed that the resolution of the digital elevation model (DEM) directly affects the orthorectification quality of Sentinel-1 imagery. Among the DEMs evaluated, the SRTM 30-meter dataset significantly reduced position errors compared to the SRTM 90-meter dataset. The geolocation accuracy evaluation showed that the resolution of the digital elevation model (DEM) directly influences the orthorectification quality of Sentinel-1 imagery. The Sentinel-1-derived interferometric DEM demonstrated competitive accuracy but showed localized inconsistencies due to coherence limitations and phase unwrapping challenges.

Statistical validation using ground control points (GCPs) showed that higher resolution DEMs yielded lower RMSE and CE-90, underscoring the importance of fine-scale elevation data in SAR geolocation. The critical role of elevation accuracy in minimizing spatial misalignment was highlighted, particularly in complex terrain areas where coarser DEMs resulted in more pronounced discrepancies. Although interferometric DEMs are a suitable alternative, their reliability depends on phase coherence. These results emphasize the importance of selecting a DEM based on the application and terrain conditions.

Conclusion

These results highlight the importance of DEM selection in obtaining accurate SAR geolocation, as higher-resolution datasets significantly improve spatial accuracy. The comparison between DEMs showed that DEM resolution directly impacts orthorectification accuracy.

With increasing confidence in SAR-based geospatial applications, the selection of an optimal DEM is critical to ensure accurate terrain representation and minimize spatial inconsistencies. Future research should investigate multi-source data fusion and adaptive filtering techniques to further improve SAR geolocation accuracy, especially in high relief environments where terrain-induced distortions remain a challenge.

Offshore Wind Turbine Site Selection in the Aegean Sea

Şule Feride Ardıç[a], Adalet Dervişoğlu[b]

[a] Istanbul Technical University, Geomatics Engineering Program, Türkiye
[b] Istanbul Technical University, Faculty of Civil Engineering, Department of Geomatics Engineering, Türkiye
ardic17@itu.edu.tr

Keywords : Offshore Wind Turbines, GIS, Site Selection, Remote Sensing, Aegean Sea.

Aim

With the increasing global energy demand, the need for renewable energy sources is also rising. The main reasons for the rise in energy demand are industrialization and population growth. The limited availability of fossil fuels, the environmental impact of carbon emissions, and the necessity to combat climate change have further accelerated the shift toward renewable energy sources. In this context, wind energy, as a sustainable and clean energy source, stands out as a significant alternative. In particular, offshore wind energy offers more stable and higher energy production capacity compared to onshore wind farms (Esteban Pérez et al., 2011). Consequently, offshore wind farms have gained a prominent place in the energy policies of many countries.

Offshore wind energy projects also offer economic opportunities. Large-scale projects with high installed capacity can enhance national energy independence by reducing energy imports in the long term. Additionally, these projects create local employment opportunities and can accelerate technological development.

Offshore wind farms (Grid-Connected Offshore Wind Farms) offer a significant solution for assessing wind potential in open seas. Offshore wind energy provides stable and high-capacity power output due to strong and consistent wind flows, making it a crucial element of modern energy strategies.

The primary objective of this study is to identify the most suitable locations for offshore wind energy farms in the Aegean Sea and comprehensively evaluate the region's wind energy potential. To achieve this, wind resources in the region have been analyzed on an hourly and annual basis, examining wind speeds, directions, and frequencies. Meteorological data obtained from weather stations, lighthouses, and buoys have been utilized to generate wind profiles and estimate wind speeds at turbine hub heights. Furthermore, a multi-criteria assessment has been conducted, considering factors such as the region's bathymetric structure, maritime traffic, environmental and ecological constraints, grid connection feasibility, and economic viability (Tercan et al., 2020; Tortumluoğlu & Doğan, 2021). Based on these findings, this study aims to provide a scientific foundation for the development of sustainable and efficient offshore wind energy potential in the Aegean Sea.

Türkiye's geographical advantage of being surrounded by seas on three sides enhances the feasibility of offshore wind energy projects. The Aegean Sea, with its high wind potential, stands out as an attractive region for such projects (Satir et al.,2018). To maximize this potential, several critical factors, including meteorological analyses, seabed depth studies, environmental considerations, and the suitability of energy transmission infrastructure, must be considered. Identifying potential suitable locations involves assessing regions with high and consistent wind flow. Additionally, site selection for offshore wind turbines aims to minimize their impact on marine ecosystems and other environmental factors.

Materials and Method

Detailed analyses are essential for optimal site selection and project planning. Remote sensing technology is recommended for examining wind potential in the Aegean Sea. In this study, hourly wind data from meteorological stations, lighthouses, and buoys operated by the Turkish State Meteorological Service, as well as remote sensing data obtained from ECMWF's Copernicus Marine Service, have been utilized to assess wind energy potential. ECMWF's Copernicus Marine Service (CMEMS) is a remote sensing data source provided by the European Centre for Medium-Range Weather Forecasts (ECMWF), which is used for monitoring various oceanographic and meteorological parameters. This service provides

crucial data on wind speed, sea surface temperature, wave height, and ocean currents. In this study, wind data obtained from CMEMS was utilized to conduct large-scale spatial analyses for assessing the wind energy potential in the Aegean Sea. This dataset plays a key role in identifying the most suitable locations for offshore wind turbines by determining near-surface wind speeds. The limited number of buoys and meteorological stations measuring wind data in Turkey's marine areas presents a challenge in accurately determining wind potential. Therefore, remote sensing data has been employed to enable large-scale and spatial analyses.

Meteorological stations typically conduct measurements at heights ranging from 5 to 20 meters. However, since wind turbines are generally installed at hub heights between 70 and 100 meters, specific methods are required to estimate wind speeds at these altitudes (Soukissian et al., 2017). In this study, the logarithmic wind profile law has been applied to adjust surface wind speed measurements obtained from meteorological stations and buoys to turbine hub heights. The wind data from the satellite were taken at a height of 10 meters, just like the data from the weather station. In order to extrapolate the wind speeds to 100 meters, which corresponds to the typical turbine hub height, the logarithmic wind profile was utilized.

Hourly wind data collected from stations, lighthouses, and buoys have been visualized as annual wind roses, and wind frequency analyses have been conducted. In addition, the Weibull probability distribution was applied to statistically characterize the wind speed regimes at each location. Remote sensing wind data has been analyzed using Geographic Information Systems (GIS) software. Spatial analyses were performed using GIS to assess wind energy potential.

Findings

The findings indicate that the western and northern parts of the Aegean Sea exhibit significant wind energy potential. Since water depth is a crucial factor in offshore wind turbine deployment, fixed-bottom wind turbines have been considered for shallow areas with depths below 50 meters, while floating platforms have been evaluated for deeper waters. This approach broadens the applicability of wind energy projects across a larger area.

Moreover, environmental constraints, such as maritime traffic, continental shelf boundaries, ecological sensitivities, and protected areas, have been considered as limiting factors. Based on GIS analyses and Weibull distribution modeling, specific locations off the coasts of Çeşme, Karaburun and Seferihisar have emerged as promising sites due to their high wind potential, suitable water depths, and proximity to energy transmission infrastructure. Figure 1 presents the annual mean wind speed distributions over the Aegean Sea for the years 2018 to 2023. The wind speed data were obtained from CMEMS satellite observations and extrapolated to 100 meters above sea level using the logarithmic wind profile law. Areas where wind speeds exceed the 7 m/s threshold—considered critical for offshore wind energy feasibility—are distinctly highlighted. These maps not only assist in identifying high-potential offshore wind zones but also enable the evaluation of interannual wind consistency. Notably, regions along the northwestern Aegean coast, particularly the Çeşme–Karaburun–Ayvalık corridor, exhibit persistent high wind speeds (>7 m/s) across all analyzed years.

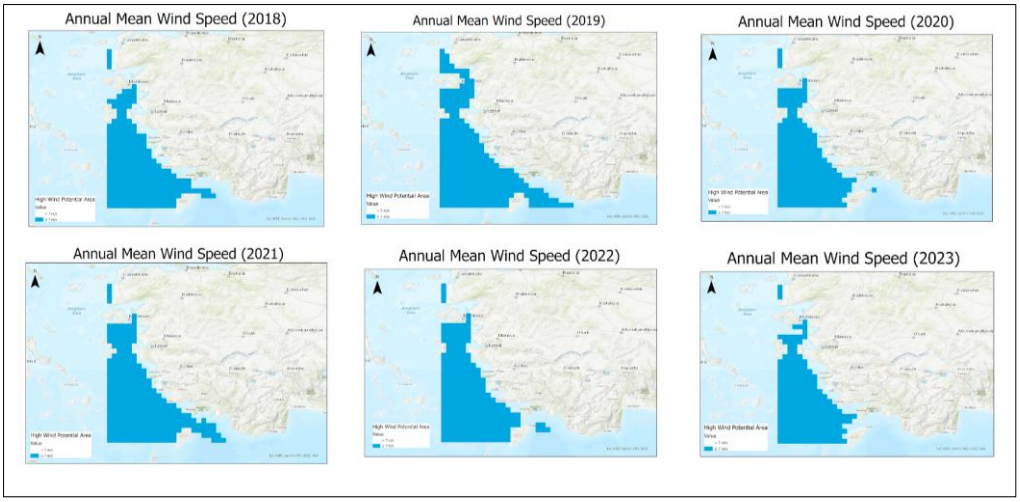

Figure 1. Annual Mean Wind Speed Maps (2018–2023) for the Aegean Sea.

Conclusion

This technology facilitates the collection of critical data regarding wind potential, marine conditions, and other environmental factors. This study provides a crucial scientific basis for identifying potential locations for offshore wind turbines in the Aegean Sea. Preliminary findings suggest that the region possesses substantial potential for wind energy production. However, in addition to technical feasibility, environmental and socio-economic factors must also be considered. The results obtained can guide energy policies and investment decisions. Future studies should incorporate more detailed meteorological modeling and environmental impact assessments to further refine the region's energy production potential.

In conclusion, specific locations in the Aegean Sea stand out as favorable sites for offshore wind turbine deployment due to their high wind potential, suitable water depths, and proximity to energy transmission infrastructure. The findings can serve as a roadmap for energy policies and investment strategies. Future research should focus on comprehensive meteorological modeling and environmental assessments to ensure the sustainable and efficient development of offshore wind energy in the Aegean Sea.

Keywords : Radar and Optical Vegetation Indices, Synthetic Aperture Radar (SAR), Dual-Polarization Backscatter, Polarimetric Decomposition, SAR-Optical Data Fusion.

Aim

Agricultural monitoring plays a crucial role in ensuring food security, optimizing resource use, and mitigating the impacts of climate change. Cotton, as one of the most economically significant crops, requires continuous observation to assess growth conditions, detect stress factors, and support precision farming practices. In regions such as the Aegean Region of Turkey, where cotton production is a major agricultural activity, remote sensing technologies provide an effective means to track crop development over large areas with high temporal and spatial resolution.

Optical remote sensing has been widely used to monitor vegetation dynamics through indices such as the Normalized Difference Vegetation Index (NDVI) and Enhanced Vegetation Index (EVI), which offer insights into vegetation vigor, chlorophyll content, and biomass. However, cloud cover and signal saturation in dense canopies often limit their effectiveness. Synthetic Aperture Radar (SAR), with its all-weather, day-and-night imaging capabilities, provides a complementary solution. Radar-derived vegetation indices, such as the Radar Vegetation Index (RVI), leverage SAR's structural sensitivity, offering additional insights into crop conditions (Hu et al., 2024). Integrating SAR and optical vegetation indices has shown promise for improving agricultural monitoring by capturing both spectral and structural crop characteristics. In particular, dual-polarization SAR data (VV and VH) and polarimetric decomposition metrics—including entropy, anisotropy, and alpha angle—can enhance the assessment of crop structure, biomass, and phenological changes.

This study aims to analyze the temporal consistency between radar-derived vegetation indices from Sentinel-1 (S1) and optical vegetation indices from Sentinel-2 (S2) for monitoring cotton elds in the Aydın province, Aegean Region of Turkey. The analysis covers the entire cotton growing season (May to October 2024), focusing on 11 adjacent fields, to assess how dual-polarization SAR backscatter metrics and advanced polarimetric features correlate with optical vegetation indices. The spatial distribution of the study area and the selected cotton fields is illustrated in Figure 1.

Figure 1. Satellite image of the study area, obtained from Google Earth.

Material and Method

The study area includes 11 neighboring cotton fields spread across three different locations in the Aegean Region of Turkey, where cotton farming holds significant economic importance. Sentinel-1 and Sentinel-2 datasets covering the full growing season from May to October 2024 are used. This temporal scope ensures the capture of key phenological stages, including

early vegetative growth, flowering, boll formation, and senescence. The key technical specifications of Sentinel-1 and Sentinel-2 sensors utilized in this study are summarized in Table 1.

Table 1. Technical specifications of Sentinel satellites (URL-1).

Feature	Sentinel-1	Sentinel-2
Sensor Type	Synthetic Aperture Radar	Multispectral Optical Sensor
Frequency/Spectral Range	C-band (5.405 GHz)	Visible, NIR, Red Edge, SWIR (13 bands)
Polarization	Dual (VV+VH)	N/A
Spatial Resolution	~10 m (IW mode)	10 m (VNIR), 20 m (Red Edge, SWIR), 60 m (atmospheric)
Temporal Resolution	6–12 days (depends on region and orbit)	5 days (at equator with twin satellites)
Swath Width	~250 km (IW mode)	290 km
Cloud Sensitivity	Not affected by clouds or weather	Affected by clouds, atmospheric conditions
Primary Strengths	Structural, moisture content, biomass detection	Vegetation vigor, chlorophyll content, land cover mapping
Main Agricultural Use	Crop structure, water stress, biomass mapping	Phenology, canopy vigor, vegetation indices

Sentinel-1 preprocessing includes radiometric calibration, speckle filtering, noise removal, and terrain correction. Backscatter coefficients (σ^0) will be used to derive VV/VH ratios and the Radar Vegetation Index (RVI) (Hu et al., 2024). Where applicable, polarimetric parameters(entropy, anisotropy, alpha angle) will be extracted, which correlate with biomass and plant height (Harfenmeister et al., 2021).

For Sentinel-2, Level-2A surface reflectance data will be used to calculate vegetation indices, with cloud masking applied using the Scene Classification Layer (SCL). Time-series analysis will include correlation and regression modeling to assess radar-optical relationships. Processing will be conducted in Google Earth Engine (GEE) and Python for scalability and reproducibility.

The specific optical and SAR vegetation indices calculated in this study are summarized in Table 2, along with their mathematical formulations and primary applications in crop monitoring. These indices were selected based on their established relevance in capturing canopy vigor, biomass, moisture dynamics, and structural characteristics of cotton fields.

Table 2. Overview of Sentinel-1 and Sentinel-2 derived vegetation indices.

Index / Parameter	Formula / Definition	Source / Spectral-SAR Bands	Purpose / Applications
NDVI	(NIR - Red) / (NIR + Red)	S2 Bands 8 & 4	Vegetation greenness, biomass, LAI
NDRE	(NIR - RedEdge) / (NIR + RedEdge)	S2 Bands 8 & 5	Chlorophyll content, nitrogen stress
EVI	2.5 * (NIR - Red) / (NIR + 6*Red - 7.5*Blue + 1)	S2 Bands 8, 4, 2	High biomass, soil/atmosphere minimized
NDWI	(NIR - SWIR) / (NIR + SWIR)	S2 Bands 8 & 11	Vegetation water content
MSAVI	(2 * NIR + 1 - sqrt((2 * NIR + 1)^2 - 8*(NIR - Red))) / 2	S2 Bands 8 & 4	Soil influence minimized
GCI	(NIR / Green) - 1	S2 Bands 8 & 3	Chlorophyll estimation
ARVI	(NIR - (2*Red - Blue)) / (NIR + (2*Red - Blue))	S2 Bands 8, 4, 2	Atmospheric resistance
SAR_ratio	VH / VV	S1 VH & VV	Vegetation structure, moisture reduction
SSD	VH - VV	S1 VH & VV	Vegetation vs bare soil indicator
SND	(VH - VV) / (VH + VV)	S1 VH & VV	Scale-invariant vegetation index
SSRM_VH	(VH^2) / sqrt(VV)	S1 VH & VV	Enhances VH vegetation signal
SSRM_VV	(VV^2) / sqrt(VH)	S1 VH & VV	Highlights VV dominant scattering
Entropy(H)	Degree of randomness (0-1)	Sentinel-1 SLC	Vegetation structure complexity, growth stage

Alpha Angle (α)	Mean scattering angle (0° surface, 45° volume, 90° double-bounce)	Sentinel-1 SLC	Dominant scattering mechanism, canopy-water detection
Anisotropy (A)	Second vs third eigenvalue ratio	Sentinel-1 SLC	Secondary scattering mechanism, complex canopies
Coherence	Phase stability (0-1)	Sentinel-1 SLC	Growth monitoring, vegetation change detection

Findings

Figure 2 presents a visual comparison of the study area using two different remote sensing datasets: Sentinel-1 VV polarization and Sentinel-2 NDVI imagery. The Sentinel-1 VV polarization (left) highlights variations in surface roughness and structural properties, making it particularly useful for distinguishing land cover types and detecting changes. In contrast, the Sentinel-2 NDVI imagery (right) provides insights into vegetation health and distribution by emphasizing chlorophyll activity. The combined analysis of these datasets enhances the understanding of land cover characteristics and vegetation conditions. The correlation analysis between Sentinel-1 SAR and Sentinel-2 optical vegetation indices was conducted across 11 representative cotton fields to assess the consistency and complementarity of radar and optical signals. As summarized in Table 3, both positive and negative correlations were observed, reflecting the complex interaction between crop structure, moisture content, and spectral responses. The spatial patterns of correlation were consistent across the three fields, confirming the robustness of these relationships. These results highlight that while general linear relationships between SAR and optical datasets are moderate, specific index combinations demonstrate strong agreement, supporting their combined use for monitoring crop conditions.

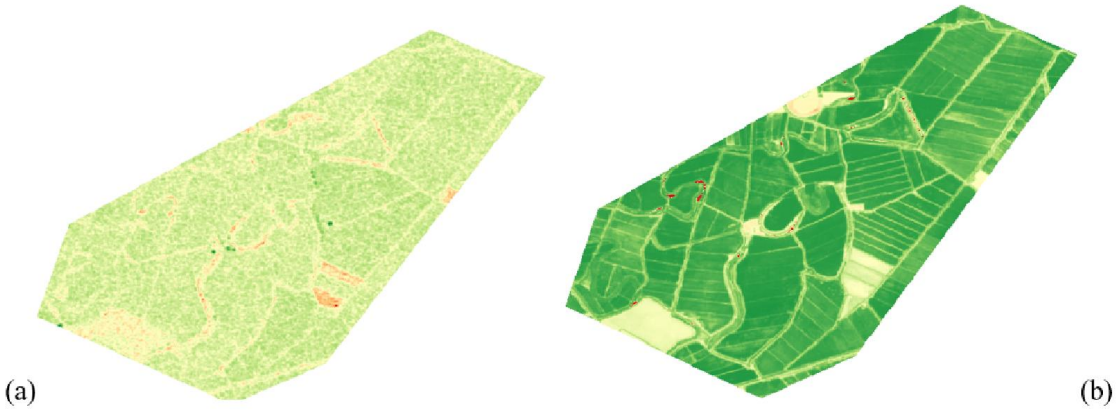

Figure 2. Visual comparison of two different satellite datasets. (a) Sentinel-1 VV polarized image. (b) Sentinel-2 NDVI image.

Table 3. Pearson correlation coefficients between Sentinel-1 and Sentinel-2 vegetation indices for three areas.

Field	Highest Positive Correlation (r) S1_Index - S2_Index	Highest Negative Correlation (r) S1_Index - S2_Index
Area-1	+0.67 VH–NDVI	-0.60 SSD-MSAVI
Area-2	+0.75 VV-MSAVI	-0.71 SSD-MSAVI
Area-3	+0.72 VH-MSAVI	-0.64 SSD-MSAVI

The strongest positive correlations were consistently found between Sentinel-1 VV mean backscatter and optical vegetation indices such as NDVI and MSAVI with coefficients exceeding +0.6. This indicates that the VV polarization backscatter is highly responsive to vegetation vigor and canopy density under specific growth conditions. On the other hand, significant negative correlations were identified between structural SAR indices, particularly SAR Simple Difference (SSD), and specific Sentinel-2 spectral bands sensitive to water content and biomass. The lowest correlation values reached -0.71, suggesting reduced radar returns in areas with dense and moist canopies.

Overall, the findings reinforce the potential of integrating SAR and optical vegetation indices to monitor cotton crop development, structure, and physiological status, offering a reliable approach for growth stage assessment and vigor analysis.

Conclusion

This study underlines the importance of integrating multi-sensor remote sensing for cotton monitoring in the Aegean Region. The temporal consistency between Sentinel-1 SAR and Sentinel-2 optical vegetation indices effectively captures cotton phenological dynamics, highlighting key growth stages where SAR metrics align with optical indicators. Notably, during boll formation and maturation, SAR-based parameters—especially polarimetric decomposition features—remain sensitive to structural and moisture variations, offering an advantage over optical indices that often saturate in dense canopies.

The findings emphasize the potential of SAR-derived entropy, anisotropy, and alpha angle as proxies for biophysical crop traits such as biomass and water content, providing critical insights for irrigation management and early stress detection. By complementing optical data, SAR extends agricultural monitoring beyond its well known all-weather capability, contributing to more robust and data-driven precision agriculture strategies for sustainable cotton production.

Generation of Proper Inflow Conditions with Hydrodynamic Stability Approach: A Case Study For An Axially-Rotating Pipe Flow

Taha Gunaydin[a], I. Bedii Ozdemir[a]

[a] İstanbul Technical University, Department of Mechanical Engineering, Fluids Group, Türkiye
gunaydin18@itu.edu.tr, bozdemir@itu.edu.tr

Keywords: Hydrodynamic Stability, Inflow Boundary Conditions, Turbulence, Unsteady Flow.

Aim

With the advancement of computers in the last few decades, computationally demanding time-dependent calculations such as Direct Numerical Simulation (DNS) and Large Eddy Simulation (LES) have become increasingly popular in many engineering flows. An inherent problem within these simulations is that they require realistic turbulent inflow conditions, which directly determine the downstream features of the flow (Klein et al., 2001). Various methods (Dhamankar et al., 2018) exist for generating inflow conditions such as transition inducing conditions, turbulence library methods, recycling-rescaling of perturbations, synthetic turbulence generation etc. An important trade-off exists between the computational effort and the accuracy of the final solutions in all of these methods. As, for example, the synthetic turbulence generation offers an easy implementation in time-dependent simulations without requiring excessive computational effort and time. The main disadvantage of this method is the need for a development region, which refers to the distance downstream of the inlet before turbulence becomes fully developed (Dhamankar et al., 2018). This is also called the adaptation region and depends highly on the characteristics of the inflow condition, and usually the aim is to decrease the size of this region as much as possible (Tabor & Baba-Ahmadi, 2010). The synthetic inflow can be constructed with respect to many constraints based on known turbulence properties, such as the turbulent spectra and Reynolds-stresses. However, methods that better represent experimental data are structurally more involved (Fathali et al., 2008) and are intrinsically more complex. A simpler method should require less computational effort.

This study aims to use hydrodynamic stability analysis to construct divergence-free space-time correlated turbulent inlet conditions for an axially rotating pipe flow with Re = 2500 and a swirl number of 0.5.

Material and Method

The method consists of using eigensolutions obtained from the hydrodynamic stability approach. The procedure of hydrodynamic stability analysis involves the decomposition of physical quantities, i.e. velocity and pressure, into their time-averaged and fluctuating parts. Then, the incompressible continuity and momentum equations in cylindrical coordinates (see Figure 1) are rewritten in terms of the decomposed quantities.

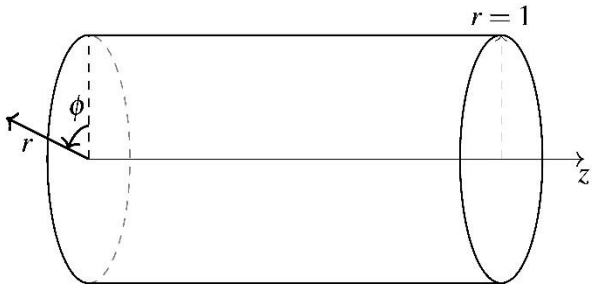

Figure 1. A sketch representing the problem domain with the cylindrical coordinates.

These equations are time averaged and subsequently subtracted from the original equations yielding the modal equations, consisting of the unknown fluctuating quantities. The yielded equations are linearized around the mean flow field obtained from previous experimental and computational studies (Facciolo, 2006) (Figure 2) to obtain a set of linear differential equations

$$\frac{\partial u_r'}{\partial r}+\frac{1}{r}u_r'+\frac{1}{r}\frac{\partial u_\phi'}{\partial \phi}+\frac{\partial u_z'}{\partial z}=0 \tag{1a}$$

$$\frac{\partial u_r'}{\partial t}+\frac{\overline{U_\phi}}{r}\frac{\partial u_r'}{\partial \phi}-2\underline{U_\phi}\frac{u_\phi'}{r}+\underline{U_z}\frac{\partial u_r'}{\partial z} = -\frac{1}{2}\frac{\partial p'}{\partial r}+\frac{1}{Re}\left[\frac{\partial^2 u_r'}{\partial r^2}+\frac{1}{r}\frac{\partial u_r'}{\partial r}+\frac{1}{r^2}\frac{\partial^2 u_r'}{\partial \phi^2}-\frac{2}{r^2}\frac{\partial u_\phi'}{\partial \phi}-\frac{u_r'}{r^2}+\frac{\partial^2 u_r'}{\partial z^2}\right] \tag{1b}$$

$$\frac{\partial u_\phi'}{\partial t}+u_r'\frac{\partial \overline{U_\phi}}{\partial r}+u_r'\frac{\overline{U_\phi}}{r}+\frac{\overline{U_\phi}}{r}\frac{\partial u_\phi'}{\partial \phi}+\underline{U_z}\frac{\partial u_\phi'}{\partial z} = -\frac{1}{2r}\frac{\partial p'}{\partial \phi}+\frac{1}{Re}\left[\frac{\partial^2 u_\phi'}{\partial r^2}+\frac{1}{r}\frac{\partial u_\phi'}{\partial r}+\frac{1}{r^2}\frac{\partial^2 u_\phi'}{\partial \phi^2}+\frac{2}{r^2}\frac{\partial u_r'}{\partial \phi}-\frac{u_\phi'}{r^2}+\frac{\partial^2 u_\phi'}{\partial z^2}\right] \tag{1c}$$

$$\frac{\partial u_z'}{\partial t}+u_r'\frac{\partial \overline{U_z}}{\partial r}+\frac{\overline{U_\phi}}{r}\frac{\partial u_z'}{\partial \phi}+\underline{U_z}\frac{\partial u_z'}{\partial z}=-\frac{1}{2}\frac{\partial p'}{\partial z}+\frac{1}{Re}\left[\frac{\partial^2 u_z'}{\partial r^2}+\frac{1}{r}\frac{\partial u_z'}{\partial r}+\frac{1}{r^2}\frac{\partial^2 u_z'}{\partial \phi^2}+\frac{\partial^2 u_z'}{\partial z^2}\right] \tag{1d}$$

In Equation 1, an overbar denotes time-averaged quantities and ( )' denotes time-fluctuating quantities, $u_j(j=r,\phi,z)$ denotes the non-dimensionalized velocity component j, p is non-dimensionalized pressure and Re is the radius-based Reynolds number.

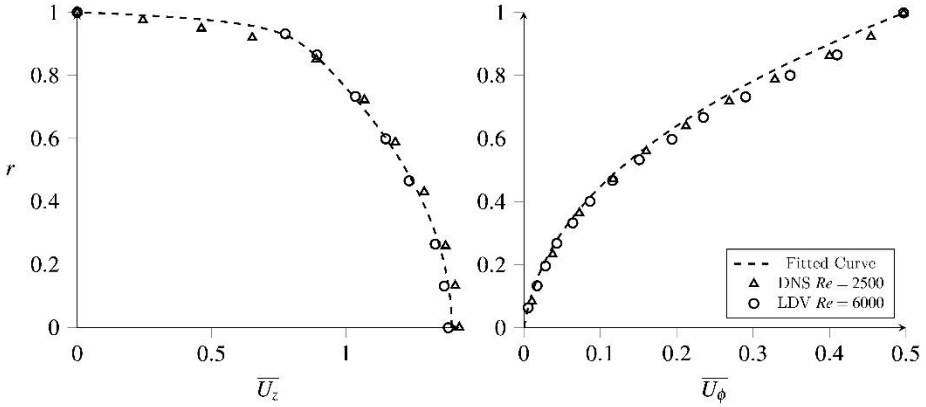

Figure 2. Mean velocity profiles obtained from previous experimental and computational studies and curves fitted to the data.

We then introduce normal-mode solutions for the fluctuating quantities such that

$$u_r' = \hat{u}_r(r)e^{i(k_z z+k_\phi \phi-\omega t)}+(*) \tag{2a}$$

$$u_\phi' = \hat{u}_\phi(r)e^{i(k_z z+k_\phi \phi-\omega t)}+(*) \tag{2b}$$

$$u_z' = \hat{u}_z(r)e^{i(k_z z+k_\phi \phi-\omega t)}+(*) \tag{2c}$$

$$p' = \hat{p}(r)e^{i(k_z z+k_\phi \phi-\omega t)}+(*) \tag{2d}$$

where a hat over a quantity denotes the eigenfunction associated with the corresponding fluctuating quantity, $(*)$ denotes the complex conjugate, i is the imaginary unit, k_z is the eigenvalue in the streamwise direction, k_ϕ is the wavenumber in the azimuthal direction and ω is the frequency associated with the corresponding eigenfunction. Inserting Equation (2) into Equation (1), we obtain an eigenvalue problem

$$\frac{d\hat{u}_r}{dr} = -\frac{\hat{u}_r}{r} - \frac{ik_\phi}{r}\hat{u}_\phi - ik_z\hat{u}_z \tag{3a}$$

$$\frac{d\hat{p}}{dr} = -2W\hat{u}_r + 4\frac{\underline{\underline{U_\phi}}}{r}\hat{u}_\phi + \frac{2}{Re}\left[\frac{d^2\hat{u}_r}{dr^2} + \frac{1}{r}\frac{d\hat{u}_r}{dr} - \frac{\hat{u}_r}{r^2} - \frac{k_\phi^2\hat{u}_r}{r^2} - k_z^2\hat{u}_r - \frac{2ik_\phi\hat{u}_\phi}{r^2}\right] \tag{3b}$$

$$\frac{d^2\hat{u}_\phi}{dr^2} = ReW\hat{u}_\phi + Re\left(\frac{d\underline{\underline{U_\phi}}}{dr} + \frac{\underline{\underline{U_\phi}}}{r}\right)\hat{u}_r + Re\frac{ik_\phi}{2r}\hat{p} - \left[\frac{1}{r}\frac{d\hat{u}_\phi}{dr} - \frac{\hat{u}_\phi}{r^2} - \frac{k_\phi^2\hat{u}_\phi}{r^2} - k_z^2\hat{u}_\phi + \frac{2ik_\phi\hat{u}_r}{r^2}\right] \tag{3c}$$

$$\frac{d^2\hat{u}_z}{dr^2} = ReW\hat{u}_z + Re\left(\frac{d\underline{U_z}}{dr}\right)\hat{u}_r + Re\frac{ik_z}{2}\hat{p} - \left[\frac{1}{r}\frac{d\hat{u}_z}{dr} - \frac{k_\phi^2\hat{u}_z}{r^2} - k_z^2\hat{u}_z\right] \tag{3d}$$

where $W = -i\omega + \frac{\underline{\underline{U_\phi}}}{r}ik_\phi + ik_z\underline{U_z}$. The eigenvalue problem as presented in Equation (3) is then converted into a boundary value problem with a normalization condition, which is an inner product of the eigenfunction $\hat{u}_z$ with its complex conjugate and with a kernel function G

$$\gamma = <\hat{u}_z, \hat{u}_z> \geq \int_0^1 \hat{u}_z G(r)\hat{u}_z^* dr = 1 \tag{4}$$

To solve the eigenvalue problem (3) with the normalization condition (4) the parallel-shooting method is employed. The parallel-shooting method involves the integration of equations from the boundaries up to a mid-point arbitrarily chosen (Keller, 2018). The boundary conditions are determined from the no-slip condition at the wall and the regularity of solutions at the center of the pipe (Meseguer & Trefethen, 2000). However, to integrate the equations, unknown conditions from both boundaries must be guessed. The equations are integrated and a discrepancy vector is obtained at the mid-point. Finally, the multivariable Newton-Raphson method is employed to update the guess values, and the discrepancy at the midpoint is eliminated iteratively (Vetterling & Press, 1992) with a relative tolerance of 1E-6.

Using the obtained Fourier modes, the instantaneous velocity fluctuations with the correct space-time correlations were calculated and added to the mean flow to obtain the inflow conditions.

Findings

The modal equations result in eigenfunctions, with associated eigenvalues and wavenumbers. It is found that all modes are decaying with downstream distance in the solution domain investigated here. This complies with previous findings of other hydrodynamic stability analyses (Lessen et al., 1968). For each frequency ω and azimuthal wavenumber k_ϕ, discrete modes exist and each eigenfunction within each mode has a unique spatial distribution in the radial direction. A dispersion relation, shown in Figure 3, displays part of the solution domain with the eigensolutions that have the least amount of spatial decay at non-dimensional frequency $\omega = 0.1$.

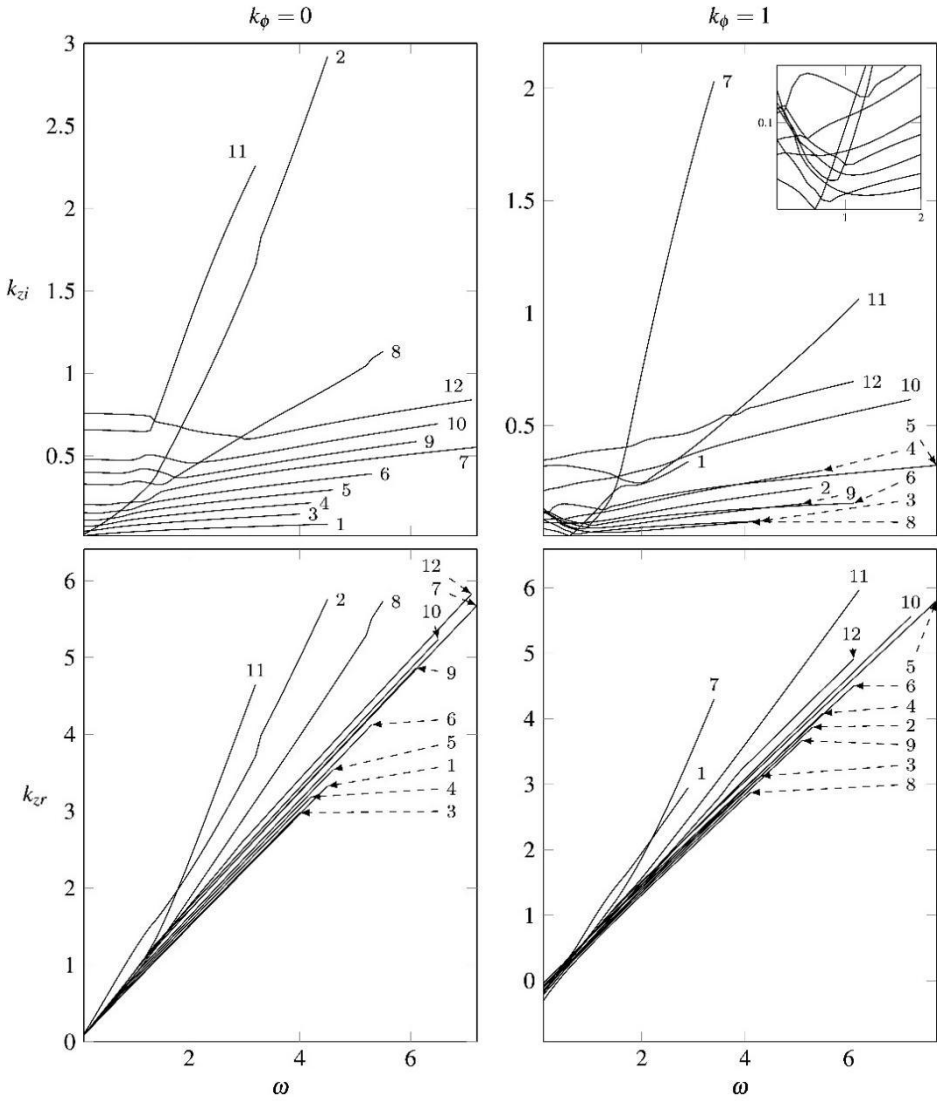

Figure 3. The dispersion relation showing the relation between the eigenvalues ω, wavenumbers k_ϕ and k_{zr}, as well as the decay rates k_{zi} of the eigensolutions.

It is found that for both axisymmetric ($k_\phi = 0$) and non-axisymmetric ($k_\phi = 1$) solutions, the decay rates k_{zi}, which are the imaginary parts of k_z for a given mode, are a function of the frequency. Local minima of k_{zi} exist for each mode, but a general increasing trend for the decay rates can be observed across all modes with increasing frequency. Moreover, a localization of the solutions is observed with increasing frequency. In Figure 4, the first 6 non-axisymmetric modes are shown. It can be seen that the localization is the shrinkage of the radial domain in which amplitudes are relatively large. The exact location around which the localization occurs (the radial point at which eigenfunctions have the maximum amplitude) depends on the mode number and is consistent for a given mode through all three components of the velocity perturbation field. The relative amplitudes of the three eigenfunctions change with frequency, however when the global contribution of kinetic energy is assessed, it is observed that the axial eigenfunctions have the largest contribution amongst the two others. On top of that, a positive correlation between the decay rate of a given mode and the position of eigenfunction maximum is seen. This implies that modes which have a higher concentration of kinetic energy near the wall region have higher decay rates. Also, these modes have relatively higher k_{zr} (real part of k_z), meaning that they have smaller phase velocities ω/k_{zr}. This clearly shows the effect of viscosity to both the decay rate and phase velocity of wave solutions.

Since viscosity has a large influence in the near-wall region due to shear, these results are relevant from a flow physics perspective.

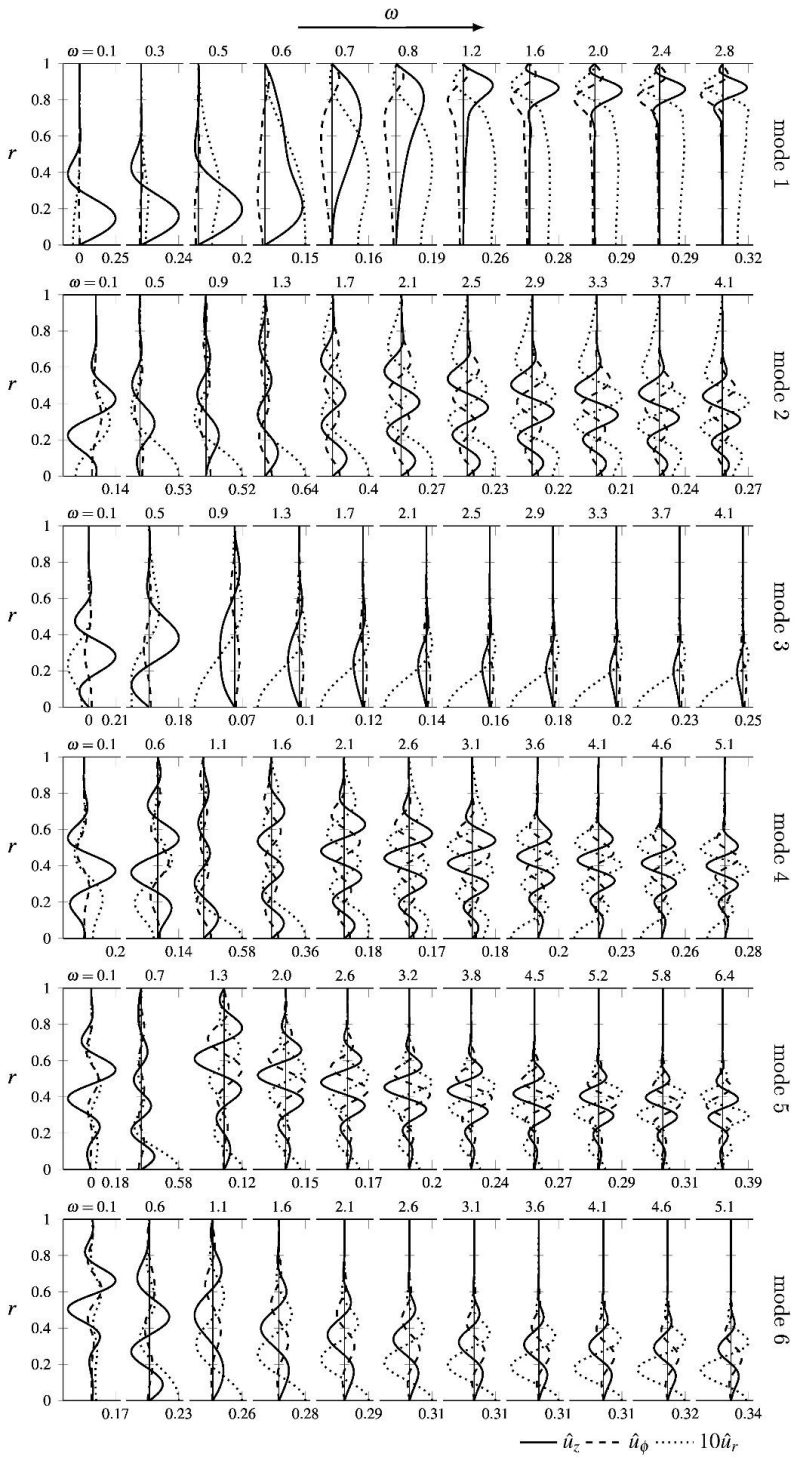

Figure 4. The first 6 non-axisymmetric ($k_\phi = 1$) modes containing the spatial distributions of $\hat{u}_z$ (axial eigenfunction, solid lines) $\hat{u}_\phi$ (azimuthal eigenfunction, dashed lines) and $\hat{u}_r$ (radial eigenfunction, dotted lines) for different frequencies ω.

For the generation of inflow conditions, 5 non-axisymmetric modes are selected, 3 of which show near-wall maxima. A total of 239 eigenfunctions sampled between dimensional frequency of 0.7 to 42 Hz are used to construct a time-dependent fluctuating velocity field. When compared with the findings of previous DNS studies (Facciolo, 2006), RMS values obtained from the perturbation field obtained with the modal analysis in this study capture the trend very well, as shown in Figure 5. The RMS values for the axial velocity field agree very well with the DNS results, whereas the azimuthal RMS values are over-predicted in the near-wall region. On the other hand, the RMS values for the radial velocity component are under-predicted over the entire domain.

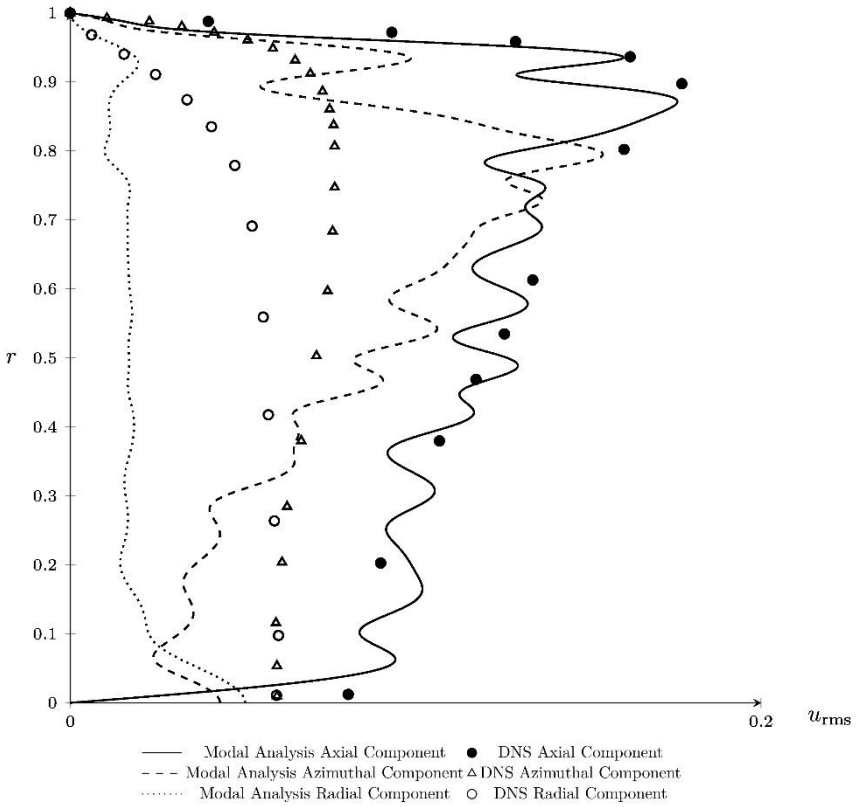

Figure 5. The RMS distributions of the fluctuating velocity field constructed with the selected eigensolutions and RMS distributions from DNS results.

Conclusion

In this study, the use of hydrodynamic stability theory for the generation of inflow conditions is assessed through the RMS distributions obtained from the fluctuating velocity field. It is found that when a specific subset of solutions are used, a fluctuating velocity field with RMS distributions close to DNS results are obtained. This clearly makes this method a good candidate to generate synthetic turbulence for time-dependent calculations such as LES and DNS. On top of that, the obtained modes present a deterministic perspective of understanding turbulence development, in that the presence of near-wall maxima show a strong correlation with the decay rate of eigenmodes and the inverse of phase velocities.

The Transformation of Armored Vehicles as a Response to Amphibious Warfare: A Comparative Analysis of the Dieppe Raid and the Normandy Landings

Göktuğ Berk Çakı[a]

[a]Istanbul Technical University, Institute of Graduate Studies, Programme in History of Science and Technology, Türkiye
caki21@itu.edu.tr

Keywords: Amphibious Warfare, Armored Vehicles, Dieppe Raid, Normandy Landings, Military Innovation.

Aim

Amphibious operations have long posed a unique set of challenges to military planners, particularly due to their reliance on cross-domain coordination, unpredictable littoral geography, and heavily defended coastlines. The evolution of armored vehicles during the interwar and Second World War periods reflects a direct response to these complexities. This study aims to investigate how the transformation of armored vehicles was shaped by the practical demands of amphibious warfare and the doctrinal efforts to reclaim offensive initiative in static, defense-dominated theatres.

The core objective of the research is to explore the extent to which this transformation resulted from accumulated battlefield experiences rather than a linear progression of technological improvement. In doing so, the study challenges technologically deterministic perspectives by emphasizing the co-constitutive role of operational failure, engineering improvisation, and institutional learning in the redesign of armored units for seaborne assaults. Rather than treating tanks as isolated instruments of mechanized warfare, the study approaches them as parts of a broader military-technical ecosystem shaped by strategic imperatives and material constraints.

By focusing on the comparative analysis of two pivotal amphibious operations—the Dieppe Raid (1942) and the Normandy Landings (1944)—this research identifies how operational shortcomings in the former catalyzed significant doctrinal and technical innovation by the time of the latter. The study asserts that vehicles like the DD tanks, LVTs, and Hobart's "Funnies" were not simply new machines, but rather integrated battlefield solutions born of specific historical problems. Ultimately, this thesis contributes to a richer understanding of amphibious warfare by examining how armored technologies were transformed not solely by invention, but by necessity.

Material and Method

This research employs a comparative historical methodology rooted in the analysis of military doctrines, engineering developments, and battlefield reports. By focusing on two amphibious operations—Dieppe (1942) and Normandy (1944)—the study identifies the tactical, operational, and technological factors that shaped the performance and transformation of armored vehicles. Each case is analyzed using a multi-scalar framework that includes three layers of interpretation: tactical execution, logistical integration, and doctrinal adaptation.

Primary sources include official after-action reports, military engineering manuals, and doctrinal writings by figures such as Heinz Guderian and Charles de Gaulle. Secondary literature provides historiographical context, with key references drawn from works on armored warfare, amphibious strategy, and military innovation.

In addition to historical documents, the study integrates strategic theory, particularly Colin S. Gray's assertion that "technology changes the character, not the nature of war," to assess how changes in vehicle design addressed enduring challenges in amphibious combat. Technological case examples—such as the Duplex Drive tanks, Landing Vehicle Tracked (LVT), and Hobart's Funnies—are not studied in isolation but as responses to specific operational shortcomings. The analysis aims to reveal how armored vehicle innovation was driven less by abstract engineering potential and more by real battlefield imperatives encountered in coastal assault scenarios.

Findings

The comparative analysis of the Dieppe Raid and the Normandy Landings highlights a fundamental shift in how armored vehicles were conceptualized, modified, and employed in amphibious warfare. At Dieppe, the Allied forces, particularly Canadian armored units, attempted a direct landing of Churchill tanks without adequate preparation for coastal obstacles. The result was operational failure: most tanks were destroyed or immobilized upon landing, unable to support infantry, and ultimately contributing to the mission's collapse.

This failure revealed critical gaps not only in equipment but also in doctrine and planning. There was no joint coordination between infantry, armor, and engineers to overcome beach obstacles, nor was there a contingency for the tanks' mechanical limitations on shingle beaches. Moreover, the absence of specialized vehicles capable of clearing mines, bridging anti-tank ditches, or navigating underwater impediments underscored a larger structural unpreparedness for integrated coastal assault.

In contrast, the Normandy Landings showcased a drastically revised approach. British and American forces fielded a range of purpose-built armored vehicles, from Sherman DD swimming tanks to Crab flails and AVREs equipped for engineering tasks. These designs directly addressed the obstacles identified at Dieppe—mines, sea walls, bunkers, soft terrain—and provided immediate firepower and logistical mobility. The deployment of LVTs and DUKWs by American forces further ensured continuous support beyond the beaches.

The success at Normandy was not due solely to superior machines, but to the integration of vehicle innovation with joint operations doctrine. Armor was no longer an isolated asset but part of a synchronized assault system involving naval fire support, air superiority, and engineering foresight. The findings confirm that battlefield performance of armored vehicles improved when technology was embedded within a holistic operational design shaped by earlier failures.

Conclusion

This study demonstrates that the transformation of armored vehicles in amphibious warfare was not the result of linear technological advancement, but a direct response to operational failure and tactical necessity. The comparison between Dieppe and Normandy illustrates a clear trajectory of institutional learning, where the shortcomings of 1942 led to the development of integrated, purpose-built solutions by 1944.

Rather than relying solely on technological innovation, success at Normandy emerged from a systemic shift in doctrine, planning, and coordination. The introduction of specialized vehicles—such as DD tanks, LVTs, and engineering-modified armor—reflects how the Allies redefined their approach to coastal assault through interdisciplinary adaptation. Engineering, logistics, and battlefield experience came together to overcome the rigid defensive structures that had paralyzed earlier amphibious attempts.

Ultimately, this research reaffirms the argument that in military history, technological tools achieve impact only when they are embedded in broader strategic thinking. Armored vehicles became effective not just because of their capabilities, but because they were redesigned and deployed in harmony with evolving doctrines of joint warfare. The transformation was not inevitable; it was earned through trial, error, and adaptation under fire.

Scientific Tendencies in Early Nineteenth-Century Britain: William Sturgeon and The Annals of Electricity, Magnetism and Chemistry

Tuğçe Esenduran[a]

[a] Istanbul Technical University, Department of Humanities and Social Sciences, History of Science and Technology, Turkey
esenduran@itu.edu.tr

Keywords: Electricity, Magnetism, Electromagnetism.

Aim

The recognition of electromagnetism as an independent phenomenon in the early nineteenth century represented a main advancement in the exploration of electricity and magnetism. However, despite substantial experimental progress, the fundamental relationship between electrical and magnetic forces remained poorly comprehended. To attain a more thorough understanding of the scientific challenges of the 19th century, it is crucial to examine the main concerns of the first half of 19th century, as these earlier intellectual developments provided the foundation for subsequent discoveries in electromagnetism.

This study is structured around the table of contents of the A*nnals of Electricity, Magnetism, and Chemistr*y, conducted by William Sturgeon between 1836 and 1843 in 10 volumes. Those Annals, attended by both the general public and academic audiences, served as a platform for both disseminating information and fostering awareness of the developments bridging philosophical inquiry and the practical applications of early electrical technologies in England. The primary aim of the annals is to facilitate the exchange of similar observations, discoveries, and inventions among experimentalists who are not affiliated with formal scientific communities.

The Annals of Electricity, Magnetism and Chemistry features translations of newly published experimental scientific works from Germany, France, Italy, and America, reflecting the interests and intellectual pursuits of its readership. Its work reflects a concerted effort to elucidate the theoretical foundations of electrical experimentation, particularly the fundamental physical laws governing the field. The experiments, researches, and publications were not only enriched scientific discourse but also played a crucial role in expanding public understanding of electricity and its importance.

Material and Method

The advancements of the early nineteenth century arise not only from the combinations of experiments and mechanical thoughts but also theoretical understanding of problems. As we collect materials from scientific journals where various facts first appeared from different countries, we begin to recognize the underlying principles behind them, rather than merely focusing on their practical development. This study seeks to enhance the understanding of first half of 19th-century scientific tendencies with investigations, experiments and instruments by examining the evolution of electrical experimentation with their principles.

The Annals of Electricity, Magnetism and Chemistry, edited by Sturgeon, served as a key periodical that focused on the study, documentation, and experimentation of electromagnetism. This publication attracted a diverse group of contributors, including experimental scientists, instrument makers, electricians, and businessmen, all of whom shared a profound interest in electrical phenomena, viewing electricity as a fundamental natural force. The periodical covered a wide range of topics, including galvanism, the measurement of electricity, electroshock effects from Voltaic pairs, and chemical reactions induced by metals. It also explored the practical applications of electric currents, such as their influence on soft iron and the construction of more powerful electromagnets. Further, it documented the evolution of electromagnetic technology, from the development of electromagnetic apparatuses to the creation of coil-machines and electromagnetic engines. The Annals also examined the impact of electricity on various natural phenomena, such as its effects on geological formations, crystals, and plants, as well as its role in atmospheric phenomena, particularly lightning. Through these contributions, the whole ten

volumes of Annals provided a comprehensive record of the advancements and experimental efforts related to electromagnetic science during this main period.

Findings

Many key investigations have found from the era, which provide a deeper understanding of the scientific tendencies during the emergence of electromagnetism. First of all, the measurement of the magnitude of the electric current obtained from Volta's piles was one of the significant endeavours of the period. In this context, the measurement had achieved by comparing the various effects produced by the current. The current intensity, determined through its physical, chemical, and physiological effects, can be derived from one another. In particular, the physical effect of the electric current on a magnetic needle can be measured with high accuracy. Experiments from the period also indicate that the electric current is capable of generating heat, and the amount of electricity produced by the piles can be determined through the quantity of heat generated. Additionally, the main concern to get a more economical and more powerful arrangement between the scientific enquirers. Whole arrangements were in an attempt to get a sustainable battery with maximum power and minimum cost of operation. (Morus, 2019)

Another significant subject of study within the field of electromagnetism was the 'Galvanometer' which is used to measure the galvanic force generated by a conducting wire and serves as the medium for an electric current flowing from the positive to the negative pole of a galvanic or voltaic battery, or to assess the strength of any electric current, regardless of its source of excitation. Its operation is based on electromagnetism, a phenomenon discovered by Oersted in 1820, and its readings are indicated by the deflection of a magnetic needle placed within the range of the electrodynamic influence. The first type of galvanometer, known as Prof. Schweigger's multiplier, was constructed following the discovery of electromagnetism. While this instrument was adequate for most purposes, it required certain modifications to be suitable for research that demanded extreme precision and sensitivity. Experimental researches have focused on constructing larger sized galvanometers or multipliers beyond that point, aiming to improve their sensitivity and accuracy for more precise measurements. The galvanometer holds a crucial position in electrodynamical research, serving as an essential instrument for detecting and measuring small electric currents and it has also become a popular subject of discussion among philosophers.

The electrochemical action of electricity became evident in the 1830s through the electrical actions exerted by simple metals on fluids. Most experiments seem exceptionally well-designed to guide our understanding towards the source of chemical action. The experimentalists had an effort to find most compelling demonstration of how a simple galvanic arrangement can activate the powerful energies involved in the chemical transformation of matter.

The second major phase of research emerged with the invention of the electromagnet, in response to the need for stronger magnetic forces and the impracticality of large batteries, Sturgeon developed the electromagnet as an educational tool, following Oersted's announcement of the phenomenon of electromagnetism. This breakthrough allowed for further studies on the relationship between electricity and magnetism, leading to advancements in the construction of electromagnets and the development of new applications, such as the creation of electromagnetic engines and more efficient electrical machinery. This innovation sparked a wave of intensive experimentation aimed at improving electromagnets, leading to rapid and remarkable advancements in their design and functionality. The development of the electromagnet made the realization of a practical electric motor possible. For several years thereafter, the electric motor was referred to as the 'electromagnetic engine'.

A magnetic electrical machine, characterized by its efficiency, affordability, and immediate usability, is essential for experimental research. These machines emerged as one of the most significant instruments in electrical experimentation. Given the cost and operational challenges associated with voltaic batteries, magnetic electrical machines were increasingly adopted as primary tools for experimental investigations during this period. As a result of these, researches in electrodynamics, both in theoretical and experimental contexts, gained considerable interest among experimental philosophers.

Following Jacobi's 1835 invention of the high-speed rotary electric motor and the publication of his paper "On the Application of Electromagnetism to the Moving of Machines", which was translated and published in Sturgeon's Annals, interest in the development of electric motors increased significantly. There was a growing demand for an affordable and accessible source of power to drive electric machinery, trains, and transportation systems. As a result, electricity became a subject of widespread public interest, extending beyond experimental philosophers to engage individuals across all levels of society. As we realize from the articles, the development of experimental and philosophical apparatuses with practical applications gained significant momentum. And William Sturgeon noted that the electromagnetic engine described in the first volume of the Annals was capable of providing motion to machinery. He mentioned that successfully demonstrated by propelling both a boat and a locomotive carriage.

Another different area of investigation is electrical theory of mineral veins which stands as a distinct and intriguing aspect of electrical research. The interactions of minerals with voltaic electricity have particularly captured the scientific community's attention. Following Robert Fox's work on the "Influence of Electrical Action on Clay", numerous discussions and studies have emerged, further advancing our understanding of this fascinating field. That exploration highlights the dynamic relationship between electrical forces and matter, contributing to the broader discourse on the nature of electrical phenomena.

Conclusion

In conclusion, *Annals of Electricity, Magnetism, and Chemistry*, edited by Sturgeon between 1836 and 1843, documents numerous experiments conducted by individuals with a keen interest in electromagnetic phenomena. It provides significant insight into the scientific tendencies of nineteenth century England. The investigations of this era, particularly those focused on electromagnetism, display a distinct evolution in both theoretical and experimental approaches. The volumes of Annals of Electricity, Magnetism and Chemistry demonstrating clearly about scientific tendencies during its time in terms of electricity and magnetism phenomena. It is a good combination of different type of researches who have the theoretical or practical point of view including philosophers, experimentalists, instrument makers, scientific enquirers.

In early nineteenth-century physical science, the conservation of energy was a key concept. The development of energy conversion processes began with Volta's invention of the battery in 1800, leading to discoveries showing how energy could transform between different forms—chemical, electrical, heat, light, motion, and magnetism. (Clagett, 1969) Through the Annals, we gain a clearer understanding of how early electrical technologies bridged the gap between philosophical inquiry and practical application, while contributing to the advancement of this branch of science. As a result, this period was a key turning point in scientific thought, leading to modern physics and shaping future technological advancements. After having had a deep understanding of studies in that decade, the next phase of this study will focus on the network analysis between William Sturgeon and others who had deep interest in electricity, as reflected in those Annals.

Brief History Of Artificial Intelligence Approaches

İlkem Ahu Şahin[a], Aytekin Çökelez [a]

[a] İstanbul Technical University, Graduate School, History Of Science And Technology, Türkiye
sahinil20@itu.edu.tr

Keywords : Emergence of Machine Learning, Expert Systems, Histories of Artificial Intelligence Approaches , Symbolic AI.

Aim

Artificial intelligence (hereafter AI) has been modeled and implemented according to the various approaches since the emergence and grounding of the field in the middle of the twentieth century. Applications of formal logic for problem solving versus attempts in modeling human cognitive systems competed and opened path for further research. The different paths for finding a solution for artificial intelligence problems already branched out following the Dartmouth Conference of 1956. Symbolic, knowledge based, and data-driven approaches evolved throughout the years of study and implementation. The aim of this paper is to explore the emergence of different approaches on artificial intelligence implementation and present a summary as part of the overall historical narrative of AI.

Material and Method

This paper contains a part of a wider research conducted for the first author's PhD thesis in the field of history of artificial intelligence. The understanding of emergence and evolution of different artificial intelligence approaches is a key element of the overall research. The study starts from the middle of the twentieth century when artificial intelligence was defined as a separate field.

Determining the Purpose: There exist various narratives about the emergence and evolution of different artificial intelligence approaches. The purpose of the study is to compile them and present in a high-level summary for corresponding audience.

Identification: The exploration of the topic was conducted by examining literature through academic journals, portals and thesis centers related to the topic. As a result, the research scope was determined as a key section of the overall study of the history of artificial intelligence.

Analysis: The emergence of algorithms and its definition during the early years of AI was investigated to understand the conceptual background. Different AI models defined following the Dartmouth Conference of 1956 and evolving throughout the years were analyzed.

Synthesis: A historical narrative of the artificial intelligence approaches was compiled as a continuously evolving area.

Findings

Alan Turing provided a description of the universal machine and a list of concrete finite steps for the "decision problem" in his article "Computable Numbers" in the first half of the twentieth century. Thereby, Turing defined an algorithm, a clear definition of the solution generation procedure (Turing, 1936).
The emergence of algorithm dates to much older times than Turing's universal machine. The first algorithm was known to be presented by Ebu Abdullah Muhammed İbn Musa el Hârizmî (780-850), of Uzbek origin, in his book Hisab el Cebir ve el Mukabala, using Arabic numerals. El Hârizmî systematically described the calculation procedures in this first book known to be written on algebra. While reaching Europe, the title of the book was translated as Algoritmi de Numero Indorum in Latin due to the difficulty of pronouncing his author's name. Eventually, the term "algorithm" was born (Hazar, 2022).

An algorithm can be described as "a self-contained sequence of instructions and actions to be performed by a computational machine" (Deng: 2018, p.172). Developments regarding artificial intelligence (hereafter AI) algorithms and programming languages have been shaped according to the different approaches to the field starting from the middle of the twentieth century. In 1956, Herbert A. Simon, Allen Newell and John Clifford Shaw developed The Logic Theory (hereafter LT) at the RAND Corporation as a virtual machine, as a prototype of a computer program. The program could prove theorems from the Principia Mathematica of Alfred N. Whitehead and Bertrand A. W. Russell (Vayre, 2021). The Logic Theory is acknowledged as the first artificial intelligence program (Url-1).

Simon and Newell (1956, p.1) described the LT as a complex information processing system to discover proofs of theorems in symbolic logic: "This system, in contrast to the systematic algorithms that are ordinarily employed in computation, relies heavily on heuristic methods similar to those that have been observed in human problem solving activity. The specification is written in a formal language, of the nature of a pseudo-code, that is suitable for coding for digital computers."

The Logic Theory was designed for solving complex mathematical problems mimicking human cognitive processes. LT's designers demonstrated problem solving capability of a computer by discovering solutions in a complex nonnumerical domain using heuristic search (Penn, 2020; Vayre, 2021). Newell and Shaw (1957) explained that the problem they sought for a solution contained sufficient information and alternatives, yet there was lack of known clean-cut way of where the path to the solution was not clear at the start and vague rules of thumb were employed. LT was designed as a heuristic program for such complex problem-solving situations.

Simon and Newell presented their program in the Dartmouth Summer Research Project conference of 1956. The conference is recognized as the event in the history where the phrase "artificial intelligence" was first recorded, and the conceptual foundations of the field were laid.

Most researchers attending the conference, including the organizers John McCarthy and Marvin L. Minsky, did not see any point in studying human cognitive processes at that time where they shared the view that AI researchers should focus on formal logic instead. John McCarthy and Marvin Minsky later developed different views. McCarthy held logic as the primary focus area, whereas Minsky followed anti-logic approach. McCarthy developed the list processing language LISP in 1958 and proposed "IF, THEN" advice taker program in 1959 and worked on circumscription that Vayre (2021) describes as "a computing process by which the obstacles potentially impeding the logic inference engines can be isolated or minimized, to allow for navigation within a knowledge-based system" (p. 34). In 1962, McCarthy left Massachusetts Institute of Technology (hereafter MIT) AI Laboratory for the Stanford University AI Laboratory and worked on knowledge-based systems (Vayre, 2021). Minsky on the other hand continued at the MIT AI Lab where he received sufficient investments including from the U.S. Defense Advanced Research Projects Agency (DARPA) to work on establishing anti-logic approach on artificial intelligence. All these attempts played an important role in the development of artificial intelligence study approaches and influenced other researcher's work (Vayre, 2021).

Artificial intelligence research and implementation technologies went through several phases since the emergence of the field. From the middle of the twentieth century, different approaches such as symbolic manipulation, expert-systems databases, and data-driven machine learning approaches were explored. The symbolic approach introduced a heuristic symbolic information processor modelling of the human reasoning whereas the expert systems studies attempted to formalize human knowledge as databases of 'if–then' rules (Ali et al., 2023). In the early years of AI, from the mid-1950s to the 1980s, the symbolic AI approach was prevalent, based on the assumption that human thinking system used symbols in representing objects and problems (Anantrasirichai and Bull, 2021). Starting from 1960, expert knowledge engineering was applied for application domains where symbolic logical rules were used for the design of programs. Expert systems as knowledge-based AI systems were however lacking learning ability. They were mainly able to take human expert like decisions based on logical reasoning usually implemented by the inference rule algorithms in the form of "if-then-else". This approached worked well in narrowly defined application domains, yet it was insufficient to address uncertainty. Expert systems are still in use where the application domain is sufficiently narrow such as in the case of chess playing programs (Deng, 2018).

The next wave of AI, the data-driven machine learning relied on statistical models and simple neural networks. Training data was used by the engine to learn or tune existing parameters to keep up with uncertainties or changing conditions (Ali

et al., 2023). With machine learning, learning programs replaced the programmer and automatically learned the necessary algorithms from the data. This was possible because a certain pattern exists in big data. In other words, the hidden model underlying the observed data was extracted (Alpaydın, 2022). Deep learning as an approach differentiates from simple machine learning by the underlying deep and layered model structure of neural networks and associated end to end learning algorithms (Deng, 2018). The neural network approaches that stem from the 1940s are implemented in the contemporary times based on large databases to learn from data by computing patterns and correlations and make future forecasts accordingly (Ali et al., 2023).

Developments in machine learning and successes in deep learning have pointed out that intelligence can be achieved applying simple algorithms patiently and constantly rather than the need for inventing complex formulas and hence artificial learning became a driving force in intelligence. All these developments were a cure for the frustration caused by the old logic-based programmed expert systems in the 1980s. In the mid-80s, artificial neural network research boomed. Not only computer science, but also various disciplines such as electrical engineering, physics, statistics, psychology, cognitive science, neuroscience and linguistics were interested in this field. The advances in very-large-scale integration (VLSI) technology that coincided with this period also showed promise for implementing artificial neural networks that would distribute computation to large numbers of parallel processing units, with the capacity to create parallel hardware containing thousands of processors. Originally designed for fast image processing and transfer in graphical interfaces, the parallel computing, and data transfer architecture of the Graphics Processing Unit (GPU) was also deemed suitable and developed for machine learning. Artificial learning systems have become stronger than preceding expert systems with their success in representing uncertainties in the real-world using probability theory and models based on learning from examples that do not require programming (Alpaydın, 2022).

Conclusion

Artificial intelligence has been implemented according to different approaches since the grounding of the field in the middle of the twentieth century. Defenders of formal logic versus human cognitive system models for defining solutions appeared throughout the different waves in the history. Symbolic, knowledge based, and data-driven approaches were adapted, and some, by having transformed, survived to the present day.

This extended abstract contains a part of the ongoing dissertation work of İlkem Ahu Şahin for the degree of PhD in the History of Science and Technology, İstanbul Technical University, Türkiye.

Spatio-Temporal Analysis of Long-Term Rainfall Erosivity Trends and Climate Impacts on Erosion Potential

Ahmet Faruk İpek[a], Ercan Kahya[a]

[a] Istanbul Technical University, Civil Engineering Department, Hydraulics Division, Turkey
faruk.ipek@itu.edu.tr

Keywords: Erosion Risk Assessment, Modified Fournier Index, Modified Mann-Kendall Method, Küçük Menderes Water Basin.

Aim

Erosion, driven by natural processes and human activities, leads to soil loss and reduced fertility. Precipitation amount and distribution play a crucial role in erosion dynamics. This study examines the impact of precipitation on erosion potential in the Küçük Menderes River Basin using 50 years (1974–2023) of monthly precipitation data. Modified Fournier Index (MFI) and Modified Mann-Kendall (M-MK) trend analysis methods are applied to assess long-term seasonal and annual variations across temporal and spatial scales. Data from five meteorological stations across coastal and inland areas provide insights into how precipitation trends influence erosion risk under varying climatic and geographical conditions. The study explores the relationship between precipitation trends and MFI, highlighting the role of intense rainfall in erosion and risk variations during dry periods. By evaluating climate variables such as precipitation regime, intensity, and distribution, the study aims to determine climate-induced erosion risks.

Study Area and Data

The Küçük Menderes River Basin, covering approximately 345,701 hectares, is primarily located in İzmir (SYGM, 2019). This study utilizes a complete 50-year (1974–2023) precipitation dataset from the Turkish State Meteorological Service. Data from five meteorological stations İzmir, Salihli, Selçuk, Ödemiş and Sultanhisar were analyzed (Figure 1).

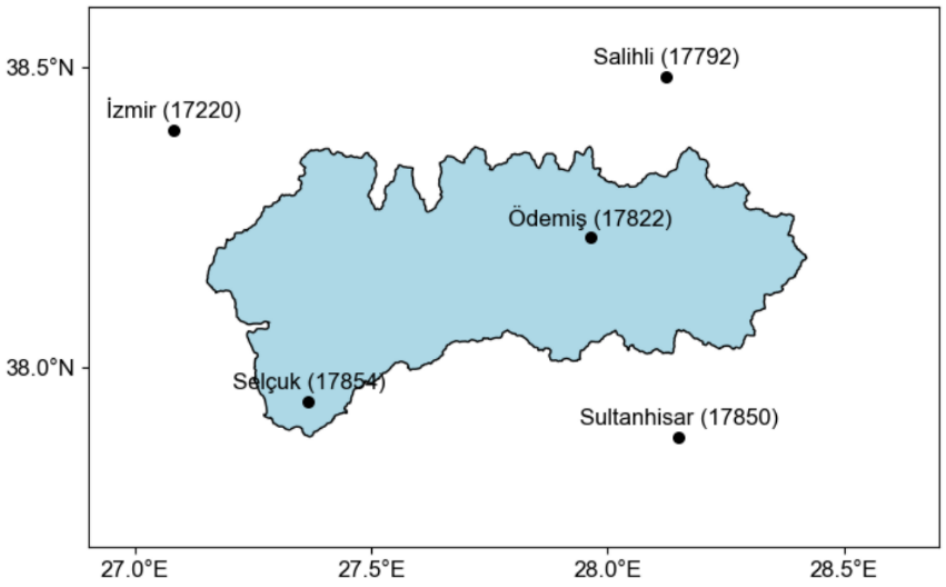

Figure 1: Meteorological observation stations.

Material and Method

Modified Fournier Index (MFI)

Introduced by Arnoldus (1977), the Modified Fournier Index (MFI) indirectly reflects precipitation's erosion potential. It is calculated as the ratio of each month's squared precipitation to the annual total and serves as a key parameter in erosion assessment.

$$MFI = (\sum (i=1 \text{ to } 12) P_i^2) / P_{total} \quad (1)$$

Here, P_i represents the montly precipitation (mm), P_{total} is the total annual precipitation (mm). With this approach, months with high precipitation are emphasized more, making the differences between dry and wet periods more distinct. Consequently, the estimation of precipitation-induced erosion risk becomes more accurate.

Modified Mann-Kendall (M-MK) Trend Test

The Modified Mann-Kendall (M-MK) test, developed by Hamed and Rao (1998), is an improved version of the Mann-Kendall test designed to detect trends in time series data while accounting for autocorrelation. In cases where data points are dependent on previous values, traditional Mann-Kendall results can be misleading. The M-MK test corrects for this by adjusting the variance before calculating significance. In this method, data points are arranged in chronological order, and each value is compared with subsequent values to compute the S statistic, which indicates whether the trend is increasing or decreasing. However, if the data exhibits autocorrelation, the variance of S is modified using a correction factor. After this adjustment, the Z statistic is computed to determine the significance of the trend. The test statistic is calculated as:

$$Z = S / \sqrt{V^*} \quad (2)$$

where S represents the trend direction, and V* is the adjusted variance that accounts for autocorrelation. If the absolute value of Z exceeds a critical threshold, the trend is considered statistically significant. A positive Z value suggests an increasing trend, while a negative Z value indicates a decreasing trend. If Z is close to zero, no significant trend is detected. By incorporating autocorrelation adjustments, the M-MK test provides a more reliable analysis for long-term datasets.

Findings

Precipitation amounts and MFI values show strong parallelism annually and monthly. In coastal stations (İzmir, Selçuk), MFI varies widely at high levels, while in continental Salihli, it remains lower and more stable. In transitional regions (Ödemiş, Sultanhisar), MFI is generally moderate (Figure 2). These findings suggest that erosion risk is higher in coastal areas due to more frequent extreme rainfall, whereas inland regions experience lower erosion potential due to more stable and limited precipitation patterns.

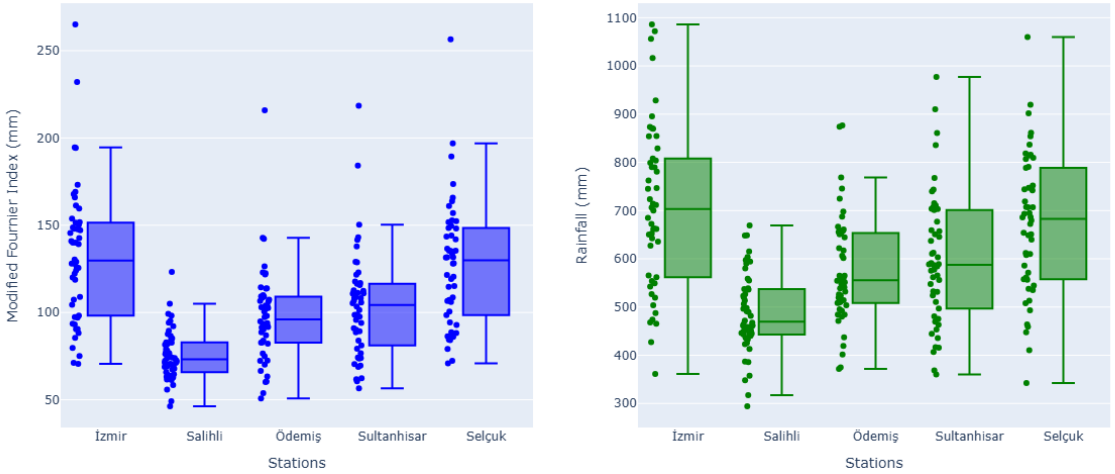

Figure 2: Boxplot representation of annual MFI and precipitation data by station.

On a monthly basis, MFI values rise to high levels in winter, with outliers exceeding 160 mm indicating increased erosion potential. In contrast, summer values drop to lower ranges, reflecting lower and less intense rainfall. High MFI values in İzmir and Selçuk highlight intense winter precipitation, while frequent winter outliers suggest occasional extreme rainfall events, further increasing erosion risk.

Additionally, an analysis of the 50-year dataset reveals significant declines in MFI values between 1991–1994 and in 2008, while sudden increases were observed in 1981 and 2001. Similarly, drought periods were identified in the Küçük Menderes Basin during 1992–1994, 2001, 2007, and 2008 (İpek & Kahya, 2022). This correlation indicates that declines in MFI align with drought conditions (Figure 3).

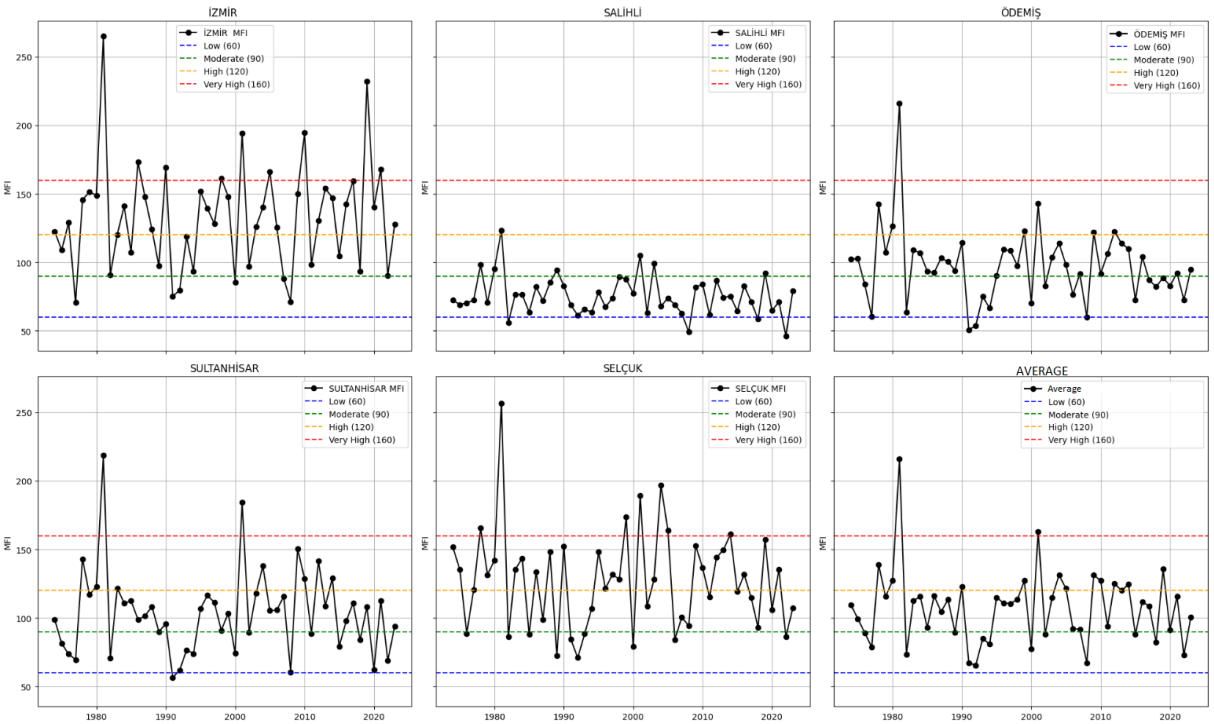

Figure 3: Modified Fournier Index (MFI) time series for individual stations and overall average.

According to Apaydın et al. (2006), high erosion potential is more frequent in maritime regions, while MFI remains stable at moderate levels inland. İzmir and Selçuk show increased erosion risk with 24 and 22 "very severe" cases and 9 and 7 "extremely severe" cases, respectively. In contrast, Salihli, with continental characteristics, is dominated by "moderate" cases (39), with almost no extreme events. Transitional regions Ödemiş and Sultanhisar have 26 and 24 "severe" cases, with 6 and 8 in the "very severe" category. These variations in MFI reflect differences in precipitation regimes from coast to inland areas (Table 1).

Table 1: The number of occurrences of erosion classes in Havza between the years 1974-2023.

Station	Low (0-60)	Moderate (61-90)	Severe (91-120)	Very Severe (121-160)	Extreme (>160)
İzmir	0	8	10	23	9
Salihli	4	39	6	1	0
Ödemiş	4	14	25	6	1
Sultanhisar	2	16	22	8	2
Selçuk	0	10	12	21	7

Precipitation and MFI (1974–2023) were analyzed using the M-MK method. Annual evaluations were conducted by eliminating seasonal influences. This was achieved by analyzing each month's data separately, preventing seasonal fluctuations from distorting overall trends. Trends were significant at $|Z| \geq 1.95$ ($p<0.05$). The results indicate that precipitation and MFI trends exhibited largely similar patterns across the basin. According to Figure 4, increasing trends are marked in blue, while decreasing trends are shown in red, with significant trends denoted by an asterisk. The parallel behavior of precipitation and MFI suggests that both variables are influenced by similar environmental and climatic processes. Though mostly not significant, notable changes appeared in specific periods and locations. In İzmir, June precipitation ($Z=2.36$) and MFI ($Z=2.39$) increased, suggesting higher summer erosion risk. Similarly, in Salihli, December precipitation ($Z=-2.14$) and MFI ($Z=-2.25$) declined, indicating irregular winter rainfall. Moreover, it was observed that increasing trends were more prevalent in summer months, while significant decreasing trends dominated in winter. This finding indicates a seasonal shift in the basin's precipitation regime, reflecting potential long-term changes in hydrological and climatic dynamics.

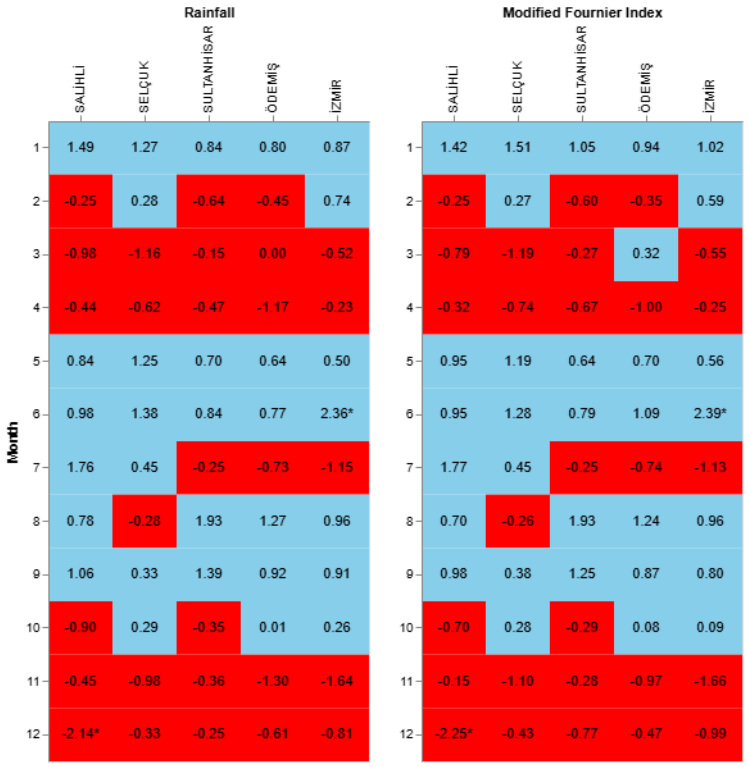

Figure 4: Comparison of monthly MFI and precipitation trends.

Trend maps used blue (increase), red (decrease), and solid arrows for significant trends Coastal areas showed rising trends, while inland regions declined due to microclimatic and topographic influences. Although most months exhibit similar trends across all stations, variations between stations were observed in certain periods. For instance, while increasing trends were detected in western stations during February, decreasing trends were observed in the eastern stations. This indicates that changes across the basin are not homogeneous and that local factors and microclimatic effects may play a significant role (Figure 5).

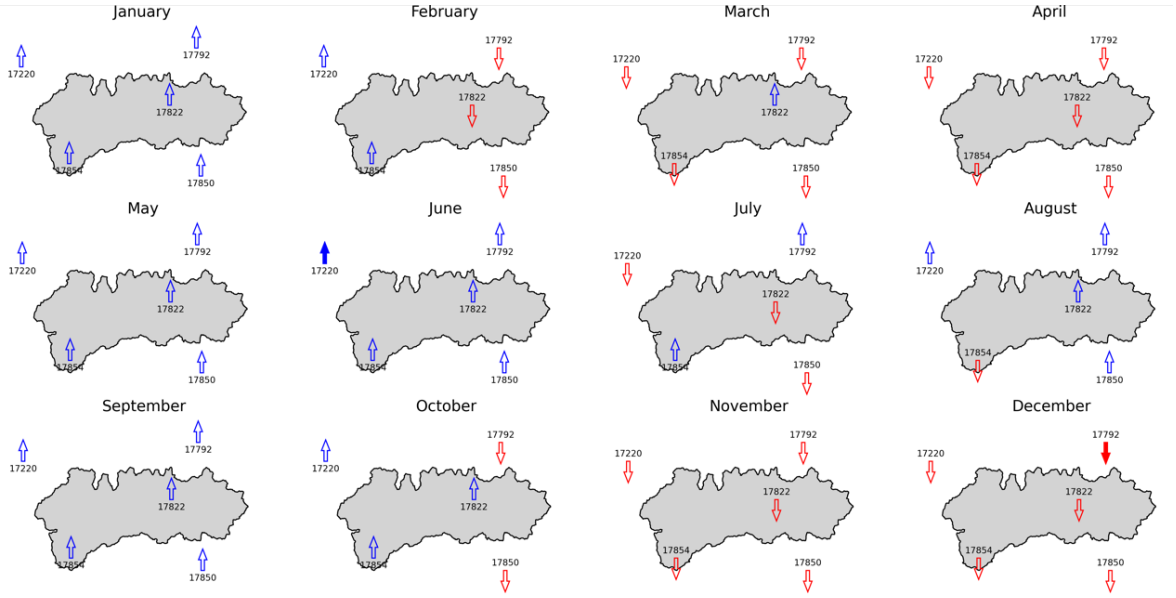

Figure 5: Monthly Modified Fournier Index trend maps.

According to the 50-year trend map, decreasing trends were observed at all stations except the İzmir station. However, these trends were not statistically significant at the 95% confidence level (Figure 6).

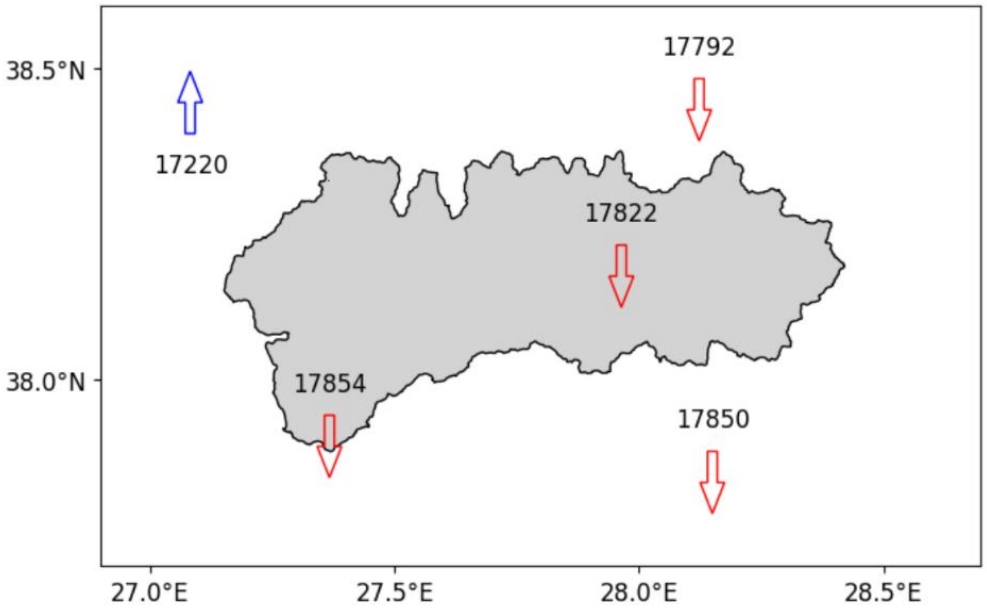

Figure 6: Yearly Modified Fournier Index trend maps.

Conclusion

In this study, the MFI and M-MK results obtained from 50 years (1974–2023) of precipitation data exhibited spatial and temporal variability. The high MFI values in coastal areas (İzmir, Selçuk) indicate a significant erosion risk due to intense rainfall, whereas in Salihli, which has a continental climate, MFI values remained at a "moderate" level, with limited

occurrences in extreme risk categories. Fluctuations observed in transitional regions (Ödemiş, Sultanhisar) highlight the influence of microclimatic and topographic factors.

On a monthly basis, MFI outliers exceeding 160 mm in winter months demonstrate the impact of short-term intense rainfall on erosion, while lower MFI levels during summer indicate a lower erosion risk. In the long term, the declines observed during drought periods in 1991–1994 and 2008, along with the sudden increases in 1981 and 2001, reveal significant fluctuations. While trend analyses did not show statistically significant trends in most stations, the positive trend in June precipitation in İzmir and the negative trend in December in Salihli suggest different scenarios for coastal and inland areas. The findings indicate that instead of a uniform pattern of change across the basin, period-specific and station-specific trends dominate, emphasizing the need to consider microclimatic, topographic, and climatic factors together.

Discovering The Choir Members' Practices: An Initial Understanding of The Intersection of Design, Music, and Community

Gürkay Aydoğmuş[a], Koray Gelmez[a]

[a] Istanbul Technical University/Graduate School, Department of Industrial Design, Industrial Design Program, Türkiye
aydogmus@itu.edu.tr

Keywords: Choir Communities, Research Through Design, User Experience.

Aim

Design, music, and community are three significant fields that transform and enhance human experience both individually and at the community level. Studies conducted at the intersection of these fields hold valuable potential to strengthen interactions between individuals and improve the experiences of communities. However, literature reviews reveal a lack of studies specifically focused on choir communities at the intersection of these three areas. In the field of music, studies examining user experiences from a design perspective are limited, highlighting a critical gap in the literature.

Babaç (2018), in an analysis of theses written between 2011 and 2018, emphasized the scarcity of studies addressing the behaviors and attitudes of choir members. Babaç (2018) noted that more rigorous research in choir management would expand the literature and suggest new pathways for the actions of choir management.

This study aims to address the aforementioned gap in the literature and conduct research to understand the user experiences of choir communities. Specifically, addressing the experiences and challenges faced by choir members offers an essential opportunity to develop user-centered design interventions. Furthermore, the other aim of the study is to develop design solutions that enhance the interactions among stakeholders within the choir ecosystem, making them more functional and effective. Stollak (1994) argued that the production of quality music requires a choir conductor to understand both the individual and collective needs and tendencies of the members. This approach provides significant insights for organizing and managing choir communities more effectively.

Material and Method

In the initial phase of the research, a literature review was conducted to examine academic studies situated at the intersection of design, music, and community. This review specifically focused on design studies aimed at understanding user experiences within music communities. However, the lack of studies dedicated to choir communities underscores the unique value and necessity of this research.

Following the literature review, an online survey was conducted with 74 members of various choirs in Türkiye. The purpose of this survey was to understand the communication dynamics within the choir ecosystem, identify issues within the community, and uncover detailed insights into the experiences of choir members. The survey included both multiple-choice and open-ended questions to evaluate participants' roles within the community, challenges in communication processes, and opinions on the organizational structure. Participants were asked a series of questions covering demographic information, time spent on choir activities, role distribution within the community, encountered challenges, use of technology, and future expectations. Participation in the survey was entirely voluntary, and respondents were invited through online platforms.

The research intends to utilize research through design approach, relying on the insights derived from the combination of designer and choir member roles. These methods enable the integration of the designer's identity with those of the musician and community member, facilitating a deep understanding. The research through design approach focuses on generating and communicating new knowledge and theories that emerge from a designer's own practices (Archer, 2004a; Hales, 1987). This process is both creatively and intellectually demanding, requiring the designer to take on the role of both an observer

and a participant within the user community. The primary goal of the study is to identify user needs and provide creative solutions by leveraging the combination of these multifaceted identities.

The "research through design" approach, increasingly used in the design field, will guide the next stages of this study. This approach positions the designer not only as a problem solver but also as an active participant in the design process. As Pedgley (2007) emphasizes in his work, the reflective practice and active participation of the designer are central to generating valuable insights and creating new knowledge. On this basis, the study aims to create both academic and practical value by delving into the experiences, observations and individual contributions of the designer, and to include this approach in future stages of the research to develop and test user-centered design interventions.

Findings

The data obtained from the survey were analyzed using thematic analysis, a qualitative method widely applied to identify recurring themes and patterns (Braun & Clarke, 2006). This approach provided in-depth insights into the experiences of choir members, highlighting both challenges and opportunities within their organizational and interpersonal dynamics.

Key issues identified included musical difficulties, time management, organizational inefficiencies, communication problems, and low motivation. Nonetheless, participants emphasized strong interpersonal cooperation and appreciated social activities that fostered cohesion.

Shared responsibility and inclusive decision-making were seen as important for sustaining the choir's functioning. While generally content, many members expressed a desire for growth—calling for more performance opportunities, a stronger internal structure, and balanced attention to musical and social development.

Technology emerged as a valuable tool, supporting communication, practice, and collaboration. These findings reveal areas where design-led interventions could enhance organizational effectiveness and strengthen the overall choral experience.

Conclusion

This study represents a unique effort to examine user experiences within choir communities from a design perspective, aiming to contribute both theoretically and practically. The literature review has highlighted a significant academic gap at the intersection of design, music, and community. Meanwhile, the survey findings clearly illustrate the prominent challenges in communication and organizational processes within choir communities, as well as the need for digital solutions to address these challenges.

By adapting research through design approach, the study enables the designer to assume an active role within the community. In future stages, it is planned to prototype user-centered design interventions, test them, and improve the processes through user feedback. This process is expected to enhance intra-community dynamics and improve the experiences of choir members.

In conclusion, this study aims not only to generate academic value but also to contribute to the transformation of choir communities into more effective, accessible, and user-focused structures. The research findings are expected to provide a new perspective on the relationship between design and music communities, offering meaningful contributions to both the literature and practical applications.

Decoding Toxic Attachment Between Design Products and the Users: Understanding by using Metaphors

Bilge Ceren Ay[a], Ozge Celikoglu[a]

[a] Istanbul Technical University, Industrial Design Department, M.Sc. Industrial Design, Turkey
ayb15@itu.edu.tr

Keywords: Emotional Design, Industrial Design, Interaction Design, Metaphor, Product Attacment.

Aim

Users often form relationships with their products, though the reasons behind these attachments vary widely. These connections might be driven by emotional significance, daily utility, added functionality, or simple enjoyment. However, these relationships can sometimes lead to unexpected shifts in behavior, and in certain cases, these changes may not benefit the user in the long run. The main research aims to delve into the intricate, everyday relationships that users establish with their personal belongings, focusing particularly on behaviors that might be seen as problematic. By referring to these behaviors as "problematic," the study is interested in patterns such as "clinging" to objects, "hoarding" or accumulating items beyond practical need, experiencing a "fear of missing out" that drives unnecessary retention of possessions, and engaging in "non-purposeful use" where items are kept or used without a clear function. These behaviors reflect complex emotional and psychological interactions with owned products, shaped by personal and social factors.

Material and Method

This metaphor-based approach will enable the study to decode the links between user behavior and product design, revealing how behavioral states relate to the designed functions of products. Ultimately, the research has the potential to provide valuable insights for designers into how users interact with their products in ways that extend beyond the intended design, highlighting how objects influence behavior in complex, unintended ways.

To understand why the users feel attached to a product, it could be said that the product unfolds a special and personal meaning for the user (Mugge et al., 2008, p.427). For example, the attachment could be created by being an heirloom (Ahde-Deal, Paavilainen & Koskinen, 2017, p.2). In addition to this, users could create an ideal vision of themselves while using the product, therefore, the attachment could be built by the self-image (Govers & Mugge, 2004, p.4). Additionally, there are several opinions about product attachment in the means of "self-extension". Ball & Tasaki states that even though it's hard to confide it to themselves, people can tie their own self-worth to their belongings if the object is a part of self-schema (1992, p.158). The search of making sense to self as a cognitive element discussed more by Greenwald (1988), Erikson (1959) and more. It could be said that the attachment is initiated by the emotional responses to self image.

Letting go of their possessions is invariably more stressful for those that attach a more emotional value to their objects. Due to these difficulties in separation, consumers frequently store unused items at home in what may be called an interim stage, or "consumption limbo." Those who tend consistently to keep belongings, commonly labelled as packrats or keepers, usually seem to attach deeper emotional values to possessions. This can lead to hoarding tendencies, which are most prevalent for the people who derive emotional security from their possessions. When packrats finally decide to discard something, they usually experience feelings of guilt or sadness, whereas purgers, or those who easily discard their possessions, generally feel relieved. (Dommer & Winterich, 2021, p.44)

The linguistic traces could be seen in the keeper's sentences such as;
I haven't used it [Code – Passive Use; Theme – Use]. I'm afraid to [Code – Fear; Theme – Emotion], but again, I probably should [Code – Expected Behavior; Theme – Use]. (Kowalski & Yoon, 2022).

Even though acknowledging the reality of the usage situation, the user may not feel ready to face the disposal of the product. Individuals with hoarding problems like having complete control over their possessions and avoid others touching them, also they tend to have more resistance to empathize with other due to their need to control and configure their feelings first (David, Aluh & Blonner, 2021, p.1233) To understand this, metaphors can be seen as a linguistic and cognitive bridge to understand the connections, relations and actions. As systematically explained by Lakoff & Johnson (1980) there are several aspects of understanding the metaphorically defined concepts such as; ontological metaphors, personification, metonymy and more.

Lastly, toxic relationships can be exemplified as involvement of one partner who causes emotional and often physical harm to the other with his or her actions. In discussions of toxic relationships, the behaviors of the toxic partner are usually in focus. But equally important is the person who endures this behavior. (Solferino & Tessitore, 2021, p.7)

Findings

For fieldwork in this study, five semi-structured interviews have been held. They have been given a set of questions, which they can add more questions to answer and additional insights. This set of questions aims to explore the metaphorical and emotional dimensions of product-human relationships by having participants reflect on a significant object to them. Through facilitated interviewing, the study examines the object's past, creation, and symbolic meaning, including spatial and relational importance. The aim is to uncover underlying stories that may indicate patterns of toxic attachment or emotional attachment. In addition, participants are also requested to reflect about how these questions and findings might be translated into an interactive or physical research kit, which would help develop future design-oriented inquiry tools.

The question kit was provided to the participants via Whatsapp. They had 24 hours to give answers and make any additional suggestions. In addition, they may ask anything about the questions or the subject if there is any additional information needed in the answering process.

According to the findings, it could be said that the toxicity could be integrated with the quality of the metaphor. The participants have been given the words such as "assistant", "travel companion" and "express" to express their relationship with the chosen product. In the means of positivity, these words fell into a rather more positive spectrum.

Bag – *Travel Companion* – a friend, fellow, helper. / **positive**
spends a lot of time with a traveller. / **positive**

Mocha Pot – *Express* – fast, easy, high speed. / **positive**

Cellphone – *Assistant* – a thing ranks below / **negative**
helper / **positive**

Basketball – *Play* – enjoyment / **positive**
energy / **positive**

Notebooks – *Serendipity* – finding valuable things by chance / **positive**

In the mocha pot example, user gets angry after a friend of hers tries to disregard the product and harms it, because the tie between product and her have its roots by being functional and ease to use. Even the design of the mocha pot doesn't change in newly produced ones, therefore she sees a space and reason to feel attached to its irreplaceability. Additionally, establishing a connection between her boyfriend and her mocha pot makes it harder to reach the disposal phase. Also, as a metaphor, she aligns the mocha pot as a warmness in a cold morning.

In the notebook example, the user sees her notebooks as a time capsule which decodes her life phases during different times. In a similarly metonymic and metaphorical gesture, the time capsules will connect the future of the present with the past of that future. Such a frame is indicative not just of one particular perspective but indeed of an ontology of detachment through which the world and ourselves come to be presented as an object of contemplation and not an actor participating with each

other in an interactive world (Durrans, 2012, p.186.). Therefore, the time capsule metaphor holds a huge power in the user such as a physical way of reminder of losing their own past.

Notebook is a time capsule. – Time holds different versions of self. – The notebook holds different versions of me.

Lastly, two of the participants depicted that people around them see the product as a self-extension of the participants. Self is a strong thing to be connected to a product, therefore, disposal of self can be more and more damaging for the user.

Table 1. Metaphors and Attachment Types in Product Attachment.

Product	**Metaphor**	**Positive Attachment**	**Negative Attachment**
Bag	*Travel Companion*	Providing reassurance and comfort on journeys.	Struggle with replacing it, even when a new bag was needed.
Mocha Pot	*Express*	Affective link based on familiarity and function.	Apprehensive about adopting a different technique of coffee brewing despite potential advantages and worried about losing the product.
Cellphone	*Assistant*	Helper	Subordinate entity stress was the result when attempting to switch off.
Notebook	*Time Capsule*	Represented self-awareness and growth, confirming emotional connection with documentation of life experiences.	Discarding old notebooks as equivalent to losing a part of who they were, so they struggled to purge.

Conclusion

This study puts the multi-sided nature of attachment to product front and center, emphasizing its implications for consumer conduct. Healthy attachment can promote sustainability and genuine experiences of ownership, whereas toxic attachment can induce hoarding, psychological dependence, and emotional distress. Metaphoric use in user-product interaction has implications for designers who aim to create products consonant with users' psychology yet not promoting ill health in emotional dependence.

Future research should investigate intervention approaches that will reduce negative attachment behavior and enhance positive user experience. Methods such as the promotion of mindful use, frequent object evaluation, and product design with flexibility that supports emotional continuity but not material abundance can help reduce the negative consequences of attachment to products.

As limitations, conducting the study with only five participants for a sample made available limited data and constrained variation in the views collected using the process. For conducting subsequent studies, though, is to up the number of participants to no less than 15 to create room for expanded variability and depth in results. Furthermore, the current questionnaire should be revised so that it opens up better possibilities for probing emotional experiences and affections among the participants. Emphasizing the phrasing and framing of the questions can assist in bringing out multi-dimensional

responses, allowing respondents to articulate their feelings and relationships with products more strongly and from different directions.

Testing the Aesthetic Responses to Small Household Appliances in The Context Of Incremental Innovation

Fatma Cizrelioğlu Karaer[a,b], H. Tengüz Ünsal[c]

[a] Marmara University, Faculty of Fine Arts, Industrial Design, Turkey
[b] Mimar Sinan Fine Arts University, Graduate School, Industrial Design, Turkey
[c] Mimar Sinan Fine Arts University, Faculty of Architecture, Industrial Design, Turkey
fatma.cizrelioglu@marmara.edu.tr

Keywords: Aesthetic Plesure, Incremental Innovation, Product Design.

Most of the products launched as a result of new product development processes consist of incremental design innovation by improving and visually differentiating existing products. Consumers can access hundreds of products with similar functions and usage features from any e-commerce site. The aesthetic pleasure of a product's appearance plays a significant role in consumer decision-making.

Aim

Through an empirical study, this research aims to analyze the aesthetic response to the appearance of small household appliances, which are similar in terms of technological features and usage characteristics. It aims to contribute to the design development processes of small household appliances by analyzing the relationships between aesthetic pleasure and the determinants of aesthetic pleasure. The results will be evaluated by comparing them with the findings of the literature.

Material and Method

The theoretical infrastructure of the research is based on Hekkert's unified model of aesthetics. Hekkert (2014) presents a general framework that can be used in research in the field of design aesthetics with his Unified Model of Aesthetics, which 'aims to explain our daily aesthetic preferences for artifacts.' Accordingly, the balance between two evolutionarily rooted and complementary pressures is at the center of aesthetic preferences. 'One of these pressures pushes us towards security and protection and leads us to favor choices that facilitate perceptual understanding, efficient processing, and group membership. The other pressure involves the desire to learn and achieve, leading to preferences for diversity, novelty, and uniqueness' (Hekkert, 2014, p. 291). These two opposing forces influence people's aesthetic choices at each of the perceptual, cognitive, and social levels of aesthetic judgment (Figure 1). At each level, aesthetic decisions are based on a trade-off between security and achievement needs, and people seek a balance between the two forces.

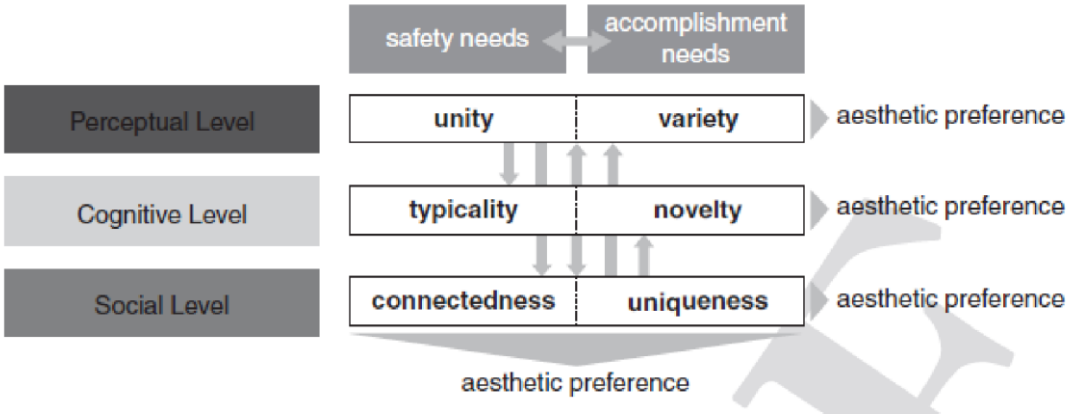

Figure 1. Aesthetic pleasure and its determinants (Hekkert, 2014).

The theory of perceptual aesthetics (Hekkert P., 2006) is based on the idea that people like anything that facilitates understanding. According to this idea, we enjoy things that support the efficient functioning of our sensory systems, including our brain. According to Gestalt psychologists, these things facilitate perceptual organization and help us to see relationships and differences so that we can regulate the flow of information more easily (Hekkert, 2014). We like some challenge in the form of variety to balance unity, even if it is only to enable us to perceive different entities; that is, at the perceptual level, we derive aesthetic pleasure from stimuli that fulfil our need for both unity and variety, creating a rich and complex aesthetic experience (Berghman & Hekkert, 2017, p. 137).

Perceptions of unity and variety enrich the aesthetic experience, but for these perceptions to become meaningful for subsequent actions, it is necessary to give them a context (Berghman & Hekkert, 2017). At the cognitive level, we try to categorize perceptual inputs by not defining them, and in doing so, we benefit from our past experiences (Berghman & Hekkert, 2017). Prioritising what is known, typicality, offers an evolutionary advantage as it enables us to make safer choices (Hekkert, 2014, p. 285). Biederman and Vessel (2006), examining the balance between typicality and novelty, found that novel stimuli are appreciated at higher levels; however, this is only the case when observers can recognize these stimuli (Berghman & Hekkert, 2017). This can be explained by Raymond Loewy's (1951) famous 'Most Advanced, Yet Acceptable (MAYA)' principle, which suggests that designs should be innovative yet familiar to be accepted by the audience. Hekkert, Snelders, and Van Wieringen (2003), in accordance with the MAYA principle, found that both novelty and typicality have independent and almost equally strong effects on aesthetic preferences.

In this study, the The Aesthetic Pleasure in Design (APiD) Scale (Blijlevens, et al., 2017) was a crucial tool used to assess aesthetic responses to products with incremental design innovation. This scale, with its ability to measure aesthetic pleasure and its determinants (novelty, variety, unity and typicality) as separate parameters, brought a level of scientific rigor and precision to the study. The scale, the validity and reliability of the Turkish form of which has been proven by previous studies (Ahat & Öztürk, 2018), was applied to the participants in Turkish. It is structured in a 5-point Likert-type format, and the response options are graded between 'Strongly Disagree' and 'Strongly Agree'.

The stimuli were selected from three product categories: Turkish coffee machine, Turkish tea maker and Electric Turkish Coffee Pot. These products have cooking characteristics specific to Turkish culture. The selection of the products to be used as stimuli in the research, an e-Marketplace was searched for each product category and the price range, colour option, material components were selected and filtered similarly (Figure 2). In order to prevent judgements that may occur due to brand image, brand names and signs on all images have been removed.

Figure 2. Product images used as stimuli.

In determining the participants, criteria such as being female due to familiarity with the product categories and, preventing gender-based evaluation differences, having purchased products from e-commerce sites because it is desired to have online purchasing experiences were used. Nine scales, three from each category, were applied to the participants (n:10). Pearson

correlation analyses were performed in Jamovi 2.6.17, an R-based open-source program, on a total of 90 data sets, 30 for each product category.

Findings

When all data were analyzed, the correlation coefficient for the relationship between **aesthetic pleasure and variety** was found to be 0.677 (Table 1). Electric tea makers are the category with the most decisive aesthetic pleasure-variety interaction (0.808). There is also a strong positive relationship between aesthetic pleasure and variety in Turkish coffee machines (0.711). For electric Turkish coffee pots, there is a moderate (0.535) relationship between aesthetic pleasure and variety. In line with these data, it can be said that the perception of variety obtained from the product's appearance is effective in revealing the aesthetic pleasure of the product. Consumers' positive inferences from the appearance of the product that the product consists of different parts and offers variety in terms of design elements are indicators that their aesthetic reactions will also be positive.

Table 1. Correlation matrix on aesthetic pleasure and its determinants.

		Variety	Unity	Novelty	Typicality
AESTHETIC PLEASURE	All data	0.677 ***	0.708 ***	0.710 ***	—
	Turkish coffee machine	0.711***	0.714***	0.656***	—
	Turkish tea maker machine	0.808***	0.700***	0.832***	—
	Electric turkish coffee pot	0.535**	0.729***	0.656***	0.393*

The correlation coefficients for the relationship between **aesthetic pleasure and unity** are very close for the whole data (0.708) and based on categories (0.729, 0.714, 0.700). There is a strong and positive relationship between aesthetic pleasure and unity (Table 2). As consumers' positive inferences about the harmony, order, and integrated appearance between the design elements of the products increased, their positive aesthetic reactions also increased.

Table 2. Correlation matrix for all data.

Correlation Martix						
		AESTHETIC PLEASURE	**NOVELTY**	**TYPICALITY**	**VARIETY**	**UNITY**
AESTHETIC PLEASURE	Pearson's r	—				
	df	—				
	p-value	—				
NOVELTY	Pearson's r	0.710***	—			
	df	88	—			
	p-value	<.001	—			
TYPICALITY	Pearson's r	0.089	-0.268*	—		
	df	88	88	—		
	p-value	0.402	0.011	—		
VARIETY	Pearson's r	0.677***	0.849***	-0.237*	—	
	df	88	88	88	—	
	p-value	<.001	<.001	0.025	—	
UNITY	Pearson's r	0.708***	0.570***	0.303**	0.544***	—
	df	88	88	88	88	—
	p-value	<.001	<.001	0.004	<.001	—

Note. *p <.05, ** p <,01, ***p <.001

The correlation coefficients for the relationship between aesthetic pleasure and unity are very close for the whole data (0.708) and based on categories (0.729, 0.714, 0.700). There is a strong and positive relationship between aesthetic pleasure and unity. As consumers' positive inferences about the harmony, order, and integrated appearance between the design elements of the products increased, their positive aesthetic reactions also increased.

When all the data are analysed, it is seen that there is no significant statistical relationship between **aesthetic pleasure and typicality**. When examined as categories, a moderate positive relationship is observed only for electric coffee pots (0.393). When all the data were analyzed together, the correlation coefficient of **aesthetic pleasure and novelty** was found to be 0.710. Accordingly, there is a positive and strong relationship between aesthetic pleasure and perceived novelty. The increase in the perceived novelty level of a design leads to an increase in the level of aesthetic pleasure obtained from the design. When analyzed by category, the highest relationship is observed in the electric tea maker category (0.832). The correlation coefficient is the same for Turkish coffee machines and electric tea makers (0.656). The significance level is

high in all three categories. It is seen that the correlation coefficients of the aesthetic pleasure-innovation relationship vary according to the categories. In the electric tea maker category, the tendency for aesthetic pleasure and innovation to positively affect each other is higher. In this case, it can be said that consumers perceive the product as newer as their positive aesthetic judgments increase while making evaluations for this product group.

The correlation coefficients for the relationship between **variety and unity** (Table 3) were 0.544 for all data, 0.443 for Turkish coffee machines, 0.694 for electric tea makers, and 0.586 for electric Turkish coffee pots. Although the significance value of the correlation for Turkish coffee machines was less than the others, a moderate and positive result was obtained for both the whole data and all categories. The findings show a directly proportional relationship between consumers' variety and unity evaluations in the evaluation of products with incremental design innovation.

Table 3. Correlation coefficients showing the relationship between variety and unity.

	Unity - Variety
All data	0.544 ***
Turkish coffee machine	0.443***
Turkish tea maker machine	0.694***
Electric turkish coffee pot	0.586**

Conclusion

Aesthetic pleasure and its determinants scale can be used as a suitable tool to test aesthetic responses to product appearance in order to choose among design alternatives in the new product development process.

According to the findings, the most critical factor affecting aesthetic pleasure in products with incremental design innovation is the perception of novelty. As the perceived novelty increases, the aesthetic pleasure received from the product's appearance also increases. Another significant result is the relationship between variety, unity, and aesthetic pleasure. According to the literature, variety, and unity evaluations are expected to be negative (Berghman & Hekkert, 2017, p. 137), but the findings show that there is a directly proportional relationship between consumers' perceptions of variety and unity in the evaluation of products with incremental design innovation. In this study, the results regarding the effect of variety and unity factors on the emergence of aesthetic pleasure are similar to the studies in the literature (Post, Nguyen, & Hekkert, 2017):

- In line with these data, it is seen that the perception of variety obtained from the product appearance is effective in the emergence of aesthetic pleasure about the product. Consumers' positive inferences from the appearance of the product that the product consists of different parts and offers variety in terms of design elements are indicators that their aesthetic reactions will also be positive.

- There is a strong and positive relationship between aesthetic pleasure and unity. As consumers' positive inferences about the harmony, order and integrated appearance between the design elements of the products increase, their positive aesthetic reactions also increase.

These findings offer various suggestions for design practice. When designing for product categories where distinctiveness factors are low, visual design factors such as symmetry, contrast, variety in elements, color differences, and gradations can be used to achieve an optimum balance between variety and unity to ensure positive aesthetic responses from consumers. At the same time, future research could examine consumer responses to controlled manipulations of these factors. In this study, the consumer group was held constant; future research could also investigate the aesthetic responses of different consumer groups.

INDUSTRIAL DESIGN

Historical, Cultural and Social Context of Design

Product Design

Theory and Methodology in Industrial Design

User Narrative as Antenarrative: A Brief Overview

Fulden Ates[a,c], Ozge Merzali Celikoglu[b]

[a] Istanbul Technical University, Graduate School, Industrial Design, Turkey
[b] Istanbul Technical University, Faculty of Architecture, Industrial Design, Turkey
[c] Marmara University, Faculty of Fine Arts, Industrial Design, Turkey
ates20@itu.edu.tr

Keywords: Antenarrative, Narrative, User Narrative, User Research.

User narratives, which encompass the stories and experiences of users in their interactions with a product or service, represent a vital form of data in design research. Designers, consciously or unconsciously, have historically integrated narratives into their work (Shaw & Nickpour, 2022) and have internalized them (Trocchianesi, 2022). Every designed entity, including products, services, systems, and environments, inherently contains or conveys a narrative (Shaw & Nickpour, 2022). Such narratives allow designers to incorporate users' lived experiences into the design process, transforming these insights into design knowledge. Consequently, designers are expected to engage actively with these narratives and serve as narrative agents (Shaw & Nickpour, 2022). Nonetheless, despite the prevalent utilization of narratives in design, contemporary literature indicates that the narrative dimension of user research remains inadequately explored.

In user-centered design, narratives are frequently perceived as linear and complete, with designers treating user input as structured and finalized accounts. However, actual user narratives often present as fragmented, inconsistent, and open-ended. Such characteristics do not align well with traditional narrative theories, which typically emphasize coherence, causality, and cultural consistency.

By adopting a narrative-centric approach to user-centered design, this research seeks to illuminate the inspirational elements of user narratives that frequently remain implicit within the design process. When employed effectively, narratives can assist designers in uncovering and empathizing with diverse lived experiences, challenging dominant social or disciplinary narratives through a user-centered framework, and amplifying previously marginalized voices to achieve more desirable and relevant designs (Shaw & Nickpour, 2022; Tassinari et al., 2017). Unlike other user research methods, including user narratives in the design process mitigates the risk of stereotyping users, preserves objective details about users, and maintains the contextual integrity of the researched subjects.

Aim

This study aims to introduce a new perspective on user narrative by applying the concept of antenarrative to the design discipline. It revisits the structure of user narratives and proposes a fresh approach to inspire a more thorough exploration of narratives in user research, ultimately leading to more effective utilization.

Material and Method

This study employs a comprehensive conceptual literature review as its primary methodological approach. Rather than collecting empirical data, the research draws on theoretical and interpretive analysis of existing literature to thoroughly explore the applicability of antenarrative theory in the context of user research within the design.

The review emphasizes two central narrative frameworks: Jerome Bruner's (1991) theory of narrative as a culturally shaped and temporally ordered meaning-making process and David Boje's (2001) concept of antenarrative. With contrasting ontological assumptions, these frameworks provide a productive tension for evaluating how user narratives are understood and utilized in design processes. The study argues that antenarrative, focusing on fragmented and speculative storytelling, offers a more suitable lens for interpreting user narratives.

Findings

Jerome Bruner's narrative theory is frequently cited in discussions surrounding traditional narrative definitions. He argues that narratives play a vital role in helping individuals understand and communicate their experiences (Bruner, 1991). However, upon closer inspection, it becomes clear that user narratives—essential to the design process—differ considerably from Bruner's narrative definitions in several important ways.

When assessing narrative in design literature, it is evident that user narratives drawn from participants' experiences during research often come across as inconsistent and unstructured. For example, a user narratives may consist of disconnected events or various opinions rather than a seamless account of interactions with a specific product or situation. These narratives provide fragmented insights into users' lives, reflecting the diverse feedback from various individuals, lacking a coherent trajectory, and often displaying inconsistencies due to the array of inputs received.

Given these characteristics, it is apparent that user narratives stand apart from Bruner's traditional narrative framework and resonate more closely with Boje's (2001) idea of antenarrative. Boje (2001, p.1) describes antenarrative as chaotic and unstructured narrative forms that emerge before a conventional narrative takes shape. He defines it as "*the fragmented, non-linear, incoherent, collective, unplotted, and pre-narrative speculation, a bet.*" Antennarratives capture the early, unrefined stages of storytelling, providing accounts that lack formal structure but are rich in potential for exploration.

Unlike narratives, antenarratives are not bound by a specific format. They embrace diverse perspectives and focus on unfolding events, engaging with potential outcomes and contemplating future possibilities. While Bruner's narratives are typically organized and follow a clear chronological order, antenarratives introduce uncertainties regarding time and sequence. Bruner's narratives tend to center on past experiences and present situations, while antenarratives look ahead, considering multiple potential futures. This contrast between Bruner's structured narrative approach and Boje's dynamic antenarrative framework is not just a theoretical discourse but a rich and engaging one.

Although the idea of antenarrative is not new, it has yet to be fully embraced within design literature. Given that design processes naturally incorporate alternatives and speculation—key aspects of antenarratives—it is exciting to consider how integrating this concept could elevate design research further. By embracing the chaotic and unstructured nature of antenarratives, design research could become more open to diverse perspectives and potential outcomes, leading to more innovative and user-centered design solutions.

Conclusion

In the design process, antenarratives enable us to engage with stories that are still evolving—those incomplete, ambiguous, and sometimes conflicting experiences shared by users before they solidify into fixed narratives. This approach is crucial because it enables us to identify emerging patterns and hidden needs that conventional user research might overlook. By working directly with these narrative fragments, we can envision alternative futures and design more inclusive and innovative solutions that address the true complexity of user experiences. These solutions, designed with empathy and consideration, are more likely to meet the diverse needs of users. Importantly, this approach encourages designers to remain reflexive and continuously challenge their assumptions and biases.

In conclusion, viewing user narratives as antenarratives opens significant opportunities for user research in design. This study serves as a call to action, urging a broader investigation into the nature of narratives in user research. Such an exploration can facilitate their more impactful application, leading to a deeper understanding of user experiences and more effective design solutions.

Prompt 'Design the Perfect Product': A Literature Review on AI Incorporation in Industrial Design Processes

Sude Kartalbaş[a], Aysun Ateş Akdeniz[b]

[a]İstanbul Technical University, Graduate School, Industrial Design Program, Turkey
[b]İstanbul Technical University, Faculty of Architecture, Department of Industrial Design, Turkey
kartalbas19@itu.edu.tr

Keywords: Industrial Design, Artificial Intelligence, Design Process.

Aim

Are we witnessing a revolution in design or just an algorithmic chaos? With the rapid development of Artificial Intelligence (AI), product design processes have been affected by it significantly. The definition of industrial design according to the World Design Organization is, the development of innovative products, services, systems, and experiences, industrial design is a strategic approach to problem-solving that fosters innovation, increases business success, and improves people's quality of life (2025). The increasing integration of AI into design presents both opportunities and challenges for designers with lots of new areas to expand. AI is developing faster than anything, keeping up with it has become crucial. The design discipline needs to devote attention to the challenges involved in integrating AI into systems, services, and products. Despite the impressive advancements in AI, there is a noticeable lack of discussion about this subject in the design community (Stoimenova & Price, 2020). This study aims to analyze the stages of the product design process where AI is utilized, examining its benefits and exploring its limitations. Emphasizing the gap which is understanding the balance between human creativity and AI-driven design, exploring how AI has been affecting and will be affecting the design process examining its implications for creativity, efficiency, and collaboration in design processes. The research starts with understanding how AI contributes to different stages of the design process in the industrial design sector, mostly including early ideation and visualization techniques. Escaping or unseeing AI is not an option anymore, choosing to learn how to manipulate and work with it can be beneficial. Like once craftsmen learn how to work with machinery, the designers will learn how to interact with AI as well.

The main goal of this paper is to do a systematic literature review on the current situation of AI in the industrial design sector and design processes providing insights. Data distribution of the reviewed articles foreshadows how AI can be incorporated into design processes differently and how it can potentially help to solve current pain points of the process efficiently—shedding light on the current situation and aiming to foresee the future. This not only educates researchers but also assists industrial designers in integrating AI safely and effectively into their processes.

Material and Method

The methodology used for this systematic review consists of using a research tool for finding the relevant literature, selecting suitable articles according to the filters, analyzing each source subsequently to the designated themes, and combining the relevant results, making room for future predictions accordingly. Enhancing the theoretical understanding of a particular problem should be the goal of a literature review, possibly by putting forth a new idea based on a variety of data (Baumeister, 2012). PRISMA Statement used for diagrams and checklists.

The tool used for finding and selecting eligible articles is EBSCOhost since it has a great variety of sources, using direct access through ITU. Also in addition, an AI-powered mapping system called LitMaps has been used to map out the literature and track how the topic has evolved showing how the papers are connected through references and citations. The collected articles are analyzed thematically by design context, design process, role of AI, methodology, AI tools, and future developments regarding AI in design workflows.

Research has been done using the definite statement which was (artificial intelligence or ai or a.i.*) AND (*design process or design method*) AND industrial design AND (*creative industries or creative industry or creative economy or creative sector*).* Only peer-reviewed and English journal articles dated between 2020-2025 are included. Applied Science & Technology Source Ultimate Publications used as the database filter. With all of the filters, initially, 26 articles remained. From these 26, a screening was done to find the associations between AI and Industrial design and the ones which are not directly related had been not selected. The final selection yields 10 articles to analyze in depth. The list of articles has been presented in Table 1.

Table 1. List of articles selected for in-depth analysis after applying the sampling and selection process.

Findings

To detect the current integration, understanding and distilling the product design steps well is essential. Including not only the traditional design process but also new product development and sustainable product development phases will give a comprehensive understanding of the current situation. While some steps are mutual and familiar to AI more than others, only a few have innovative ways to use AI in design processes. AI is integrated into various phases of product design, including Idea Generation Steps, Prototyping and Simulation, Automation of Repetitive Tasks, and Presentation. The coding scheme used to analyse the articles are presented in Table 2.

Table 2. Coding scheme used to analyse the selected articles.

Categories	**General Question**	**Sub-Categories**
Context	Which Industrial Design Field?	Design sector Environment Creative Economy
Design Process	Which design step/steps consist AI?	Product Development Innovation Methods
Methodology	How the AI process was followed through the research?	Research strategy AI development Usage decisions
Tools	Which AI tools were used?	Generation Method Technology Controllability
Future Callings	Is there any foreshadowing for future usage of AI?	Implications of future Arguments Leading Concepts

The AI tools included in the studies are a mix of text to text, text to image, and image to image. These tools feed and rely on each other to navigate the designers in their process. With all of the papers analyzed, it can be said that AI is especially used for visualization in the design process. This included the basic conceptual designs for the end product. There are some utilization for other steps of the Traditional Design Process, yet To increase design efficiency and productivity, modern designers should become proficient in generative AI applications (Lu et al., 2024). Most of the papers focus on aesthetics and concepts rather than the current design problems such as Manufacturing Efficiency, Product Life Cycle or Sustainability. According to Verganti et al. with the development of AI more into the design practices, a counter act can be taken like a more effective and human-centered approach (2020).

Conclusion

It can be said that the design profession still mostly relies on humans and probably will stay like that for a while. Rather than being scared of it or seeing it as a threat, learning and exploring new ways to work with AI no matter what will be favorable. Despite its benefits, AI in design still has a lot to 'learn'. While AI technologies are essential for growing

creativity in industrial design and engineering, their influence is often seen as primarily supporting as their acceptance and effectiveness rely on the level of trust that is built between people and AI (Tsang & Lee, 2022).

Overall, this research provides a situational assessment of AI's role in product design processes and a foreshadowing for future usage scenarios. While this research is a great start to understanding the logic behind the current situation and evolution of AI in creative fields, further research is mandatory to explore this rapid progression and its long-term impacts on the industries in each region of the world. The impact of AI in design should be further investigated, in future studies and processes about sustainability and user-centered approaches.

This research only consists of some portion of the current studies and can be used as a guidance for the topic. There were only 26 related articles to the topic, due to it being relatively new and detailed. Also due to the nature of the development of AI, keeping up with the latest research and innovations is a must to make sure industrial designers have the ability to make use of the latest AI tools, adjust to changing design approaches, and handle new ethical and practical issues in the industry.

Exploring Emotions in Design Research: An Initial Mapping of Emotion-based Concepts

Gamze Uğurlukişi[a], Koray Gelmez[a]

[a] Istanbul Technical University, Graduate School, Department of Industrial Design, Industrial Design Master of Science Program, Türkiye

ugurlukisi18@itu.edu.tr

Keywords: Emotional, Bonding, Attachment, Longevity.

Aim

Emotional design is an approach that aims to evoke positive experiences in users, as introduced by Donald Norman in his book Emotional Design: Why We Love (or Hate) Everyday Things (2004). It is an effective method for designers who aim to trigger strong associations with emotions in the user. The importance of the emotional design approach is based on the bond between the user and the product, as a result of emotional interaction, which contributes to long-term success by increasing user satisfaction and loyalty (Yusa et al., 2023). The concept of emotional design, which has a wide range in the literature, provides a roadmap for examining the connections established by users, understanding user motivations, and integrating products into their daily routines more successfully.

Since design literature is a multidisciplinary and comprehensive field, it is a common fact that concepts often overlap across themes. Therefore, there is a need for studies that underline the fundamentals of emotional design.

This study aims to categorize the prominent studies that frame emotional concepts in design. The main purpose of the study is to understand the theoretical basis of the emotion-driven design concept and its versatile application forms and to provide an introductory-level map for researchers in this field.

This study does not propose a new emotional model, such as Norman's Three-Level Framework (2004) or Desmet's Product Emotion Model (2010). It contributes to the field by offering a broader thematic perspective, highlighting the conceptual relationships within emotional design literature. For example, while Yusa et al. (2023) conducted an application-oriented review and Ho & Siu (2012) focused on terminological distinctions, this study differs by providing an introductory-level mapping that synthesizes theoretical and strategic perspectives, rather than focusing on specific implementations or definitions.

Material and Method

This study identifies and organizes emotion-based concepts in design research. It presents an introductory-level map by categorizing base frameworks and common strategies.

The search process involved emotion-related keywords, such as "emotional bonding", "emotional attachment", "emotional interactions", and their relations to design. In order to identify prominent publications, keyword-based searches were conducted in academic databases such as Google Scholar and relevant design journals such as the International Journal of Design.

At the end of the search process, the selected studies were divided into two main categories: Theoretical framework and method/strategy. A conceptual map was created by separating these main categories into specific themes. This structure is intended to provide an overview for design researchers examining the emotional design literature.

Findings

An initial map was prepared (Fig. 1), which includes studies related to emotion. Category titles align with the study's aim to provide an overview of emotions in design research. The *theoretical framework* category includes studies that introduce frameworks and definitions. Under the *method/strategy* category, there are studies and approaches focused on examining or enhancing the emotional bond between users and products. Categories are divided into subthemes and color-coded to enhance readability.

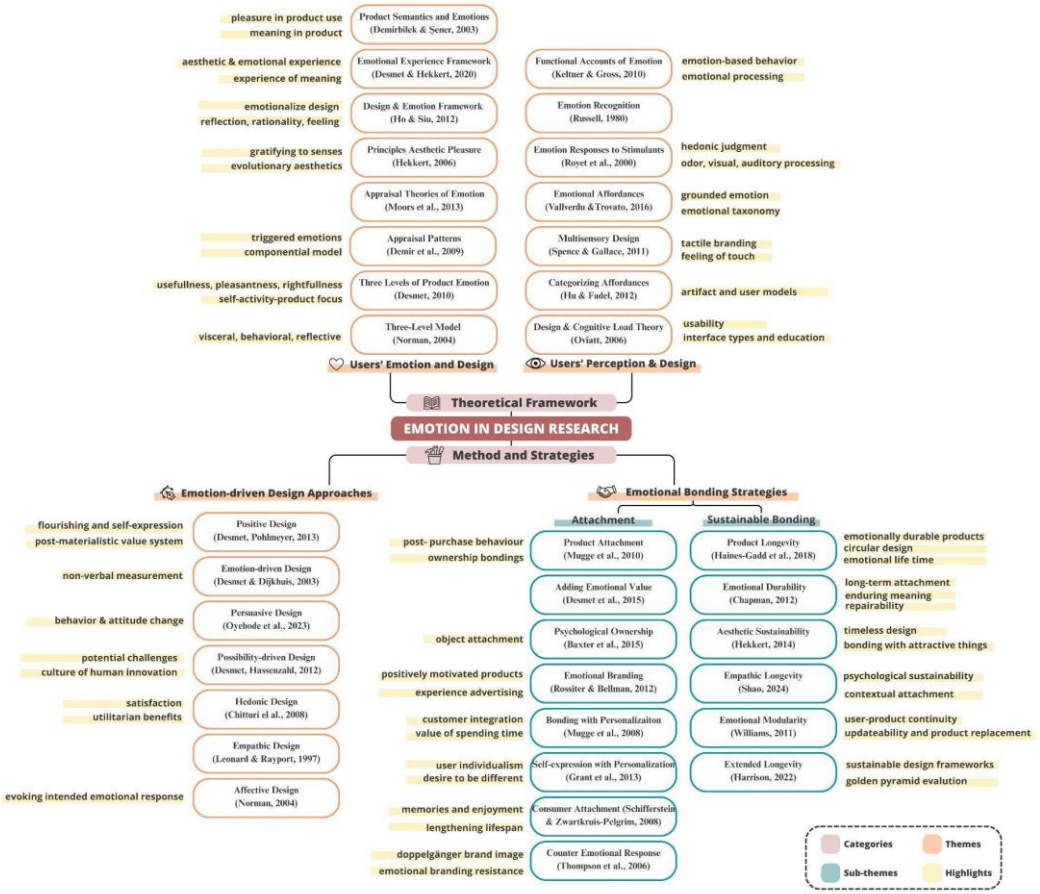

Figure 1: The Conceptual Map of Emotion in Design Research.

1. Theoretical Framework

The theoretical framework category includes studies based on core theories in emotion-based design research. It was divided into two themes:

(a) *Users' Emotion & Design,* which focuses on creating a theoretical framework to understand users' emotions; and

(b) *Users' Perception & Design,* which includes studies aimed at understanding the perceptual aspects of users and combining cognitive theories with the field of design.

a. Users' Emotion & Design

Among the studies that explore users' emotional responses, the Three-Level Model stands out (see Norman, 2004). Studies on appraisal theories are key in explaining emotion-focused evaluation processes (see Lazarus, 1991; Demir et al., 2009;

Moors et al., 2013). There are also important studies that propose a three-layered analysis structure for emotional experience (see Desmet, 2010; Desmet & Hekkert, 2020).

Ho and Siu (2012) introduce terminology and propose the *'emotionalize design'* from a new perspective. On the other hand, Hekkert outlined the principles of aesthetic pleasure in the study he published in 2006.

These studies have the potential to be a starting point for researchers, as they form the conceptual foundation for understanding the role of emotion in design.

b. Users' Perception & Design

In studies examining the users' perceptual engagement with design, affordance stands out as a key concept (see Hu & Fadel, 2012; Vallverdu & Trovato, 2016). These studies are prominent in understanding users' interpretation of actions embedded in products.

Additionally, the examination of tactile, visual, and auditory interactions appears as another important topic in this section. Studies investigating how emotional perception is formed by multisensory themes provide a foundation (see Royet et al., 2000; Spence & Gallace, 2011).

These studies emphasize that emotional reactions are shaped by direct sensory and perceptual engagement within the emotion theories in design. For researchers, the perceptual aspect of the emotional design concept and understanding how users interpret and react will provide additional information.

2. Methods & Strategy

The second main category includes methods and strategies that build an emotional connection between users and products. These studies propose ways to integrate emotion into design processes.

This category is divided into two themes:

(a) Emotion-based Design Approaches, which include methodologies that center emotions in the design process; and

(b) Emotion Bonding Strategies, which focus on strategies to create or strengthen the bond between the user and the products.

a. Emotion-based Design Approaches

Designing to evoke specific emotional responses is discussed within the scope of *affective design* (see Norman, 2004). Also, some concepts focus on emotional dimensions in specific contexts. For example, *positive design* emphasizes self-expression and flourishing for users; *persuasive design* aims to behavior change by influencing emotions; and *possibility-driven design* that accepts diverse emotions as a challenge (see Desmet & Pohlmeyer, 2013; Oyebode et al., 2023; Desmet & Hassenzahl, 2012).

In addition, it will be beneficial to examine the design for fun or hedonic purposes and how they differ from utilitarian benefits (see Chitturi et al., 2008; Desmet & Dijkhuis, 2003).

These studies can be guiding for researchers, as they represent approaches that share a common goal of integrating emotional depth into design processes.

b. Emotion Bonding Strategies

Personalization is a prominent strategy among many strategies aimed at building an emotional bond between user and product (see Mugge et al., 2008; Grant et al., 2013). Another study is *psychological ownership*, which highlights the importance of time and effort spent by the user (see Baxter et al., 2015).

Product attachment is another approach, which includes studies about emotional responses such as trust, satisfaction, and loyalty (see Schifferstein & Zwartkruis-Pelgrim, 2008; Mugge et. al, 2010).

Additionally, some studies aim to extend the psychological and physical lifespan of products, examine the role of user effort in sustaining bonds, and discuss repairability and dignified product aging. Within the scope of sustainability-oriented bonding, the concepts of product longevity, emotional durability, and aesthetic sustainability stand out (see Chapman, 2012; Haines-Gadd et al., 2018; Hekkert, 2014)

These studies focus on improving both the individual user experience and extending the product life through bonding while strengthening the emotional depth.

Conclusion

This study offers an introductory overview of emotion concepts in design research, organized in two main categories: theoretical framework and methods & strategies. The resulting map provides a structured understanding of diverse approaches for design researchers.

Rather than offering a detailed literature review, this paper outlines the prominent concepts and offers a conceptual foundation. This categorization supports future research about emotional design. As emotional design is a broad field, mapping studies like this help guide researchers.

Understanding Creativity: A Survey-Based Investigation into the Psychology of Designers' Creativity during the Ideation Phase

Naz Feryal Cezayirli[a], Aysun Ateş Akdeniz[b]

[a] Istanbul Technical University/Graduate School Industrial Design Program, Türkiye
[b] Istanbul Technical University, Faculty of Architecture, Department of Industrial Design, Türkiye
cezayirli23@itu.edu.tr

Keywords: Cognitive Biases, Creativity Triggers, Design Intuition, Eureka Moments, Spontaneous Transfer.

Aim

Designers hold a unique place between creativity and reality. They have the ability to generate limitless ideas and bring them to the real world, by "changing existing situations into preferred ones" (Simon, 2019). This raises the question of how designers form these ideas? Can the habits and behaviors of these creative individuals guide one to the doors of creativity? With these questions in mind, this study aims to shed light on the cognitive and psychological processes industrial designers undergo during idea generation. By utilizing a survey aimed at designers, their habits and mental processes during the design ideation phase are explored. It should be noted that although the processes of individuals are highly subjective, the similarities are to be explored in order to find a repeating pattern that could be used to lead the way to creativity. There have been a number of studies studying design creativity and how it is related to design. One study compares university design students' and tutors' creativity. In this study it is revealed that there are clear differences between tutors and students in how they assess their creative potential, although both find it difficult to define it (Rodgers & Jones, 2017). Another study explores the idea generation phase among designers depending on experience. It is stated that designers utilize their knowledge of existing designs and how they transform these to suit new designs. (Sarkar & Chakrabarti, 2017). One study examines the creative processes through a psychoanalytic lens, exploring concepts of play, particularly word play, aesthetic and sensory experiences and repetition (Holm-Hadulla, 2003). In light of these findings, this study aims to utilize the findings utilize previous studies to explore and identify the creative tools in ideation phase further in order to shed light on cognitive and psychological processes among industrial designers.

Material and Method

This study utilizes an online survey method for data collection. 20 designers practicing in Turkey, aged 23 through 34 have participated in the survey. The survey questions for this study have been designed using Dr. Max A. Houck's Upside Down Triangle survey method, and is consisting of three main parts. The first part is demographics and consists of 9 open ended questions. This part is necessary to be able to view the data from a sociological perspective and is necessary during the contextual analysis phase. The second part of the survey includes 7 open ended questions on design behavior and design habits. These questions are asked in a way that urges the designer to raise awareness of their own processes. The third and last part of the survey includes 7 open ended questions which are more specific and challenging. They are aimed directly at specific cognitive processes using specific keywords that aim to pave the way for further research.
Once the participants start exploring their cognitive processes, the questions guide them to think about more unconscious processes like their cognitive biases, design intuition and Eureka moments. Finally the main question of this study is explored, which is how designers trigger creativity moments.

Findings

The answers for the survey have been analyzed using thematic analysis. The reason why thematic analysis has been chosen to analyze the data is because it offers rich yet complex qualitative analysis, as well as provides theoretical freedom (Braun & Clarke, 2006).

The results have been gathered under 5 sub categories according to the analysis results. The study initiates by exploring designers' habits and rituals during the beginning of the design ideation phase.
The first aspect that has been explored was how designers start their processes. Almost half of the participants expressed that they start their ideation process through research, while the rest utilize a diving in approach and starting with idea generation directly.
During their creative processes, it is revealed that all designers adapted their own ways to foster creativity. While some explore previous works for inspiration, others utilize workshops and DIY projects or visit exhibitions and museums. Not surprisingly, the ones who chose solitary activities also preferred to work alone during idea generation.
Strernberg and Lubart define six resources for creativity; intelligence, knowledge, thinking styles, personality, motivation, and environment (Sternberg et al., 1996). This supports the findings of the study that each designer adapts their own way of fostering creativity.
Another aspect this study explored is cognitive biases during the ideation phase. The designers who were aware of and could navigate their cognitive biases also seemed to trust their intuition. In a study about cognitive biases, it is suggested that these biases are "maps to the design of the mind" (Haselton, 2015). This suggests that designers who are aware of their cognitive processes are more in tune with their ideas, allowing them to navigate their creative processes more easily than those who aren't. Consequently, this awareness may contribute to a stronger trust in their intuition overall.
When asked if they explore seemingly unrelated topics to gain inspiration, 10 participants stated they don't while the other 10 stated they do. One way of doing this was stated as talking to friends from other fields as well as expanding their own knowledge through research. In research this is called "spontaneous" transfer, where knowledge and insights from one domain are applied to another, leading to novel ideas (Weisberg, 2006; Price & Driscoll, 1997).
Another aspect that is explored in the study is Eureka moments. In literature it is described as moments of spontaneous and inspired breakthrough insights (Steyn & Buys, 2011). Almost half of the participants reported never having these Eureka moments, however a quarter of the participants mentioned they have experienced it during seemingly unrelated moments. This suggests that there may be a correlation between these seemingly random ideation moments and the unconscious mental processes. It may suggest that the unconscious mind continues working on design problems in the background, bringing insights to the consciousness when the mind is at ease.
Finally the participants are asked how they trigger creative moments. Although almost half of the participants didn't believe this wasn't possible, the rest stated they have their own methods. Some prefer walking or listening to music in order to quiet their minds, the rest adapted a dive-in approach where they actively create through activities like writing and by simply doing. This correlates with research where immersive activities can foster creativity (Csikszentmihalyi, 1990).

Conclusion

This study is aimed at exploring the cognitive processes of designers during the ideation phase, revealing their creative habits and triggers of their innovative ideas. The results revealed a variety of approaches among the participants, demonstrating that there is no one-size-fits-all method for fostering creativity. The study also highlighted the importance of understanding cognitive biases, with those who are more aware of their biases often having a stronger trust in their design intuition.
Additionally, the study found that inspiration can come from engaging with unrelated fields and expanding knowledge through research, called "spontaneous transfer" in creative processes. Eureka moments, although not very frequent for many designers, also revealed important aspects of the creative process, suggesting that unconscious mental processes continue to contribute to idea generation even when designers aren't consciously focused on a problem.

In terms of triggering creativity, immersive activities such as walking, listening to music, or diving into a task were reported by the participants as effective methods during idea generation. These findings are supported with previous research suggesting that engaging the mind in different ways can lead to increased creativity.
The reliance on an online survey restricted the depth of information gathered, as it mostly captured what designers were consciously aware of in their processes. Additionally, the limited sample size of the survey prevents a broader generalization

of the results. To build upon these initial findings, future research will incorporate in-depth qualitative methods, such as one-on-one interviews and design workshops, to further explore the unconscious processes that influence creativity.

Multi Criteria Decision Making For Selecting Best Banking Service Channel

Mustafa Akça[a], Yusuf İlker Topçu[a]

[a] Istanbul Technical University/Institute of Science, Industrial Engineering, Engineering Management Program, Turkey
akcam15@itu.edu.tr

Keywords: AHP, Banking, Decision Making.

Aim

The aim of this study is to find the most appropriate alternative among the possible banking service channels utilizing the Analytic Hierarchy Process (AHP) which is one of the most widely used multi-criteria decision-making method and revealing criteria importance for ranking options of banking service types. The alternatives which are state/private and digital/physical are choosen based on the literatüre and today's trend in banking.

Material and Method

In today's banking world, customer behaviors are analyzed to determine whether a banking model that prioritizes physical branches or a model that focuses on digital channels by providing services through internet and mobile banking is the most appropriate approach. In this study, , first the necessary criteria and related sub-criteria for the model will be determined by considering previous studies and expert opinions on this topic. Then, the Analytic Hierarchy Process (AHP) method will be used to reveal the importance of the criteria and the sub-criteria based on the experts' judgments. These criteria are listed as physical conditions, technical infrastructure, security and privacy. As a final step, the model will evaluate four alternatives service channels based on the branch-focused banking model and the digital-focused banking model. The objective data for the performance of alternatives with repsect to criteria will be obtained using the data of a private bank operating in Turkey. In the study, four alternatives will be evaluated . These alternatives are defined as follows: the state-supported digital-only banking model, the state-supported banking model providing both digital and physical services, the private capital-supported digital-only banking model, and the private capital-supported banking model offering both digital and physical services. the TOPSIS method will be utilized to recommend the most suitable banking modelThe findings obtained from this study are also expected to serve as a reference for decision-makers who are bank managers and finance executives in future studies on banking models.

Findings

Finance and banking expert preferences may differentiate based on criteria such as the region they work in, as well as their socioeconomic status of working region, education level, age, and gender. In this study, state hybrid models takes first place then private hybrid model, state digital model and private digital model follows in order. To achieve a more robust solution, increasing the number of survey participants and reaching out to individuals while considering these criteria can be applied in future studies.

Conclusion

The state-supported digital-only bank, the state-supported bank providing both physical and digital services, the private digital-only bank, and the private bank offering both physical and digital services will been evaluated using the AHP method. These four alternatives have then been ranked using the TOPSIS method. As a result, this ranking also provides insight into the foundations of banking services offered without physical branches, which are becoming increasingly widespread in the country. Also privacy and security criteria affects selection of the why the state hybrid model are takes first place.

Keywords: Electric Vehicles, Machine Learning, MCDM, TOPSIS-Sort-B, Decision Tree, Multinominal Logistic Regression, Sustainable Transportation.

Aim

The transition to sustainable transportation has gained significant attention due to growing environmental concerns, particularly greenhouse gas emissions caused by conventional internal combustion engine vehicles. Electric vehicles (EVs) have emerged as a promising solution to this problem; however, selecting the most suitable EV remains a complex decision-making problem due to multiple conflicting criteria, including cost, performance, battery technology and sustainability factors. The complexity of this decision necessitates robust classification methods that can accommodate both quantitative and qualitative factors. In this context, multi-criteria decision-making (MCDM) approaches provide structured and interpretable classification, whereas machine learning (ML) techniques offer data-driven solutions with high predictive performance.

The aim of this study is to make a comparison between MCDM-based sorting and ML-based classification methodologies in the context of EV selection. In sorting problems, a predefined set of categories must be established, and actions are assigned to these categories independently of other actions (Figueira et al., 2005). In this problem, the decision-maker (DM) attempts to partition the set of alternatives into several categories (Bouyssou et al., 2006) In the context of MCDM approaches, sorting methods have been shown to be favoured over ranking and choosing techniques due to facilitating the decision-making process for decision makers by reducing cognitive burden. In this study, sorting of EVs into preference-based classes has been shown to render the selection process more structured and manageble.

Material and Method

First, hierarchical clustering is employed to determine the optimal number of preference-based categories, followed by the application of TOPSIS-Sort-B for MCDM-based classification. Concurrently, machine learning (ML) classification methods, encompassing decision tree, multinomial logistic regression, naive bayes, linear discriminant analysis (LDA), support vector machine (SVM), and artificial neural networks (ANN), are implemented to categorize EVs based on their features. The classification outcomes of these methodologies are then compared to assess their reliability and accuracy in EV selection.

The present study utilises data obtained from ev-database.org, the largest publicly available EV database, containing detailed specifications of 439 electric vehicles currently on the market. The dataset comprises multiple attributes relevant to EV selection, organized into the following performance metrics: acceleration, top speed, range, battery architecture, battery warranty (both in years and kilometres), charging speed, fast charging speed, fuel equivalent, vehicle weight, seating capacity, turning circle, price, vehicle volume, total cargo volume, drive type, automatic charging support, pre-conditioning, V2L support, tow hitch availability, dedicated EV platform, and heat pump.

In order to ensure data quality and consistency, pre-processing steps were implemented. Missing values were handled using an imputation strategy based on the average values within each vehicle segment, thereby preserving segment-specific characteristics. Categorical variables were converted into numerical representations using one-hot encoding to facilitate

their integration into machine learning (ML) models. Additionally, min-max scaling was applied to numerical variables, normalizing their range between 0 and 1 to ensure comparability across features.

Prior to the implementation of the sorting algorithm, a preliminary clustering analysis was conducted to determine the optimal number of categories. To address the lack of labels in the dataset, hierarchical clustering was employed, utilising a range of linkage methods. The dendrogram suggested that three clusters represented the optimal grouping, corresponding to high, medium, and low preference classes. This data-driven clustering approach provided a robust foundation for the subsequent classification process.

Following the clustering phase, classification was conducted using two distinct methodologies. The first approach employed the TOPSIS-Sort-B method, an MCDM-based sorting technique, to classify EVs into high, medium, and low preference categories. This sorting process required predefined limit profiles, which were systematically determined using the lower and upper quartiles of each attribute to ensure a balanced distribution of categories. Additionally, criteria weights were established through the Analytic Hierarchy Process (AHP), where two domain experts assigned weights via pairwise comparisons. The results highlighted that price, range, fast charging speed, and battery warranty period were the most influential factors in EV selection, aligning with consumer preferences and market trends.

The second approach involved the use of machine learning (ML) classification, leveraging multiple algorithms to validate the categorisation derived from the MCDM sorting process. The dataset was split into a training set (90%) and a testing set (10% - nearly 40 instances) to evaluate the generalisation performance of each model. Model performance was assessed using standard classification metrics, including accuracy, precision, recall, and F1-score. The ML classification results were subsequently compared with the MCDM sorting outputs to examine their agreement and reliability.

Findings

Among the ML models tested, multinomial logistic regression exhibited the highest classification accuracy, achieving 98%, followed by ANN with 95%, decision tree with 90%, and SVM with 90%. The performance metrics for all models are summarized in Table 1. The results of this investigation demonstrated strong consistency between MCDM sorting and ML-based approaches.

Table 1. Performance Metrics**.**

Model	Accuracy	Precision	Recall	F1-Score
Decision Tree	0.90	0.90	0.90	0.90
Multinominal Logistic Regression	0.98	0.98	0.98	0.97
Naive Bayes	0.83	0.84	0.83	0.82
LDA	0.88	0.88	0.88	0.87
SVM	0.90	0.92	0.90	0.90
ANN	0.95	0.96	0.95	0.95

Conclusion

This research emphasises the merits of integrating MCDM sorting with ML-based classification to establish a dependable and interpretable decision-making framework for EV categorisation. The methodological approach adopted in this study offers significant insights for policymakers, industry experts, and consumers by enhancing decision support mechanisms in sustainable transportation. Future research could explore hybrid decision-making frameworks, incorporate additional EV attributes, or extend the dataset to enhance the classification robustness. The findings contribute to the broader goal of facilitating informed EV selection, ultimately supporting the transition toward sustainable mobility.

A Bayesian Network-Based Approach for Analyzing Railway Accidents

Derya Cephe[a], Umut Asan[a]

[a] Istanbul Technical University, Industrial Engineering, MSc in Industrial Engineering, Türkiye
deryacephe18@gmail.com, cephe22@itu.edu.tr

Keywords: Bayesian Network, Railway Safety, Accident Analysis, GeNIe.

With the increasing demand for transportation, railway systems have gained significant momentum due to their economic and environmental advantages. However, if necessary safety measures are not implemented, accidents may result in severe injuries and fatalities. The primary objective in such accidents is to prevent loss of life and serious injuries. Effective accident prevention strategies can significantly reduce, or even eliminate, these adverse consequences. However, in order to develop preventive measures, past accident data must first be systematically analyzed.

In recent years, the fatality rate associated with railway accidents has shown a declining trend globally. Between 2010 and 2021, the average number of significant accidents per million train-kilometers in European Union (EU) countries was recorded as 0.5 (European Union Agency for Railways [ERA], 2023), whereas in Turkey, this rate was approximately 2.48 for the same period (Turkish State Railways [TCDD], 2023). Analyzing the statistics of the Turkish State Railways, this rate, which was around 5 per million train-kilometers in the 2010s, decreased to 1.3 by 2021, showing remarkable improvement (TCDD, 2023). However, existing data indicate that Turkey still has significantly higher accident rates compared to European countries (Figure 1).

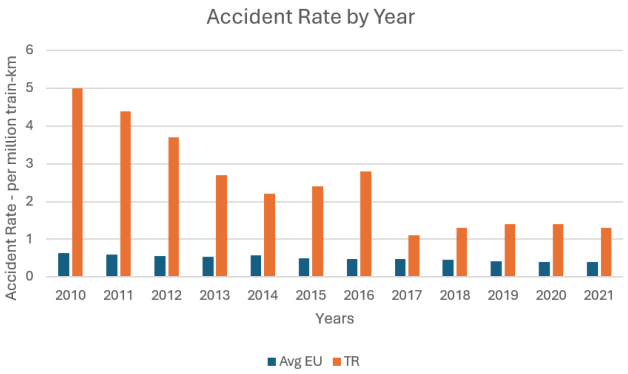

Figure 1. Accident Rates per Million Train-Km in European Countries and Turkey (2010-2021).

Aim

The primary objective of this study is to conduct an in-depth analysis of railway accidents in Turkey and propose preventive measures to avoid similar accidents in the future, providing guidance for the sector. In this context, Bayesian Network-based probabilistic prediction models were employed, expert opinions were utilized, and analyses were conducted using a model developed in the GeNIe software.

This study offers unique academic and industrial contributions, including: The development of a model that accounts for uncertainties, allowing for a more accurate representation of real-world conditions. It is the first study to analyze railway accidents in Turkey using the Bayesian Network approach. A hybrid Bayesian approach was adopted, integrating both data-driven analysis and expert knowledge. This methodology provides a novel contribution to international literature. International studies predominantly develop data-driven models based on existing accident data, with hybrid models used in cases of data scarcity. However, in this study, expert opinions were not only used to address data gaps but also to gain a deeper understanding of railway safety and develop a needs-based approach.

Material and Method

This study thoroughly examines railway accident data from the past seven years in Turkey. The methodology consists of three main stages: data collection and variable identification, statistical analyses and Bayesian Network modeling, and scenario development.

The data used in this study were obtained from TCDD's statistical yearbooks and face-to-face interviews with TCDD officials. The selection of variables was guided by international literature and safety-related accident variables defined in the ERA directives.

The categorical variables used in the study and their definitions are as follows:

- Technology Level: Represents the level of technology in the year of the accident.
- Season: Indicates the season in which the accident occurred.
- Railway Line: Denotes the name of the railway line where the accident occurred.
- Minor Injury: Indicates whether minor injuries occurred in the accident.
- Serious Injury: Indicates whether serious injuries occurred in the accident.
- Fatality: Indicates whether the accident resulted in fatalities.
- Cost Amount: Represents the financial cost incurred due to the accident.
- Accident Level : Defines the level of the accident in terms of safety impact.
- Accident Type: Describes the type of accident.
- Accident Cause: Identifies the primary cause of the accident.

To systematically analyze the relationships among these variables and assess their statistical significance, IBM SPSS software was utilized. The applied statistical methods include Crosstab Analysis, which was used to visualize associations between categorical variables, and the Chi-Square Test, which determined the presence of statistically significant relationships among categorical variables. The strength of these significant relationships was further assessed using Cramér's V and Phi coefficients.

In order to investigate railway accidents in greater depth, a Bayesian Network-based modeling approach was employed. The modeling process consisted of two key stages. In the qualitative stage, relationships between variables were identified based on statistical analysis results and expert evaluations. In the quantitative stage, Conditional Probability Distributions (CPDs) between variables were calculated, and the model underwent statistical validation (Asan, n.d.).

During the model development process, the data were initially organized in MS Office Excel and subsequently processed in the GeNIe Academic software to construct the Bayesian Network model (Figure 2). This model was designed to analyze accident patterns under various scenarios, offering decision-makers valuable insights to improve railway safety management.

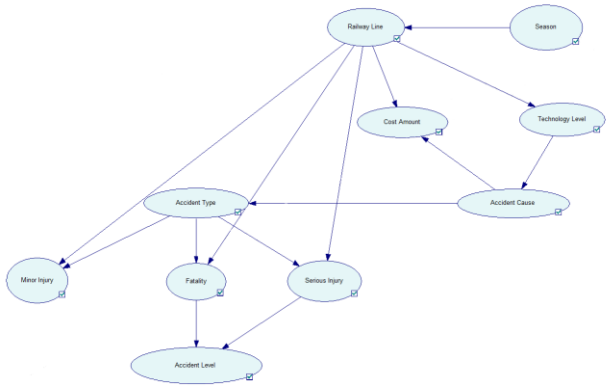

Figure 2. Bayesian Network Model Developed in GeNIe.

The analysis included four distinct scenarios. Scenario-0, the Current Situation, represents the existing accident conditions, serving as a baseline for comparison. Scenario-1, the Best-Case Scenario, simulates an ideal condition where accidents are minimized to a "minor" level, aligning with global safety strategies and best practices. Scenario-2, the Worst-Case Scenario, reflects the most adverse conditions, where accidents are categorized as "major," leading to increased fatality and severe injury rates. Scenario-3, the Line-Based Scenario, examines how different railway lines are impacted by geographical location, management structure, and environmental factors, providing a more granular perspective on accident risks. These scenarios are structured to guide decision-makers in strengthening railway safety management and preventing future accidents.

Findings

The statistical analyses and Bayesian Network model outputs reveal several critical insights into railway accident patterns. Seasonal variations have a notable impact on the occurrence and distribution of railway accidents, indicating a need for adaptive safety measures throughout the year. The causes, types, and financial costs of accidents exhibit significant variation depending on the railway line, suggesting that infrastructure, operational conditions, and environmental factors play a crucial role in accident dynamics. Furthermore, accident costs are influenced by multiple factors, including seasonal conditions, railway line characteristics, technological advancements, and the underlying cause of the accident. The level of technology implemented on a railway line not only affects the primary cause of accidents but also determines the financial burden associated with them. The findings also indicate that the cause of an accident is a strong determinant of the accident type, which, in turn, directly influences the severity of consequences, including fatalities, serious injuries, and minor injuries. Additionally, the number of fatalities is impacted not only by the type of accident but also by the specific railway line where the incident occurs, emphasizing the role of infrastructure and safety standards in different regions. Lastly, accident severity is primarily determined by the number of fatalities and serious injuries, highlighting the importance of preventive measures and rapid emergency response strategies in mitigating the most severe outcomes of railway accidents.
The results obtained from the scenario testing provide significant insights into the patterns and severity of railway accidents under different conditions. In Scenario-0 (Current Situation), the majority of accidents occur at a minor level, with relatively low fatality and serious injury rates. However, derailments and collisions remain critical risks, highlighting the need for further safety improvements. Human errors and equipment failures are identified as major contributing factors, and the current level of technology indicates room for enhancement in accident prevention measures.
In Scenario-1 (Best-Case Scenario), where accidents are minimized to a minor level, fatalities and serious injuries are entirely eliminated, aligning with the expectations of an optimized safety strategy. This scenario underscores the potential effectiveness of preventive measures in significantly reducing accident severity.
Conversely, Scenario-2 (Worst-Case Scenario) presents the most adverse conditions, where accidents are classified as major, leading to a substantial increase in fatality and serious injury rates. Pedestrian collisions and level crossing accidents emerge as dominant contributors, particularly in specific railway lines. The findings indicate that human errors remain the most influential factor in this scenario, further emphasizing the importance of human-centered safety interventions and infrastructural improvements.
Scenario-3 (Line-Based Scenario) reveals notable variations in accident severity and frequency across different railway lines. While serious accidents constitute only 3% of the overall dataset, this rate increases to 6% on Line-3 but decreases to 0% on Lines 4 and 8. A closer examination of fatality rates shows an upward trend on Lines 3 and 4, whereas Line 2 exhibits a complete elimination of fatalities. When analyzing the underlying causes of accidents, human errors occurring outside the system increase to 33% on Line-4, while equipment-related failures become more prevalent on Line-2. In terms of accident types, derailments and collisions remain the most frequently observed incidents, with certain railway lines exhibiting an increasing trend. These findings highlight the necessity of tailored safety measures that address the specific risks associated with different railway lines, ensuring a more effective accident prevention approach.

Conclusion

In conclusion, this study provides a comprehensive analysis aimed at reducing accident severity in Turkish railway systems, utilizing a Bayesian Network model to uncover key findings. The results indicate that accident severity is directly influenced by fatalities and serious injuries, while human factors have an indirect impact. As the first study to analyze railway accidents in Turkey using Bayesian Networks, it makes a significant contribution to the development of safety policies and the implementation of risk-based maintenance strategies to minimize accident severity.

Future research should focus on refining the dataset by incorporating signal level variables for railway lines and sections. This would allow decision-makers to develop line-specific recommendations to reduce the severity of potential accidents. Additionally, expert feedback suggests that further investigation is needed to explore the relationship between accident type and accident severity. Therefore, future studies should concentrate on specific railway lines, conduct comparisons with international and European safety standards, and evaluate compliance with global safety norms.

Manufacturing Management

Impact of Organizational Life Cycle on R&D Project Prioritization Criteria

Furkan Yasin Taksim[a], Erhan Bozdağ[a]

[a] Istanbul Technical University, Department of Industrial Engineering, Engineering Management M.Sc. Program, Turkey
taksim22@itu.edu.tr

Keywords: R&D Project Selection, Organizational Life Cycle, BWM, AHP.

Aim

Research and Development (R&D) is a fundamental driver of innovation, economic growth, and competitive advantage in a dynamic business environment. It provides organizations with a systematic process of exploring new knowledge, technologies, and methodologies to create new products, improve existing products, and enhance their operational processes. By encouraging creativity and scientific expertise, R&D serves various industries, from technology to manufacturing. The role of R&D is critical for enabling organizations to meet the needs of evolving markets, anticipate future trends, and sustain long-term growth. Management of the R&D process requires a strategic approach, balancing creativity with practicality and risk with potential reward. Organizations must allocate resources wisely, select appropriate projects, and establish mechanisms for knowledge transfer and intellectual property protection. Moreover, encouraging a culture of innovation, and interdisciplinary collaboration can increase the effectiveness of R&D efforts [1].

To create the culture of R&D with continuous improvement and sustainable growth, organizations should prioritize the right R&D projects. Therefore, there is a need for a selection strategy for organizations. For assessing these projects, the criteria set used in this selection process should be determined by strategic objectives, industry dynamics, and available resources. Since these variables are different in each of the life cycle stages, the weight and priority of these criteria can change depending on the phases of the lifecycle of the company [2]. Companies have different objectives, needs, and priorities in various lifecycle stages, like startup, growth, maturity, and decline. This difference highlights the necessity of addressing R&D project selection criteria by considering lifecycle stages. This study aims to explore the differentiation in R&D project selection criteria across the various stages of the organizational life cycle.

Material and Method

In this study, first, a literature review on R&D project selection and R&D itself is conducted. In the literature review, the study by Souza et al. is used as a base for the criteria set for R&D project selection [3]. In this study, there are 66 relevant studies from 1970 to 2020 analyzed and 263 criteria were retrieved from these studies. With the help of decision-makers, these criteria are grouped into 23 criteria. Since 23 criteria cover a large part of the criteria used in the literature, it is used as a base set in our study as well. Studies that are before 2020 but not on the article list covered by Souza et. al and studies after 2020 both in the world and in Türkiye are also examined in our study. Besides these articles, studies about R&D and Innovation are also examined to check whether any criteria are not on the criteria acquired from the literature review or not. The final set of criteria used in this study and reference of articles to these criteria are given in Table 1.

Table 1. Summary of criteria set and their references used in this study.

After the literature review and determination of criteria, definitions of organizational life cycle theory and its implementation in our study are structured. Literature reviews of organizational life cycle theory and organizational

characteristics by life cycle are examined. The list of characteristics is determined for each life cycle of organizations. In this study, 4 stages of the organizational life cycle are used: Birth, Growth, Mature, and Decline. Companies are defined by authors in each organizational life cycle to be used in surveys. Then, surveys are conducted for each organizations and participants are asked to fill out 2 of these surveys: One of them is Company A, one of them is either Company B, C or D. In this method, the aim is to have one answer for one company to check the consistency of decision-makers. And the other answer is used to check whether other organizational life cycle stages cause difference in R&D project selection criteria or not. There are 3 decision-makers in this study from industry and the experience of these decision-makers are 6-years, 6-years and 5-years.

After getting results from decision-makers, the Analytical Hierarchy Process (AHP) and Best-Worst Method (BWM) are used to calculate criteria. Since BWM has similar results with AHP with fewer comparisons for decision-makers [9], BWM is used to prioritize 8 main criteria sets and AHP is used to prioritize sub-criteria ranging from 2 to 4. In this way, the comparisons required in this study are reduced. Then, Spearman's Rank Correlation method is used to analyze relations between decision-makers and stages of the organizational life cycle.

Findings

To calculate global weights, criteria weights for the main criteria and sub-criterion are calculated and multiplied. The results of global criteria weights for each decision-maker and organization are given in Table 2. Based on this, the findings about criteria change are given below.

Table 2. Criteria weights acquired in this study.

- Environmental Impact is the least important criterion in each stages of organizational life cycle.
- Organizational Requirements shifts most significantly through life cycle stages. It is 3rd important criterion in mature stages, where 20th in birth stage, 12th in growth stage and 14th in decline stage.
- Work Resources is the most important criterion in birth stage, 6th important criterion in growth stage and decline stage and 2nd important criterion in mature stage.
- Corporate Image is the most important criterion in growth stage, 3rd important criterion in birth stage, 7th important criterion in mature stage and 4th important criterion in decline stage.
- Strategic Fitness is the most important criterion in mature and decline stage, 8th important criterion in birth stage and 5th important criterion in growth stage.

It can be concluded that some of the criteria can change by the organizational life cycle of the organizations but in order to check whether there is a significant difference between these stages or not, Spearman's Rank Correlation method is used to analyze relations between decision-makers and different companies. The result of Spearman's Rank Correlation is given in Table 3.

Table 3. Spearman's Rank Correlation Coefficients.

Company A			**Company B**	**Company C**	**Company D**	**Coefficient**
DM1	**DM2**	**DM3**	**DM1**	**DM2**	**DM3**	
■	■					0,65
■		■				0,39
■			■			0,35
■				■		0,55
■					■	0,48
	■	■				0,57
	■		■			0,23
	■			■		0,30
	■				■	0,45
		■	■			0,59
		■		■		0,45
		■			■	0,71
			■	■		0,72
			■		■	0,83
				■	■	0,64

The coefficient of Spearman's Rank Correlation interprets the relation between two ranked variables. The coefficient value of 1 means perfect positive correlation, value of -1 means perfect negative correlation and value of 0 means there is no correlation [9]. Based on this, the findings of this study are given below.

- Coefficient values for Company A for each evaluation pairs are between 0 and 1. Therefore, it is concluded that there is a consensus among decision-makers.

- Coefficient values for Company A and Company C for each evaluation pairs are between 0 and 1. Therefore, there is a correlation between these companies and no significant difference in criteria weights in the birth and mature stages.
- Coefficient values for Company A and Company D for each evaluation pairs are between 0 and 1. Therefore, there is a correlation between these companies and no significant difference for criteria weights in birth and decline stages.
- The coefficient value for Company B and Company C for each evaluation pairs are between 0 and 1. Therefore, there is a correlation between these companies and no significant difference in criteria weights in growth and mature stages.
- The coefficient value for Company B and Company D for each evaluation pairs are between 0 and 1. Therefore, there is a correlation between these companies and no significant difference in criteria weights in the growth and decline stages.
- The coefficient value for Company C and Company D for each evaluation pairs are between 0 and 1. Therefore, there is a correlation between these companies and no significant difference in criteria weights in the mature and decline stages.

Conclusion

In this paper, the effect of organizational life cycle stages on R&D project selection criteria is studied. After deciding the criteria set, the survey that consists of both BWM and AHP is conducted. Referring to the findings, even though some criteria weights change by life cycle stages of the organization, it is concluded that there is no significant difference in criteria weights of R&D project selection for different stages. Therefore, it is important for R&D professionals to understand in what stage they are evaluating while they are prioritizing R&D projects. It will help them to make their decisions better. For future research, scholars can reach more decision-makers to check whether the result can change or not. It is also possible to research the effect of organizational life cycle stages on R&D project portfolio selection instead of R&D project selection since it brings different criteria to the problem.

Structuring Challenges for Textile Industry in Adopting the Digital Product Passport

Sena Nur Dursun[a], Seyda Serdarasan[a]

[a]Istanbul Technical University, Industrial Engineering Department, Türkiye
dursuns17@itu.edu.tr

Keywords : Digital Product Passport, ISM, MICMAC, Supply Chain Management, Textile Industry.

Aim

The textile and apparel industry is a significant contributor to environmental pollution, necessitating the integration of sustainability practices across its supply chain. The European Union's Digital Product Passport (DPP) initiative aims to revolutionize the textile industry by enhancing sustainability, transparency, and traceability throughout the product lifecycle, from raw materials to the end consumer. This study aims to identify and analyze the challenges hindering the adoption and implementation of DPP in textile industry and to determine the interrelationships and driving forces among these challenges using Interpretive Structural Modeling (ISM) and MICMAC analysis. Ultimately, this research seeks to provide strategic insights for stakeholders to facilitate a smoother transition towards DPP compliance and enhanced sustainability in textile industry.

Challenges in the Adoption of DPP in the Textile Industry

The adoption and implementation of DPP in the textile and apparel industry face several challenges, as identified through a review of the literature and insights from industry experts. These barriers hinder the effective integration of DPP and highlight the complexities associated with digital traceability in the textile industry. The key challenges include:

1. Technological and Data Management Challenges:
    - Complex data collection across the product lifecycle: Gathering and maintaining accurate data from raw material sourcing to end-of-life poses significant difficulties [1, 3]
    - High costs of sensor-based data collection: Implementing advanced tracking technologies such as RFID and blockchain requires substantial investment [1]
    - Issues related to data quality, security, and storage: Ensuring the integrity and protection of digital product information is a key concern. [1, 2]
    - Lack of secure data sharing infrastructure: Companies hesitate to share sensitive product data due to security risks and a lack of standardized frameworks [1]
    - Lack of standardized data formats and infrastructure: Inconsistent data management practices hinder interoperability across the supply chain. [1, 3]
    - Interoperability issues between systems: Incompatibility between different digital systems used by stakeholders disrupts seamless data exchange. [6]

2. Organizational and Logistical Challenges:
    - Reluctance to share information among partners: Competitive concerns and distrust among supply chain actors slow down data sharing. [1, 3]
    - Lack of expertise and specialized knowledge: Many stakeholders lack technical proficiency in DPP implementation [1, 2]
    - Need for standardization across the supply chain: Harmonizing processes and criteria for DPP compliance remains a challenge. [1, 3]
    - Difficulty in matching materials with eco inventories:Proper classification of materials based on

sustainability credentials is complex and resource-intensive [1]

3. Financial and Economic Barriers:
    - High costs of technology implementation (e.g., blockchain):
    - Investment in digital infrastructure is a significant barrier, especially for SMEs. [2, 3]
    - Insufficient financial resources: Many textile firms, particularly small and medium enterprises, struggle to allocate funds for DPP-related projects. [1, 2, 6]
    - High costs of certifications and verifications: Compliance with sustainability standards adds additional financial burdens. [2]

4. Regulatory and Legal Uncertainty:
    - Uncertainty around future regulations and compliance requirements: Businesses face difficulties in planning due to evolving regulatory landscapes. [1, 3]
    - Lack of clear legislative framework and guidance:
    - Unclear policies hinder the structured implementation of DPP [2, 3]
    - Confusion regarding DPP implementation steps and roles: Stakeholders lack clarity on how to effectively integrate DPP into their operations. [1]

5. Knowledge and Expertise Gaps:
    - Lack of expertise in DPP-related methodologies and eco-design: A shortage of trained personnel slows down the adoption process. [1, 2]
    - Insufficient training and specialized knowledge among stakeholders: Capacity-building initiatives are needed to support widespread implementation [2]

6. Consumer and Market-Related Issues:
    - Consumer reluctance to engage with product information: Limited awareness and interest among consumers reduce the demand for DPP-enabled products.[3]
    - Concerns about the utility and cost-effectiveness of DPP for consumers: The added value of DPP must be clearly communicated to end-users. [2, 3]
    - Lack of involvement from sales and marketing departments: A weak connection between sustainability initiatives and marketing strategies affects adoption rates. [2]

7. Other Barriers:
    - Resistance to change within organizations: Traditional business models and corporate inertia slow down the transition.[3]
    - Lack of a systematic approach to integrating environmental improvements: Fragmented sustainability initiatives hinder holistic implementation. [2]

Material and Method

This research will employ a mixed-methods approach, commencing with a comprehensive literature review to identify key challenges associated with DPP implementation in the textile industry, considering both academic studies and industry reports. This review will also analyze relevant EU regulations and global best practices in DPP implementation.
To explore the complex relationships among challenges identified from existing literature and expert opinions, data will be collected through a sectoral survey targeting various stakeholders in the textile industry, including manufacturers, suppliers, brands, consumers, associations, and regulatory bodies. The study will then apply Interpretive Structural Modeling (ISM) and MICMAC analysis to establish a hierarchical structure and assess the influence-dependence power of each challenge.

Interpretive Structural Modeling (ISM) was developed by Warfield in the 1970s as a method for structuring complex systems [7]. ISM applies graph theory iteratively to represent a complex system as a directed graph. It is a process that transforms poorly defined and ambiguous cognitive models into well-defined models that are useful for various analytical purposes and especially useful when dealing with ambiguous and qualitative issues, turning them into structured decision-making tools.[5]. In this study, ISM will be used to systematically analyze the challenges identified, establishing a hierarchical structure that illustrates their contextual relationships.

Following the ISM analysis, MICMAC (Matrice d'Impacts Croisés Multiplication Appliquée à un Classement / Cross Impact Matrix Multiplication Applied to Classification), one of the quantitative methods of cross-impact analysis, used to examine events and/or trends (variables) and their interrelationships [4], will be applied. MICMAC will classify the identified challenges based on their driving power and dependence, thereby identifying key driver variables and providing a deeper understanding of their structural interdependencies within the system. It complements ISM by offering quantitative insight into the system's dynamics, supporting more effective decision-making. Together, these methods provide a robust analytical foundation to support strategic planning for DPP implementation in the textile sector.

Findings

This study is expected to provide a structured analysis of the key challenges hindering the implementation of the Digital Product Passport (DPP) in the textile industry. By applying ISM and MICMAC methodologies, the research will identify critical barriers and their interdependencies, offering a strategic roadmap for effective DPP adoption. The expected findings will support stakeholders—particularly small and medium-sized enterprises (SMEs)—in developing targeted actions to overcome these obstacles. Ultimately, the study aims to contribute to enhanced supply chain transparency, improved sustainability practices, and better alignment with EU regulatory frameworks.

Conclusion

This research will offer a systematic analysis of the challenges hindering the adoption of DPP in the textile industry, utilizing ISM and MICMAC methodologies to map interdependencies and driving factors. The findings will assist industry stakeholders—ranging from manufacturers to policymakers—in formulating targeted strategies to mitigate barriers and facilitate a seamless transition towards DPP compliance.

By addressing these challenges, the study aims to support the textile industry's sustainability efforts, improve supply chain transparency, and enhance compliance with EU regulations. Special emphasis will be placed on how small and medium-sized enterprises (SMEs) can navigate these obstacles, ensuring an inclusive and equitable implementation process for all stakeholders involved in the textile supply chain.

Through these insights, this study contributes to advancing sustainable practices and digital traceability in the textile industry, reinforcing the importance of integrating technological innovations with regulatory frameworks to drive meaningful environmental and economic impact.

Sector-Specific Supplier Evaluation Based on LARGS Dimensions

Gözde Çinkay [a], Şeyda Serdar Asan [a]

[a] İstanbul Technical University, Industrial Engineering, Türkiye
cinkay23@itu.edu.tr

Keywords: LARGS, Organizational Supplier Assessment (OSA), Supplier Selection, Supply Chain Management.

Aim

Supply Chain Management (SCM) encompasses the flow of materials, information, and financial resources across organizational boundaries. In today's dynamic and complex supply chain environments, supplier selection has become increasingly strategic. Supplier management significantly influences a company's overall performance and the sustainability of long-term partnerships. Contemporary companies are now evaluating suppliers not only on the basis of cost and quality but also on their resilience, environmental impact, and adaptability [1]. These evolving expectations necessitate comprehensive frameworks capable of addressing multidimensional requirements, especially in intricate sectors such as automotive manufacturing. This shift is reflected in the Lean, Agile, Resilient, Green, and Sustainable (LARGS) paradigms. Traditional supplier evaluation models typically emphasize cost, quality, and delivery performance, often neglecting critical aspects such as sustainability and resilience. This creates a misalignment between evaluation practices and the strategic competencies required to remain competitive in volatile and uncertain environments [2].
Considering the increasing complexity and interconnectivity of supply chains, particularly within the automotive industry, companies must develop and integrate competencies related to flexibility, resilience, and sustainability. The present study aims to investigate whether industry-specific supplier evaluation criteria align with the LARGS dimensions, utilizing Organizational Supplier Assessments (OSA) to provide empirical insights into supplier performance.

Material and Method

Literature Review

Lean:

Lean supply chain management, pioneered by Toyota, aims to reduce costs through waste elimination and enhance efficiency by creating value streams [3]. It requires effective cooperation and coordination among supply chain actors, with a focus on optimizing the flow of goods, information, and finances. Lean emphasizes operational and managerial efficiency, responding quickly and predictably to customer demands by minimizing time, inventory, and unnecessary expenditures [4].

Agile:

Agility in the supply chain refers to the capacity to respond rapidly to variable demand and to manage high-volume, diverse product portfolios in a cost-effective manner [3]. While lean emphasizes waste reduction, agile supply chains prioritize responsiveness, competence, flexibility/adaptability, and speed. Agile suppliers are capable of quickly adapting to changes in market conditions and customer requirements, thus enhancing the ability to manage uncertainty and gain a competitive edge.

Resilient:

A resilient supply chain is defined by its ability to withstand unexpected disruptions, maintain operational continuity, and control performance outcomes. It encompasses the capacity to mitigate disruption impacts, recover efficiently, and leverage new opportunities. Resilient suppliers are characterized by flexibility, cost efficiency, risk mitigation, and adherence to safety and environmental standards [4]. Strategies such as inventory buffering, production network diversification, nearshoring, multi-sourcing, and ecosystem partnerships can be employed to build supply chain resilience.

Green:

Emerging in the early 1990s, green supply chain management gained prominence alongside increasing environmental awareness. Its primary goal is to prevent pollution and enhance environmental performance throughout the supply chain. Green supply chains contribute to cost savings, innovation, corporate image enhancement, and social responsibility. Practices include recycling, remanufacturing, reduction, and refurbishment. Tools such as green procurement and environmental management systems promote cleaner production, reduced transportation emissions, and sustainable logistics practices [5].

Sustainable:

Sustainable supply chain management integrates economic, social, and environmental objectives to foster inter-organizational collaboration and support long-term development goals. It aims to reduce ecological footprints and costs while ensuring compliance with regulations and maintain competitiveness. This approach is increasingly recognized as a key pillar of industrial sustainability [6].

Challenges in automotive sector SC:

The automotive industry is exposed to a wide array of risks stemming from political, environmental, social, and technological factors. It is highly interconnected globally, technologically sophisticated, and subject to rapid changes in regulatory and market conditions. The LARGS framework aligns well with sectoral needs, offering capabilities for operational efficiency (Lean), quick responsiveness (Agile), risk mitigation (Resilient), environmental compliance (Green), and long-term viability (Sustainable). To maintain competitiveness, automotive manufacturers adhere to local regulations, comply with international quality standards, and develop alternative suppliers or materials. Suppliers are expected to adopt sustainable practices to fulfill environmental and social responsibilities and align with green and sustainability standards [12].

Although various supplier evaluation frameworks exist in the literature, few address all five LARGS dimensions comprehensively. Table 1 presents a summary of the relevant criteria identified in previous studies.

Table 1. Table 1. LARGS Dimensions According to the Literature.

LARGS Dimension	Key Evaluation Criteria	References
Lean	- Manufacturing process effectiveness	[3], [4], [7], [8]
	- Management effectiveness	
	- Supply redundancy / Inventory management	
Agile	- Supply chain robustness / Response speed	[3], [4], [8]
	- Customization / Product flexibility	
	- Collaboration	
Resilient	- Risk management	[3], [4], [9]
	- Supplier selection processes / Dual sourcing	
	- Production planning	
Green	- Eco-friendly processes	[3], [4], [10]
	- Carbon footprint reduction	
	- Waste management / Circular economy	
Sustainable	- Social sustainability	[3], [4], [11]
	- Environmental sustainability	
	- Regulatory compliance	

Methodology

This study assesses supplier selection criteria in the context of the LARGS framework by analyzing OSA data from an automotive manufacturer's supplier network. The methodology involves the following key steps:

1. Data Collection: Supplier evaluation criteria identified from the literature were mapped to the LARGS dimensions. These were then matched with the criteria used in the manufacturer's Organizational Supplier Assessment system.
2. Confirmatory Factor Analysis (CFA): CFA was employed to validate whether the supplier evaluation criteria reflect the LARGS dimensions as latent variables.
3. Scoring Suppliers: Supplier scores for each LARGS dimension were calculated using factor loadings derived from the CFA.
4. Evaluation Framework: The current supplier ranking was compared with the rankings obtained using the LARGS-based evaluation framework.

Findings

The process of matching OSA criteria with LARGS dimensions has been completed, and data from the supplier database are currently being analyzed. Preliminary analyses involve conducting Confirmatory Factor Analysis (CFA) to verify the alignment of evaluation criteria with LARGS constructs. An evaluation framework is being developed to assist decision-makers in interpreting the results and making informed supplier selections.

Conclusion

This study introduces a sector-specific supplier evaluation model grounded in the LARGS framework. The model enhances the accuracy of decision-making processes and enables supply chain managers to identify suppliers that are not only cost-efficient but also agile, resilient, environmentally responsible, and sustainable.

The proposed LARGS-based model is expected to surpass traditional evaluation approaches by offering a more holistic and future-oriented perspective. It provides strategic value in complex and rapidly evolving sectors such as automotive manufacturing.

Future research may focus on adapting the model to other industries or integrating it with decision-support tools to enhance its applicability and impact.

Customer Preferences For Mobile Operating Systems In Smartphones Using Conjoint Analysis

Cansu Aksu[a]

[a] Istanbul Technical University, Department of Industrial Engineering of the Graduate School, Engineering Management Master of Science Program, Türkiye
aksuc21@itu.edu.tr

Keywords: Customer Preference, Conjoint, Mobile OS.

Aim

Smartphones have become an integral part of modern life and have greatly affected customers' interactions with technology. In this context, the choice of operating systems (OS) of a smartphone is an important factor that reflects customers' expectations and needs from their devices. Customer preferences play a critical role in directing the development of OS and affecting market dynamics (Böhm et al., 2015). This research was conducted to understand customer preferences for mobile OS in smartphones and to determine which attributes shape these preferences using conjoint analysis.

Material and Method

Conjoint analysis is a multivariate technique used to determine end users' preferences and understand how they make decisions when faced with multiple trade-offs. It operates on the assumption that various factors influence the decision-making process simultaneously. There is a conjoint analysis research in the literature focusing on consumer perspectives regarding mobile service platforms (Nikou et al., 2014).

In this research, a conjoint analysis was conducted to understand customer preferences for mobile OS in smartphones. Conjoint analysis is applied via Sawtooth Software, in this research. Sawtooth Software is a widely used tool in academic and market research for conducting conjoint analysis (Sawtooth Software, 2025). The researcher inputs the determined attributes and their levels into the software, selects the appropriate conjoint analysis method, and designs a survey through the software. Subsequently, the conjoint analysis is conducted within the software using the responses collected from participants.

A literature review was conducted to identify the attributes, analyzing 41 academic articles. During the attributes selection process, articles related to customer preferences, satisfaction, and perspective in mobile operating systems were examined, along with comparative and general information on mobile OS. As a result, 86 attributes, categorized as software-related and hardware-related, were identified. In this research, to conduct the conjoint analysis, software-related attributes were selected.

From the 19 identified software-related attributes, it was necessary to reduce them to 7 due to the impracticality of implementing a survey with more than 7 attributes. To determine these 7 attributes, a survey using 7-point Likert scale was designed. The survey began with demographic questions, followed by a task where participants were asked: "When purchasing a smartphone, which features of the operating system are most important to you? Please rate the following features based on their importance to you." A total of 47 participants completed the survey, and the result of the top 7 most important attributes identified is shown in Table 1.

Table 1. Result of attributes selection survey.

Ranking	Factors	Importance		Frequency in the articles
		Mean	Standard Deviation	
1	Freeze/Crash	6.21	1.41	10
2	Security	6.17	1.45	21
3	Privacy	6.15	1.47	10
4	Reliability of Apps	6.04	1.41	25
5	User Experience	6.00	1.38	26
6	Quality of Apps	5.87	1.44	6
7	Multitasking	5.64	1.42	4

Regarding to Table 1, importance of selected attributes and the frequency of these attributes in the 41 articles were consistent with each other. It was found that 5 of the attributes determined through the survey matched those frequently mentioned in the literature. By integrating both survey results and academic literature, a more reliable and comprehensive analysis was conducted.

The research is conducted using the conjoint analysis methodology via Sawtooth Software. For the conjoint analysis, the Adaptive Choice-Based Conjoint (ACBC) method was used to be the most suitable approach based on factors such as sample size and the number of attributes (Orme, 2013). The identified 7 attributes and their levels were defined in the Sawtooth Software system and presented to 47 participants through various scenarios immediately after the demographic questions. The identified attributes and their levels are shown in Table 2.

Table 2. Attributes and levels determined for the research.

Attributes	Level 1	Level 2
Freeze/Crash	Rare	Sometimes
Security	Advanced security, comprehensive protection	Basic security
Privacy	Guaranteed high data confidentiality	The best possible data privacy
Reliability of Apps	Only verified, approved apps	More apps available for download from anywhere
User Experience	Simple, understandable, quick to learn	A little more complex, may take some time to learn
Quality of Apps	Fulfil the functions expected from the application, usually without error	Basically, it works properly, but sometimes small errors occur
Multitasking	Ability to use multiple applications almost flawlessly	Basic level of trouble-free use when running multiple applications

Findings

From conjoint analysis using Sawtooth Software, it was found that the Freeze/Crash is the most important attribute when preferring an operating system for smartphones, with an average importance of 22.01%. Then, with varying average importance given to Security, Reliability of Apps, User Experience, Quality of Apps, Privacy and finally Multitasking resulted as the other preferred attributes while choosing an operating system for smartphones, respectively. Result of conjoint analysis is shown in Table 3. When result of conjoint analysis and result of attributes selection survey are compared, it seems that attributes ranking of importance is different. This difference indicates the benefit of conjoint analysis.

Table 3. Result of conjoint analysis.

Attributes	Average Importance
Freeze/Crash	22.01%
Security	17.62%
Reliability of Apps	14.81%
User Experience	14.51%
Quality of Apps	11.97%
Privacy	9.64%
Multitasking	9.44%

When the average importance values are examined based on demographic responses, the most important operating system attribute in both age groups between 18-24 and 25-34 is Freeze/Crash. The least important attribute is the Quality of Apps at the age of 18-24, while it is Multitasking for 25-34.
In terms of undergraduate and graduate education, the most important attribute for both is Freeze/Crash. The least important attribute is Multitasking for undergraduate education, while it is Privacy for graduate education.
Based on the operating system used, Freeze/Crash is the most important attribute for both Android and iOS users. The least important attribute for Android users is Privacy, while it is Multitasking for iOS users.
In terms of the smartphone usage purpose, the most important attribute in both personal use and personal and business use is Freeze/Crash. While the Quality of Apps is the least important for personal use, Multitasking is the least important for personal and business use.
For gender, Freeze/Crash is the most important attribute for both men and women. Multitasking is the least important attribute for women, while Privacy is the least important attribute for men.

Conclusion

The aim of this research is to understand customer preferences for mobile operating system in smartphones and to determine which attributes shape these preferences using conjoint analysis. According to the findings obtained from conjoint analysis, it was observed that Freeze/Crash is the most important attribute when preferring an operating system in smartphones, with different average importance values according to all demographic segments. When examined in terms of the operating system attribute that is given the least importance in operating system preference in smartphones, differences are seen according to demographic segments, and it was observed that the Multitasking has the least importance. In addition, it can be said that the operating system attribute that operating system developers should pay the most attention to in smartphones is Freeze/Crash. The fact that the number of attributes is 7 and the number of levels for each attribute is limited to 2 in order to make the survey more understandable and easier to answer, and the small sample size may create a limit for this research. Therefore, the findings obtained from this research can be hypothesized and tested using a larger sample size in the future research.
I would like to sincerely thank Sawtooth Software for their valuable support.

Predicting the Closing Time of Debt Files in Legal Stage Using Machine Learning and Deep Learning Methods

Şeyda İrem Bilgehan[a], Başar Öztayşi[a]

[a] Istanbul Technical University/Graduate School, Industrial Engineering, Türkiye
bilgehan@itu.edu.tr

Keywords: Deep Learning, Legal Debt Collection, Machine Learning.

Aim

Nowadays, in many sectors, ensuring regular income distribution and reducing financial risks have become important goals. Companies and banks face situations where they have difficulty receiving payment for the products, loans or services they provide. In situations of these kind, it may seriously affect their financial situations, cash flows and even the reputation of the business. Debt collection processes are carried out to collect the outstanding amount in case of unpaid invoices or loan payments. For a successful debt collection process, it is of great importance to analyze large-scale datasets coming to debt collection agencies from banks, telecommunication companies, energy and natural resource companies using data science methods (Onar et al., 2018). If outstanding debts are not paid within the specified time, their cases will proceed to the legal stage and will followed up by lawyers within the scope of legal debt collection (Altınok et al., 2021). In this study, it is aimed to make analyses for predicting closing time of debt files in legal proceedings based on the debtor' s and debt collection agency' s features using machine learning and deep learning algorithms. It is also aimed to help make operational decision, enhance financial management, improve cash flow and collection speed in the light of these predictions.

Material and Method

In this study, a dataset containing details of the debtor' s and debt collection agency' s features is used. The dataset consists of 20 base features, 13 of which are numerical, five are temporal, and two are string data types and with a total of 4,000 rows. Base features are total debt amount, follow-up type, enforcement type, geographic region, geographic region score, agencies speed score, communication quality score, creditor speed score, country general speed score, lien data quality, legal follow-up application date, finalization legal proceedings date, asset detection date, collection start date, collection completion date, follow-up completion time, asset detection time, collection start time, collection completion time and legal file closing time. In this study, the columns with temporal data type were initially converted to date format, while the columns with object data types were converted to categorical data type and then to numerical data type by using label encoder. Secondly, all rows containing missing values were removed from the dataset in order to ensure data completeness and avoid issues related to missing values. Subsequently, columns which are categorical data type were converted to numerical data type by using one-hot encoding method. With the aim of evaluating which categorical data transformation method yields more successful results, two distinct models were developed for each machine learning and deep learning technique, one applying the one-hot encoding method and the other applying the label encoding technique. Then, for the purpose of identifying the independent variables that enhance the predictive power and accuracy of the model, correlation analysis was conducted between the dependent variable and the independent variables. Additionally, correlation analysis was performed among the independent variables, and feature selection was performed based on these analyses. After data preparation and feature selection were completed, eleven machine learning and deep learning algorithms, including Linear Regression, Ridge Regression, Lasso Regression, Elastic Net Regression, Decision Tree Regression, Random Forest Regression, Gradient Boosting Regression, Support Vector Regression, K-Nearest Neighbour Regression, Artificial Neural Network Regression and Convolutional Neural Network Regression were applied to the dataset during the modelling process. Most of these machine learning and deep learning algorithms are frequently used in the literature and generally said to give high performance (Bashar et al., 2023; Kim et al., 2016). In this study, in addition to classical machine learning

and deep learning algorithms, four stacking algorithms were also applied to the dataset. In the first Stacking Regression model, K-Nearest Neighbour Regression and Logistic Regression were applied as base learners, followed by Logistic Regression as the meta model. In the second Stacking Regression model, Ridge Regression, Random Forest Regression, Gradient Boosting Regression, and Support Vector Regression models were applied as base learners, followed by Ridge Regression as the meta model. In the third Stacking Regression model, Linear Regression, Decision Tree Regression, Support Vector Regression, and Random Forest Regression models were applied as base learners, followed by Polynomial Regression as the meta model. In the fourth Stacking Regression model, Linear Regression, Decision Tree Regression, Support Vector Regression, and Random Forest Regression models were applied as base learners, followed by Linear Regression as the meta model. It was used three key metrics, such as Root Mean Squared Error, Mean Absolute Percentage Error, R-Squared and Adjusted R-Squared to evaluate the performance of the regression models.

Findings

The results indicated that the three top-performing models were the third Stacking Regression model, Linear Regression model and Ridge Regression model, respectively. Their R-Squared values were 0.85525, 0.85521 and 0.85518, respectively. These models were followed by Support Vector Regression model, the fourth Stacking Regression model and Elastic Net Regression within 0.85515, 0.85512 and 0.85498 R-Squared values, respectively. It was observed that the one-hot encoding transformation technique was used in five of them. Moreover, the second Stacking Regression model and Lasso Regression model exhibited high R-Squared values, both above 0.85. It was observed that deep learning algorithms did not perform efficiently due to the relatively small to medium size of the dataset.

Conclusion

In conclusion, 11 of 15 applied regression models has R-squared values between 0.80897 and 0.85525 and provided an efficient solution to predict legal follow-up file closing time. However, it was observed that deep learning algorithms could not provide a sufficient solution. In the continuation this study, improvement efforts will be undertaken to increase the number of rows and improve data quality in order to develop models that produce better results. We expect that stacking and deep learning algorithms will perform better with medium to large-sized datasets. Moreover, deep learning algorithms such as Long Short-Term Memomry and Gated Recurrent Unit will be applied and to enhance the overall performance and obtain better results.

Understanding University Reputation: A Stakeholder-Centered Model for Reputation

Orhan Dursun[a], Çiğdem Altın Gümüşsoy[a]

[a] Istanbul Technical University, Industrial Engineering PhD Program, Türkiye
dursunorh@itu.edu.tr

Keywords: University Reputation, Corporate Quality, Emotional Appeal, Measurement Model.

Aim

Reputation is a complex and evolving concept, with its interpretation varying across contexts and academic disciplines. Traditionally, reputation has been described as "beliefs or statements regarding the character of a person or entity" (Longman, 1978). According to Drucker (2004), reputation is primarily shaped by stakeholder perceptions, whereas Deephouse (2000) conceptualized it as an aggregate outcome of social interactions and information exchange. Recent studies have extended these ideas, with scholars like Albino et al. (2023) exploring how reputation is influenced by not only traditional factors like product quality and customer service but also organizations' environmental and social responsibility efforts. Moreover, an increasing body of literature, such as the work of Dutton & Heaphy (2023), points out that reputation is increasingly shaped by the evolving relationship between organizations and their stakeholders, especially in the digital age.

Stakeholders are individuals or groups that can affect or are affected by an organization's activities, goals, and policies (Freeman, 1983). Their perceptions and expectations are critical in shaping corporate reputation. The degree to which stakeholders influence an organization varies and each group emphasizes specific reputation attributes (Brown & Dacin, 1997). Measuring reputation is crucial for its management, as organizations cannot manage what they cannot measure (Drucker, 1954). Reputation management is especially critical in universities, where core services such as education and research are directly influenced by stakeholder perceptions. As organizations face increasing scrutiny from diverse stakeholder groups, reputation management will remain an essential part of strategic decision-making. Recent studies (Coombs & Holladay, 2020) argue that organizations must proactively manage their reputations by anticipating stakeholder expectations and responding swiftly to reputational crises. Therefore, in the current study, we aim to identify significant factors that affect the university's reputation. First, a literature review on reputation and university reputation was conducted, and then the interviews with different university stakeholders were done to reveal important concepts related to university reputation.

Material and Method

First, a literature review was conducted to explore significant factors of the university's reputation, and then semi-structured interviews were conducted with the stakeholders about the university's reputation perceptions. In the interviews phase, in-depth, face-to-face interviews were conducted with a total of 14 stakeholders. The sample included 2 academicians, 3 university students, 2 administrative staff members, 1 alumni association representative, 1 press representative, 1 municipal official, 1 tutoring center representative, 2 industry chamber representatives, and 1 civil society organization representative. The inclusion of diverse stakeholder groups in the sample aligns with the principle of encompassing both internal and external perspectives on university corporate reputation management. The interviews ranged from 1 to 2.5 hours. Audio recordings were taken and later transcribed. The primary objective was to identify the specific implications of reputation for universities and the national context.

Findings

Literature Review:

The literature review shows that traditional reputation models have examined dimensions with the perceived quality and prominence (Rindova et al., 2005), academic and external performance (Alessandri et al., 2006), and affective and cognitive reputation perceptions (Perez & Torres, 2017). Dumitriu (2018) explores educational service quality, while Foroudi et al. (2019) analyze the role of website features and online engagement.

More recent studies emphasize stakeholder engagement, transparency, and digital influence as central to reputation management (Albino, Smith, & Taylor, 2023; Berens, van Riel, & Heaphy, 2023; Dutton & Heaphy, 2023; Xu, Li, & Zhao, 2023; Zhao, Wang, & Liu, 2023). Berens et al. (2023) argue that greater transparency and accountability are essential in higher education, where feedback mechanisms from students, faculty, and external actors directly influence institutional perception. The role of digital platforms in reputation formation has become increasingly significant. Dutton and Heaphy (2023) emphasize that online communities and social media discourse are pivotal in shaping public perception, with digital engagement influencing university branding. Zhao et al. (2023) stress the importance of social media sentiment and online interactions, demonstrating how universities must actively monitor and respond to digital reputation trends. The concept of resilience in reputation management is also gaining attention. Xu, Li, and Zhao (2023) argue that institutions with strong reputations can better withstand crises and recover more effectively. This aligns with previous studies on corporate reputation, which emphasize trust and consistency as fundamental to long-term success.

While many studies focus on specific stakeholder groups—such as students (Sung & Yang, 2009; Polat, 2011; Sultan & Wong, 2019), alumni (Dumitriu, 2018), and faculty (Perez & Torres, 2017)—few adopt a comprehensive, multi-stakeholder perspective. The present study addresses this gap by proposing a University Reputation Model that integrates stakeholder trust, transparency, and digital engagement as key components of reputation management.

Interviews:

The results of the interview revealed the topics such as "the definition of reputation," "the definition of reputation in universities," "factors influencing reputation," "experiences associated with reputation," "international reputation perception," and "factors negatively affecting reputation." The key statements identified as critical during the interviews are listed below:

- Reputation is an abstract concept.
- Trust is perceived as the concept most closely related to reputation.
- Reputation is the cumulative result of sustained university efforts and serves as an indicator of either continuity or decline.
- A sense of belonging, like trust, is another critical concept.
- "Excellence" or the "aspiration for leadership" should also be considered essential in enhancing reputation.
- The quality of university output influences reputation.
- Faculty and staff quality is crucial to a university's reputation, with particular emphasis on respected faculty members.
- International visibility and collaborations contribute to reputation.
- Service quality, in terms of process quality, and producing highly competent graduates, in terms of output quality, impact reputation.
- Scientific competence is another key indicator of quality.
- Social responsibility projects and contributions to civil society are also considered elements of reputation.
- Personalized engagement with students is regarded as a significant indicator of university quality, with a specific mention of its impact on the reputation
- Strengthening university capabilities (ensuring quality) should come first, followed by improving communication and reputation. In other words, reputation cannot be enhanced without first meeting fundamental quality criteria.

- "Training students with practical skills" has been identified as a crucial factor in educational quality, serving as an indicator of service quality.
- Establishing international ties and collaborating with international partners is essential for universities.

Based on the literature, interview findings, and analysis, **reputation** can be defined as an abstract and multifaceted construct shaped by stakeholder perceptions and organizational quality. In universities, it reflects academic excellence, faculty competence, service quality, international recognition, and social responsibility. It serves as both an outcome and an indicator of sustained organizational success.

The key factors for evaluating universities can be categorized into six primary constructs. **Academic leadership** is defined by a university's prominence in the scientific field, its reputation for success, and international recognition (Alessandri et al., 2006; Karaköse, 2006). **Quality of services** encompasses the provision of high-quality education, the ability to produce qualified graduates, and the emphasis on practical training alongside theoretical instruction (Alessandri et al., 2006; Icil, 2008). **Emotional appeal** reflects students' and stakeholders' sense of belonging, trust, and positive perception of the institution (Alessandri et al., 2006; Alniacik et al., 2010). **Employee competence** highlights the expertise and professionalism of academic and administrative staff, ensuring high standards (Safir & Sumer, 2006). **Social responsibility** is the commitment of an organization to contribute to societal and environmental well-being in ways that also support its own sustainability and reputation (Fombrun & Foss, 2001). Finally, **student orientation** evaluates the university's commitment to delivering value to students and fostering a supportive academic environment (Sung & Yang, 2009). University reputation is shaped by academic leadership, service quality, emotional appeal, employee competence, and student orientation, each contributing to institutional credibility and stakeholder perception. Strong academic leadership and service quality enhance a university's global standing, while emotional appeal, competent staff, and student-centered approaches foster trust, engagement, and long-term sustainability.

Conclusion

This study examines the determinants of university reputation by the following factors: employee competence, academic leadership, student orientation, social responsibility, quality of services, and emotional appeal. Each factor and its relationship with the university's reputation are explained.

Given the increasing importance of corporate reputation in higher education, universities must continuously measure and manage their reputation by aligning their strategic priorities with stakeholder expectations. Future research could expand this analysis to include cross-cultural comparisons or longitudinal studies to track reputation changes.

Analysing the Automotive Production: A Bibliometric Analysis on Lean-Green Management

Ayşe Melissa Ergün [a], Hür Bersam Sidal [a]

[a] Istanbul Technical University (ITU), The Department of Management Engineering, Master in Management Program, Turkiye
erguna17@itu.edu.tr

Keywords: Lean-Green Management, Lean, Green, Automotive, Bibliometric Analysis.

Aim

The lean management concept is a widely used and implemented production improvement solution especially in the automotive sector. Lean management, originating from the Toyota Production System, focuses on maximizing value for customers while minimizing waste through the continuous improvement of processes. These principles have historically enabled automotive companies to achieve higher efficiency levels with a reduction of costs and resource waste (Kiran, 2017). However, in recent years the need for an efficient production system became no longer sufficient for companies. The increasing importance of green production and environmental sustainability pushed companies to modify their manufacturing systems in a more environmentally conscious way (Schutzbach et al., 2022). As a result, the recent improvements in the automotive sector has surpassed the lean management directives and currently are in need of a more sustainable and green transformation. Especially after the wave started by the Paris Agreement and consequently the European Green Deal, the adoption of sustainable and environmentally conscious practices gained importance with the urgency of combating climate change and aiming to transition towards a greener and more sustainable industry. At this point a comprehensive approach like Lean-Green (LG) Management, which combines lean management and green applications, gained popularity in the sector. This approach integrates lean principles with environmental sustainability, emphasizing resource conservation, energy efficiency, and the reduction of carbon footprints (Tripathi et al., 2021). By embracing this dual strategy of Lean-Green Management, the automotive industry is not only aiming to enhance operational efficiency but also demonstrates its commitment to long-term sustainability and global ecological well-being. Overall, LG management is a subject open to improvement and further research. For this reason, this study seeks to identify the literature progress regarding LG management, by conducting bibliometric research in the automotive sector. It aims to identify the current standing of the literature and explore the future research directions for scholars.

Material and Method

The bibliometric analysis in this study has been conducted by limiting the available data by its publication year. The study is focused on publications after the year 2015 as it includes environmental sustainability, 2015 can be seen as a milestone for sustainability research with the help of the Paris Agreement (Bendig et al., 2023). Thus, it was decided that for LG management, analysing more current publications i.e. after 2015 will be more meaningful. The study is also concentrated on the automotive sector as the building blocks of lean management were set in the automotive sector. Additionally, the innovative and competitive nature of the automotive industry played a role in this selection as the sector motivates the companies to become more efficient and ecological (Kosasih et al., 2023). Using the Scopus database, the research was done within the titles, abstracts and keywords of the publications by focusing on the subject LG management and automotive with a limitation on the publication years. This database choice was done as Scopus is a reliable and up-to-date scientific database with a rigorous indexing criterion and detailed citation data availability, which are particularly important for a bibliometric analysis. The 1516 publications found through this research were then subjected to a screening process. At the end of this process 58 publications were selected to be included in this study. The selection criteria being the

availability for retrieval, the sectoral compatibility with the analysis and the content coherence. The gathered data is then uploaded to Biblioshiny software in order to create tables and illustrations from the selected publications.

Findings

This bibliometric analysis provides a comprehensive overview of the published research documents on lean and green management within the automotive sector. The analysed publications consist of 48 articles, 7 conference papers and 3 reviews with an international co-authorship of 33.66%. The findings highlight the increasing academic and industrial interest especially after 2021 in integrating lean principles with green practices to address contemporary environmental and operational challenges. The keyword analysis identified the keywords as sustainable development with 16 occurrences; manufacturing, sustainability, industrial research and lean production with 8 occurrences; supply chain management with 7 occurrences; agile manufacturing systems, manufacture, green economy, environmental management with 6 occurrences. As LG management was born by combining the more conventional approaches such as lean management with newly emerging sustainable approaches, the fact that sustainable development was highly researched is only a natural consequence. Moreover, the conducted analysis shows that researchers focus on collaborative frameworks which are combining productivity, efficiency and ecological responsibility. The bibliometric analyses also identified the core publications in the LG management field by using Bradford's law. This law is a bibliometric principle that describes the distribution of scientific literature on a specific subject. It suggests that journals can be divided into groups based on their productivity in publishing relevant articles. The core sources are the ones which publish a significantly large number of articles on the subject. The core sources defined by using Bradford's law for LG management include Sustainability (Switzerland), Production Planning and Control, Journal of Cleaner Production, Business Strategy and The Environment and IFIP Advances in Information and Communication Technology. These findings can navigate researchers towards these core sources to easily stay updated in a rapidly evolving field. Overall, the annual growth rate of the publications analysed is 32.5%. This high annual growth rate shows that in the academic community Lean-Green (LG) Management became a hot-topic in recent years.

Conclusion

The comprehensive approach of Lean-Green (LG) Management, which integrates lean management principles with green applications, has attracted attention of the automotive sector in recent years. This approach combines lean principles with environmental sustainability, prioritizing resource conservation, energy efficiency, and the reduction of carbon footprints. This study sheds a light on the progression of literature and maps the academic landscape of Lean-Green (LG) management studies by conducting a bibliometric analysis within the automotive sector. By identifying and highlighting the trends and the themes within this domain, the analysis identifies the core publications that have significantly contributed to the advancement of knowledge in LG management. In conclusion, the integration of lean management principles with environmentally sustainable practices has emerged as an important approach in the automotive industry, addressing both operational efficiency and ecological responsibility. By combining the waste reduction and productivity enhancing strategies of lean management with sustainable solutions aiming to minimise environmental impact, LG Management offers a comprehensive framework for optimizing manufacturing processes while decreasing resource consumption and pollution. This approach promotes economic performance by lowering costs and improving productivity and aligns with global sustainability goals by ensuring energy efficiency and lower carbon emissions. Despite its contributions, this research is not without its limitations. Overall, one notable limitation of this research is its reliance on a single database, which may constrain the comprehensiveness of the findings. To develop a wider understanding of the literature, future studies could integrate multiple databases other than Scopus. As Lean-Green (LG) Management can also be suitable for different sectors than the automotive industry, it is possible to include diverse disciplines and industries for future research. This broader scope would create a more integrated and impactful accumulation of knowledge in Lean-Green (LG) Management. As industries continue to face increasing environmental challenges and productivity goals, the evolution of LG Management should be ensured and researched as a framework for sustainable industrial practices.

Improvement Study In The Inner Door Production Area With Lean Production Approach

İsa Emre Gül[a], Seda Yanık [b]

[a] Istanbul Technical University, Graduate School, Industrial Engineering, Istanbul, Turkey
[b] Istanbul Technical University, Faculty of Management, Department of Industrial Engineering, Istanbul, Turkey
guli15@itu.edu.tr

Keywords: EAWS, Lean Production, MTM-UAS, Productivity.

Aim

Lean production is a philosophy of a manufacturing method that is frequently used worldwide. According to this method, any process that the customer would not be willing to pay for and that does not add value to the final product should be eliminated. Companies also adopt the lean production philosophy and use lean production methods to reduce their costs in order to maintain their commercial existence and preference. Bhuiyan and Baghel said that the aim of lean manufacturing is to produce the products with high quality in the most efficient way possible while providing less human effort, inventory, time for product development and space to respond to customer demands at a higher level (Bhuiyan & Baghel, 2005). Eliminating these wastes will contribute to the profitability of companies. In the study of Yamamoto, Mistead and Lloyd, in the philosophy of lean production, there are seven types of waste known as the seven wastes, which are transportation, waiting time, overproduction, defective production, inventory, motion, and overprocessing (Yamamoto et al., 2019).
The aim of this study is to contribute to the annual productivity target of the refrigerator factory by improving the flow in the inner door production area. The flow of this area will be examined, and processes identified as contrary to the lean manufacturing principles will be eliminated, thereby increasing the availability of employees during their cycle time and reducing the number of workers to achieve efficiency targets. With this study, in addition to improving efficiency, it is aimed to reduce the scrap rate in the production of inner doors by simplifying the flow. By reducing scrap rates, another form of waste will be eliminated.

Material and Method

The inner door material subject to the study is the plastic part, generally white in colour, located on the inner side of refrigerator doors, where the door shelves are assembled. These parts are shaped using a mold after undergoing a pre-heating process in the inner door production area. Fridge and freezer inner doors can be seen in the Figure 1.

Figure 1. Freezer and fridge inner doors.

The inner doors produced in the manufacturing area are then subjected to a process called door foaming on the assembly line. In this process, a substance called polyurethane is filled between the door sheet metal and the inner door to provide insulation for the door. To ensure that the protrusion called "nail" and "dike" on the inner door are completely filled with polyurethane and to allow the air trapped between the inner door and the door sheet to be expelled, a drilling process is applied. The drilling process can be observed in the Figure 2.

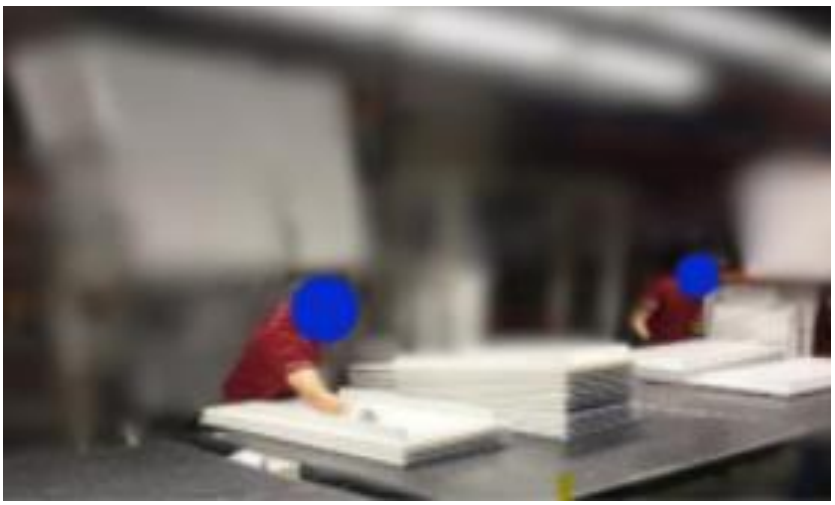

Figure 2. Drilling operation.

In order to examine the current flow in the inner door production area, two methods have been applied. First of all, a flowchart of the production area was drawn. The flowchart of the area has been prepared from the plastic roll loaded on the machine to its readiness for door foaming on the assembly line. Another flow determination method used was the Spaghetti diagram. The movements of employees in the production area were examined using a Spaghetti diagram over the layout plan. Thanks to these two diagrams, processes that could be considered waste in the inner door production area have been identified, and within the scope of the study, the improvement of these points has been planned. In the study, attention was paid to layout and operation sequences to plan for increased efficiency and reduced scrap.

A target work plan was created for the areas identified for improvement using flowcharts and spaghetti diagrams. Two methods called MTM-UAS and EAWS were used to determine the suitability of this work plan. A method time study was conducted to check whether the process times of the workers in the new work plan to be implemented are in accordance with the cycle time of the production machine. When we examined the method time techniques in the literature, it was determined that the most commonly used method in production is the MTM method. According to a study conducted by Çakmakçı and Karasu (2007), there are many MTM methods and before applying these methods, the method appropriate to the variables should be selected. MTM-UAS was selected as the MTM method suitable for the conditions specified in this article. Niu stated that almost a quarter of the workers in Europe suffer from back and muscle pains after a survey study (Niu, 2010). Thus, for the ergonomics study, methods that evaluate ergonomics in terms of posture and weights to assess the loads and risks on employees' bodies were examined. When we examined the articles in the literature, we found that industrial organizations generally use the EAWS method. According to Fischer et al. (2023), the EAWS method is a comprehensive ergonomic analysis and evaluation method used especially in the automotive industry to evaluate working postures and working conditions. Therefore, the EAWS Digital application, which employs the EAWS method, was used in this study.

Findings

As a result of this study, the number of employees in the inner door production area has been reduced with proper working conditions in terms of ergonomics. Ergonomic assessment results can be observed in Figure 3. Also, MTM-UAS studies can be observed in Table 1 for freezer operator and Table 2 for fridge operator. With the reduction in the number of employees, improvements have been achieved both in the company's employee costs and in productivity measurements. By reducing the number of workers in the area by 1 person per shift and 3 people daily, the company achieved a savings of 46,038 Euros in employee costs.

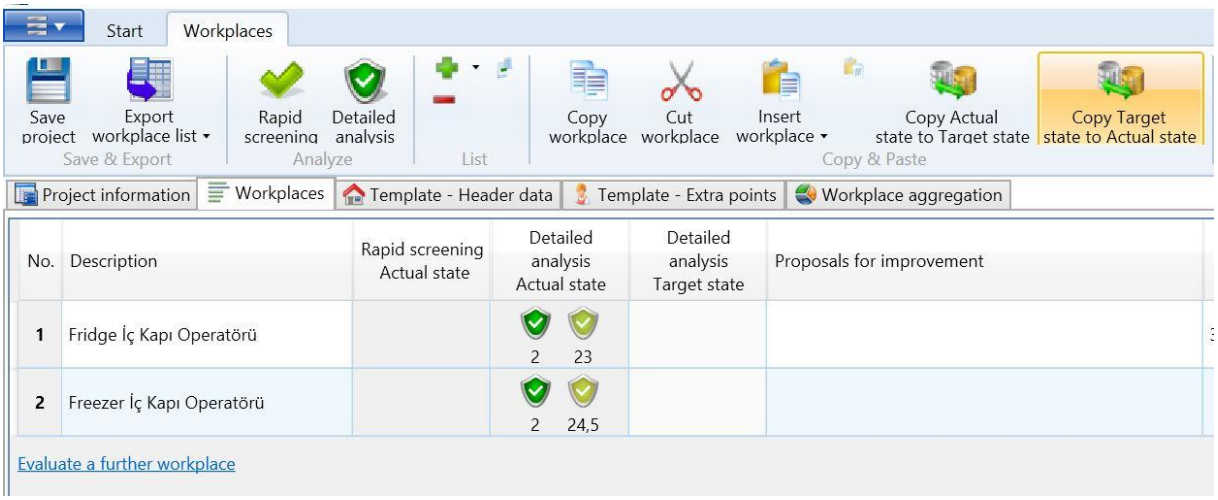

Figure 3. EAWS Results.

		ZA1	5.00	1.00
	Total Time (TMU)		546.67	
	Total Time (s)		19.68	

On the other hand, since 3 out of the 23 people working in the field were reduced, the efficiency value of the inner door production area was improved to 15% in the efficiency measurements. Similarly, since 3 out of the 1432 employees working in the factory were reduced, an overall productivity improvement of 0.21% was achieved in the factory. As a result of simplifying the flow, which can be observed in Figure 4, and early detection of errors, a decrease from 7% to 4% in scrap rates was observed in the inner door production area, and a reduction in scrap costs was experienced. When calculating scrap costs, the recyclability of the plastic was taken into account, resulting in a gain of 30,772.45 Euros.

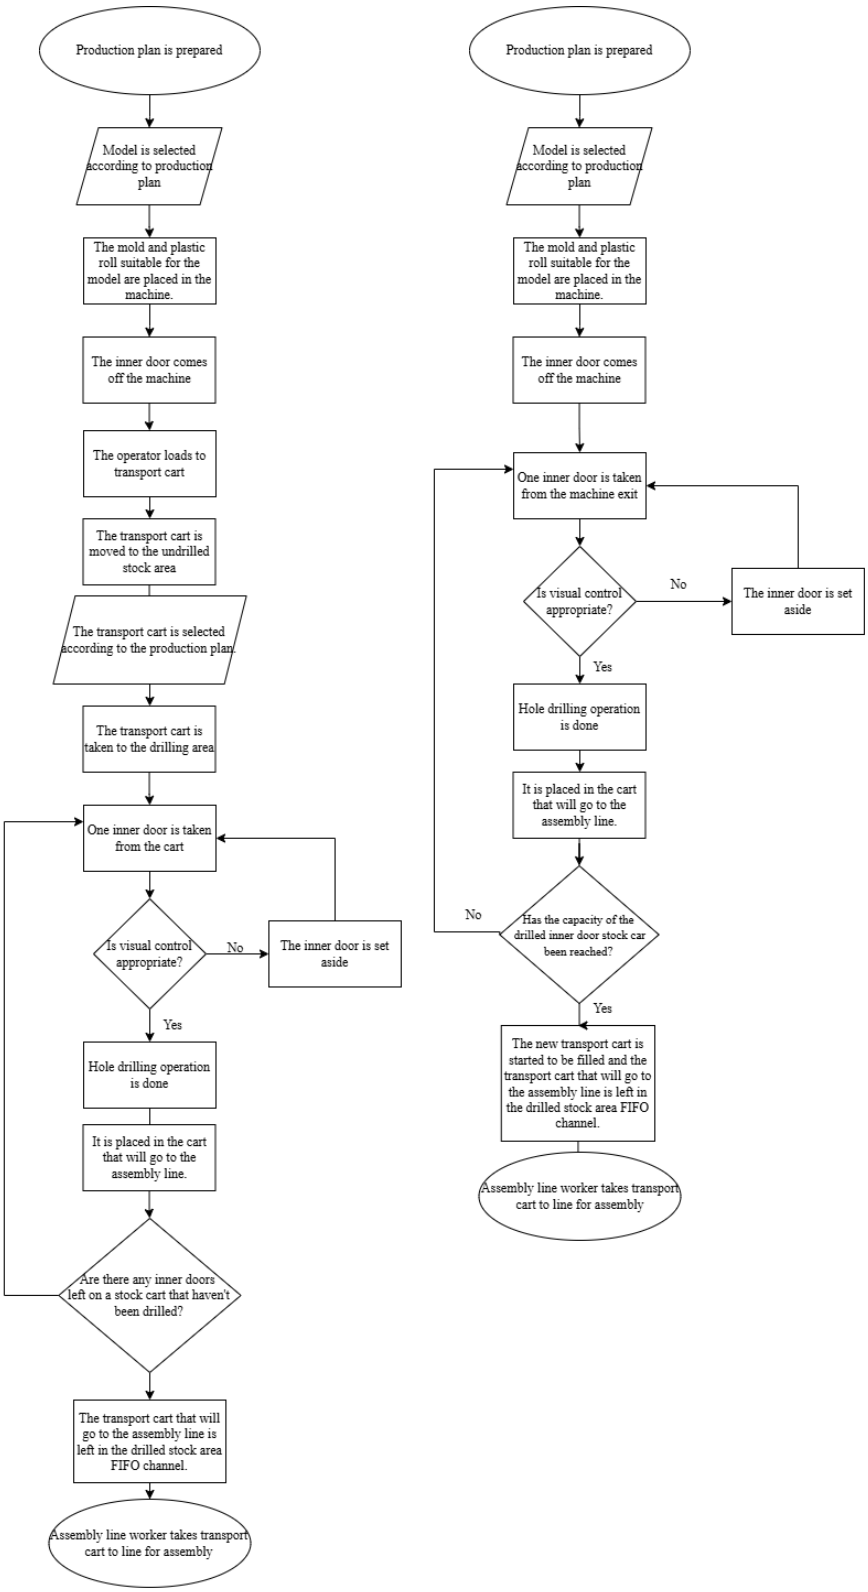

Figure 4. Flow in the production area.

Conclusion

To summarize the work done, the philosophy of lean production is an important approach for companies to increase their profits today. The adoption of this philosophy and the elimination of waste within this method are greatly aided by the use of flowcharts and spaghetti diagrams as two very useful visualization tools. The use of these tools not only allows for the easy identification of points where waste occurs but also makes the dimensions of improvements more comprehensible when compared to the diagrams and charts drawn in the new situation. Additionally, by valuing employees, it should be ensured that they can comfortably work within the cycle time through time studies, and it is necessary to eliminate the risk of future problems related to musculoskeletal health through ergonomic analysis. Eliminating these wastes can both increase workplace productivity and reduce scrap rates.

A Decision Support Model Proposal For Urban Green Space Site Selection Problem Based on Multi-Criteria Decision Making

Erdal Kondakcı[a], Gülen Çağdaş[a]

Keywords: Urban Green Spaces, Site Selection Problem, Multi-criteria Decision Making, Multi-objective Optimization.

Aim

As a result of the increasing urban population and densification around the world, the pressure on the existing urban green spaces is increasing and the service potential of green spaces is decreasing. In addition, due to the change of land use types from green space to other functions, it is seen that the quantity of green spaces decreases and remains insufficient. Attempting to provide ecosystem services with limited green infrastructure, which is threatened by density growth, has emerged as a major challenge (Haaland and Van den Bosch, 2015). Considering the ecological, climatic, social, economic and health benefits/services it provides, the loss of urban green spaces in the urban fabric is evaluated as a serious problem area. In addition to its benefits, green infrastructure is an important part of sustainable urban development due to its low cost, ease of transformation, renewal and development (Spatari et al., 2011). For this reason, many studies aiming to improve and increase urban green spaces' quality and quantity are carried out. In the urban studies literature, the determination of the most suitable places to be green spaces in the urban fabric is considered as a location allocation problem that includes many criteria and purposes. Since there are many factors affecting a suitable site selection, effective results can be obtained to support the decision-making processes by using GIS and computational methods. Even when urban green space site selection is considered as a multi-criteria decision-making (MCDM) problem including various discrete and continuous models, the methods, techniques, objectives and criteria used for planning a green system including new green spaces differ depending on the geography, context and scope.

Based on the mentioned context, the aim of the research is to address the problem of site selection for urban green spaces within the framework of a decision support model (DSM) based on multi-objective optimization (MOO). The aim of this model is to ensure that the location of new green spaces is selected in the most efficient way to increase the benefits provided by green spaces. For this purpose, the literature review on green space site selection is analyzed by PRISMA systematic analysis method and a DSM is proposed in line with the obtained site selection methods and criteria.

Material and Method

Research Design

The research is designed as three stages: 1) Problem statement and systematic literature review, 2) Determination of criteria and data collection, 3) Developing a DSM proposal (Figure 1).

Considering the aim of the research and related works, a systematic literature review methodology is adopted, which deals with the urban green space site selection problem by using computational methods. For this purpose, the main research questions are as follows: 1) What are the MCDM methods used in the site selection of urban green spaces? 2) What are the main objectives determined for the site selection of urban green spaces? 3) What criteria and constraints are used in the site selection of urban green spaces? 4) What spatial data and data models are used in the site selection of urban green spaces?

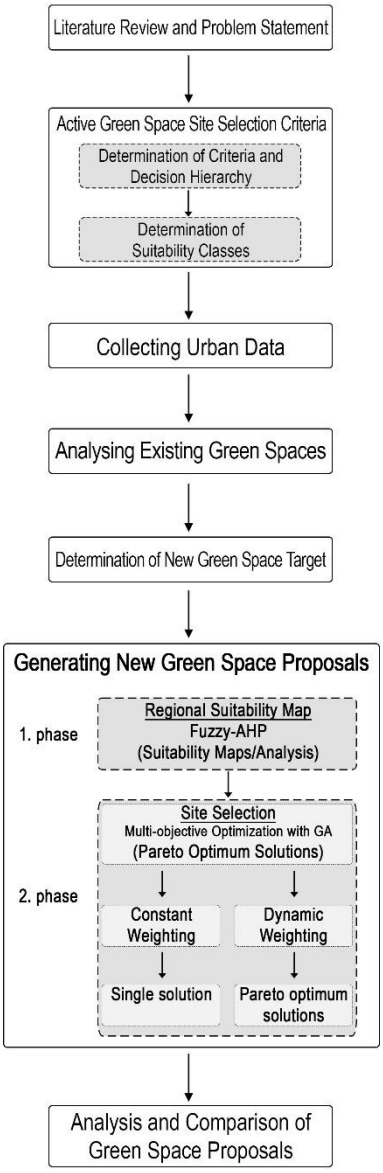

Figure 1. Research design and DSM flow chart.

Literature Review

Systematic literature review is made by following PRISMA protocol (Figure 2). Structured searches in selected major scientific databases (Scopus and Web of Science) is carried out and additional records will be added through cross-referencing and authors' knowledge on the domain. Outcomes of literature analysis are provided a methodological framework, to identify key features of urban green space site selection problem domain and to identify research gaps for guiding future research to be carried out in different geographies for developing sustainable and resilient cities.

Studies in this field are generally categorized into two groups. The first group treats green space site selection as an MCDM problem, where the most suitable zones are mapped regionally. Methods like AHP and Fuzzy-AHP, combined with GIS techniques, are typically used to generate suitability maps that highlight areas with the highest and lowest suitability values. In the second group, the site selection problem is addressed directly through MOO methods, resulting in point-by-point

selection maps. While MOO models typically aim to calculate 3-4 objectives, green space studies often involve more objectives, which can make it challenging for optimization models to produce functional and consistent results. Additionally, due to the large number of criteria in urban green space planning, not all criteria can be defined as objective functions, leading to some being excluded from the model. For example, Neema and Ohgai (2010, 2013), Neema et al. (2013), Yuan et al. (2011), and Zhang et al. (2017) defined different numbers of objectives, including factors such as population density, air quality, noise pollution, heat island effects, water quality, recreational value, and day-night temperature differences.

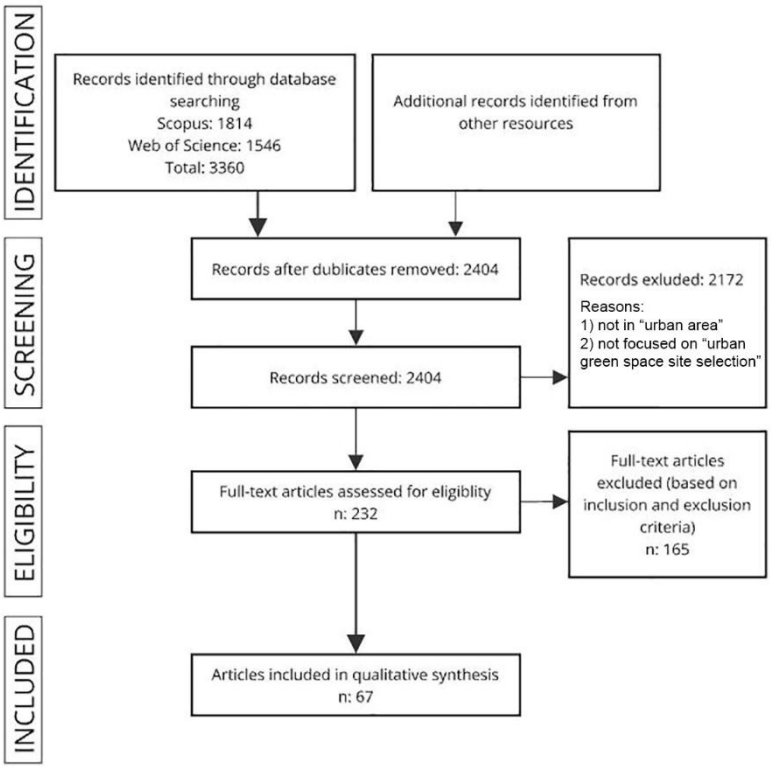

Figure 2. PRISMA protocol flow chart.

Determination of Criteria and Data Collection

The small number of objectives addressed in the multi-objective optimization approach, the exclusion of some basic criteria for green space planning, and the limited inclusion of expert knowledge make it necessary to discuss the effectiveness of the results. In particular, it is possible that a DSM that takes into account expert knowledge, global and local criteria instead of site selection models based solely on mathematical calculation may produce more effective results. For this purpose, firstly, the results obtained from the literature review are used to structure the decision hierarchy model which constitutes the basic data set of the decision support system including green space site selection criteria as two categories namely physical criteria and ecological criteria (Figure 3).

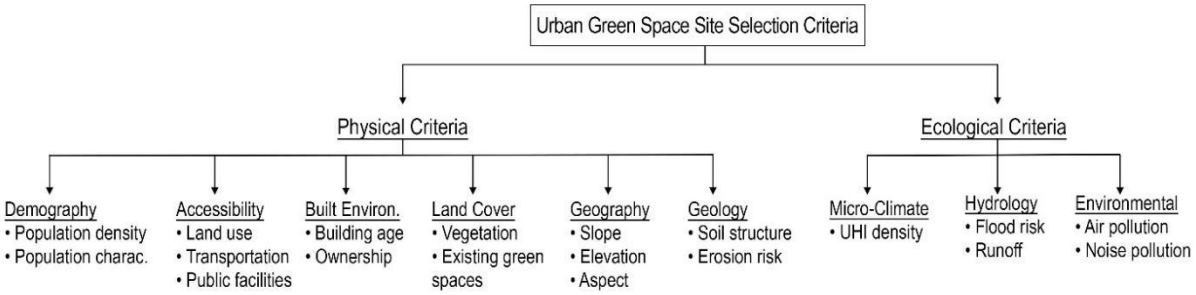

Figure 3. Decision hierarchy model.

Following procedures are adopted for the determination of the criteria and data collection to analyze existing urban green spaces:

1) Determination of the criteria to be used for site selection of active green areas: As a result of the systematic literature review, the factors to be considered in green space planning are determined. These are grouped hierarchically as main criteria and sub-criteria and a decision hierarchy model is created.
2) Determining the suitability classes of the criteria: As a result of the literature review, 5 different suitability classes (very high, high, medium, low, very low) are defined for some of the criteria, also, suitability classes based on fuzzy membership function are defined.
3) Collection and preparation of urban data to be used in the research: Open source maps (openstreetmap, Google Maps/Earth, etc.), city guide maps of municipalities, Landsat satellite images, geological maps, official sources related to the existing built environment and demographics, and maps used in related research are used for data collection. The collected data are organized and analyzed in GIS environment and processed with spatial analysis tools in different layers.
4) Analysis of existing green areas: At this stage, the existing green areas are analyzed in line with the accessibility criteria and service capacity to reveal the needs in the current situation. In order to examine the accessibility and service capacity, green areas are analyzed in the GIS environment by considering the ideal service distances related with population density.

Model Proposal

A review of the literature reveals that a holistic model of site selection, starting from the upper scale (regionally) and progressing towards exact site selection, is an innovative and unique approach to urban green space site selection. Based on this, a two-stage DSM is developed. In the first stage of the model, Fuzzy-AHP method is used to generate regional level suitability maps for site selection, and in the second stage, MOO method is used to propose exact locations for different types of green spaces (Figure 4). In this way, it is aimed to create a holistic DSM.

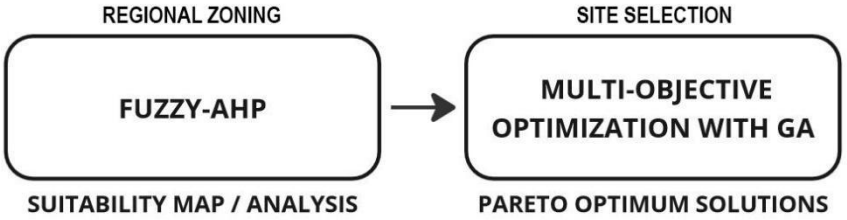

Figure 4. DSM diagram.

In order to identify the most suitable locations for active green spaces within the city, a DSM is developed that both takes into account the main factors affecting site selection and aims to increase the ecological, environmental and climatic benefits provided by green spaces while utilizing MCDM methods. A flowchart of the design of this model and the procedures

adopted to create the knowledge generation mechanism was given previously in Figure 1. Accordingly, the steps including computational methods and techniques followed to find optimum locations for new green spaces are summarized below:

1) Planning new green space target: At this stage, variables such as the number, type and total size of new active green areas are determined.
2) Generation of new green space proposals: In this stage, a two-stage DSM is used to generate green space proposals. In the first stage, Fuzzy-AHP method is used to generate suitability maps and in the second stage, multi-objective optimization method is used for exact location selection.
   2.1) Suitability map (Fuzzy-AHP): Two different suitability maps are obtained by weighting the main criteria and sub-criteria, which are divided into two groups as physical and ecological site selection criteria, with the Fuzzy-AHP method. Expert/author knowledge is used for weighting.
   2.2) Site selection optimization: In this stage, MOO is performed to pinpoint the locations of new green space proposals. Three objectives are identified: meeting physical criteria, meeting ecological criteria and increasing the average recreation value. The principle of minimizing the weighted total distance is applied. Two strategies are followed for weighting:
      a) Fixed weighting: Weighting is done for the three objectives to be optimized using expert/author knowledge. In line with the determined weights, a site selection proposal for active green areas is produced.
      b) Dynamic weighting: While a single solution is produced in fixed weighting, more than one solution is produced with different weight combinations in dynamic weighting. For this, multi-objective optimization methods based on evolutionary algorithms are used.

Conclusion

The proposed DSM systematically addresses the problem of urban green space site selection and provides analysis from the upper scale to the neighborhood scale. In this way, the ecological, environmental and climatic benefits provided by green spaces can be maximized and the results of different alternatives can be seen in advance. The model is also scalable in terms of the number of criteria and objectives. In addition, different types of green areas can be included in the model and the complex patterns they will create can be analyzed. Basically, a model that represents different layers of the city and provides decision support by analyzing the relationship between layers from a holistic perspective has been put forward. Site selection for new green spaces in densely built urban areas is challenging due to property rights. In countries like Turkey, where urban transformation against earthquakes is on the agenda, it would be beneficial to consider criteria such as ownership, building stock quality, and green space adequacy together when making new planning decisions in densely built-up areas. The multi-layered structure of the model is seen effective in developing new solutions in this context.

Computational Memorability Model Based on Object Size

Fatma Seven[a], Sema Alaçam[a]

[a] Istanbul Technical University/Graduate School, Informatics, Architectural Design Computing, Turkey
sevenf22@itu.edu.tr

Keywords: Visual Perception, Computational Model, Architectural Design, Object Size.

Aim

People make sense of and sustain their lives with the help of the information they receive from the environment. Although perception is a very complex process, it occurs in a very short period of time. Perception is the process of interpreting the stimuli coming from the external world in the mind and gaining meaning. For this reason, this process is not only shaped by the senses. Factors such as cultural background, experiences and personality characteristics of individuals shape perception (Wade & Swanston, 2013). The type of perception that people use at the highest level is visual perception. The fact that the area in the brain for visual perception is larger than the sum of the areas related to the other four senses is also related to this situation. Humans perceive their environment dominantly through vision. Visual perception has an important role in the perception of architectural design. It enables strategic design decisions in areas such as education, museums and exhibition places, and retail environment designs (Shynu & Suseelan, 2023). Therefore, understanding the relationship between spatial elements and visual perception enables the shaping of people's perceptions in spaces (Yılmaz, 2004).
In a space with many objects, even if the light from the objects hits the eye, not all of them are remembered. Remembering, being aware of the objects in the environment is related to perception. Previous studies have shown that the objects that people remember and forget the most in a scene are similar (Dubey et al., 2015). Therefore, what is the common feature that makes objects memorable or forgettable? Studies conducted to answer this question have examined many factors affecting remembering. Dubey et al. tried to find an answer to this question by examining factors such as color, visual salience, object categories (Dubey et al., 2015). Celikkale et al. (2015) examined the effect of semantic features and visual attention on memorability. Basavaraju et al. (2019) examined the memorability of objects from the perspective of location and size factors. The aim of this study is to examine the relationship between object size and memorability. In this context, a computational model that evaluates visual perception based on memorability was designed. The main difference in this study is the scoring of a video's memorability and the use of more abstract representations of objects.

Material and Method

The methodology of the study consists of four steps. In the first step, the experimental environment was created, then a computational model was developed, data was collected from participants, and finally, the collected data was evaluated. Figure 1 shows the methodology of the study. For this study, a case study was conducted with forty-three participants.

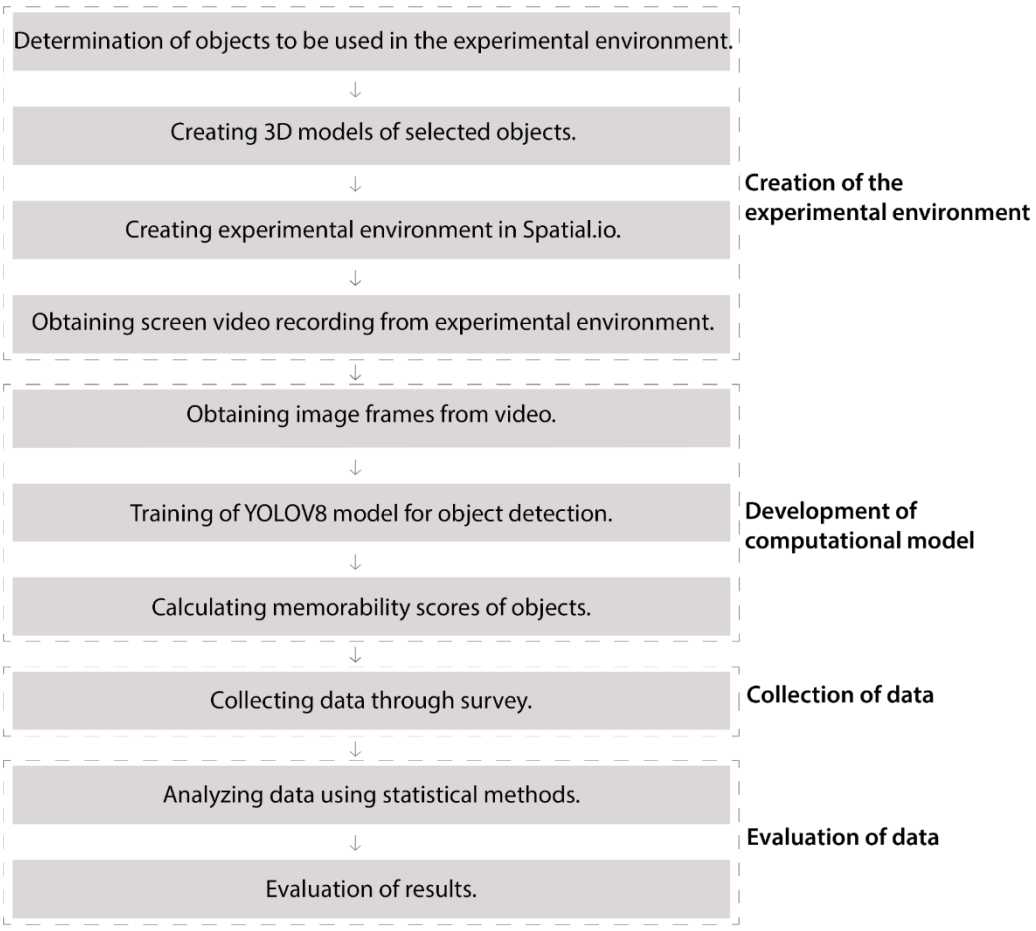

Figure 1. Methodology Diagram.

An experimental environment was prepared through the Spatial.io platform for the first part of the study. This experimental environment contains 9 selected objects of different sizes. These objects are the wardrobe, radio, oven, stool, drawer, suitcase, vending machine, briefcase and monitor that people see in daily life. Color, texture and material factors that could affect visual perception were kept same for all objects.

A virtual tour was conducted in the designed experimental environment. This tour lasted 20.5 seconds. During the tour, the screen was recorded to obtain a video that would later be shown to participants and used to compute the memorability score. Then, frames were extracted from this video. Two frames for each second were obtained through the VLC Media Player program. For the 20.5 second tour, 41 image frames of 1920x880 pixels were saved. Figure 2 shows a sample frame saved. Some of these frames were used to train the YOLOv8 model.

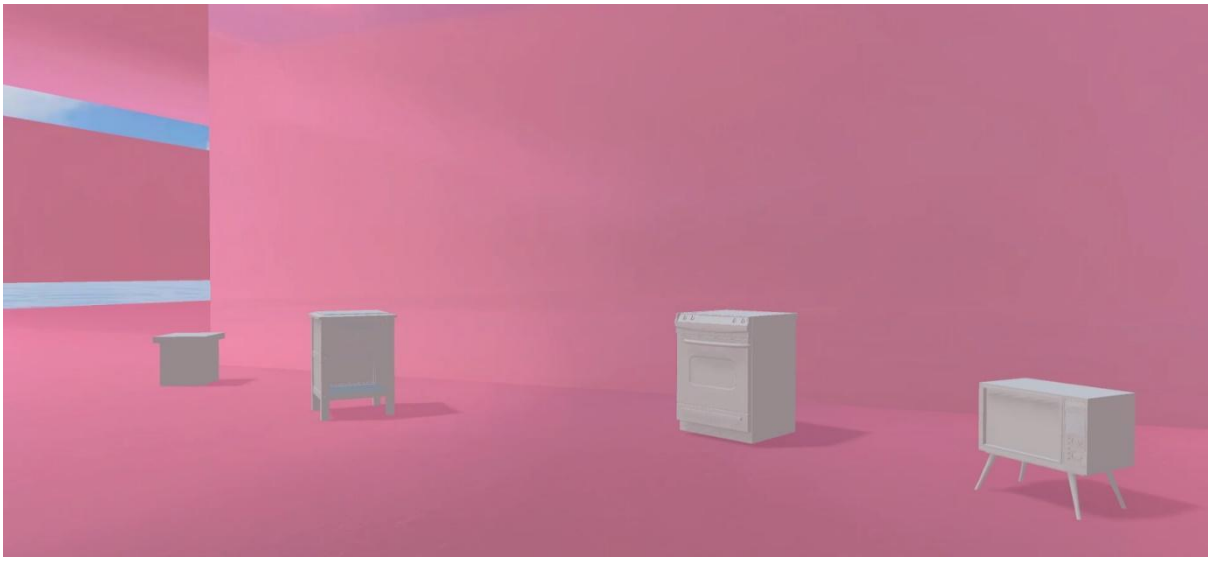

Figure 2. Sample frame from video of the experimental environment.

In the next step, object detection was performed on the image frames. The object detection model YOLOv8 was used for this process. A dataset was created for training via Roboflow using video frames. For the 21 selected frames, 9 classes were identified and object labeling was performed. At the end of the labeling process, the number of images in the dataset was increased to 51 by rotation. The dataset was divided into three parts: training, validation and testing. The dataset prepared in Roboflow was transferred to the Google Colab environment. After this step, the training process started. For the YOLOv8 model, the task was set to detect, mode to train and the number of epochs was set to 25. In this way, all objects in each frame were identified and their bounding box data was obtained.

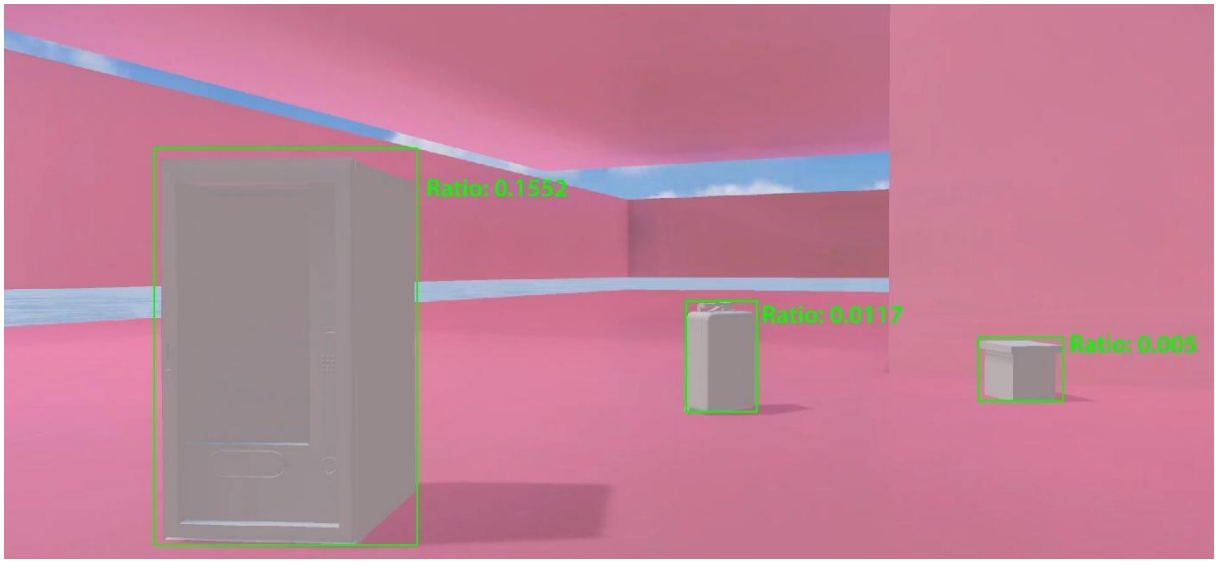

Figure 3. Example of a frame with calculated ratio values.

After this stage, the aim was to determine the area covered by each object in the image for each frame. For this purpose, the bounding box area of the relevant object was divided by the area of the entire image. Figure 3 shows a sample frame for which the ratios were calculated. This process was performed for every object in the image frame. In some images, the model used was incomplete or inaccurate in object detection. In these cases, the ratios of the objects were calculated

manually. The size ratio information for the objects was calculated for the 41 image frames. The calculated values were recorded in an Excel table. Table 1 shows the size ratio of each object for the first 5 image frames. The size ratios obtained for each object were summed up, taking all frames into account. The sum of the values was called the memorability score. Table 2 shows the memorability score calculated for each object.

Table 1. Size ratios for the first 5 frames.

FRAMES	Briefcase	Monitor	Vending	Suitcase	Stool	Drawer	Oven	Radio	Wardrobe
F1	0,0238	0	0,0122	0,0023	0,0014	0,0038	0,0043	0	0
F2	0,0239	0	0,0121	0,0024	0,0014	0,0038	0,0044	0	0
F3	0,029	0,0079	0,0125	0,0024	0,0015	0,0043	0,0042	0	0
F4	0,0384	0,0103	0,0142	0,0028	0,0016	0,0048	0,0013	0	0
F5	0,025	0,0129	0,0159	0,0031	0,0018	0,0054	0	0	0

Table 2. Memorability scores.

	Briefcase	Monitor	Vending	Suitcase	Stool	Drawer	Oven	Radio	Wardrobe
Memorability Scores	0,144	0,1197	0,9044	0,2841	0,1726	0,4531	0,6299	0,3401	0,9552

Participants were asked to watch the screen recording video and answer a survey twenty minutes later. In the survey, each object was shown, and participants were asked to rate how well they remembered them on a scale of 1 to 7. From the survey results, average memorability scores were obtained for each object based on participant data.

Findings

The participants' data and the data obtained from the developed model were compared. According to our model, the wardrobe and vending machine got the highest memorability scores, while the monitor and briefcase got the lowest scores. Figure 4 shows the memorability scores obtained from the model in graph format. According to the participants, the most memorable object was the wardrobe, while the least memorable object was the monitor. Figure 5 shows the average memorability scores obtained from participants. Furthermore, a correlation analysis was performed between the average scores obtained from the survey and the scores obtained from the model. The Pearson correlation coefficient was 0.69. This indicates that our model has a strong positive relationship with the data obtained from the participants.

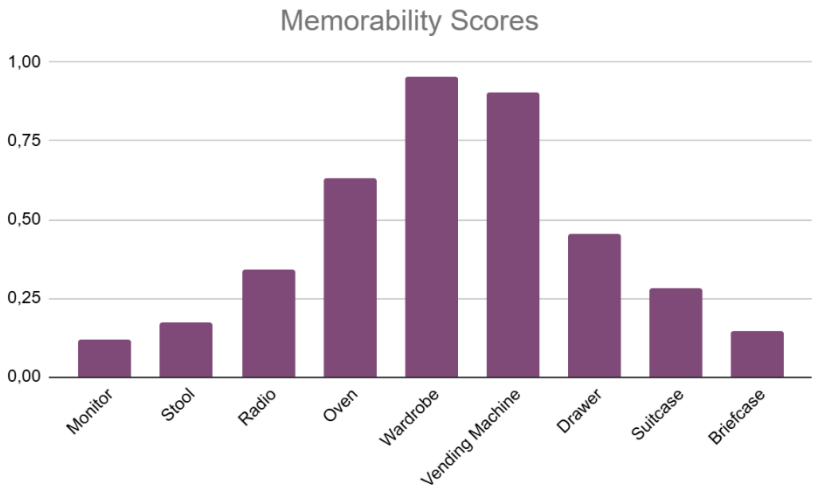

Figure 4. Memorability graph from model's data.

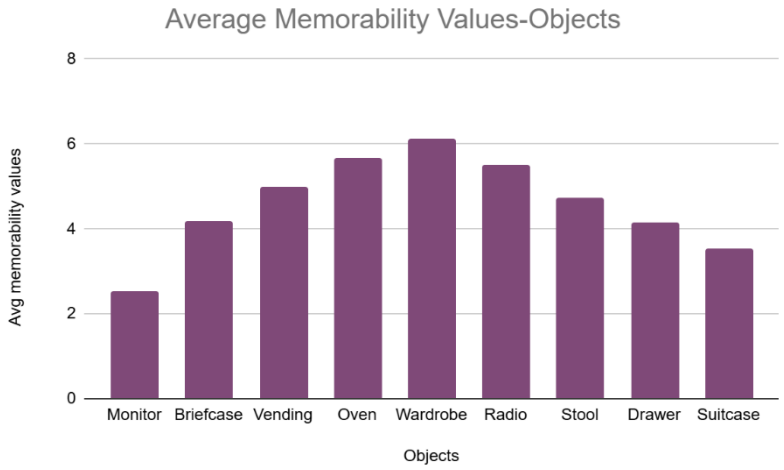

Figure 4. Memorability graph from participants' data.

Conclusion

This research contributes to the study of visual perception through a computational model and offers practical insights in areas such as architectural design, education and advertising. The study analyzes the effects of object size on visual perception and memorability and predicts the degree of memorability of objects of different sizes.

As a result of the surveys, it was determined that the size factor has a strong positive relationship with memorability. The number and variety of participants in the case study is one of the limitations of the study. In addition, due to the abstract representation of objects, object detection has not worked correctly and completely for every image frame. As a result of this abstraction, many factors affecting visual perception have not been included in the model. The study was conducted by analyzing video recordings rather than in real time. Future studies can be conducted with a higher number of participants from similar professions to reduce individual differences. Furthermore, real-time perception measurement can be performed. Future studies can offer new perspectives for further development of the model by examining the impact of factors such as location and semantic features.

Acknowledgement

This case study was conducted with the approval of the ITU Social and Human Sciences Scientific Research and Publication Ethics Committee. In the early stages of this study, the project titled "Modelling Visual Perception of Timevarying Scenes Using Likelihood" at Istanbul Technical University Scientific Research Projects Department made a significant contribution. We would also like to thank the participants.

ozkanm22@itu.edu.tr, guzelci@itu.edu.tr

Keywords: Biodegradable Materials, Digital Fabrication, Interior Design, Mycelium-Based Materials, Sustainable Design.

This study explores the integration of digital fabrication technologies into the design and production of mycelium-based components. Initially, it introduces mycelium through a literature review, outlining its properties and how it is adopted in design-related disciplines. Subsequently, modular and customized suspended ceiling components are designed for a given space using a parametric design approach. Molds are produced via 3D printing to shape mycelium-based components, and the molding process is sequentially applied to plaster, silicone, and mycelium materials. This process is repeated at three different scales, ranging from smaller to larger. The material's overall form, level of detail, texture, and growth process are examined based on experimental results. This approach contributes to the integration of sustainable design, biomaterials, and innovative production techniques.

Introduction and Research Aim

In recent years, the construction industry has significantly impacted the ecosystem while remaining essential to modern society. With rapid production advancements, it has become a major consumer of natural resources (Balaras et al., 2005). Although sustainable materials are increasingly used, their long-term effects remain uncertain (Du Plessis, 2007). Achieving sustainability requires not only renewable materials but also environmentally compatible design approaches that enhance the quality of life. Designers, inspired by nature, integrate natural processes into digital design methods and explore new materials, including microorganisms (Elbasdi and Alaçam, 2016).
The primary goal of this study is to find an answer to the following question:

- How mycelium-based biomaterials, which aim to provide a solution to environmental problems, can be more effectively used within the discipline of interior design?

In the field of interior design, a suspended ceiling has been chosen as an interior design element where the potential of mycelium can be utilized. In this context, a suspended ceiling design has been developed that does not limit the nature and structural properties of the material. The molds required for the implementation of the design and the improvement of mycelium have been produced using 3D printing. This study focuses on optimizing the overall form of mycelium using molds produced at different scales and to evaluate the effects of substrate variables on the final product by observing them and comparing the findings with previous research results.

Materials and Methods

Mycelium is the vegetative, or root structure, of fungi and consists of hyphae, which are long, branching filamentous structures. It forms a dense network capable of connecting various substrates, creating strong and lightweight composites (Goidea et al., 2020). These mycelium-based materials can be cultivated using agricultural waste, making them a sustainable alternative to traditional construction materials. Due to their high potential, they have been the subject of various applications and academic research over the last two decades (Madusanka et al., 2024). However, despite the novelty of the material, a gap still exists between its use in architectural applications and large-scale commercial production. Most existing research and projects remain at the proof-of-concept stage, but their common goal is to raise societal awareness for the

transition to bio-based products (Ross et al., 2016). Therefore, developing designs and prototypes using mycelium is a valuable step toward achieving innovative solutions for a bio-based future.

The small size and volume limitations of current mycelium-based products pose challenges for the construction industry. Producing large, solid mycelium blocks is nearly impossible at this stage due to the organism's need for oxygen for optimal growth. Therefore, new production methods should be developed, taking into account the microorganism's natural aerobic characteristics and durability (Elsacker et al., 2021). Molding and 3D printing are commonly used to shape mycelium composites; however, traditional molding methods limit the organism's viability and restrict design capacity. As a result, digital fabrication techniques should be incorporated into the process (Mohseni, 2023). These methods not only overcome structural design limitations but also enable the creation of complex forms that are difficult to achieve with traditional techniques (Elsacker et al., 2021).

Experiments

Within the scope of this research, an experimental study was conducted that included the parametric design and material-based fabrication phases. The design was developed to align with the natural properties of mycelium, maximizing its potential. Several key criteria were considered: (i) creating a design that respects the unique characteristics of mycelium rather than forcing it into molds designed for traditional materials, and (ii) ensuring a modular structure that facilitates both production and implementation. To carry out the application experiment, the designed suspended ceiling molds were 3D printed in three different scales. Each mold was tested sequentially with plaster, silicone, and finally mycelium to explore how different production processes influence material properties. Plaster and silicone experiments were conducted to assess mold functionality, while mycelium experiments used wood chips and paper pulp as substrate components, providing essential nutrients for fungal growth. After each experiment, the molds were refined and re-produced to enhance material and design compatibility. The research was conducted in four stages, each involving systematic experimentation to refine the mold and optimize product development:

(i) Design Process: The previous efforts at producing mycelium-based suspended ceilings and treating mycelium as a direct substitute for traditional materials have been seen as a limitation to fully utilizing its potential. To address this problem, a custom-designed suspended ceiling form was developed using Rhinoceros 3D, ensuring alignment with the material's natural texture and properties. As shown in Figure 1 on the left, a three-layer mold was designed. Since the system follows a modular approach, a divider mold was used at the bottom. This divider ensures that each of the 42 individual modules can grow independently. The middle layer is the formwork component that shapes the mycelium, while the top layer serves as the mold's cover. This cover compresses the material to help it retain the intended form and creates a dark environment conducive to optimal mycelium growth. The image on the right presents the design's interior view.

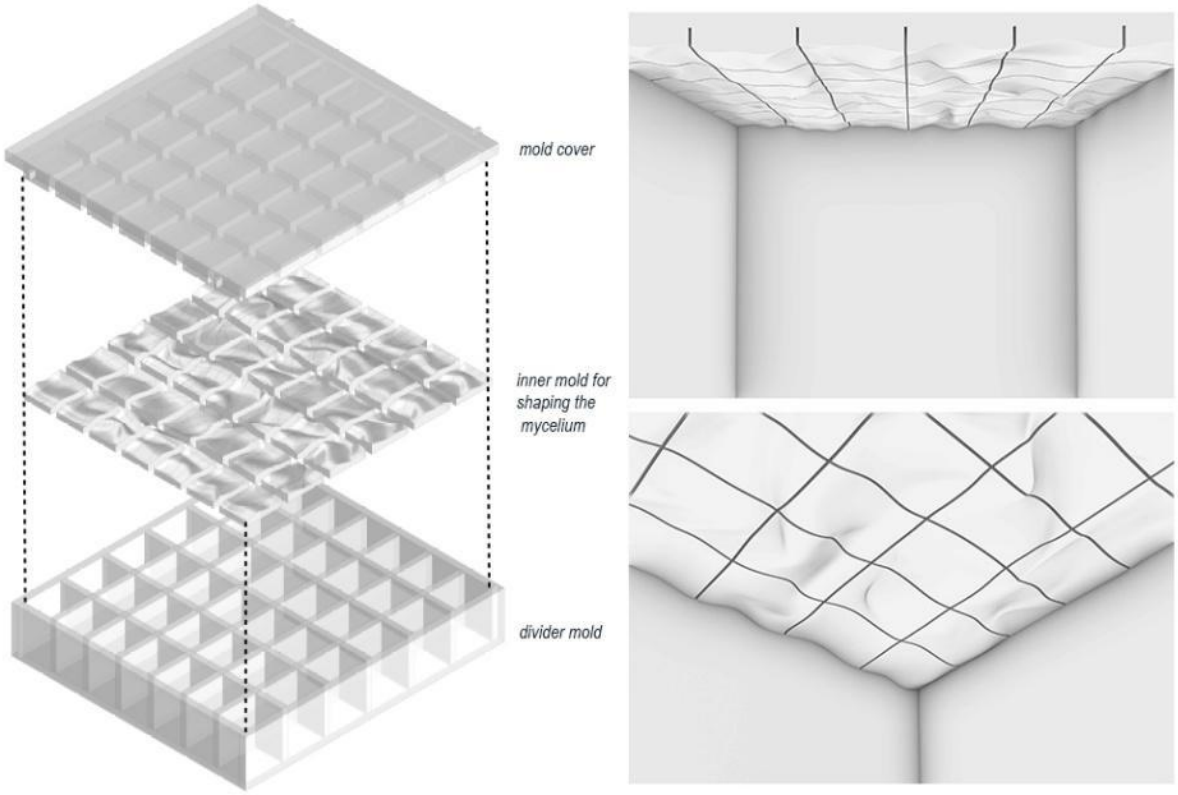

Figure 1. The design is modeled in Rhinoceros 3D. Left: Layers of the final mold; Right: Appearance of the ceiling from the interior space.

(ii) Mold Material: The designed suspended ceiling was divided into equal parts (curved surfaces) to facilitate integration into the space. The final design consists of 42 unique pieces, each with distinct forms. The mold was modeled and 3D-printed using to incorporate mycelium into the design effectively. To evaluate the final product, the molds were printed at three different scales (Figure 2). After each iteration, tests were conducted, and the mold design was optimized accordingly. The Figure 2 (right) shows a close-up view of the intermediate part of the final version of the mold. This component represents the middle layer of the three-part mold system and is the section responsible for shaping the mycelium.

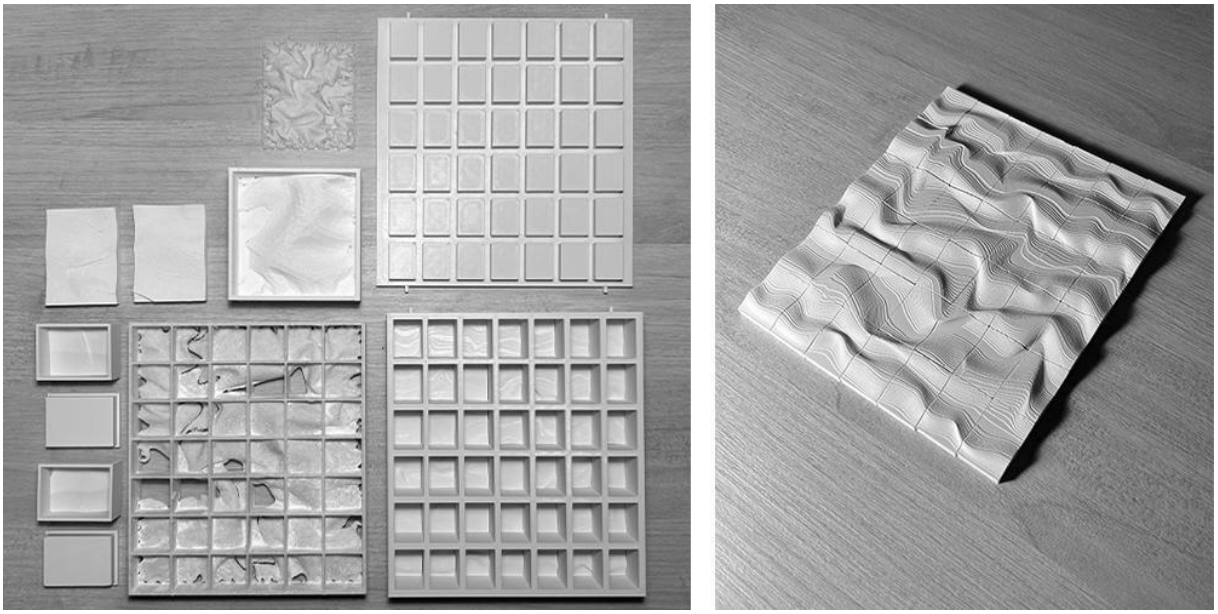

Figure 2. Left: 3D-printed molds visuals in various scales; Right: Final form that will shape the mycelium.

(iii) Material Application: Three different materials—plaster, silicone, and mycelium—were selected for the experiment. Plaster and silicone were either poured or placed into molds, while mycelium was placed and left to grow (Figure 3). The materials were tested at three different scales and left to either dry or grow, depending on their properties.

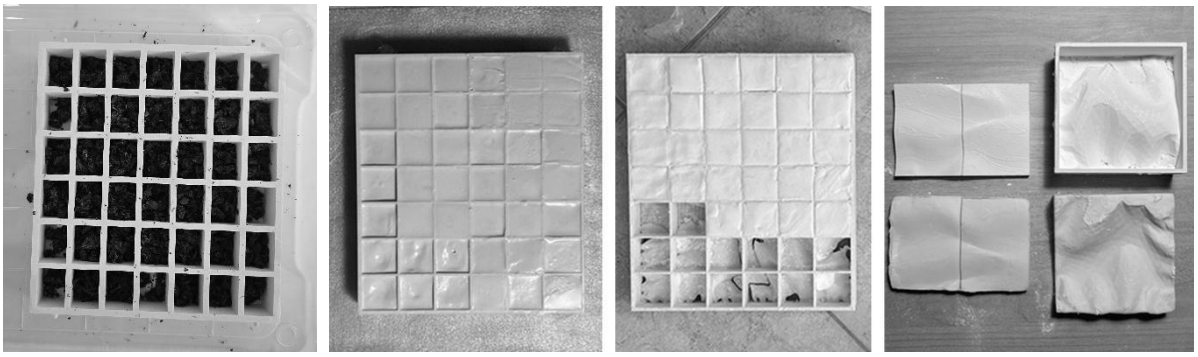

Figure 3. Molds are filled with various materials. From left to right: Mycelium, plaster, silicone, and silicone removed from the mold.

(iv) Evaluation of Results: The mycelium placed in the molds was observed for a growth period of 15 days (Figure 4). This phase of the study is ongoing; upon completion of the growth process, drying procedures will be conducted to obtain the final product. The resulting modules will be 3D scanned using Polycam, and their form accuracy and formation behavior will be assessed through physical comparisons in CloudCompare, thereby concluding the fourth phase.

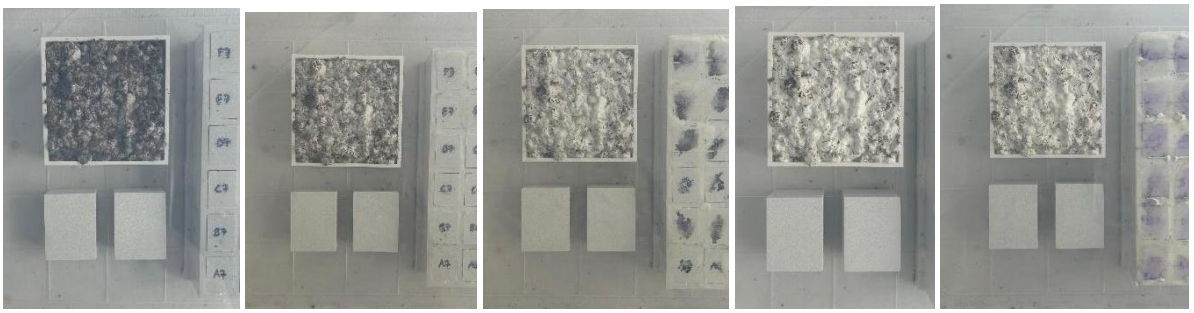

Figure 4. Progression of mycelium growth in the mold. From left to right: Days 4, 6, 7, 9, and 15.

Finding and Conclusion

Despite its promising potential, scaling up mycelium-based production presents challenges such as ensuring repeatability, optimizing growth conditions, managing the complexity of the sterilization process, and integrating these materials into existing construction applications. Ongoing research seeks to address these issues by exploring new fungal species and refining production processes. However, due to the interactive nature of microorganisms and their highly sensitive material properties, significant constraints may arise in the design process. Rather than perceiving these constraints as limitations, they can be seen as opportunities for developing functional architectural solutions.

The literature review revealed that mycelium-based suspended ceiling designs have often followed the same design and molding techniques used for traditional materials, treating them as direct substitutes. This approach is believed to hinder the material's full potential. To overcome this limitation, a material-specific design was developed that allows mycelium to retain its natural texture and growth pattern. As part of this study, molds were initially tested using plaster, followed by silicone. In the first mold, the plaster could not be removed, necessitating the use of silicone. While the silicone was successfully removed, it damaged the material. The same tests were repeated for the other two mold scales. Throughout these experiments, the molds were refined and optimized to enable the safe removal of mycelium without damage. To ensure a dark environment for mycelium to grow, a cover was designed to compress the material inside the mold, allowing it to take full shape. Since mycelium is a material that must be used within a short timeframe, preliminary preparations were made to minimize errors.

This study is derived from an ongoing master's thesis. At its current stage, the optimized forms of suspended ceiling components and their corresponding molds are being tested with mycelium material. In the future study, the acoustic performance of the designed and manufactured suspended ceiling components can be examined. The findings and outcomes of this study are expected to offer a new perspective for future research with mycelium-based materials.

A Strategy for Dataset Preparation in AI Model Training: The Case of Hotel Room Interiors

Yaren Cengiz [a], Orkan Zeynel Güzelci[b], Derya Güleç Özer[c], Koray Kıdış[d]

[a]Istanbul Technical University, Graduate School, International Master of Interior Architectural Design Program, Türkiye
[b]Istanbul Technical University, Department of Interior Architecture, Türkiye
[c] Istanbul Technical University, Department of Architecture, Türkiye
[d] Yeşim Kozanlı Architecture (YKA), Türkiye
cengizy23@itu.edu.tr

Keywords: Artificial Intelligence, Interior Design, Training, Text to Image, Dataset Preparation.

In recent years, the use of artificial intelligence in architecture and interior design has increased. Specifically, text-to-image models generate consistent results when trained with customized datasets. This study examines strategies for training an AI model and preparing a dataset to generate images reflecting the style of a design studio. Descriptive texts accompanying the images (renders) were prepared, and the model was trained and tested. Initial findings indicate that automated labeling methods are insufficient compared to expert annotations, spelling errors in English negatively affect the results, non-3D graphic-like elements hinder model training, and data diversity is crucial for both effective model training and outcomes.

Introduction and Research Aim

In recent years, the use of artificial intelligence in design disciplines such as architecture and interior design has been increasing. Current, studies emphasize that AI models generate more successful results when trained with customized datasets (Gan et al., 2023; Lee et al., 2024). However, the training process of AI models functions as a 'black box,' preventing direct user intervention and observation. This highlights the need for a comprehensive investigation into how this process works and to what extent different parameters influence model training.
In this context, the primary aim of this research is to train a text-to-image AI model that can generate hotel room interior images matched with the style of a design studio practicing in the field of interior design Yeşim Kozanlı Architecture (YKA) and to develop a strategy for generating descriptive captions for the images required for this training.

Material and Method

Text-to-image diffusion models utilize artificial intelligence techniques to take a text input and generate corresponding images based on that text. In this context, MidJourney, DALL-E, and Stable Diffusion are examples of widely used generative AI tools for text-to-image creation. Among these tools, Stable Diffusion 1.5 is open-source and provides free usage. Additionally, Stable Diffusion 1.5 allows the use of customized datasets as input folder. Users can generate images with Stable Diffusion 1.5 by running it locally on Windows-based computers through the Terminal window using various interfaces. In this study, the subscription-based version of eden.art, a cloud-based platform for model training and image generation, was used. In this context, renderings of a design studio Yeşim Kozanlı Architecture (YKA) constituted the study's material.

Experiments

In the scope of this study, the development and test of the AI model was carried out including: data collection, dataset preparation, model training, image generation with trained model, and observation of the outputs (Figure 1).

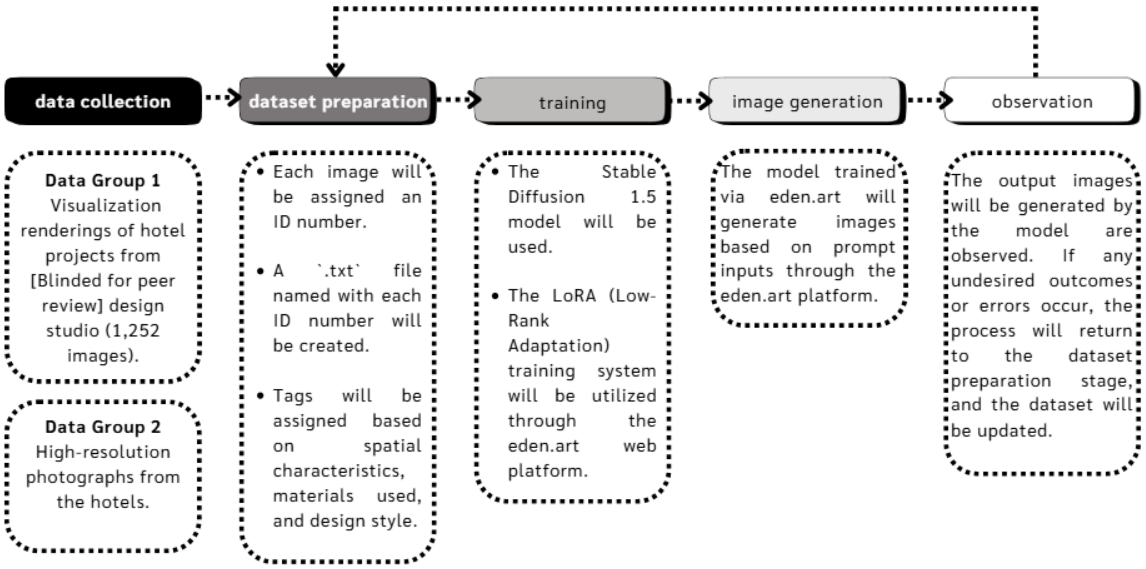

Figure 1. Training and testing phases of the AI model.

Data Collection: Accessing high-quality datasets from the web in fields such as interior design is a challenge. In this case, data can be obtained through collaboration with interior design offices. The collected data must be sufficient in quantity for effective model training (Gan et al., 2023) and should have diversity (Lee et al., 2024). In this context, to train AI in line with a specific style and enable it to generate images accordingly, 1252 renderings from nine hotel projects of a design studio Yeşim Kozanlı Architecture (YKA) were obtained.

Dataset Preparation: For training the AI model, the processes of data classification and generating descriptive text for the images were applied. In the data classification process, the collected data was divided into subsets to evaluate the model's performance. In this study, the renderings created for nine hotel projects by Yeşim Kozanlı Architecture (YKA) were first categorized by space types and then by perspectives/viewpoints.

In the captioning phase, the images used for training and their corresponding descriptive texts were named sequentially with the same filenames, such as 1.png and 1.txt, and collected in an input folder. While writing captions for interior renders, details of furniture, colors, materials, textures, lighting, composition, and other design elements were specified. In addition to architectural knowledge, captions were written in English with grammatically structured sentences, as noted by Lee et al. (2024), to ensure the AI model could effectively interpret them.

Model Training and Image Generation: Using the prepared dataset, seven different models were trained through eden.art platform. Among these models, five were trained exclusively with renderings taken from specific angles, one was trained with mixed images from different angles, and another was trained using captions generated by the wd-v1-4-vit-tagger-v2 auto-tagging tool.

Subsequently, each model was tested by running it with given prompts, and the outputs were observed by the authors (Figures 2 and 3). For example, when the results were found unsatisfactory due to discrepancies such as differences in requested viewpoints, incorrect placement and forms of interior elements, or material inconsistencies, or if evident errors were detected, the dataset preparation, training, and generation phases were repeated.

Caption: front view of mediterranean designed hotel room, double sized bed on the pine wood platform, rattan oval bedhead, three blue and sea themed drawings on the wall above bedhead, light greige fabric wallcovering on the half of the wall that behind the bedhead, two wood frame on the wall, light grey fabric sofa on the pine wood platform, blue and grey patterned pillows on the sofa and bed, foldable oval wood coffee table in front of the sofa, light brown wallpaper on the wall, black side door on the right, pendant rattan ventilator lamp above the sofa

Figure 2. Dataset creation example (the image belongs to the design studio).

Prompt: *right-perspective view of mediterranean hotel room, double sized bed, rattan oval bedhead, white sheets and pillows, natural elements, wardrobe with rattan doors, grey sofa, sunlight coming from the outside.*

Figure 3. Image Generation Example (Image generated by the trained AI model.)

Findings and Conclusion

The findings obtained from the experienced process and outputs are as follows:

- The automatic labeling method was found to be less successful compared to descriptive texts prepared by the experts.
- English expression errors led to incorrect image generations.
- When the number of interior design elements was not explicitly specified in the prompt, there was a risk of uncontrolled element additions.
- The required number of interior images and descriptive texts was determined to prevent overfitting during AI model training and testing.
- Non-architectural 2D graphical elements (text, poster, logo, etc.) in the training dataset were not effectively learned by the model.
- Interior design elements that were not fully visible in the training dataset were also generated incompletely during the testing phase.

The findings listed above regarding image selection and descriptive text writing for model training will be expanded with tests presented in the next step of the research. Additionally, these findings will be systematically detailed to develop a strategy for future model training.

Introduction

Since ancient times, the relationship between landscapes and cities has evolved through a continuous dialogue in both the East and the West. The urban and landscape development of Seoul, however, has been shaped within the framework of the traditional Korean landscape philosophy, which emphasizes harmony with nature, particularly during the Joseon Dynasty (1392–1910). The selection of Seoul as the capital was guided by the principles of Pungsu-jiri (the Korean adaptation of Feng Shui), which dictated that the city be surrounded by four sacred mountains—Bukaksan, Naksan, Namsan, and Inwangsan. This positioning both provided geographical protection and ensured a spiritually and energetically balanced environment. Within this understanding, the free and harmonious flow of Qi was prioritized, and the balance of Yin and Yang was maintained, making Seoul not just an administrative center but also a city designed to embody ecological and cosmological harmony (Lee, 2008, pp. 389-390; Kim, 2003, p. 3).

However, throughout the 20th century, Seoul underwent radical transformations within the context of globalization. The destructive effects of Japanese colonial rule (1910–1945), the upheavals of World War II, and the deep trauma caused by the Korean War (1950–1953) not only reshaped the physical structure of the city but also profoundly altered its memory, the representation of its landscapes in the urban context, and its collective identity. These historical breaking points played a decisive role in shaping Seoul's future development policies, intensifying the tension between tradition and modernization (Kim, 2003; Hwang, 2003).

Seoul stands as a rare example among global cities. In the early 1950s, it was a war-ravaged, non-capitalist city. Yet, within just 35 years, it experienced rapid economic growth and successfully introduced itself as a dynamic metropolis on the world stage through the 1988 Summer Olympics. This extraordinarily swift transformation—and its ongoing evolution—offers critical insight into how landscapes, once infused with deep cultural and historical meaning, have been redefined as instruments of global marketing. It highlights how urban identity has been strategically commodified and turned into a consumable object within the capitalist dynamics of the global arena.

Aim

This study aims to examine how the conceptual framework of traditional Korean landscapes has evolved over time. Focusing on landscape transformation through the lens of commodification, it explores how traditional Korean landscapes have been reshaped by modernization, how urban identity has been marketed on a global scale, and how landscapes have been positioned within the discourse of the global city. Based on the findings of the extensive literature review, critical

breaking points that shape Seoul's landscape transformation from the Joseon Dynasty to the present have been identified, followed by an analysis of archival materials, such as historical photographs from the colonial period, alongside photographs taken on-site in Seoul. The interplay between traditional Korean landscapes and modern/global landscapes, along with representational strategies and identity transformation, is examined within an analytical framework.

Material and Method

Based on the findings of the extensive literature review, critical breaking points that shape Seoul's landscape transformation from the Joseon Dynasty to the present have been identified, followed by an analysis of archival materials, such as historical photographs from the colonial period, alongside photographs taken on-site in Seoul. The interplay between traditional Korean landscapes and modern/global landscapes, along with representational strategies and identity transformation, is examined within an analytical framework.

Findings

Based on the findings, the relationship between traditional Korean landscapes and globalization can be traced back to Seoul's initial encounters with Western urban planning practices. The Treaty of Ganghwa, signed with Japan in 1876, marked a significant turning point in Korea's opening to the outside world (Hwang, 2003, p. 370). However, early modernization efforts were interrupted by the Japanese occupation in 1910, during which urban space became a tool for colonial representation. Under Japanese rule, Seoul's spatial structure and landscapes were transformed to reflect imperial power (Kim, 2003; Hwang, 2003) and historically significant sites—such as palace gardens, which had been central to the traditional landscape—were repurposed into amusement parks and zoos (Kim, 2017) by stripping them of their original cultural significance. Likewise, natural landscape elements such as sacred mountains were adapted to fit the concept of "public parks," not as spaces for public use but as symbols of colonial hegemony (Hwang, 2003, p. 382).

In the post-World War II era, capitalist countries implemented various reforms to recover quickly and rebuild by aiming to prevent a return to the turbulent pre-war conditions (Harvey, 2003). However, Seoul's case diverges from this pattern. Although Korea gained independence from Japan in 1945, this independence did not immediately lead to stability and peace. The division of Korea into North and South—under Soviet and American influence, respectively—intensified regional tensions. In 1950, the outbreak of the Korean War devastated the nation, both politically and economically. Following the Korean War, the country's reconstruction was heavily supported by Western economic and political aid (Hüseyinoğlu, 2007, p. 141) Modernization efforts gained momentum in the 1960s, and by the 1970s, development of urban housing and infrastructure was seen as a solution to improving quality of life. By the 1980s, radical steps were taken to position Seoul as a global city. In preparation for the Olympics, the south side of the Han River was designated as the city's new business center, while reimagining the river and its surroundings as the city's key representative space (SMG, 2015, p. 10, 15; Hwang, 2003). Thus, the 1988 Olympics played a pivotal role in reinforcing Seoul's global image while marking a significant milestone in its transformation into one of the key showcase sites of global capitalism (Joo et. al, 2017).

The 1997 Asian financial crisis (IMF crisis) brought fundamental changes to Seoul's urban development strategies. In an effort to mitigate the economic downturn, a series of reforms were implemented by embracing neoliberal urban dynamics and introducing the strategic use of urban identity as a branding tool. From this critical turning point onward, urban transformation was both about physical restructuring and about aesthetic and managerial strategies (Joo, 2018). Mega projects, initiatives such as the "Design Seoul" campaign, and other city branding efforts were shaped by a growing emphasis on attracting global capital. Public space redevelopment, often justified through discourses on environmental sustainability and cultural heritage preservation, became an integral part of the city's branding process (Hwang, 2014; Paek, 2017; Križnik, 2011). Consequently, urban landscapes have increasingly become commodified and consumable image elements that respond to the demands of global investors and tourism.

Conclusion

In conclusion, Seoul's development underscores the intricate relationship between tradition and globalization. The city's landscapes, initially shaped by traditional Korean philosophies, have undergone substantial transformation due to historical events and processes of modernization. This study illustrates how these landscapes have evolved into global assets, thereby influencing the city's urban identity. It is imperative to preserve the cultural significance of these spaces while addressing the challenges posed by globalization, ensuring the retention of Seoul's distinct character within the contemporary urban context.

Landscape Design

The Use of Computer Vision in Observing Human Behavior in Landscape Architecture

Gizem Yağmur Gölbaşı[a], Melih Bozkurt[a]

[a] Istanbul Technical University, Department of Landscape Architecture, Turkey

Keywords: Computer Vision (CV), Landscape Architecture, Observation, Human Behavior.

Aim

Artificial Intelligence (AI) is rapidly spreading across various disciplines, offering numerous opportunities. Computer Vision (CV) is a sub-branch of AI and is a system designed based on natural vision to extract meaningful information from digital images such as photos and videos (Marasinghe et al., 2023). The increasing integration of AI and CV technologies with various disciplines has created new possibilities for analyzing human behavior in urban areas. Landscape architecture, a field focused on the planning, design and management of outdoor spaces, benefits greatly from understanding how people interact with their environment, especially in public spaces (Ibrahim et al., 2020). While CV has great potential for visual data processing, its use in landscape architecture is not yet widespread. This study aims to explore the potential of CV in detecting and analyzing human interactions in public spaces through methods such as classification, segmentation and localization, object tracking, action recognition, and perception (Pai et al., 2024). This research aims to provide insights into how individuals navigate through landscapes, interact with urban elements and react to different environmental conditions. The findings from this study can help landscape architects to design more accessible, functional and user-centered public spaces by incorporating data-driven decision-making processes (Wilkins et al., 2022).

Material and Method

The proposed methodology includes four processes: collection of visual material, data labeling for the training dataset, CV model training and application of the trained model to the visual material.

Compilation of Visual Data: In the visual material compilation phase, visual data appropriate to the relevant topic are collected. Visuals can be obtained from online open sources, existing data sets or field studies. In this process, the aim is to create the most appropriate data set for model training by evaluating whether the data is suitable in terms of quality, resolution and diversity.

Data Labeling for the Training Dataset: In the data labeling phase for the training data set, the collected visual materials are labeled according to the determined spatial criteria. Since the existing training data sets cannot meet the needs of the research to be conducted within the scope of landscape architecture, it is a very important stage to create a training data set on the spatial data axis. This process may involve different approaches such as detection of people and objects in space, segmentation or classification. The labeling process can be performed manually (bounding box, polygon, mask, etc.) or using semi-automatic or automatic tools. An accurate and consistent labeling process is critical to the success of the model.

CV Model Training: In the CV model training phase, the model was trained on the labeled dataset using supervised learning techniques. In this process, the architecture of the model is selected first (for example, approaches such as CNN, YOLO, Mask R-CNN may be preferred). Then, data preprocessing steps (normalization, data augmentation, etc.) are applied to make the model learn more efficiently. During the training process, certain hyperparameters are used to analyze the model's performance metrics such as accuracy, error rate, etc., and the model with the best results is selected.

Applying the Trained Model to Visual Material: At the stage of applying the trained model to the visual material, the model is tested on new images, and its performance is evaluated. In this process, the objects or regions detected by the model are marked on the images and the prediction results are analyzed. The accuracy and error rates of the model are calculated to determine its success. In addition, the results are analyzed in detail using manual analysis and different performance metrics. In line with the data obtained, the model is improved and retrained when necessary to achieve more successful results.

Findings

The application of CV techniques in landscape architecture stands out as an important method for the analysis of human behavior and movement patterns. CV-based data collection and analysis methods minimize the margin of human error by providing objective and verifiable results. In this context, they provide significant advantages in terms of identifying problems related to the use of urban areas, effectively prioritizing the solution processes of existing problems and developing more efficient planning strategies.

These methods based on visual data analysis enable faster and more effective decision-making processes compared to traditional observation and assessment techniques. By enabling the processing of large-scale data sets, CV technology supports spatial planning decisions and helps us understand human behavior at the urban scale in detail.

Future research can extend these findings by integrating additional factors such as demographic differences, environmental conditions and long-term behavioral trends. By integrating technological innovations with landscape architecture, it will be possible to design smarter and adaptive urban spaces that are sensitive to user needs (Wilkins et al., 2022). In this direction, AI-supported analysis systems will contribute to more efficient, sustainable and human-oriented design of public spaces.

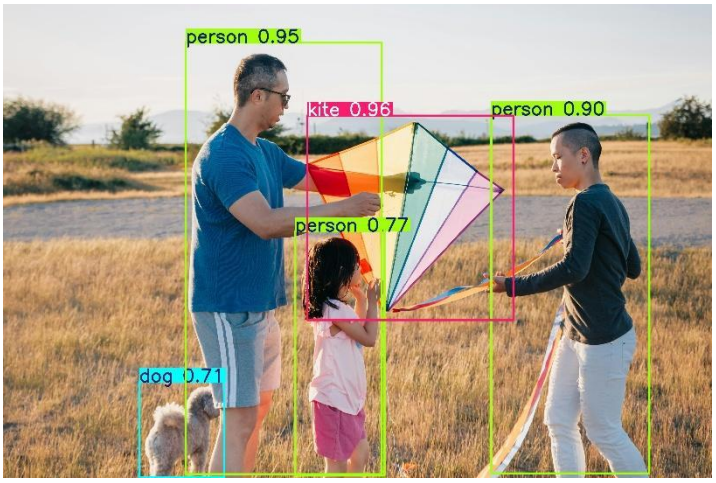

Figure 1. Human, animal and object detection with computer vision.

Conclusion

This research reveals that CV techniques are powerful and innovative tools for observing and analyzing human behavior in landscape architecture. By utilizing AI-assisted sensing and monitoring techniques, it is possible to obtain in-depth and meaningful data about space and user interactions (Väisänen et al., 2021).

Data-driven design decisions guide the creation of user-friendly and functional public spaces by enabling more systematic and objective assessments compared to traditional observation methodologies. CV-based analysis methods not only examine current spatial use, but also predict future trends, allowing urban design processes to become dynamic and adaptive.

As a result, the integration of CV and AI-supported analytics into landscape architecture enhances the analytical capabilities of the discipline, encouraging the development of more comprehensive, data-driven and innovative approaches in landscape architecture. In this way, it will be possible to design sustainable and user-centered urban spaces that better understand human-environment interaction. This study underscores the transformative role of CV in landscape architectural research, promoting a paradigm shift from intuition-based design to evidence-driven, adaptive planning strategies.

Understanding Play: How Playground Exuipment Shapes Cognitive, Social, and Pyhsical Behaviors in Children Aged 3-12: A Case Study in Maltepe Orhangazi City Park

İçim Gündoğan Ata[a], Melih Bozkurt[a]

[a] Istanbul Technical University, Faculty of Architecture, Department of Landscape Architecture, Turkey
gundogan18@itu.edu.tr

Keywords: Behavior, Children, Play Equipment.

Aim

Play is an activity that children, as well as individuals of all ages, engage in during their own time and for their own purposes (Shackell et al., 2008). Play provides numerous benefits for children; therefore, they should be given ample opportunities to engage in it (Bredekamp & Copple, 1997). Outdoor play, in particular, offers a wide range of benefits for a child's development (Bilton, 2010). Children who play outside demonstrate better cognitive, emotional, social, physical, and intellectual development (Bilton, 2010).

The study aims to analyze how cognitive behaviors, social interactions, and activity levels are influenced by playground equipment and to evaluate the suitability of the play structures in Maltepe Orhangazi City Park for supporting child development. By examining this data, the study seeks to establish criteria that can inform the design of playground equipment to better support children's development.

Material and Method

Maltepe Orhangazi City Park was chosen as the case study area due to its high recreational value and significant foot traffic. The park attracts a diverse range of users from different socioeconomic and educational backgrounds (Korkut et al., 2021), ensuring a more objective study. Additionally, the park features a variety of playground equipment, allowing for the observation of children engaging with different play structures.

The park includes parkour equipment, fixed equipment such as swings and seesaws, climbing structures, and tower equipment, made from different materials. Overall, it contains five parkour structures, 29 fixed structures, eight climbing structures, and 14 tower structures. These play elements cater to different age groups. For the study, the 3–12 age group was selected, with 3–5 years representing preschool children and 5–12 years representing school-aged children (Banumathe et al., 2012; National Program for Playground Safety, 2010).

To observe physical activity, age, and gender, the SOPLAY (System for Observing Play and Leisure Activity in Youth) observation method was employed, with additional cognitive and social parameters derived from the literature. SOPLAY categorizes physical activity levels as sedentary, walking, and very active (McKenzie et al., 2000). Cognitive parameters included dramatic, constructive, and functional play behaviors (Piaget, 1932; Smilansky, 1968). Dramatic play, also known as symbolic play, occurs when children pretend to be someone else or use an object imaginatively (Piaget, 1932). Constructive play is goal-oriented, such as climbing to the top of a structure (Piaget, 1932; Smilansky, 1968). Functional play involves repetitive movements, such as swinging (Piaget, 1932; Smilansky, 1968). Social interactions were classified as solitary, parallel, and positive or negative interactions (Maxwell et al., 2008). Solitary play was noted when children played alone, whereas parallel play was recorded when children played near others but did not interact directly (Parten, 1932).

Once the parameters were determined, direct observation commenced. A total of 685 children were observed in Maltepe Orhangazi City Park, with each child observed for three minutes and recorded only once. Pearson chi-square tests were used to analyze the data (Can, 2023).

Findings

The analysis revealed that gender had no significant relationship with playground equipment preferences. The distribution of boys and girls across different equipment types, including climbing structures, towers, and static equipment, showed minimal variation. The data indicates that both boys and girls use all types of playground equipment in relatively similar proportions, with girls slightly favoring static and tower-type elements (56.0% and 51.1%, respectively) and boys showing a minor preference for climbing structures (51.9%). This finding suggests that playground designs should focus on inclusivity rather than gender-specific features.

Age, however, emerged as a crucial factor influencing playground equipment preferences. Younger children (ages 3–5) preferred static and tower-type equipment, while older children (ages 5–12) were more inclined toward physically demanding structures such as climbing and parkour elements.

Distinct relationships were observed between playground equipment and play behaviors. Static equipment primarily supported functional play, such as repetitive physical activities, while climbing and parkour elements encouraged constructive play. Tower structures, on the other hand, facilitated both constructive and dramatic play behaviors.

Social interactions varied across equipment types. Parallel play, where children engage in side-by-side activities, was most commonly observed on climbing, parkour, and tower equipment. Static equipment supported independent play and positive interactions, such as collaboration and sharing, but also showed instances of negative interactions.

Physical activity levels also varied significantly with equipment types. Static elements were associated with sedentary behavior, while towers encouraged moderate activity.

Conclusion

In conclusion, the study demonstrates that age, cognitive behaviors, social interactions, and physical activity levels are significantly influenced by playground equipment, while gender has no notable effect. These findings highlight the importance of diverse playground equipment in fostering various play behaviors and promoting child development by addressing different developmental needs.

To translate these insights into practice, playgrounds should be designed to be inclusive and age-appropriate, with gender-neutral equipment and distinct zones for younger (3–5) and older (6–12) children. A balanced mix of static, tower, and climbing elements should support different types of play—functional, constructive, dramatic, and social—encouraging both independent and group interactions. Layouts must promote movement through thoughtful spatial planning, while ensuring safety and accessibility for all users.

Additionally, the study provides valuable insights for urban planners and designers, emphasizing the necessity of balanced equipment arrangements that cater to different age groups and encourage holistic development. However, further research is needed to examine long-term impacts and explore variations across different cultural and socioeconomic contexts. This study offers a framework for designing inclusive and developmentally supportive playgrounds.

Central Bank Digital Currencies (CBDCs): a countermeasure to Anti-Money Laundering (AML) challenges posed by cryptocurrencies?

Albina Gaisina[a], Matthias Finger[b]

[a] Istanbul Technical University, Graduate School, PhD in Economics Program, Türkiye
[b] Istanbul Technical University, Department of Economics, Türkiye
gaisina21@itu.edu.tr

Keywords: Central Bank Digital Currency (CBDC), Cryptocurrency, AML, CeFi, DeFi.

Aim

This study examines whether Central Bank Digital Currencies (CBDCs) are developed to address money laundering risks associated with cryptocurrencies. It focuses on piloted/launched CBDCs to assess this relationship empirically.
While existing research has analysed the rise of cryptocurrencies and the development of CBDCs independently, there is a gap in comprehensively analysing the relationship between these two. Specifically, there is limited exploration into how the money laundering aspect of cryptocurrencies in both CeFi and DeFi spaces influences central banks' decisions to develop CBDCs in such a way that, technology- and regulation-wise, they represent a potential response.
Consequently, our research aims to fill this gap by empirically analysing the impact of cryptocurrency-related money laundering on the effectiveness of AML measures in countries adopting CBDCs. Furthermore, the study aims to contribute to the topic theoretically by introducing a layered theoretical concept of privacy, compliance, and regulation by design in CBDCs which is linked with Kane's regulatory dialectic theory (Dupuis et al., 2022).

Material and Method

As for the theory behind the study, we utilise Kane's regulatory dialectic (1977, 1988) to explain why CBDCs emerged as a response to the challenges posed by cryptocurrencies. According to Kane's framework, as cryptocurrencies introduce new evasion tactics, regulatory bodies struggle to enforce effective AML measures. In response, CBDCs with built-in compliance, like KYC protocols and real-time monitoring, aim to address regulatory loopholes. Furthermore, we introduce a novel layered framework of CBDC design principles for AML enforcement, where: "privacy by design" uses tiered privacy mechanisms to balance user anonymity with traceability for high-risk transactions; "compliance by design" integrates privacy-enhancing technologies (PETs) to enforce AML rules while maintaining user privacy; and "regulation by design", where regulatory principles are embedded directly into the CBDC infrastructure, aligning with the "code is law" concept and RegTech to prevent money laundering proactively.
Overall, based on the comprehensive literature review, the following research hypotheses are formulated to build our empirical analysis. See Table 1:

Table 1. Summary of Hypotheses.

Hypothesis	Statement	Expected relationship
H1	The enhancement of financial inclusion through CBDCs improves AML effectiveness, as they can be a more trustworthy payment option.	Positive
H2	The reduction of the shadow economy via CBDC adoption enhances AML effectiveness due to higher transparency.	Positive
H3	Higher levels of crypto ownership in countries are negatively associated with AML effectiveness due to challenges in monitoring.	Negative
H4	The selection of CBDC technology providers is aligned with central banks' regulatory goals.	Positive
H5	The use of DLT in CBDCs is a key proxy for improving transparency and regulatory compliance.	Positive
H6	The type of CBDC (wholesale vs. retail) serves as a proxy for AML effectiveness.	Positive
H7	The CBDC structure (token vs. account-based) influences AML effectiveness, with account-based models preferred for better monitoring.	Positive
H8	CBDC adoption improves AML effectiveness but creates challenges in balancing privacy with regulatory compliance.	Positive
H9	Greater privacy in CBDCs negatively impacts AML effectiveness.	Negative
H10	CeFi activity is negatively associated with AML effectiveness.	Negative
H11	DeFi activity is negatively associated with AML effectiveness.	Negative
H12	Cryptocurrency regulation is positively associated with AML effectiveness.	Positive
H13	CBDCs with built-in AML compliance enhance AML effectiveness.	Positive
Source: Authors' compilation		

The research empirically tests the hypotheses using cross-sectional data from multiple jurisdictions that have launched or adopted CBDCs. Models were estimated as of December 2024 using Ordinary Least Squares (OLS) with heteroscedastic-robust standard errors on cross-sectional data in the main results.
The initial regression model is specified as follows:

$$\text{AML_Effectiveness}_i = \beta_0 + \beta_1 \text{CeFi}_i + \beta_2 \text{DeFi}_i + \text{CBDC}_i\theta + X_i\gamma + \epsilon_i \ldots . \text{Eqn1} \text{ (Equation 1)}$$

The dependent variable (AML effectiveness) is represented by the FATF AML index, the AML Basel score (inverted) and the AML organised crime index, obtained from the corresponding websites. For all AML proxies higher rankings correspond with countries with stronger AML frameworks.
Key independent indicators include cryptocurrency adoption in both the CeFi and DeFi spaces obtained from the Chainalysis report, as well as CBDC-related data focused on technological factors. Specifically, CBDC proxies were derived from the CBDC tracker and the Atlantic Council's CBDC tracker as follows: adoption status (launched/pilot), type

(retail/wholesale/both), structure (account/token), technology provider (local/international), technology platform (defined/not defined), and usage of DLT (DLT/no DLT).

The control variables include: cryptocurrency regulation (legal/partial ban/general ban); data privacy (presence or absence of data protection/privacy laws); shadow economy (in %); crypto ownership (in %); financial inclusion (account, % age 15+); internet penetration (in %); GDP per capita (ln). Control variables were sourced from publicly available macroeconomic databases.

Data availability and consistency across jurisdictions influenced the use of a cross-sectional approach. As of December 2024, only three countries have fully launched CBDCs, meaning that there are low within-country variations for panel analysis. Since the AML proxies and CBDC adoption vary substantially between countries but not necessarily within countries over short periods, a cross-sectional approach is sufficient for identifying differences at a given point in time. Additionally, key variables of the study (AML Effectiveness and CBDC proxies) are either slow-moving or remain constant over time, implying low within-country variations over time. By starting with these variables based on backward elimination, we are able to detect the effects of our main CBDC proxies when they are introduced.

Several robustness checks were conducted to validate our results. A Two-Stage Least Squares (2SLS) regression was used, treating CeFi and DeFi variables as endogenous and instrumented with crypto trading volume, trading volume per internet user, and crypto trade volume relative to average monthly wage. Additionally, GMM estimation was applied, and checks were done using a fully retail CBDC sub-sample, as well as an interaction term between crypto regulation and CBDC adoption status.

Findings

Table 2 below presents the results for the three models for each AML proxy separately.

Source: Authors' own work

The obtained coefficients demonstrate that only hypotheses H3, H4, H10 and H12 were empirically validated in this study. See the explanations below.

The results suggest that in countries with higher cryptocurrency ownership, AML effectiveness tends to be lower **(H3).** Similarly, Alnasaa et al. (2022) examined the relationship between cryptocurrency adoption, corruption, and financial controls. Their results indicate that higher levels of cryptocurrency adoption are associated with higher corruption and more restrictive capital controls. The authors conclude that to manage the risks associated with cryptocurrencies, it is needed to implement robust KYC.

Secondly, our results illustrate that higher CeFi trading has a negative relationship with AML effectiveness **(H10)**. Leuprecht et al. (2023) confirm the role of CeFi exchanges in facilitating money laundering, particularly in the placement and layering stages. Furthermore, the study by Carpentier-Desjardins et al. (2025) investigated 1,153 crime events in the crypto industry from 2017 to 2022. Their findings indicated that two-thirds of the financial losses were attributed to CeFi and one-third to DeFi. Hence, CeFi still remains a main channel for financial crime.

A key insight from our study is that CBDC technology providers play a significant role in shaping AML effectiveness **(H4).** In our findings, AML effectiveness is lower in countries with local CBDC providers, suggesting to use international providers for better AML. While we could not find explicit empirical support for this, DiGiammara et al. (2023) emphasised how central banks select tech providers to align with regulatory environments. For example, the Central Bank of the Bahamas chose NZIA Ltd. due to its multi-factor authentication and transaction monitoring, whereas the Eastern Caribbean CBDC adopted IBM Hyperledger Fabric for its secure and scalable blockchain.

Further, our results indicate that AML effectiveness is higher in jurisdictions allowing legal cryptocurrency use (compared to bans) **(H12)**. The paper by Griffith and Clancey-Shang (2023) showed that even if the 2021 Chinese crypto ban led to a price drop and increased volatility, it did not eliminate crypto activity but shifted cryptocurrency markets to less regulated environments, making further AML regulation even harder. These spillover effects after China's 2017 cryptocurrency regulatory changes were also observed in the empirical study by Borri and Shakhnov (2020). Shirakawa and Korwatanasakul (2019) investigated the relationship between institutional strength, financial openness, and regulatory approaches to cryptocurrency across 218 economies. They found that jurisdictions with stronger governance frameworks are more likely to adopt a less restrictive regulatory stance on cryptocurrency.

Finally, our results show that AML effectiveness is higher in countries with higher GDP per capita, indicating the countries' capacity to combat illicit activities. While we did not cover this in our literature review, the empirical result turned significant. In line with this, Šikman and Grujić (2021) find that higher GDP per capita is associated with greater AML effectiveness. In an analysis of 165 countries, Ofoeda et al. (2022) found that stronger AML frameworks are positively associated with higher GDP per capita, however up to a threshold, with developed countries generally enforcing more effective AML regulations. Interestingly, Matsui and Perez (2021) apply machine learning techniques to identify key drivers of CBDC adoption, finding that GDP per capita, alongside financial development and institutional quality, is one of the strongest predictors of CBDC adoption.

It should be noted that since the highest number of observations for most of the estimated models in our study was 36, there was insufficient statistical support for all the hypotheses of the affected variables.

Conclusion

This research focused on the potential impact of CBDCs on AML, inspired by the risks associated with cryptocurrencies. Our findings highlight how the nature of cryptocurrencies and the level of their regulation influence AML effectiveness. However, given the early stage of CBDC adoption, the lack of consistent, quantified data poses challenges for data

collection. Among CBDC indicators, the only statistically significant variable was the CBDC technology provider. Results suggest that international CBDC providers may better align with global AML laws.

Furthermore, the core idea of our research is that carefully designed CBDCs with built-in AML features have the potential to enhance AML effectiveness across jurisdictions, since they can be more trustworthy than cryptocurrencies if they balance privacy. According to our results, for cryptocurrencies the focus should be on strong AML regulatory frameworks rather than bans.

This study represents one of the first empirical attempts to assess the AML implications of CBDCs in light of the risks associated with cryptocurrencies. Given several limitations dictated by data availability, we recommend the following directions for future research. As more countries adopt CBDCs, larger datasets will become available. Moreover, future research could collect additional information about CBDC design, such as consensus mechanisms, tier systems, and the use of PETs. Additionally, a shock regression panel analysis could be applied by dividing datasets into pre- and post-CBDC periods.

Investor Attention and Asymmetric Conditional Volatility: Evidence from GARCH-X and GJR-GARCH-X Models

Müge Özdemir[a], Oktay Taş[b]

[a] Istanbul Technical University, PhD Program in Management, Türkiye
[b] Istanbul Technical University, Department of Management Engineering, Türkiye,
ozdemir19@itu.edu.tr

Keywords: Investor Attention, Conditional Volatility, Behavioral Finance, Emerging Markets.

Aim

This study investigates the dynamic role of investor attention in shaping the conditional volatility of stock returns, with a particular focus on volatility asymmetries. We examine whether investor attention—quantified through the Abnormal Search Volume Index (ASVI) as proposed by Da et al. (2011)—contributes significantly to the persistence and responsiveness of market volatility, particularly in the context of emerging markets. Unlike conventional GARCH-type models (Bollerslev, 1986; Glosten et al., 1993), which rely solely on historical return dynamics, our approach incorporates a behavioral dimension by embedding ASVI into both GARCH-X and GJR-GARCH-X frameworks. We initially estimate standard GARCH and GJR-GARCH models separately for low-attention, high-attention, and long-short (high-minus-low) portfolios to assess attention-specific volatility profiles. In a second step, we extend this framework by embedding ASVI into conditional volatility models for risk-adjusted returns derived from CAPM (Sharpe, 1964), Fama-French three-factor (Fama & French, 1993), and Carhart four-factor (Carhart, 1997) models. This two-stage design enables a comprehensive assessment of attention-driven volatility both at the raw return and residual return level. By systematically integrating behavioral attention metrics into volatility modeling, this study contributes to the growing body of research in behavioral asset pricing and provides practical insights for risk forecasting, especially in attention-sensitive and information-inefficient markets such as Borsa Istanbul.

Material and Method

This study employs a weekly dataset comprising 364 stocks listed on the Borsa Istanbul All Shares Index (XUTUM), covering the period from October 2016 to October 2021. Stock-level financial variables—including weekly returns, market capitalization, book-to-market ratios, and momentum indicators—are obtained from the Reuters database. Investor attention is proxied using the Abnormal Search Volume Index (ASVI), which is calculated from Google Trends following the methodology of Da et al. (2011). To improve measurement accuracy, a keyword filtering strategy is implemented to exclude ticker symbols with dual meanings in Turkish (e.g., SISE, MAVI), ensuring that ASVI captures genuine financial attention. Each week, stocks are ranked by their ASVI values and categorized into three groups: the top 30% (high-attention portfolio), the bottom 30% (low-attention portfolio), and the middle 40% (excluded from the analysis). A dynamic long-short trading strategy is then constructed by taking long positions in high-attention stocks and short positions in low-attention stocks, with portfolios rebalanced weekly.
To assess abnormal returns of these attention-based portfolios, we estimate the following benchmark factor models:

$$R_{p,t} - R_{f,t} = \alpha_p + \beta_1\left(R_{m,t} - R_{f,t}\right) + \varepsilon_{p,t} \quad (1)$$

$$R_{p,t} - R_{f,t} = \alpha_p + \beta_1\left(R_{m,t} - R_{f,t}\right) + \beta_2 SMB_t + \beta_3 HML_t + \varepsilon_{p,t} \quad (2)$$

$$R_{p,t} - R_{f,t} = \alpha_p + \beta_1\left(R_{m,t} - R_{f,t}\right) + \beta_2 SMB_t + \beta_3 HML_t + \beta_4 WML_t + \varepsilon_{p,t} \quad (3)$$

In the second part of the analysis, we investigate how investor attention influences conditional volatility patterns. Initially, GARCH(1,1) and GJR-GARCH(1,1) models are applied to raw return series of the low-, high-, and long-short (high-low) portfolios to assess how attention correlates with volatility persistence and asymmetries. The models are further extended by incorporating lagged ASVI as an exogenous regressor:

$$\sigma_t^2 = w + \alpha\varepsilon_{t-1}^2 + \beta\sigma_{t-1}^2 + \lambda ASVI_{t-1} \quad (4)$$

$$\sigma_t^2 = w + \alpha\varepsilon_{t-1}^2 + \gamma\varepsilon_{t-1}^2 I_{t-1} + \beta\sigma_{t-1}^2 + \lambda ASVI_{t-1} \quad (5)$$

$$I_{t-1} = \{1 \quad if \quad \varepsilon_{t-1} < 0\ (negative\ shock)\ 0 \quad if \quad \varepsilon_{t-1} \geq 0\ (positive\ shock)\ \} \quad (6)$$

To isolate the behavioral component in volatility beyond factor exposures, we then model the conditional variance of the residuals from the CAPM, Fama-French, and Carhart regressions using GARCH-X and GJR-GARCH-X frameworks. This approach captures attention-induced risk that is orthogonal to traditional risk factors.

All volatility models are estimated via Quasi-Maximum Likelihood Estimation (QMLE), which provides robust estimates even under non-normal error distributions. Model performance is evaluated using Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC). Additionally, residual diagnostics including the Ljung-Box test (for autocorrelation), ARCH-LM test (for remaining ARCH effects), and Jarque-Bera test (for normality) are conducted to ensure model adequacy.

This two-stage modeling approach enables a comprehensive evaluation of how investor attention influences both return generation and time-varying risk, thereby highlighting the behavioral dynamics embedded in market volatility.

Findings

Table 1 demonstrates that investor attention, proxied by the Abnormal Search Volume Index (ASVI), significantly impacts portfolio-level return performance. Dynamic long-short portfolios—formed by taking long positions in high-attention stocks and short positions in low-attention stocks—exhibit statistically significant alpha values across all benchmark models. Equally weighted portfolios deliver the strongest results: under the CAPM model, weekly alpha reaches 210 basis points (t = 16.393), and under the Fama-French and Carhart models, alpha remains robust at approximately 190 basis points ($p < 0.01$). These outcomes underscore the predictive validity of attention-based signals and are in line with earlier findings by Da et al. (2011), Ying et al. (2015), and Tan and Taş (2019), especially within the context of small-cap stocks, where information frictions are more pronounced.

Table 1. Risk-adjusted performance of attention-based portfolios under the factor models.

	Equal weighted portfolio (attention based)					
	Alpha	Rm-Rf	SMB	HML	WML	R^2
(1) CAPM Model	0.021***	0.063				0.006
	(16.393)	(1.216)				
(2) Fama-French Three Factor	0.019***	0.108**	0.195***	-0.625***		0.296
	(12.441)	(2.440)	(2.781)	(-9.032)		
(3) Carhart Four Factor	0.019***	0.109**	0.187***	-0.559***	0.122**	0.455
	(12.732)	(2.490)	(2.688)	(-7.649)	(2.513)	

Note. ***, **, and * symbols represent the statistical significance of the results at the 1%, 5%, and 10% significance levels, respectively. t-statistics are provided in parentheses.

Turning to volatility dynamics, Tables 2 and 3 present the conditional variance estimates obtained from GARCH-X and GJR-GARCH-X models. The ASVI coefficient (λ) is consistently positive and statistically significant across all specifications, supporting the hypothesis that increased investor attention correlates with heightened return volatility. The GJR-GARCH-X model applied to high-low portfolios yields the strongest explanatory power, with $\lambda = 0.534^{***}$ and $R^2 = 0.894$, confirming the predictive relevance of ASVI in volatility modeling.

R^2	0.728	0.743	0.753	0.808	0.817	0.894

Note. ***, **, and * symbols represent the statistical significance of the results at the 1%, 5%, and 10% significance levels, respectively. t-statistics are provided in parentheses.

Notably, the asymmetry parameter γ is significant in nearly all GJR-GARCH-X estimations, reinforcing the leverage effect (Black, 1976; Christie, 1982). These results suggest that negative return shocks, particularly in high-attention portfolios, generate disproportionately larger increases in volatility. This behavioral asymmetry aligns with findings from Barber and Odean (2008), who argue that investors overreact more strongly to adverse information. Collectively, these results indicate that attention not only influences returns but also plays a structural role in volatility persistence and asymmetry.

Conclusion

This study provides compelling empirical evidence that investor attention, proxied by the Abnormal Search Volume Index (ASVI), plays a pivotal role in shaping the conditional volatility of stock returns in an emerging market context. By integrating ASVI into GARCH-X and GJR-GARCH-X models, we demonstrate that attention not only amplifies volatility but also induces asymmetric and persistent effects—particularly in response to negative return shocks.

The findings show that attention-based long-short portfolios yield statistically significant alpha even after adjusting for standard risk factors using CAPM, Fama-French, and Carhart models. Moreover, ASVI consistently emerges as a significant explanatory variable across all volatility model specifications, enhancing both in-sample fit and out-of-sample forecasting power. Among the models tested, GJR-GARCH-X proves to be the most comprehensive framework, capturing volatility clustering, asymmetric responses, and attention-driven dynamics in a unified structure. Our results confirm that investor attention is not merely a reflection of market activity but an active force that shapes volatility patterns—particularly in high-attention and small-cap stocks. This behavioral volatility channel aligns with theoretical expectations from the leverage effect (Black, 1976; Christie, 1982) and information-based trading hypotheses such as the Mixture of Distributions Hypothesis (Clark, 1973) and Sequential Information Flow Hypothesis (Copeland, 1976).

In practical terms, incorporating attention-based signals into volatility modeling offers valuable improvements for asset pricing, portfolio risk management, and systemic risk monitoring. These implications are particularly relevant in emerging markets like Borsa Istanbul, where market inefficiencies and investor sentiment play an outsized role in shaping price dynamics (Özdemir & Taş, 2025).

Overall, this study contributes to the behavioral finance literature by formalizing the role of real-time attention measures in volatility forecasting. It underscores the importance of incorporating investor psychology into econometric models of risk, offering actionable insights for both academics and financial practitioners operating in increasingly sentiment-sensitive market environments.

How Was Financial Performance Affected by ESG In The After- Covid Era? A Global Analysis

Sırma Şeker[a], Cumhur Ekinci[a]

[a] Istanbul Technical University, Department of Management Engineering/Faculty of Management, Türkiye

seker16@itu.edu.tr/ekincicu@itu.edu.tr

Keywords: Covid, Sustainability, Financial Performance.

Aim

Covid-19 emphasized ethical and social values that are important for our ecosystem. Therefore, companies have started to develop new strategies regarding their sustainability performance measured by ESG (Environmental, Social and Governance) scores. The level of companies' sustainability performance affects their profits in normal times (Velte, 2017; Chen et al., 2023). But what about times of crisis? Certain intangible assets, such as image or reputational capital, act as a shield in times of crisis (Aliyah, 2024). These capitals can be gained through ESG, especially during economic downturns (Liu et al., 2023). Supporting this view, some studies find ESG improves financial performance during (Cardillo et al., 2023; Liu et al., 2023) and after Covid period (Aksoy & Yılmaz, 2024). However, others find ESG decreases financial performance (Demers et al., 2020) or does not create a significant positive change on financial performance (Bodhanwala & Bodhanwala., 2023). There may be several reasons for these complex findings. Unlike some studies, this relationship needs to be analyzed over a longer period in order to see the effects of social image and reputation. With these benefits, the company can start to be positively evaluated by its stakeholders (Hwang et al., 2021). Most of the studies are limited to only during Covid period (Liu et al, 2023, Cardillo et al., 2023), not after Covid period. In addition, Covid may have different effects on different ESG pillars (E, S or G). Since the cause of the outbreak of the pandemic is indirectly linked to environmental damage, the value attributed to different ESG pillars may have differentiated, which can significantly effect financial performance. Based on these facts, with nearly 13,000 companies from 58 different stock exchanges, we analyze whether there is a difference in the impact of ESG (E, S or G) on long-term financial performance during and after Covid-19.[10]

Material and Method

Data

The dataset consists of sustainability performance scores such as ESG (Environmental, Social and Governance) scores and its subscores (E, S and G); financials such as sales revenue, total assets, total liabilities, market capitalization, net income; company informations such as country of headquarters, the date of establishment, board statistics such as number of board meetings and number of female and male board members. The data is retrieved from Thomson Reuters database.

Method

In order to examine whether ESG, E, S or G actually increases profits and to compare 2020 during crisis period with 2021 and 2022 post crisis period, we need to employ difference-in-difference (DID) analysis (Li et al, 2012). We converted basic framework of DID into the emprical specification is outlined by the following equations:

[10] This study was funded by TUBITAK (Project No 122K345).

$$ROA/TQ_{i,t}=\beta_0 + \beta_1 Tm_t + \beta_2 Td_i + \beta_3(Tm_t*Td_i) + \beta_4 LSize_{i,t} + \beta_5 SAss_{i,t} + \beta_6 Lev_{i,t} + \beta_7 LAge_{i,t} + \beta_8 LNbm_{i,t} + \beta_9 Bgd_{i,t} + \alpha_i + \delta_t + \epsilon_{it}$$

where ROA (Return on Assets) or TQ (Tobin's Q) as firm performance, Tm_t is a dummy variable equal to one after or before the crisis period and zero otherwise, Td_i is a dummy variable equal to one for the company above median ESG and zero otherwise. Tm_t*Td_i refers to the interaction effect (DID estimator) and equal to one if the company is in a crisis period with higher ESG than the median, ε_{it} is the error term representing unobservable factors. β_3 shows the difference in the change in performance of firms with high ESG, E, S, G score compared to firms with a lower score in 2021 or 2022 compared to 2020. β_4- β_9 shows the effect of control variables (LSize is the logarithm of total assets, SAss is the ratio of sales revenue to total assets, Lev is the ratio of total debt to total assets, LAge is the logarithm of firm age, LNbm is the logarithm of the number of board meetings, Bgd is the percentage of board gender diversity in 2021 or 2022).

Findings

Table 1 presents the descriptives of the variables. For each variable, there are mean, standard deviation, minimum, maximum and median values. For example, companies average ESG score is 47.25 during and after Covid period. Again, we see a gradual increase in ESG scores in Covid period. Based on the average ESG pillars, we conclude that E scores are lower than S and G scores (37.55<48.70 or 52.17). The strongest in each pillar is the G score (>50). So, stakeholders attributed more value to the governance score in pandemic.

Table 1: Descriptive Statistics Of ESG (E, S and G) Scores.

Variable	Value	Variable	Value	Variable	Value	Variable	Value
MeanEsg	47,25	**MeanE**	37,55	**MeanS**	48,7	**MeanG**	52,17
SdEsg	20,11	**SdE**	28,42	**SdS**	23,14	**SdG**	21,8
MinEsg	1,11	**MinE**	0,05	**MinS**	0,21	**MinG**	0,18
MaxEsg	95,52	**MaxE**	99,22	**MaxS**	98,6	**MaxG**	99,62
MedianEsg	46,68	**MedianE**	35,99	**MedianS**	48,16	**MedianG**	52,63

In addition to the descriptives, we applied Pearson correlation and multicollinearity tests. We conclude that there is no correlation problem between our independent variables. Moreover, we applied the Breusch-Pagan test and find that the data is heteroskedastic. Therefore, we used robust standard errors in the OLS-based DID analysis.

In table 2, there are the results of difference-in-difference analysis using OLS comparing Covid period 2020 with 2021 measuring ESG, E, S and G on financial performance. D (Timet*Treatedi) refers to the interaction effect and equal to one if the company is in a crisis period with higher ESG than the median. The coefficient is positive in all models (both ROA and TQ). Hence, in 2021, firms with high ESG (than the median) had better financial performance than firms with low ESG. Coefficients are low for ROA, but quite high for TQ.Therefore, we conclude that those who invested in ESG during 2020 gained higher profits in 2021. In table 3, for more longer period, we compare 2020 to 2022. All of the findings are the same for overall ESG. In table 2 and 3, the coefficients of control variables are not reported due to space limitations, but all of the variables are significant (except for board gender diversity in some models). According to our findings, the only difference between table 2 and table 3 is about ESG pillars. In table 2, we see that E, S and G are more profitable in terms of TQ, while E, G and S in terms of ROA, respectively. But in table 3, we see that E, G and S are more profitable in terms of TQ, while E, S and G in terms of ROA, respectively.

Conclusion

The aim of our study is to examine whether ESG actually increases profits in a time of crisis like Covid-19. According to our findings, firms invested in ESG gained short-term profits in 2021 and 2022, but gained much more long-term profits in 2021 and 2022. So, we conclude that ESG kind of investments is valuable after crisis periods and positively evaluated by stakeholders with a more longer period of time. Therefore, even if there is a cost impact, the ability of financially strong companies to make investments such as ESG in times of crisis is not harmful for shareholders, rather becomes a profitable situation in the long run. Our findings are in line with legitimacy theory, which states that ESG provides important benefits such as legitimacy. But these benefits can be seen in a more longer period of time.

After Covid, we observe that especially S and G scores has a similar impact on financial performance. However, those who invested in E score during Covid acquired a significant market value after Covid. From our point of view, in Covid, stakeholders started to pay more attention to environmental issues and allocated more funds to green investments in post-Covid recovery policies (EU Green Deal, "Green Recovery" in the US). This became value enhancing. Therefore, we conclude that, the value judgements of stakeholders that identifies with crisis are important in these kind of situations.

Our findings are very important for managers and decision makers. Managers should engage in such investments in times of crisis to generate long-term profits. However, they should identify which issues (ESG sub-scores) are valued more by stakeholders in times of crisis. Our findings reveal that environmental issues (environmental resource consumption, carbon emissions and innovation) were more important during and after Covid period. Further studies may reveal which environmental subscores (environmental resource consumption, carbon emissions or innovation) were more profitable in Covid period.

Remote Work and Virtual Presenteeism: Insights from the Turkish Organizational Context

Deniz Mat Artun[a], Prof. Dr. Fatma Küsküa[a]

[a] Istanbul Technical University, Management Program, Turkey

matartun20@itu.edu.tr

Keywords: Remote Work, Virtual Presenteeism, Qualitative Analysis.

Aim

Following the COVID-19 pandemic, work environments has significantly changed worldwide, forcing organizations to adapt to remote work. Workplace dynamics have been majorly transformed since remote work has become an essential part of work settings. Remote work practices have also altered how employees engage with work while being sick or feeling unwell (Biron et al., 2021; Shimura et al., 2021). This study investigates how remote work affects virtual presenteeism, a relatively unexplored phenomenon in the presenteeism literature. Traditionally, presenteeism has been defined as "showing up for work when one is ill" (Johns, 2010). However, recent studies have expanded this definition and included being present physically but not functioning properly (Cooper, 1996; Cooper and Lu, 2016). As organizations adapt to remote work settings, virtual presenteeism has emerged as the act of continuing to work from home despite feeling unwell (Ruhle and Schmoll, 2021; Salvoni et al., 2024). Presenteeism has been addressed as one of the major factors that negatively affect productivity (Patel et al., 2023), cause severe health issues (Karanika et al., 2021), and result in employee absence (Bergström et al.,2009). Therefore, it is a critical topic to explore to improve the productivity of remote employees. By addressing this research gap, this study aims to provide insights into how remote work practices affect presenteeism.

While presenteeism has mainly been studied in traditional work settings, such as offices (Johns, 2010; Cooper & Lu, 2016), more in-depth research about how remote work settings affect this phenomenon is needed (Fiorini, 2024). Studying virtual presenteeism has become a crucial need since remote employees face challenges regarding a lack of visibility and supervisory pressures. Moreover, research on presenteeism has been dominated by North American and Scandinavian samples (Böckerman and Laukkanen, 2010; Johns, 2010). However, cultural differences and national values are significant factors that affect the presenteeism behavior of employees (Cooper & Lu, 2016; Ferreira et al., 2022). As a result, studies from the Turkish organizational context that investigate presenteeism and especially its new form under virtual work settings are essential.

Material and Method

This study utilizes a qualitative approach using open-ended survey responses from professionals in Türkiye to capture in-depth insights into remote work experiences. We combined qualitative content analysis with thematic analysis to capture both the structured and emergent dimensions of virtual presenteeism in remote work settings. While qualitative content analysis provided a systematic framework for classifying and organizing key concepts, thematic analysis enabled the identification of underlying patterns and meanings within participants' responses. Following an extensive literature review, a semi-structured questionnaire has been formulated to allow respondents to narrate their experiences without any restrictions.

This survey was distributed via LinkedIn. 439 respondents have answered the open-ended survey questions. Statements from 168 respondents, who work remotely at private institutions, have been selected to ensure the homogeneity of the sample and focus on the virtual presenteeism dynamics in corporate work settings.

In the survey, 14 demographic questions have been asked to gather data about the age, gender, educational level, sector, department, position, title, seniority, marital status, and number of children. The open-ended survey question about presenteeism has been formulated as:

When you work remotely, do you continue to work if you feel sick or unwell? Does this situation affect you and your job? How does your manager act towards taking sick leave? Could you give some examples?

While this study does not use traditional qualitative methods such as interviews or focus groups, the open-ended questions encouraged participants to share detailed insights in their own words. This approach helped us to reach a broader and more diverse sample while capturing rich, qualitative data. Thematic analysis can still be effective applied to the open-ended survey responses by analyzing them as qualitative textual data. We have identified themes through a systematic coding process, and developed themes that capture recurring patterns in the data (see Table 1). Through thematic analysis, we identified key patterns and find out the common themes related to virtual presenteeism (see Table 2). In order to improve the coding reliability, two researchers worked at different stages of coding. Additionally, researcher reflexivity has been practiced during the study as the researchers are familiar with the context of the research. While personal assumptions and interpretations have been critically examined in order to minimize bias, findings have been cross-checked to ensure the inclusion of diverse narratives, rather than emphasizing certain cases.

Table 2: Examples of Conceptualization and Categorization of Presenteeism Statements.

Participant Quote	Conceptualization	Categorization	Theme
Even when I am too ill to go to work, I continue to work, though my performance tends to be compromised.	Working while sick/not feeling well	Working while sick	Presenteeism
I don't have the luxury of being sick. If I had taken sick leave, they would likely have continued to send me work, assuming I could manage it from bed.	Working while on sick leave		
	The perception that being sick is a luxury		
When we're at home, they don't want us to take sick leave. If we do, they say, "It's up to you, but your salary will be deducted."	The deduction of salary when taking sick leave	Perception of "working from home is equivalent of leave"	
My manager sees working from home as taking time off.	The perception of working from home as being equivalent to taking time off		
Even if you're feeling ill, you're still held accountable for the tasks that need to be completed that day, with the assumption that being at home means you should be able to handle them.	The attitude of "You're at home anyway."		
There is this mindset that you can't be sick when you're working from home.	One cannot be sick while working from home		
I've barely been able to take sick leave, even when I'm feeling unwell. There seems to be a perception that you can't be sick when you're working from home.	One cannot be sick while working from home		
My boss thinks that I do not work enough because I am married and I have a kid. So, I work more and try to prove that I am working. For this reason, I do not take sick leave when I am sick	Perceived bias due to marital or parental status		
Even when I wasn't feeling well, I continued working. They say I can share my condition and request time off, but when I did, I received responses like, "This is a really bad time, we're going through a busy period—would it be possible to take leave later?"	Sick leave not being considered a valid reason for time off	The supervisor's attitude towards sickness and sick leaves	Supervisor Behaviour
He says, "You can take the sick leave, but I am the one who approves the leave."			
As someone who has had COVID, I can truly say I felt like I was on the verge of death. With hospital tests, medical reports, and the sick leave prescribed by my doctor, I still receive no sympathy—no "get well soon" even when I mention it. Even when I was working in the office, no one paid	Lack of empathy or acknowledgement from supervisor		

attention, as if they didn't even notice when I was barely holding on.			
There is this perception that if I get worse, no one will believe me.	Fear of stigma and disbelief		

Findings

Our findings reveal that married female employees with children narrate higher instances of virtual presenteeism since they avoid taking sick leaves in order to prove their dedication to work. Supervisory pressure has been noted as one of the factors that lead to virtual presenteeism. Since remote work has made it challenging for employees to be visible, they perceive the need to continuously signal their commitment to work, which can lead to working while sick. Respondents also note that they feel guilty for attending to family responsibilities while working from home; therefore, they tend to work when they are sick or unwell in an effort to compensate. This finding is also valid for single remote employees.

Consequently, the dual demands of professional work and domestic responsibilities, along with the pressures from the workplace, create emotional and physical challenges for remote employees, often leading to virtual presenteeism. In our sample, married female employees with children have been the ones who have reported severe cases of virtual presenteeism.

Conclusion

This study highlights virtual presenteeism as a negative impact of remote work, since it can lead to burnout, reduced productivity, and health-related risks (Hemp, 2004). Since remote work has become an essential part of work settings (Toscano et al., 2024), organizations should implement new sick leave policies that are compatible with remote work settings to mitigate virtual presenteeism. The main limitation of this research is the generalizability of the results is also limited as the sample of this study is limited to employees who work at private corporations. Future research should further explore how virtual presenteeism differs across industries and what the long-term effects of virtual presenteeism would be.

Navigating the Paradox of Connectivity and Isolation: Impacts on Digital Nomads' Psychological Well-Being

Mahin Farshbaf Maherian[a], Adnan Veysel Ertemel[a]

[a]Istanbul Technical University, Department of Management, Istanbul, Turkey

maherian@itu.edu.tr

Keywords: Digital Nomads, Isolation, Connectivity, Well-Being, Loneliness.

Aim

Digital nomads utilize technology to work remotely while traveling, enjoying freedom and flexibility, but at the cost of potential social isolation. As of 2023, their numbers have grown to millions [1]. This study examines the paradox of connectivity and isolation in the digital nomad lifestyle. While digital nomads rely on constant connectivity for work and relationships, the absence of stable in-person communities presents unique psychological challenges. [2]. There is a clear gap in the literature regarding how digital nomads balance constant connectivity with frequent periods of isolation. This study explores how they perceive and manage these dual demands and the impact of this balance on their psychological well-being [3]. This research examines the strategies employed by digital nomads to maintain social connections, cope with loneliness, and assesses their impact on mental health. It is hypothesized that nomads who effectively balance connectivity and solitude will report higher psychological well-being than those who struggle with this balance [4]. This study aims to illuminate the overlooked interplay between constant connectivity and the isolation inherent in the digital nomad lifestyle. It also examines whether effective connectivity management can act as a protective factor for mental health [5].

Materials and Methods

1. Research Design & Sample

A quantitative survey captured the social and psychological experiences of digital nomads. The study targeted N = 300 self-identified digital nomads, achieving 300 valid responses (100% of the target). Participants were recruited through online communities frequented by digital nomads, including Facebook groups, subreddits, and Nomad List [6]. To ensure a relevant sample, the inclusion criteria required respondents to self-identify as a digital nomad, work remotely as their primary income source, have maintained a location-independent lifestyle for at least six months, be 18 years or older, and be proficient in English [2]. Individuals new to digital nomadism, as well as those who are primarily remote workers, were excluded from the focus on experienced digital nomads. [7]. The final sample comprised a diverse cross-section of digital nomads, representing a range of ages, nationalities, and professions, with a predominant focus on the tech, creative, and freelance sectors, providing a robust basis for examining general patterns.

2. Data Collection

- Data were collected through a structured online questionnaire over a year, covering demographics, work/travel patterns, and standardized scales. Participants provided informed consent and could withdraw anytime; all responses were anonymized. The study utilized the following validated instruments:
- Lubben Social Network Scale (LSNS-6) [8]: A 6-item measure assessing social network size, frequency of contact, and perceived support. Higher scores indicate stronger social networks and lower isolation.
- Revised UCLA Loneliness Scale (R-UCLA) [9]: A 20-item scale measuring subjective loneliness and social isolation, with higher scores reflecting greater loneliness.

- Social Media Use Integration Scale (SMUIS) [10]: A 7-item scale evaluating social media's role in daily social routines and identity. Higher scores indicate greater digital connectivity and integration.
- Warwick-Edinburgh Mental Well-Being Scale (WEMWBS)[11]: A 14-item scale assessing mental well-being, including happiness, relaxation, and optimism. Higher scores denote better psychological well-being.

3. Data Analysis

Responses were analyzed using SPSS. Descriptive statistics characterized the sample and key variables. Internal consistency was assessed, with Cronbach's alpha values of 0.73 (R-UCLA), 0.65 (LSNS-6), 0.97 (SMUIS), and 0.95 (WEMWBS), indicating acceptable to excellent reliability. [9]; [8]; [12]; [11]).

Pearson correlation analyses explored relationships between connectivity, isolation, and well-being. Multiple regression tested the predictive effects of isolation (R-UCLA, LSNS-6) and connectivity (SMUIS) on well-being (WEMWBS), controlling for age, gender, and nomad duration [5].

To test whether digital connectivity buffers the impact of loneliness, a moderation analysis included an interaction term (R-UCLA × SMUIS) in the regression. Statistical significance was set at $p < 0.05$ (two-tailed), with results presented in tables and charts for clarity.

Findings

Digital nomads exhibited notable variability in social connectivity and well-being. Loneliness levels were moderate, with R-UCLA scores near the mid-point, indicating that while not extreme, loneliness remains a concern for many. Social network strength was also moderate, with most participants maintaining contact with 2–4 close friends or family members on a monthly basis, but lacking extensive local networks.

Table 1. R-UCLA Loneliness Scale - Item Statistics.

Item Code	R_UCLA - Item Statistics	
	Mean	Standard Deviation (Std)

Table 2. LSNS6- Lubben Social Network Scale - Item Statistics.

Item Code	LSNS6- Item Statistics	
	Mean	Standard Deviation (Std)
LSNS6_Q1	4.163	0.812
LSNS6_Q2	2.903	1.048
LSNS6_Q3	2.960	1.078
LSNS6_Q4	2.397	0.896
LSNS6_Q5	2.930	1.004
LSNS6_Q6	3.600	0.933

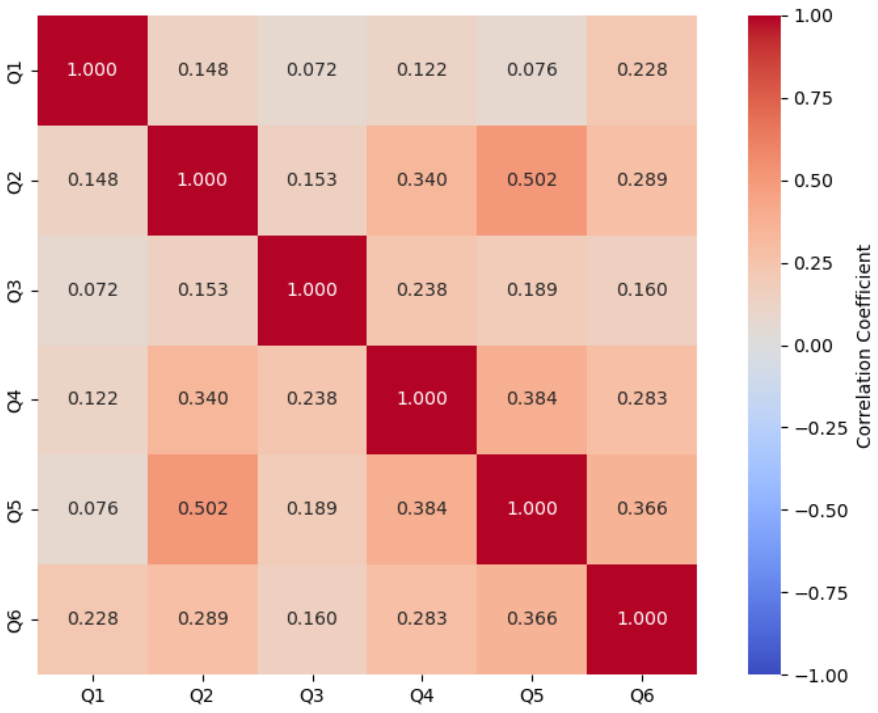

Figure 2. LSNS6- Inter-Item Correlation Matrix.

SMUIS were moderate to high. Most participants used social media daily for social and professional connections, though integration varied—some relied on it heavily, while others used it more sparingly. The average SMUIS score (around 2.0–2.3 on a 5-point scale) indicates a fair but not overwhelming reliance on digital connectivity.

Table 3. SMUIS- Social Media Use Integration Scale - Item Statistics.

Item Code	SMUIS - Item Statistics	
	Mean	**Standard Deviation (Std)**
SMUIS_Q1	1.947	0.840
SMUIS_Q2	2.143	0.852
SMUIS_Q3	1.980	0.858
SMUIS_Q4	2.007	0.985
SMUIS_Q5	2.360	0.987
SMUIS_Q6	1.823	0.841
SMUIS_Q7	2.387	1.043

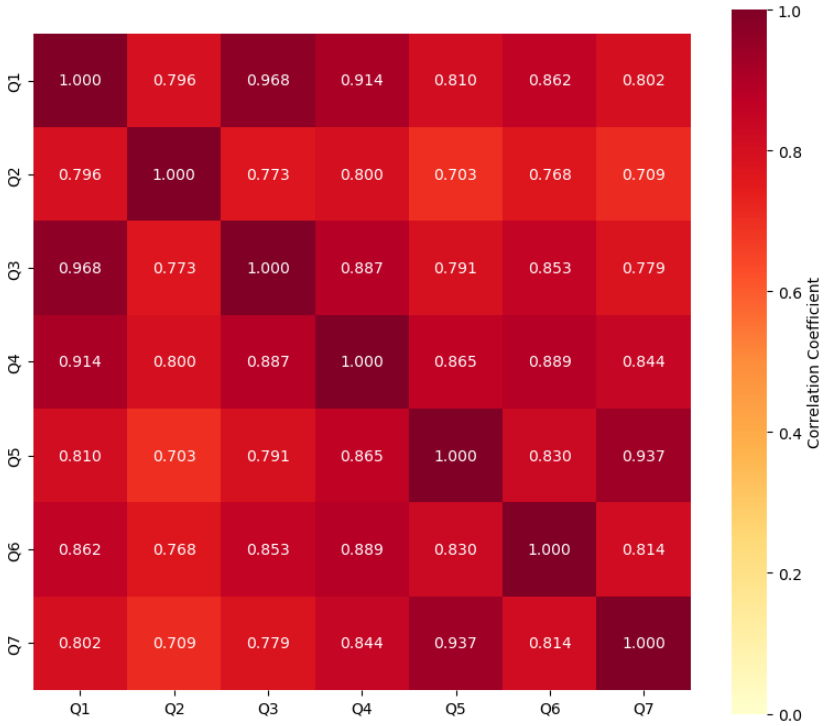

Figure 3. SMUIS- Inter-Item Correlation Matrix.

Mental well-being (WEMWBS) was generally positive, with average scores in the upper half of the scale (around 3.5–4 per item on a 1–5 scale), suggesting that most respondents felt content and mentally healthy despite occasional loneliness. Notably, even participants experiencing loneliness did not always report poor well-being, hinting at personal resilience or effective coping strategies.

Table 4. WEMWBS- Warwick-Edinburgh Mental Wellbeing Scale - Item Statistics.

Item Code	WEMWBS - Item Statistics	
	Mean	Standard Deviation (Std)
WEMWBS_Q1	3.557	0.858
WEMWBS_Q2	3.563	0.861
WEMWBS_Q3	3.167	0.796
WEMWBS_Q4	3.513	0.955
WEMWBS_Q5	3.440	0.814
WEMWBS_Q6	3.587	0.832
WEMWBS_Q7	3.483	0.941
WEMWBS_Q8	3.830	0.908
WEMWBS_Q9	3.420	1.226
WEMWBS_Q10	3.430	1.218
WEMWBS_Q11	4.410	0.886
WEMWBS_Q12	3.310	0.918
WEMWBS_Q13	3.983	0.927
WEMWBS_Q14	3.617	0.860

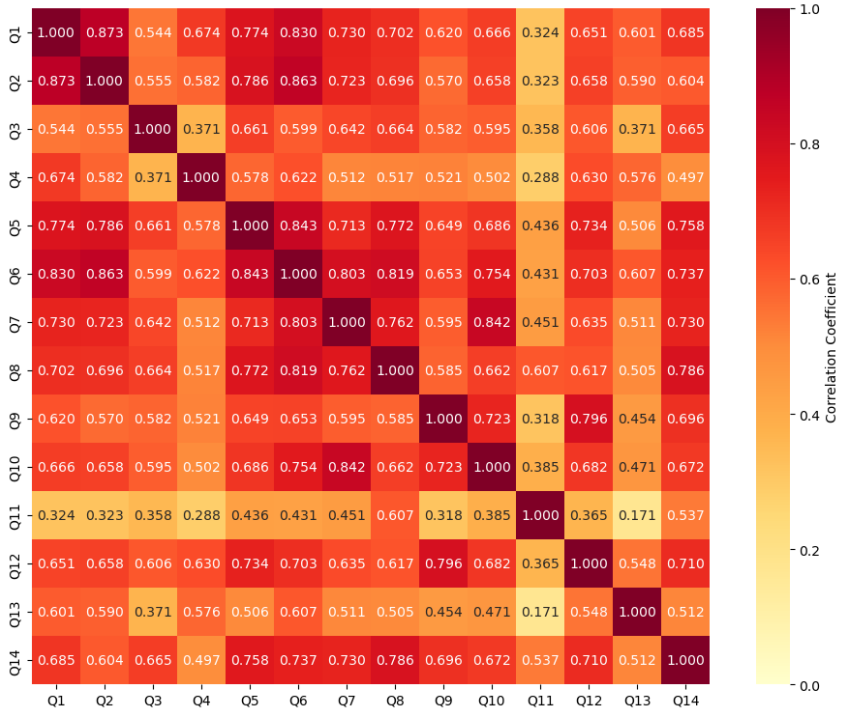

Figure 4. WEMWBS- Inter-Item Correlation Matrix.

All scales demonstrated reliability, with SMUIS (α = 0.97) and WEMWBS (α = 0.95) showing excellent internal consistency. R-UCLA (α = 0.73) and LSNS-6 (α = 0.65) had slightly lower values, likely due to the broader constructs they measure. LSNS-6's lower reliability may reflect the varied social connections of digital nomads, such as strong friendships but weaker family ties or vice versa.

Correlation Analysis: Table 5 presents Pearson correlation coefficients among loneliness (R-UCLA), social network size (LSNS-6), social media integration (SMUIS), and well-being (WEMWBS). Several relationships were statistically significant and aligned with expectations.

Table 5. Correlation Matrix of Key Study Variables (N = 300).

	(R-UCLA)	(LSNS-6)	(SMUIS)	(WEMWBS)
(R-UCLA)	1	-0.50**	-0.18*	-0.56**
(LSNS-6)	-0.50**	1	0.1	+0.45**
(SMUIS)	-0.18	0.1	1	0.12
(WEMWBS)	-0.56**	+0.45**	0.12	1

*p < 0.05, **p < 0.01 (two-tailed tests)

As shown in Table 5, loneliness was strongly negatively correlated with well-being ($r \approx -0.56$, $p < 0.01$), supporting Hypothesis 2. Social network strength (LSNS-6) was positively associated with well-being ($r \approx +0.45$, $p < 0.01$) and negatively related to loneliness ($r \approx -0.50$, $p < 0.01$), highlighting the importance of social connectedness for mental health.

Digital connectivity showed a more nuanced effect. Social media integration (SMUIS) had a slight negative correlation with loneliness ($r \approx -0.18$, $p < 0.05$), suggesting it may slightly reduce loneliness but not eliminate it. However, its correlation with well-being was insignificant ($r \approx +0.12$, p = n.s.), indicating that frequent social media use does not necessarily improve mental health. This suggests that the nature of online engagement—meaningful interactions versus passive browsing—matters more than the frequency of usage. While digital connectivity provided a slight buffer against loneliness, face-to-face connections remained more influential for well-being.

Regression and Moderation Analysis

Regression analysis confirmed that loneliness strongly predicts lower well-being ($p < 0.001$), while stronger social networks correlate with higher well-being ($p < 0.001$). Digital connectivity (SMUIS) showed a weak positive association with well-being but was not a strong standalone predictor.

Moderation analysis revealed that loneliness had a less severe impact on well-being for highly connected digital nomads compared to those with lower digital connectivity ($p < 0.05$). This suggests online engagement can buffer loneliness but not fully replace in-person connections.

Social support remains the strongest predictor of well-being, with digital connectivity providing only partial protection against isolation.

Conclusion

This study reveals that digital nomads navigate a delicate balance between connectivity and isolation, employing structured strategies that enable them to tolerate loneliness as a trade-off for autonomy, while cautioning against excessive and passive social media use, which can undermine their well-being. Although divorced participants showed lower social media engagement, resilience and purposeful digital interaction helped buffer the effects of isolation, partially supporting H1 and H3 and disproving H2's assumption that isolation invariably harms well-being. These findings underscore the importance of intentional digital engagement and highlight the potential benefits of coworking spaces and targeted coping strategies in promoting psychological well-being among digital nomads.

Organizing Through Code: A Bibliometric Review of Algorithms in Organizational Contexts

Hakan Sanrı[a]

[a] University of Glasgow, Adam Smith Business School, United Kingdom
2421355s@student.gla.ac.uk

Keywords: Algorithms, Bibliometric Analysis, Keyword Co-Occurrences, Organizations.

Aim

The integration of algorithms into organizational contexts has transformed the nature of doing business. Going beyond a mathematical computation, algorithms have become not only technological tools but also organizational actors. Algorithms, once being studied almost exclusively from technical perspective, have lately been popular among management researchers. Despite this growing body of literature, there remains a lack of comprehensive studies that unpack the evolutionary trajectory of the field, highlight the research trends – particularly from organizational perspective. Considering these gaps, I ask:

• How has the volume and thematic focus of academic publications on algorithms in organizational contexts evolved over time?
• Which countries, disciplines, and studies have contributed most significantly to this field?
• What are the major themes and trends in the research area?

This study aims to map the evolving landscape of research on algorithms used in organizational contexts. Specifically, I am interested in understanding the main characteristics of the field which grows rapidly. To achieve research objectives, I analysed 282 documents indexed in Scopus database by applying bibliometric analysis techniques. The results show that there has been a massive increase in publication output. Organizational and managerial implications of algorithms are gaining increasing attention within the academic community and more researchers are focusing on or building upon work in that field. The co-occurrence analysis of 168 keywords revealed six thematic clusters. While the number of publications on human-machine interaction and platform capitalism has shown a declining trend over time, interest in impact of algorithms on employee well-being has grown. Identifying thematic structure of the field and understanding how it evolves can offer valuable insights for managers to better align organizational strategies.

Material and Method

I conducted a bibliometric analysis to better understand how algorithm-related studies are organized within the field of organizational studies. To avoid the publications dealing with the technical or mathematical aspects of algorithms and better screen the studies focusing on organizational contexts, the following search string was carefully designed and used to retrieve data from the Scopus database:

TITLE-ABS-KEY ("artificial intelligence in organizations" OR "AI in business" OR "AI in organizations" OR "artificial intelligence in business" OR "algorithmic management" OR "algorithms in the workplace" OR "machine learning in organizations" OR "machine learning in business" OR "predictive analytics in business" OR "algorithmic technologies") AND TITLE-ABS-KEY ("organization*" OR "organizational change" OR "organizational structure" OR "organizational design" OR "organizational decision making" OR "workplace" OR "employee*" OR "digital work" OR "algorithmic work" OR "platform work" OR "gig economy") AND PUBYEAR > 2016 AND PUBYEAR < 2026 AND (LIMIT-TO (SRCTYPE , "j")) AND (LIMIT-TO (DOCTYPE , "ar")) AND (LIMIT-TO (LANGUAGE , "English"))

I limited the source type to journal, document type to article and language to English. The initial search targeting article titles, abstracts and keywords for the period from 2017 to April 2025 returned 291 documents. After a quick screening based on abstract content, 9 documents were excluded from the dataset and 282 records were retrieved for analysis. I used an open-source tool, the VOSviewer software, to visualize bibliometric network and identify the structure and evolution of the field (Van Eck & Waltman, 2010).

Findings

This section is organized as follows. First, I describe the characteristics of my dataset through descriptive bibliometric analysis. Second, I introduce the six clusters emerged from Co-Occurrence Analysis (Keyword Analysis) which reveals thematic structure of the field. I further discuss the research focuses of these clusters, explaining how these research patterns evolved over time.

Descriptive Bibliometric Analysis

There has been a massive increase in publication output in just seven years. From just 2 publications in 2017, the scholarly output grew by an average annual growth rate of approximately 72%, soared to 104 in 2024. Although the vast majority of the published documents come from the field of Social Sciences (almost 80%), studying algorithms in organizational contexts has increasingly received attention within Computer Science subject area as well (13.6%). The leading countries in knowledge production within this field are United States, United Kingdom and Germany. European Commission is the top funding institution for this domain, followed by The National Natural Science Foundation of China and Ministry of Science and Technology of the People's Republic of China. The results show that organizational and managerial implications of algorithms are gaining increasing attention within the academic community and more researchers are focusing on or building upon work in that area (see Figure 1). Table 1 shows the publications with the highest number of citations.

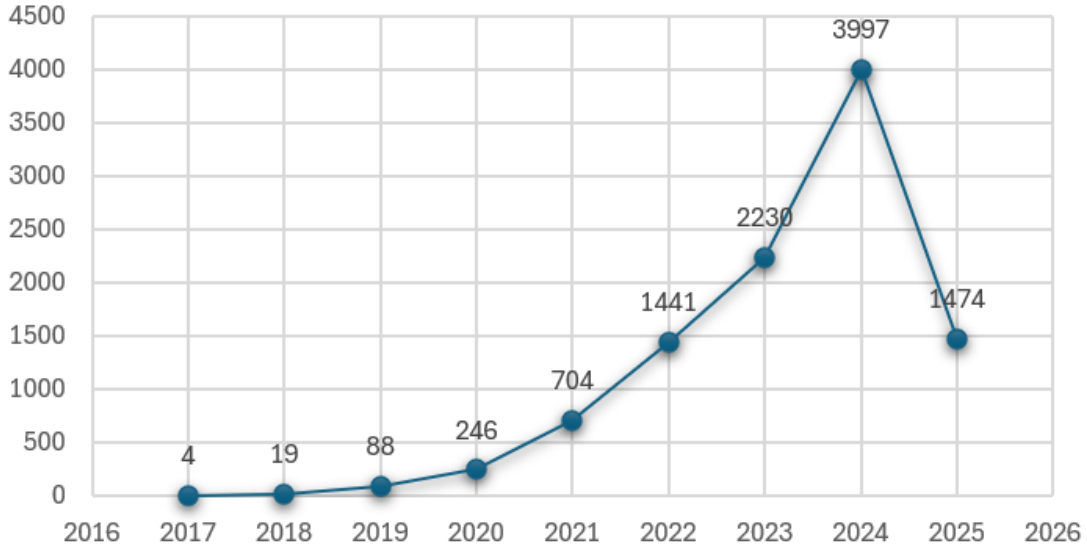

Figure 1. Number of citations.

Table 1. Most cited articles in the field.

Document Title	Author(s)	Publication Year	Journal Title	Total Citations
Good Gig, Bad Gig: Autonomy and Algorithmic Control in the Global Gig Economy	Wood, A.J., Graham, M., Lehdonvirta, V., Hjorth, I.	2019	Work, Employment and Society	1093
Algorithms at work: The new contested terrain of control	Kellogg, K.C., Valentine, M.A., Christin, A.	2020	Academy of Management Annals	1010
Artificial intelligence and management: The automation-augmentation paradox	Raisch, S., Krakowski, S.	2021	Academy of Management Review	808
Platform-Capital's 'App-etite' for Control: A Labour Process Analysis of Food-Delivery Work in Australia	Veen, A., Barratt, T., Goods, C.	2020	Work, Employment and Society	418
Artificial intelligence in business: State of the art and future research agenda	Loureiro, S.M.C., Guerreiro, J., Tussyadiah, I.	2021	Journal of Business Research	306

Co-Occurrence Analysis (Keyword Analysis)

Co-occurrence analysis is one of the widely used techniques to understand the thematic structure of the field. The co-occurrence analysis of 168 keywords revealed six thematic clusters in the domain of algorithms in organizational contexts (see Figure 2). The total link strength of 2310 across 1480 keyword links indicates a rich and well-connected thematic structure in the field.

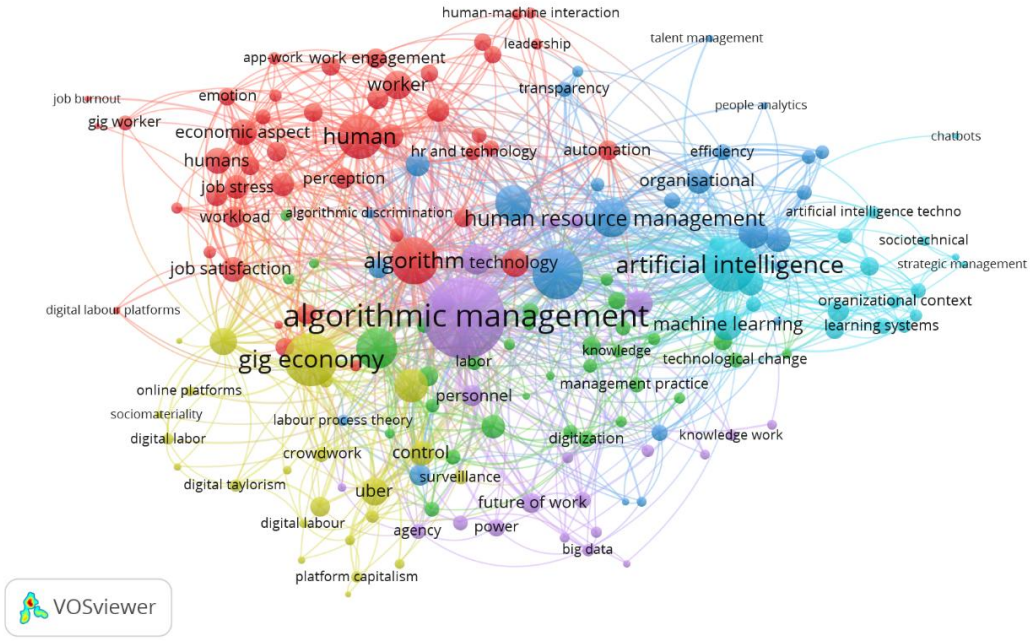

Figure 2. Keyword co-occurrence network map.

Cluster 1 (red cluster) has 46 items. This cluster focuses on how algorithms affect employee well-being. The studies in this cluster prioritize the human element at the algorithmic workplace. Cluster 2 (green cluster) has 32 items and discusses work practices, micro-level dynamics of algorithmic systems at work. Cluster 3 (blue cluster) has 26 items and captures research focused on integration of algorithmic innovations into HR practices. The studies in this cluster also concentrate on algorithmic governance. Cluster 4 (yellow cluster) has 23 items. This cluster explores the employment relationships in gig work. Cluster 5 (purple cluster) seems an emerging cluster with 22 items. This cluster focus on philosophical and future-oriented challenges of algorithmic technologies. The final cluster, Cluster 6 (turquoise cluster) is centered on how organizations integrate AI into their business operations considering their strategic management implications. After interpreting each cluster, I labelled them with a representing research theme (see Table 2).

Table 2. Thematic groups.

Cluster	Theme	Representative Keywords
Cluster 1	The impact of algorithmic technologies on workplace well-being	automation, emotion, gig worker, job burnout, job satisfaction, job stress, platform labour, workload
Cluster 2	Algorithms and changing nature of work	algorithmic control, digital transformation, flexibility, management practice, technology affordances
Cluster 3	Algorithmic human resource management	algorithmic discrimination, algorithmic fairness, management by algorithm, people analytics, performance, workers

Cluster 4	Platform work and digital labour	digital capitalism, digital labour, digital Taylorism, gig work, platform capitalism, platforms, resistance
Cluster 5	Philosophical and future-oriented challenges of algorithmic technologies	agency, AI, future of work, philosophical aspects, sociotechnical systems, technological unemployment
Cluster 6	AI adoption in organizations	adoption, artificial intelligence technologies, deep learning, learning systems, strategic management

Conclusion

This study does not attempt to provide a timeline of algorithms nor present the technical details behind the algorithmic technologies, but it hopes to contribute to our understanding of algorithms in organizational contexts and shed light on future research. To understand the research structure of the field, I conducted a co-occurrence analysis to the dataset including 282 documents. The data shows a massive increase in research output over the years, with a notable surge in the last few years. The deployment of algorithmic innovations and their significant effects on organizations can be considered the reason behind this jump and a turning point for research on algorithms. The findings suggest that the discussions within the field can be categorized into six distinct clusters. While the number of publications on human-machine interaction and platform capitalism has shown a declining trend over time, interest in impact of algorithms on employee well-being has grown. Identifying thematic structure of the field and understanding how it evolves can offer valuable insights for managers to better align organizational strategies.

Supplier Performance Evaluation with Balanced Scorecard

Hanife Özcan[a], Hür Bersam Sidal[a]

[a]Istanbul Technical University, Department of Management, Management, Turkey

ozcanh15@itu.edu.tr

Keywords: Balanced Scorecard, Supplier Performance Evaluation, Supplier Selection, Digital Era İn Textile İndustry, Multi-Criteria Decision Making.

Aim

In today's competitive business world, supply chain management has become a critical factor for businesses to achieve sustainable growth and competitive advantage. In today's world, the textile sector stands out as a sector where the complexity of the supply chain, market conditions and customer expectations change rapidly and constantly, and digitalization in production processes has become important. For this reason, the sector attaches great importance to effective supplier management. The ability of businesses to demonstrate high performance in the sector in which they operate does not only depend on the performance of the business itself. The success of the suppliers with whom businesses work directly impacts their performance. Therefore, special attention should be given to supplier selection in order to gain a competitive advantage, succeed, and maintain sustainable success.

It has become inevitable for supplier selection processes to adapt to this transformation with the spread of Industry 4.0 technologies. By establishing strong relationships with their suppliers, businesses aim to increase their operational efficiency, reduce costs and make the most of the advantages offered by digitalization. In this context, supplier performance evaluation is an important process that supports businesses in achieving their strategic goals.

Material and Method

In this study, an evaluation model that includes the effects of digitalization in the textile sector has been created based on the Balanced Scorecard (BSC) method used for supplier performance evaluation. By translating long term business strategies into short term operational practices, the organization will be able to react and adapt to current and future changes and developments immediately with a balanced scorecard. Including these criteria in a structure allows management to measure performance more comprehensively and over the long term, rather than focusing on immediate goals. The study aims to evaluate supplier performance using the Balanced Scorecard method, which integrates multiple performance dimensions beyond financial metrics. This research provides a broader perspective such as financial, internal processes, customer, learning and development, enabling a comprehensive evaluation of suppliers in the textile sector.

Findings

In order to determine the criteria for the sector in question, a list of possible criteria specific to the textile sector was created with a focus on digitalization, using literature studies. First, the main criteria were determined, and similar studies in the literature were used as a basis for determining these criteria. Quality, price, delivery, service, technological competence and innovation capability were determined as six main criteria. Then, possible performance evaluation criteria were analyzed separately and included under the relevant main criteria, and thus grouped performance criteria were created, as seen in Table 1. The sub-criteria of the quality main criterion are product quality, error-free product quantity, quality standards, and smart and environmentally friendly production processes. Sub-criteria related to the main price criterion are; affordable/competitive price, discount rate, payment terms (term), and strategic partnerships by purchasing shares from suppliers with critical technologies. Delivery-related sub-criteria are on-time delivery, complete delivery, order delivery times and shortening supply chain cycle times. Another selection criterion, technological competence, includes the level of digitalization, automation and

rapid prototyping, machinery and equipment competence. Sub-criteria related to the main service criterion consist of rapid response to processes and flexibility, capacity adequacy, sustainability oriented approach and customer satisfaction levels, respectively. The last main selection criterion, innovation capability, includes the tendency of suppliers to be innovative, the ability to develop new products and personnel training. It was determined and finalized in line with the deep interviews conducted with experts who actively work in the purchasing and product of well-known companies in the textile sector. Then, it is categorized under BSC dimensions. In summary, performance evaluation criteria are indicators that enable the monitoring of the responsibilities expected from suppliers. Furthermore, Multi-Criteria Decision-Making (MCDM) methods have been utilized to analytically determine the importance levels of the identified criteria. This method allows the selection of the most suitable suppliers by determining the weights of the criteria. Determining the criteria weights shows businesses the most important selection criterion in the study and also provides information about the performance of their suppliers. When the business is viewed from this perspective, the balanced scorecard provides a detailed picture of the organization's performance and guides managers in performance management. The model developed in the study provides a comprehensive decision-making strategic management mechanism to improve the supplier selection processes of businesses in the textile sector.

Table 1: Balanced Scorecard and Perspectives.

FINANCIAL	
Main criterion	**Sub-criterion**
Price	Affordable/competitive price
	Discount rate
	Payment terms (term)
	Strategic partnerships by purchasing shares from suppliers with critical technologies
CUSTOMER	
Main criterion	**Sub-criterion**
Quality	Product quality,
	Error-free product quantity,
	Quality standards
	Smart and environmentally friendly production processes
Delivery	On-time delivery
	Complete delivery
	Order delivery times
	Shortening supply chain cycle times

INTERNAL BUSINESS	
Main criterion	**Sub-criterion**
Service	Rapid response to processes and flexibility
	Capacity adequacy
	Sustainability oriented approach
	Customer satisfaction levels
Technological Competence	Level of digitalization
	Automation and rapid prototyping
	Machinery and equipment competence
LEARNING AND GROWTH	
Main criterion	**Sub-criterion**
Innovation Capability	The tendency of suppliers to be innovative
	The ability to develop new products
	Personnel training

Conclusion

The results of the study show that the model developed to measure the impact of digitalization on the supplier selection process contributes to businesses' alignment with their digital transformation strategies. The integration of the Balanced Scorecard and Multi-Criteria Decision-Making methods offers a systematic, multi-dimensional, and digitalization-sensitive approach to supplier performance evaluation. By conducting an example Balanced Scorecard scoring specific to the textile sector, a ready-to-use supplier performance evaluation system has been provided to the industry. It is recommended that businesses that are selecting suppliers consider their supply chain as a whole and regularly evaluate supplier performance, clarify suppliers that are open to improvement in addition to those that will be discontinued, and provide them with the necessary support. According to the findings of the study, it is important for suppliers who currently stay away from Industry 4.0 technologies and do not invest in this area to be aware that they will have difficulties in being preferred in the face of rapidly developing technologies. This will guide them in creating their own strategic plans to reduce production costs, increase production efficiency, and transform supply chain processes. The study contributes to both the academic literature and industry practices by offering a scientific perspective on supply chain management and supplier selection processes in the textile sector from a digitalization standpoint.

Performance Evaluation Model Based on Balanced Scorecard for Industry 4.0 Applications in the Fast Moving Consumer Goods Sector (FMCG)

Ceren Dilbaz[a], Hür Bersam Sidal[a]

[a] Istanbul Technical University, Management Program, Türkiye
dilbaz@itu.edu.tr

Keywords: Balanced Scorecard, Fast-Moving Consumer Goods, Industry 4.0, Performance Evaluation.

Aim

Industry 4.0 technologies offer innovative solutions to optimize production, enhance resource efficiency, and respond quickly to customer demands.The opportunities offered by Industry 4.0, such as digitalization, automation, and data analytics, provide companies with more precise and accurate measurement tools to monitor and manage their performance [1]. Thus, proposing a model to evaluate the performance of Industry 4.0 applications is essential. The implementation of Industry 4.0 applications in the Fast-Moving Consumer Goods (FMCG) sector is essential for enhancing operational efficiency, improving supply chain transparency, and meeting the rapidly evolving consumer demands. Performance evaluation of these technologies, including IoT, big data analytics, and automation, is crucial to assess their impact on productivity, cost reduction, and sustainability, thereby enabling firms to adapt strategically in a highly competitive market [2]. This study proposes a model based on the Balanced Scorecard to help FMCG companies assess Industry 4.0 performance, improve efficiency, and gain a competitive edge.

Material and Method

This study employs the Balanced Scorecard (BSC) model as a foundation for measuring Industry 4.0 performance. BSC consists of four main dimensions: financial, customer, internal processes, and learning and growth [3].The sub-dimensions within these categories were determined through an extensive literature review. Following the completion of the model's design process, a comprehensive survey was conducted to determine the relative importance of the main and sub-dimensions.

Within the scope of this study, data were collected from managers working in various companies in the fast-moving consumer goods (FMCG) sector using a Likert scale-based questionnaire. The survey results were analyzed in detail using the Analytic Hierarchy Process (AHP), a multi-criteria decision-making method. Based on the importance weights derived through AHP, an Industry 4.0 performance evaluation was conducted for a selected company operating in the FMCG sector. To facilitate the company's self-assessment, a survey was administered to managers from different departments. The responses, collected using the Likert scale, were analyzed by evaluating the performance of each unit separately. As a result of this analysis, Industry 4.0 performance scores were calculated both at the unit level and overall, enabling comparisons between the main dimensions and across departments.

Findings

The results of the BSC analysis, conducted based on the AHP method, indicate that the financial dimension is the most critical factor in the evaluation of Industry 4.0 performance. An examination of the sub-criteria within the financial dimension reveals that company-wide total cost holds a weight of 24%, inventory management 12%, and profitability 10%. Within the customer dimension, customer satisfaction was found to have an importance weight of 12%, while customer reliability was assigned a weight of 7%. In the internal processes dimension, product quality accounted for 8%, whereas operational efficiency carried a weight of 2%. Within the learning and growth dimension, qualified workforce was determined to have an importance weight of 5%, while reducing employee turnover was assigned a weight of 1%. The importance weights related to the Balanced Scorecard are presented in Table 1. These findings suggest that financial indicators and customer-oriented criteria are prioritized in the

assessment, whereas factors such as process flexibility and employee engagement are comparatively less significant.

Table 1. Importance Weights of the BSC**.**

Main Criteria	Weight of Main Criteria	Sub-Criteria	Weight of Sub-Criteria	Overall Weight	Percentage %
Financial Dimension	0,49	Company-Wide Total Cost	0,49	0,24	24%
		Inventory Management	0,24	0,12	12%
		Profitability	0,20	0,10	10%
		Sales	0,12	0,06	6%
Customer Dimension	0,28	Customer Satisfaction	0,44	0,12	12%
		Customer Reliability	0,25	0,07	7%
		Response Speed to Customers	0,20	0,06	6%
		Market Share	0,11	0,03	3%
Internal Processes Dimension	0,16	Product Quality	0,48	0,08	8%
		Reduction of Defective Product Rate	0,29	0,05	5%
		Operational Efficiency	0,16	0,02	2%
		Flexibility in Production Processes	0,07	0,01	1%
Learning and Growth Dimension	0,08	Qualified Workforce	0,59	0,05	5%
		Employee Motivation	0,28	0,02	2%
		Reduction in Employee Turnover Rate	0,13	0,01	1%

In AHP analysis, the consistency ratio (CR) is calculated to assess the accuracy and reliability of the decision matrix. According to Saaty, CR should be less than 10%. First, the maximum eigenvalue (λ_max) is used to compute the consistency index (CI) using the Equation 1.

$$CI=(\lambda_{max}-n)/(n-1) \quad \text{(Equation 1)}$$

In the AHP method, λ_max is calculated by multiplying the pairwise comparison matrix with the weight vector, then dividing the resulting values by the corresponding weights and taking their average. It is used for consistency analysis.Then, the consistency ratio is determined using Equation 2, where RI (random index) values are obtained from standard tables.

$$CR=\frac{CI}{RI} \quad \text{(Equation 2)}$$

The values of the random index values for n-dimensional matrices are provided in Table 2. A CR of 10% or below indicates that the decision-making process is consistent and reliable. These calculations help identify and correct inconsistencies in the analysis [4]. As shown in Table 3, the consistency ratios of the sub-criteria under the financial dimension, customer dimension, internal processes dimension, and learning and growth dimension, along with the main criteria, were found to be below 10%. This confirms that all criteria are consistent.

Table 2. Random Index Values.

n	1	2	3	4	5	6	7	8	9	10
RI	0	0	0,58	0,90	1,12	1,24	1,32	1,41	1,45	1,49

Table 3. The λ_max Values, consistency indices, and Consistency Ratio Values of the Criteria.

	Main Criteria	Financial Dimension Sub-Criteria	Customer Dimension Sub-Criteria	Internal Processes Dimension Sub-Criteria	Learning and Growth Dimension Sub-Criteria
λ_max	4,28	4,18	4,15	4,28	3,12
Consistency Index	0,09	0,06	0,05	0,09	0,06
Consistency Ratio	0,10	0,07	0,06	0,10	0,10

In accordance with the importance weights determined using the AHP method, the impact of Industry 4.0 applications on performance was analyzed within the scope of an Industry 4.0 performance evaluation for a company operating in the FMCG sector, specifically focusing on the production, supply chain, and information technology departments. The corresponding impact scores are presented in Table 4.

Table 4. Performance Comparison of Industry 4.0 Applications Across Departments Based on the Balanced Scorecard Main Dimensions.

	Performance Evaluation Score Information Technology Department	Performance Evaluation Score Supply Chain Department	Performance Evaluation Score Production Department
Financial Dimension	1,8	1,89	1,87
Customer Dimension	1,1	1,1	1,3
Internal Processes Dimension	0,6	0,69	0,62
Learning and Growth Dimension	0,2	0,28	0,24
Total Score	3,7	3,96	4,03

In this context, the financial dimension evaluates the contribution of Industry 4.0 applications to the company's economic benefits. The Information Technology Department has shown the lowest performance with a score of 1.8. The Supply Chain Department, with a score of 1.89, holds the leading position, indicating that Industry 4.0 applications have optimized financial processes within the supply chain. The Production Department ranks second with a score of 1.87. The findings suggest that the Supply Chain Department gains the most benefit from Industry 4.0 applications in the financial dimension.

In the customer dimension, the impact of Industry 4.0 applications on customer satisfaction and expectations was evaluated. Both the Information Technology and Supply Chain departments performed equally with a score of 1.1. The Production Department achieved the highest performance in this dimension with a score of 1.3. This result indicates that the Production Department has more effectively integrated customer-focused Industry 4.0 applications.

In the internal processes dimension, the level of digitalization and efficiency of internal operations was considered. The Information Technology Department recorded the lowest performance with a score of 0.6. The Supply Chain Department achieved the highest performance with a score of 0.69, while the Production Department ranked second with a score of 0.62. The leadership of the Supply Chain Department demonstrates that Industry 4.0 applications are more effectively utilized in process management, while the Information Technology Department shows a need for improvement in the digitalization of processes.

In the learning and growth dimension, the impact of Industry 4.0 applications on knowledge sharing, employee development, and organizational learning was analyzed. The Information Technology Department scored the lowest with 0.2, while the Supply Chain Department achieved the highest performance with 0.28. The Production Department ranked second with a score of 0.24. Overall, low scores were observed across all departments in this dimension, indicating that Industry 4.0 applications have not been sufficiently integrated into learning and development processes.

Based on the analysis and calculations conducted for all departments, the company's overall Industry 4.0 performance score was determined to be 3.93 out of 5.

Conclusion

It has been demonstrated through existing research that traditional performance measurement criteria, which rely solely on financial indicators, are insufficient in today's competitive environment. In this context, this study, which specifically focuses on the fast-moving consumer goods sector, aims to comprehensively analyze the effects of Industry 4.0 applications in line with the sector's unique dynamics.

In this study, the Balanced Scorecard method, which includes both financial and non-financial elements, was adopted as a holistic performance evaluation model. The analyses conducted based on the importance weights determined by the AHP method reveal that the effects of Industry 4.0 applications on performance vary across departments, with the supply chain and production departments benefiting more from this transformation process. Notably, the optimization of financial processes stands out as one of the most tangible gains of digital transformation, while organizational learning and development processes have not fully benefited from this transformation.

To monitor the long-term impact of Industry 4.0 and maintain a sustainable competitive edge, companies should repeat the evaluation regularly (e.g., annually or semi-annually). Involving multiple departments in the process can offer a broader perspective, aiding strategic decisions. Prioritizing the learning and growth dimension is crucial for securing long-term competitiveness.

[a] Istanbul Technical University, Management Engineering, Management Engineering (Dr), Turkey
ataker22@itu.edu.tr

Keywords: ESG (Environmental, Social, Governance) Scores, Financial Performance, Long-Term Stock Returns, Borsa Istanbul.

Aim

This research explores how Environmental, Social, and Governance (ESG) ratings affect the financial success of companies listed on Borsa Istanbul. The main goal is to figure out if firms with better ESG scores typically do better than the overall market, as shown by the BIST-100 index, over different time periods—like 1 month, 3 months, 6 months, and 1 year. The study also breaks down how much each part of ESG—the Environmental (E), Social (S), and Governance (G) aspects—contributes on its own, as well as how any ESG-related controversies might affect a company's performance. By looking at an emerging market like Turkey, the research aims to gather real-world evidence on the financial impact of ESG practices in a setting where rules and investor understanding of sustainability are still developing.

This research really hits the mark, especially with the world increasingly focusing on sustainable investing and demanding more openness in how companies are run. As everyone from investors to regulators puts more stock in sustainability, figuring out how environmental, social, and governance (ESG) factors impact a company's bottom line is becoming super important. This study adds to what we already know by shedding light on how ESG practices affect a company's performance in a developing market, where the way ESG is adopted might be quite different from what we see in more established economies.

Material and Method

This research uses Refinitiv's ESG ratings for companies listed on Borsa Istanbul in 2022 and 2023. It measures these firms' financial success by looking at their stock returns over various periods, using methods like Ordinary Least Squares (OLS) regression and panel data analysis. The main factors considered are the overall ESG score and its individual parts (Environmental, Social, and Governance), with the firms' stock returns, compared to the BIST-100 index, as the outcome of interest. The study also considers ESG controversy scores to see how they affect stock performance. It examines three main models: (1) the combined ESG score against financial performance, (2) the individual ESG parts against financial performance, and (3) the detailed sub-components of ESG against financial performance. This approach, driven by data, keeps the impact of company size and transparency to a minimum, offering a strong and reliable examination of how ESG scores connect to financial results.

Findings

The study's findings show that companies with better ESG scores tend to do better financially, beating out their competitors. It turns out that the Social (S) part of ESG has the biggest influence on how well a company does, followed by the Environmental (E) and then the Governance (G) parts. This implies that things like how a company treats its employees, its stance on human rights, and how responsibly it makes its products are really important for its financial success. On the flip side, when companies get caught up in ESG-related controversies, it hurts their stock prices, emphasizing how crucial it is for businesses to be open and ethical in how they operate.

Interestingly, while ESG factors significantly influence individual firm returns, no significant relationship is found between ESG scores and the performance of the BIST-100 index. This indicates that ESG effects are firm-specific rather than market-wide, meaning that companies with strong ESG practices may outperform their peers but do

not necessarily drive broader market trends. These findings align with global research, which has consistently shown that ESG integration can lead to improved financial performance, particularly in terms of risk management and long-term value creation.

Conclusion

The study concludes that ESG ratings play a crucial role in enhancing firm financial performance, particularly in emerging markets like Turkey. Firms with higher ESG scores tend to achieve better stock returns, with the Social component being the most influential driver of financial success. The findings support several theoretical frameworks, including Stakeholder Theory, Resource-Based View, Legitimacy Theory, and Signaling Theory, by demonstrating that ESG practices contribute to long-term value creation, risk mitigation, and investor confidence.
For investors, ESG scores can serve as reliable indicators of financial stability and long-term value creation. The study suggests that investors should consider firm-specific ESG practices rather than relying solely on overall market trends when making investment decisions. Companies with strong social performance, in particular, may offer better risk-adjusted returns, making social factors a key focus for sustainable investment strategies.
For firms, integrating ESG considerations into corporate strategies is essential for improving financial performance and managing reputational risks. The study highlights the importance of addressing ESG controversies, as they can have a significant negative impact on stock performance. Firms should also adopt sector-specific ESG strategies, as different industries respond uniquely to ESG drivers.
For policymakers, the study provides evidence to support the development of stronger ESG disclosure regulations and incentives for sustainable business practices. Regulatory bodies should consider implementing measures such as tax benefits, grants, or preferential access to capital markets to encourage ESG adoption. Additionally, promoting ESG-focused financial instruments, such as green bonds and sustainability-linked loans, could further support sustainable business practices in emerging markets.
Despite its contributions, the study acknowledges several limitations. The research relies on ESG scores from Refinitiv, which may not fully capture all aspects of a firm's sustainability efforts. Future studies could incorporate alternative ESG ratings and proprietary sustainability metrics to provide a more comprehensive analysis. The study's time horizon is also limited to 2022 and 2023, which restricts the ability to assess long-term financial impacts. Expanding the timeframe could provide deeper insights into ESG trends and performance over multiple economic cycles.
Furthermore, while the study identifies correlations between ESG scores and financial performance, it does not establish a definitive causal link. Future research could employ causal inference techniques, such as difference-in-differences (DiD) or instrumental variable (IV) approaches, to strengthen causal claims. Additionally, a more detailed industry-level analysis could provide more granular insights into how ESG factors influence firm performance across different sectors.
In conclusion, this research underscores the growing importance of ESG factors in financial performance, particularly in emerging markets like Borsa Istanbul. The findings provide meaningful insights for investors, corporate managers, and policymakers, encouraging the integration of ESG principles into investment strategies and corporate decision-making. Future research can build on these insights by incorporating longer-term data, alternative ESG rating methodologies, and more sophisticated econometric models to further refine our understanding of the ESG-financial performance nexus.

TEFAS's Effect on the Turkish Mutual Funds Landscape

Mehmet Sami Boz[a]

[a] Bogazici University, Economics, Turkey
sami.boz@bogazici.edu.tr

Keywords: Fund Competition , Mutual Funds , TEFAS.

Aim

This study rigorously examines the impact of the Turkey Electronic Fund Trading Platform (TEFAS) on the Turkish mutual fund market. Introduced in January 2015, TEFAS aimed to enhance market transparency, accessibility, and competition by allowing investors to access a wide array of mutual funds through a single platform. This research focuses on dissecting the multifaceted effects of TEFAS on competition dynamics, fee structures, and performance characteristics within the Turkish mutual fund landscape. Specifically, the research aims to:

1. **Assess the impact of TEFAS on competition within the Turkish mutual fund market:** This involves evaluating whether TEFAS has led to increased competitive pressures, as evidenced by changes in market concentration, fund entry/exit rates, and shifts in market share among different fund management companies.
2. **Determine whether TEFAS has influenced fee structures:** This includes analyzing whether TEFAS has resulted in a reduction in average fees, a convergence of fees across similar fund categories, and changes in the distribution of fee levels.
3. **Investigate the relationship between fees and performance:** This explores whether the introduction of TEFAS has altered the relationship between fund fees and performance, particularly in the context of existing literature suggesting that lower-performing funds often charge higher fees. The research seeks to determine whether TEFAS has mitigated this phenomenon by increasing investor awareness and price sensitivity.
4. **Analyze the role of regulatory interventions in shaping market dynamics:** This acknowledges that the effects of TEFAS are intertwined with other regulatory changes and interventions by the Capital Market Board of Turkey (SPK). The research aims to disentangle the specific impact of TEFAS from these concurrent regulatory influences.
5. **Provide insights into investor outcomes:** Ultimately, the study aims to understand how the changes brought about by TEFAS have affected investor welfare, including access to diverse investment options, cost efficiency, and overall portfolio performance.

Material and Method

This study employs a quantitative research design, utilizing a comprehensive dataset of Turkish mutual fund data spanning from January 2005 to June 2020. The data was meticulously sourced and cleaned to ensure accuracy and reliability. The dataset includes; daily fund prices, assets under management (AUM), fund fees (Expense Ratios), fund names and categories, company affiliations, and benchmarks.
The analysis period is primarily focused on January 2011 to January 2019 to create a balanced pre- and post-TEFAS implementation dataset. Funds with less than one year of total duration were excluded to ensure data quality. The final dataset for regression analysis comprises 465 funds.
The research is structured into three primary analytical components:

1. **Descriptive Analysis:**
    - **Fund Entry and Exit Trends:** Analyzing the number of new fund entrants and exits over time, particularly around the TEFAS introduction date, to assess its impact on market dynamism.

- **Market Share Evolution:** Tracking the market share of different fund categories and fund management companies to understand changes in competitive positioning.
- **Concentration Measures:** Calculating the Herfindahl-Hirschman Index (HHI) to assess market concentration and identify potential shifts in competitive intensity.

2. **Fee Versus Performance Analysis:**
   - **Performance Evaluation:** Calculating Jensen's alpha using the Capital Asset Pricing Model (CAPM) to evaluate fund performance relative to appropriate benchmarks for each category. The alpha is regressed upon the fee level of the fund.
   - **Regression Analysis:** Conducting regressions to examine the relationship between alpha and fund fees, controlling for other factors such as fund size and market share. Assessing the statistical significance of the relationship between fees and performance and comparing the pre- and post-TEFAS periods.
3. **Competition Analysis:**
   - **Panel Data Regressions:** Employing panel data regressions to assess the competitive effects of TEFAS on fee structures, using fund fees as the dependent variable and a treatment dummy for the post-TEFAS period.
   - **Control Variables:** Including control variables such as fund performance (alpha), company size (categorized using k-means clustering on AUM), and market share to account for other factors that may influence fee levels.
   - **Fixed Effects:** Incorporating fixed effects for years to control for time-invariant unobserved heterogeneity and isolate the impact of TEFAS.
   - **Robust Standard Errors:** Clustering standard errors at the fund level to address potential serial correlation within funds.
   - **Herfindahl-Hirschman Index (HHI):** Including HHI as a control variable in the regressions to account for the influence of market concentration on fee structures.

Findings

The analysis yielded several key findings:

1. **Increased Market Access and Competition:** The introduction of TEFAS was followed by a significant increase in the number of new mutual fund entrants, suggesting that the platform has lowered barriers to entry and promoted market dynamism.
2. **Categorization Changes:** Significant shifts were observed in the distribution of funds across categories, particularly in variable and equity funds, reflecting the impact of regulatory changes and evolving investor preferences.
3. **Market Share Dynamics:** The market share analysis revealed trends of increasing dominance in specific categories, such as equity funds, post-TEFAS implementation. However, smaller categories like commodity and eurobond funds remained relatively stable. The slight increase in market concentration, as measured by the Herfindahl-Hirschman Index (HHI) we found.
4. **Mixed Signals on Fee and Performance Relationships:** We get mixed signals about fee and performance links. Also, no significant result between fee and performance can be seen in pre and post-treatment periods. The equity fund category exhibited a positive and significant relationship between alpha and fees. Variable funds showed a predominantly negative relationship. Money market funds also showed positive relationships.
5. **Fee Convergence and Variance Reduction:** Introducing TEFAS has led to decreased general fees for funds in each category, with the most substantial declines observed in the money market and eurobond funds, suggesting increased competitive pressure. The regression analysis for variance in fee levels across different mutual fund categories yields insightful results regarding the competitive dynamics following the introduction of the TEFAS platform. Specifically that introducing TEFAS has led to a decrease in fee variance in equity, variable, money market, and bond funds. Increased fee variance in private sector bond,

commodity, and eurobond funds. Also we find that higher market concentration generally led to lower fee variance, indicating more standardized fee structures in concentrated markets.

6. **Heterogeneous Effects Across Categories:** The impact of TEFAS varied across different fund categories, with some categories experiencing more pronounced changes in fee structures and market concentration than others.

Table 1. Regression with Mean Fee as Dependent Variable.

	Equity	Variable	Money Market	Bond	Private Sector Bond	Commodity	Eurobond
Treatment	-0.009***	-0.009***	-0.019***	-0.009***	-0.008	-0.008***	-0.015***
Company Size	0.001	0.006	0.003	0.018***	-0.002	0.018	0.003
Market Share	0.039***	-0.083***	0.003	0.004	-0.001	-0.004	0.001
Alpha	1.200***	0.916***	-0.001	-2.050*	-0.947	-1.395***	-2.582

Notes:
*p<0.1; **p<0.05; ***p<0.01.
Fixed year effects are used. Standard errors were clustered at the fund level to ensure robustness.

Conclusion

This study concludes that the introduction of TEFAS has had a significant and multifaceted impact on the Turkish mutual fund market. The platform has facilitated market access, increased competition, and promoted fee convergence in major fund categories. While the evidence on fee and performance relationships remains mixed. The findings are not fully consistent with international literature, suggesting that there may be unique factors at play in the Turkish market. The varying effects across different fund categories underscore the importance of considering specific market segments in regulatory and competitive analyses. Overall, these results highlight the complexity of market dynamics and the importance of considering specific category characteristics in regulatory and competitive analyses.

Furthermore, while TEFAS appears to have achieved its aim of increasing competition and accessibility, the increase in market concentration warrants further monitoring to ensure a balanced and competitive market environment. Regulators should consider targeted interventions to promote competition in specific fund categories and address potential distortions in the fee-performance relationship. Further research could explore the long-term effects of TEFAS, the impact of specific regulatory interventions, and the dynamics of investor behavior in the Turkish mutual fund market.

Quantitative Methods

Adoption of Smart Small Home Appliances: An Analysis of Social and Behavioral Factors

Betül İmamoğlu[a], Huriye Şebnem Burnaz

[a] Istanbul Technical University/Departmant of Management, Management Engineering Program, Turkey
imamoglub19@itu.edu.tr

Keywords: Smart Home Appliances, Technology Adoption, Consumer Behavior.

Aim

This study aims to develop a conceptual model that explains how consumers in Turkey adopt and interact with smart small home appliances, especially those featuring mobile-based remote control functionalities. Unlike Western markets, where fully integrated smart home systems are more common, Turkish consumers often use isolated smart products—such as connected washing machines or robot vacuums—without broader platform adoption.
This behavioral pattern suggests that traditional technology adoption models focusing on economic or technical rationality may be insufficient to explain usage in this context. Therefore, this study emphasizes perceptual, behavioral, and contextual dimensions of adoption, aiming to create an integrated framework that includes both technological and personal drivers. The model is developed through a combination of literature review and expert insights, and is designed to be empirically tested in a forthcoming quantitative phase.

Material and Method

This research uses a two-step mixed methods design. The first step stands on a qualitative study to understand the topic in depth. The second step incorporates a survey-based quantitative study that will based on qualitative insights along with literature survey.

Phase 1 – Qualitative Study

Semi-structured interviews were conducted with three professionals from a multinational white goods and small appliance company operating in Turkey:

A Website Marketing Executive, A Website Marketing Specialist, A Brand Marketing Manager.

Phase 2 – Planned Quantitative Study

Based on the first phase, a survey has been created to measure the eight variables using a 7-point Likert scale. The survey will also collect demographic data and past usage behavior. The goal is to reach smart appliance users and potential adopters from different regions and age groups in Turkey.

Findings

The qualitative phase yielded valuable insights from three expert interviews (60–90 minutes each) with professionals in website marketing, digital strategy, and brand management. Their observations illuminated why many Turkish consumers fail to adopt smart appliance features—despite owning compatible devices. The findings point to a complex mix of perception gaps, habitual behavior, and communication barriers.

Eight major themes emerged from the data:
1. Limited Perceived Usefulness:

Users often misunderstand smart features. As the Website Marketing Executive stated:

"They assume if there's remote diagnostics, the machine is going to break. But 'start laundry from work' gets a positive response."
Usefulness must be framed within relatable, daily contexts (Davis, 1989; Li et al., 2023).

2. Habitual Use Resists Change:

"People go back to manual mode—they trust what they grew up with."
Even when aware, users often default to old routines (Li et al., 2021).

3. Low Ease of Use from Technical Barriers:

"If Wi-Fi drops, users don't know how to reconnect. Installers don't help."
Lack of support reduces usability (Basarir-Ozel et al., 2023).

4. Lack of Visibility and Social Proof:

"If influencers don't show the smart feature, no one does."
Low visibility weakens adoption (Moore & Benbasat, 1991; Ferreira et al., 2023).

5. Misunderstood Value:

"Less foam means not clean to them. So detergent-saving sounds bad."
Users apply outdated heuristics to judge performance (Schwartz, 1992; Li et al., 2023).

6. Segmented Innovativeness:

"Urban professionals are open. In smaller cities, people fear data sharing."
Adoption varies by region and lifestyle (Li et al., 2023; Li et al., 2021).

7. Lack of Trust:

"They ask, 'Who has access to my dishwasher?'"
Data security concerns create psychological resistance (Li et al., 2023).

8. Low Trialability:

"If they could try it in the store even once, it would help."
Hands-on experience reduces uncertainty (Moore & Benbasat, 1991).

Together, these findings show that ownership does not equal adoption. While consumers may purchase smart appliances, a wide array of behavioral, perceptual, and contextual barriers prevent them from using key features—especially remote-control capabilities. These barriers mirror the constructs outlined in the proposed model and will serve as the empirical basis for the quantitative phase.

Conclusion

This research introduces a model to help understand why Turkish consumers accept or resist using smart small home appliances. The model brings together ideas from well-known theories and adapts them based on real feedback from professionals in the field. So far, the findings are based only on interviews. The next step will

involve testing the model with a broader group of users through a national survey. Once this step is completed, we hope to provide clear insights into the factors that shape technology acceptance. Until then, the model and findings should be treated as exploratory. No policy or marketing recommendations are offered at this stage.

Understanding Consumer Acceptance and Purchase Intentions in Unmanned Retail Stores

Gözde Erdoğan[a]

[a] Istanbul Technical University, Faculty of Management, Engineering Management Master of Science Program, Türkiye
gencg23@itu.edu.tr

Keywords: Consumer Acceptance, Shopping Intentions, Technology Paradoxes, Technology Readiness, Unmanned Stores.

Aim

This study aims to thoroughly explore consumer shopping intentions in unmanned retail stores. Unmanned stores provide an innovative shopping experience that operates without human intervention through the integration of automated systems, offering the potential to reduce labor costs in the retail sector. (Figure 1.). The objective of the research is to determine how technological innovations are accepted, alongside the perceived benefits and ease of use by users, and how these factors influence shopping behavior. Specifically, the relationship between the level of technological readiness and shopping intentions will be examined. Additionally, by investigating the effects of users' perceptions of enjoyment on shopping intentions, strategies aimed at increasing customer satisfaction in unmanned stores will be developed.

Figure 1. Unmanned Store.

Material and Method

The study began with a comprehensive literature review examining factors that influence consumer behavior in unmanned retail stores, drawing from academic publications across various disciplines. In this study, survey-based data collection methods reported in the literature were taken as the basis. Surveys were used as the primary data collection tool in the reviewed studies; however, no original survey was conducted within the scope of this research. According to the reviewed literature, the survey participants were individuals from diverse demographic backgrounds who had experience shopping in unmanned retail stores.

In the relevant literature, variables such as shopping intentions, perceived ease of use, perceived benefit, perceived enjoyment, and levels of technological readiness were commonly measured using 5-point and 7-point Likert scales. This study compiled and comparatively analyzed the findings from these sources.

The data obtained from the literature were interpreted to better understand the relationships between variables, particularly by referencing studies that employed structural equation modeling (SEM). Additionally, findings from studies that included hypothesis testing were examined to identify and interpret the relationships among the variables.

The Technology Acceptance Model (TAM), a widely recognized model, has been extensively employed in the literature. The Technology Acceptance Model (TAM) examines consumers' intentions to use technology, discussing perceived ease of use and perceived benefit to understand shopping intentions.
The main components in the survey can be defined as follows:

Perceived Ease of Use: The level of difficulty and obstacles users encounter during the shopping process in unmanned stores.

Perceived Benefit: The advantages of shopping in unmanned stores, such as time savings and shopping convenience.

Perceived Enjoyment: The pleasure and satisfaction experienced by customers while shopping in an unmanned store.

Shopping Intentions: Factors determining consumers' desire and motivation to shop in unmanned stores.
Technological Readiness: Consumers' abilities to adapt to new technologies and their perceptions towards these technologies, divided into four categories: (Figure 2.)

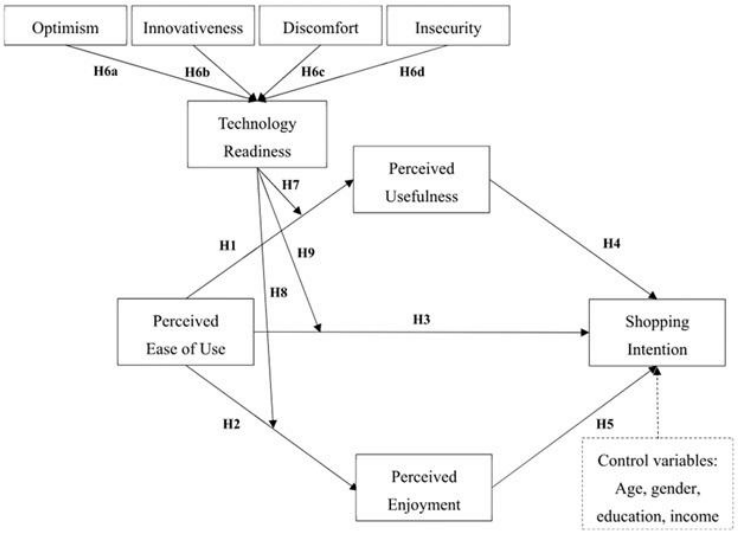

Figure 2. Factors that affect and are affected by technology readiness (Chang, Y-W. and Chen J. 2021).

- Optimism: Belief in the control, flexibility, and efficiency offered by technology.
- Innovativeness: Tendency to be a pioneer in technology.
- Discomfort: Negative feelings arising from a lack of control over technology.
- Insecurity: Distrust in technology and concerns about potential harm.

Paradoxes of Technology: A technology paradox occurs when the very innovations designed to enhance efficiency, control, or privacy simultaneously introduce challenges such as inefficiencies, chaos, or public exposure, leading to a conflicted user experience. (Figure 3.)

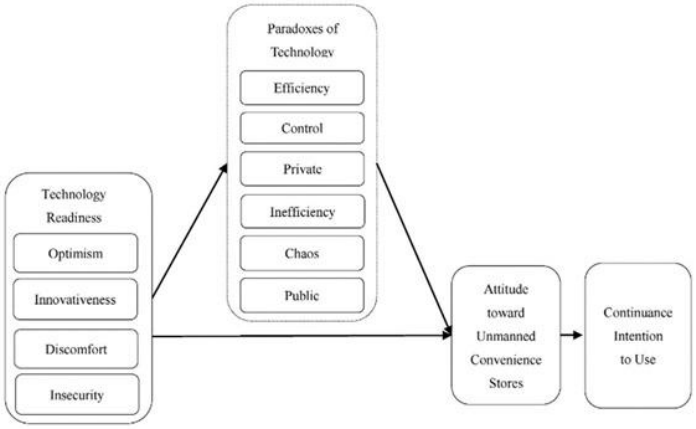

Figure 3. Factors that affect and are affected by paradoxes of technology (Park, H J. and Zhang Y. 2022).

Efficiency/Inefficiency Paradox: While technology can speed up the shopping process and save time, errors or limited human assistance may lead to inefficiencies. Users may feel frustrated due to negative experiences despite the benefits of efficiency.

Control/Chaos Paradox: Technologies like self-service checkouts offer users greater control during shopping. However, situations such as crowds and long waits can create chaos, leading to confusion even when users believe they are in control.

Private/Public Paradox: Technology can cater to users' private needs, yet some may develop negative attitudes towards it due to concerns over miscommunication and confusion during shopping. This paradox creates a conflict between the unique benefits of innovation and the overall user experience.

The analysis of collected data was conducted in detail to test hypotheses and derive conclusions. Structural equation modeling was used to determine the relationships between variables, examining the impact of the level of technological readiness and the dynamics between other components.

Findings

The research results show that perceived ease of use has a significantly positive effect on perceived benefit and perceived enjoyment. This indicates that the use of unmanned stores is an important factor in enhancing consumer experience. Additionally, technological readiness was found to positively influence the relationships between perceived ease of use and shopping intentions. These findings highlight the elements needed to make consumers' experiences in unmanned stores more positive. It was determined that perceived enjoyment increases consumers' desire to shop and plays an important role in shopping intentions.

Furthermore, it was identified that among control variables, only education level had a significant effect on shopping intentions, while other demographic factors were not influential. It was observed that individuals with higher education levels are more open to new technologies and interact more comfortably in unmanned stores. This demonstrates the important role of education level in the acceptance of technological innovations.

The study also highlighted the effects of technological readiness factors (optimism, innovativeness, discomfort, and insecurity). Optimism and innovativeness positively affected consumers' perceived benefit and ease of use. In contrast, negative factors such as discomfort and insecurity have the potential to diminish these positive relationships. Users with low technological readiness experience more anxiety in their interactions with unmanned stores, leading to a negative attitude toward technology use.

In this context, it was determined that the elements of technological readiness play a crucial role in influencing consumer behavior. Reducing concerns related to the acceptance of technological innovations can help consumers have a more positive shopping experience in unmanned stores. Specifically, fostering a positive perception of technology has the potential to strengthen consumers' shopping intentions.

Moreover, other factors affecting user experiences in unmanned stores should also be considered. For instance, factors such as store atmosphere, product variety, and customer service can directly impact consumer satisfaction

and shopping intentions. In this context, it is important for retailers to pay attention to these elements and develop strategies to enhance the shopping experience.

The Efficiency/Inefficiency Paradox highlights how technology can save time in shopping but also create issues like errors and limited human assistance, leading to frustration despite its efficiency. The Control/Chaos Paradox shows that while technologies like self-service checkouts give users more control, factors like crowds and long waits can cause chaos and confusion. Lastly, the Private/Public Paradox illustrates that while technology caters to private needs, concerns over miscommunication can lead to negative attitudes, creating a conflict between the benefits and the overall experience. Retailers need to address these tensions to improve acceptance and satisfaction in unmanned stores.

In conclusion, it was determined that consumers' perceived privacy protection, efficiency, and trust perceptions vary, with individuals open to high technology having a more positive experience. Conversely, those with low technological readiness had more negative experiences, adversely affecting the use of technology.

Table 1. Literature Review.

No	Journal Title	Year	Article Title	Authors	Abstract
1	Journal of Retailing and Consumer Services	2025	Consumer preferences for unmanned stores: A choice experiment study	Yasser Moustafa Shehawy, Syed Md Faisal Ali Khan, Nasser Ali M Khalufi, Riyaz Sheikh Abdullah	The study examines factors affecting shopping intentions in AI-powered automated stores, identifying positive effects of innovativeness and optimism and negative effects of insecurity. Perceived ease of use, benefit, enjoyment, personalization, and interaction are significant determinants of shopping intentions.
2	Journal of Retailing and Consumer Services	2025	Consumer preferences for unmanned stores: A choice experiment study	Youngwon Nam, Sihyun Lee, Hoyoung Lee,	The study examines consumer preferences for unmanned stores and reveals that both technological and store-related features influence consumer choices. It was found that as advanced technology levels increase, consumer preferences decrease, and payment technologies differ from other features.
3	Journal of Retailing and Consumer Services	2022	Technology readiness and technology paradox of unmanned convenience store users	Hyun Jung Park, Yining Zhang	Technological readiness does not directly affect the use of unmanned stores. Instead, it is affected through technology paradoxes. Users open to high technology experience greater paradoxical satisfaction, while those with lower technological readiness exhibit more negative attitudes, influencing the intention for continuous use of the technology.

4	Journal of Retailing and Consumer Services	2021	What motivates customers to shop in smart shops? The impacts of smart technology and technology readiness	Yu-Wei Chang, Jiahe Chen	The study examines the motivations influencing consumer shopping intentions in smart stores, particularly evaluating the role of technological readiness in this process. The results indicate that perceived ease of use affects shopping intentions and that technological readiness strengthens this effect.
5	Journal of Retailing and Consumer Services	2020	Shopping intention at AI-powered automated retail stores (AIPARS)	Rajasshrie Pillai, Brijesh Sivathanu, Yogesh K. Dwivedi	Using the Technology Acceptance Model, the study examined factors influencing the adoption of robot-assisted retail services and identified perceived benefit as a significant mediator in customer acceptance. Education and socio-cultural norms affect customers' attitudes toward and adoption of robots.

Conclusion

The research contributes to the literature by identifying key factors affecting consumer acceptance of unmanned stores. Notably, the positive effects of perceived ease of use and benefits on shopping intentions highlight the importance of adopting these technologies in the retail sector. For effective deployment of unmanned stores, consumer perceptions of security, privacy, and ease of use are crucial.

Retailers can accelerate the adoption of this new shopping experience by enhancing technology preparedness and developing strategies. Future research should delve deeper into cultural and demographic factors and contribute to the literature.

While technological innovations have the potential to enhance customer satisfaction and workforce efficiency, necessary measures for acceptance are discussed in the literature. The experience in unmanned stores can reshape socioeconomic structures and employment dynamics. Therefore, the societal impacts of these systems should be emphasized in the literature.

Moreover, the efficiency/inefficiency paradox arises as technology can significantly speed up the shopping process and save time; however, errors or limited human assistance may lead to inefficiencies. Users may feel frustrated due to negative experiences despite the efficiency benefits these innovations promise. Similarly, the control/chaos paradox is evident in technologies like self-service checkouts, which offer greater control to users during shopping. Nevertheless, situations such as crowded stores and long wait times can lead to chaos and confusion, ultimately detracting from the shopping experience even when users believe they are in control.

Furthermore, the private/public paradox is noteworthy in that technology can cater to users' private needs effectively, yet some may develop negative attitudes towards it due to concerns over miscommunication and confusion during the shopping process. This paradox creates a conflict between the unique benefits of innovation and the overall user experience, impacting consumers' willingness to embrace unmanned retail technologies.

In conclusion, by developing user-friendly applications and solutions that meet consumer needs, retailers can lay the foundation for a sustainable future in unmanned retail, contributing not only to the literature but also to the overall enhancement of consumer experiences. Addressing these paradoxes in future research will provide deeper insights into the complexities surrounding technology adoption in retail settings.

MARITIME STUDIES

Maritime Human Resources

Maritime Security

Importance of Safety Awareness and Safety Culture Onboard with Alternative Fuels

Aysel Camci[a], Firat Bolat[b]

[b] Istanbul Technical University, Maritime Faculty, Maritime Transportation Management, Türkiye
camci23@itu.edu.tr

Keywords: Human Factor, Maritime, Maritime Safety, Safety Awareness.

Aim

Approximately 90% of global transportation is conducted via maritime routes, underscoring the sector's critical role in economic sustainability and international trade. However, maritime transportation faces several challenges threatening its long-term viability. While the industry is influenced by political, environmental, and technological factors, onboard safety remains a fundamental pillar for sustainable development (Pyć, 2020).

Although safety is essential in all industrial sectors (Kamis et al., 2020), maritime safety presents unique complexities compared to land-based industries. According to the International Maritime Organization (IMO), seafaring is among the most hazardous occupations globally (Maritime Safety, n.d.). Studies show that maritime operations share characteristics with other high-risk industries, especially in how safety culture affects behavior and safety outcomes (Andrei et al., 2020). Following historical tragedies such as the Titanic disaster, international frameworks like the Safety of Life at Sea (SOLAS) Convention were implemented to mitigate accidents (SOLAS, n.d.). Nevertheless, the evolving nature of the maritime sector requires continuous advancements in safety understanding and implementation.

Three core elements define onboard safety: the human factor, regulatory frameworks, and technological innovation (Baig et al., 2024). The concept of "safety culture" emerged after the Chernobyl disaster, introduced by the International Atomic Energy Agency (Berg, 2013). The National Institute for Occupational Safety and Health (NIOSH) defines it as the collective attitudes, perceptions, and experiences related to safety within an organization (Definition Examples of Safety Culture and Overlap With Safety Climate, n.d.). Among various components, "seafarers' awareness of safety culture" is crucial (Jung, 2021).

Human error is the primary contributor to maritime incidents. It accounts for around 80% of all accidents (Pyć, 2020; Sha, 2020; Jung, 2021), 85% of collisions (Sha, 2020), and a significant majority of tanker incidents and onboard fires (Berg, 2013). In South Korea alone, 338 maritime accidents were reported in 2019 (Jung, 2021). Furthermore, maritime transportation is reportedly 25 times riskier than aviation in terms of fatalities per 100 kilometers traveled (Berg, 2013).

Maritime safety culture relies on collaboration among seafarers, regulatory authorities, and ship management (Håvold, 2010). Measures like double-hull requirements and the International Safety Management (ISM) Code have aimed to enhance safety onboard (The International Safety Management (ISM) Code, n.d.). However, the central role of the human factor persists. From a legal and political perspective, instruments like the International Code of Safety for Ships Using Gases or Other Low-flashpoint Fuels (IGF Code) remain inadequate for covering many emerging alternative fuels.

From a managerial perspective, the adoption of ship-specific and adaptable safety strategies is essential for effective implementation (Baig et al., 2024; Berg, 2013; Teperi et al., 2018). However, human factors remain difficult to address comprehensively. Although the International Convention on Standards of Training, Certification and Watchkeeping for Seafarers (STCW) provides a regulatory framework (STCW, n.d.), concerns persist regarding its adequacy in addressing technological advancements and alternative fuel operations (Cicek et al., 2019). It is claimed that training alone is insufficient to instill a robust safety culture (Håvold, 2010), particularly as knowledge gaps and low competency levels continue to contribute to human error (Elsokary et al., 2025).

A recent study in Egypt illustrates regional disparities in safety knowledge, with port workers in Port Said outperforming those in Alexandria and other areas (Elsokary et al., 2025). Additionally, psychological and environmental stressors, including fatigue, multicultural crew dynamics, digitalization, and exposure to adverse physical conditions (e.g., noise, temperature, and humidity), complicate the establishment of an effective safety culture (Sha, 2020; Formela et al., 2019; Pyć, 2020). Insufficient awareness often leads to negligent behavior, which is a leading cause of collisions and accidents (Hsu et al., 2023; Baig et al., 2024).

Technological advancements have significantly reduced crew sizes over the past decades—from 40–50 crew members to approximately 20 on tankers (Håvold, 2010). While this change has enhanced operational efficiency, it has also intensified fatigue and stress levels. Critics argue that, despite the ISM Code's intentions, low manning levels and constant operational demands hinder effective adherence to safety protocols (Størkersen et al., 2016). Safety outcomes are closely linked to communication and risk management practices (Andrei et al., 2020), yet the current operational landscape often imposes excessive working hours and mental health burdens such as depression and anxiety (Håvold, 2010).

Compounding these issues is the maritime industry's transition to alternative fuels in response to stringent environmental targets. The IMO aims to reduce greenhouse gas (GHG) emissions by 50% by 2050 and CO_2 emissions by 70% by 2030, relative to 2008 levels (2023 IMO Strategy on Reduction of GHG Emissions From Ships, n.d.). Lloyd's Register identifies several alternative fuels with potential—ammonia, biofuels, electric, hydrogen, LNG, LPG, and methanol (Fuel for Thought - Alternative Marine Fuels | LR, n.d.). Among these, LNG is notable for its infrastructure readiness, yet its low flashpoint (-184°C) presents serious safety hazards (LNG Powers Unprecedented Year for Orders of Alternative-fuelled Vessels, 2025). Methanol and ammonia also pose risks due to their low flashpoints and corrosive or toxic properties (Zincir & Deniz, 2021).

While hydrogen and electric fuels show promise for short-distance shipping, their applicability for long voyages remains limited. The shift to gaseous fuels introduces new hazards, especially for non-tanker vessels traditionally less exposed to fuel-related risks. Despite improved safety technologies, human error—including procedural deviations and inadequate safety awareness—continues to undermine maritime safety (Nair, 2022).

Method & Findings

In this context, the present study assesses the readiness of the maritime industry's safety culture for alternative fuel adoption. A PESTEL analysis reveals that political and economic factors significantly influence safety culture development. For instance, crew reduction policies exacerbate fatigue and stress, undermining safety performance. Furthermore, training curricula have not adequately evolved to address the operational requirements of hazardous fuels. Although some familiarization programs and certifications exist—especially for LNG-fueled vessels—comprehensive safety culture education remains lacking even for conventional fuel systems.

Conclusion

In conclusion, the human factor is central to the sustainability of global maritime operations. Given that most maritime accidents stem from human error, enhancing safety awareness and culture among crew members is imperative. Although alternative fuels are being introduced to align with emission reduction goals, they introduce unique safety challenges. Economic considerations are important, but greater investment in safety training and education is essential to mitigate the additional risks associated with these new fuels.

Improvement of the Selenium Retention and Control of the Color Stability in Selenium Containing Glasses

Elif Fagıye Yaylacı[a,b], Merve Akdemir Kutluğ[b], Ahmet Caner Kayaalp[b], Reha Yavuz[a]

[a]Istanbul Technical University, Faculty of Chemical and Metallurgical Engineering, Department of Chemical Engineering, Türkiye
[b] Şişecam Science Technology and Design Center, Türkiye
yaylaci18@itu.edu.tr

Keywords: Manganese Dioxide, Oxidizing Agent, Selenium Retention, Sodium Nitrate.

Aim

Selenium is utilized as a coloring agent in glass products, in conjunction with other colorants, to produce pink, bronze, and grey-colored glasses. Besides, it is also used as a decolorizing agent during the production of clear glass batches. Selenium can be incorporated into the glass batch in various raw material forms. Selenium has different oxidation states within the glass structure, including 2-, 0, 4+, and 6+. The color of the glass changes depending on these different oxidation states of selenium. The Se^{2-}, Se^{4+} and Se^{6+} forms have a colorless effect on the glass, the Se0 form gives the glass a pink color and the Se_x^{2-} forms form a polyselenide called FeSe, which gives the glass red-brown color (Longobardo, 1994). The valence levels of selenium present in the glass and their effects on the coloration of soda-lime-silicate glasses are given in Table 1.

Table 1. The oxidation states of selenium and their impact on the coloration of soda-lime-silicate glasses (Jitwatcharakomol, 2005).

Different Oxidation States of Selenium	Effect on the color of the glass
Selenide (Se^{2-})	Colorless
Elemental Selenium (Se^{0})	Pink
Selenite (Se^{4+})	Colorless
Selenate (Se^{6+})	Colorless
Polyselenide (Se_x^{2-} (x > 1))	Red-Brown

Selenium exhibits two absorption peaks in the visible region, with a maximum at 500 nm and a flatter peak around 750 nm (Jitwatcharakomol, 2005). In contrast, iron selenide (FeSe) displays a broad absorption peak in the 400-500 nm range, starting around 400 nm and reaching a maximum at approximately 490 nm (Bamford, 1977). Spectral absorption graph of elemental selenium and iron selenide is shown in Figure 1.

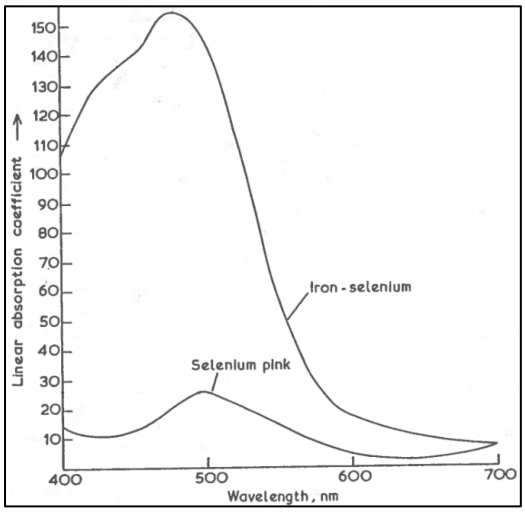

Figure 1. Spectral absorption graph of elemental selenium and iron selenide (Bamford, 1977).

Selenium has a melting point of 217°C and a boiling point of 685°C at standard atmospheric pressure (1 atm) (Jones & Boulos, 1996). The primary disadvantage of selenium is its low retention in bulk glass due to its high volatility. This issue makes it challenging to use selenium effectively in glass production. It is known that selenium, which cannot be retained in the glass batch, separates from the melt in the form of selenium dioxide (SeO_2). This separation prevents selenium from remaining within the glass, making it difficult to achieve the desired color and properties. Various studies and experimental research have shown that approximately 80% to 90% of selenium evaporates during the melting process (Jitwatcharakomol, 2005). The volatilization of selenium depends on various parameters such as the furnace atmosphere, the moisture content of the batch, the melting temperature, and the chemistry of the glass batch (e.g., the reduction state of the glass). One of the challenges associated with the high evaporation rate of selenium is the increased production costs. Due to the high cost of selenium and selenium-containing compounds, the high volatility of these materials leads to increased raw material costs. Additionally, the high volatility causes issues with color stability in products manufactured using selenium. Furthermore, it may pose environmental risks. The high volatilization of selenium-containing compounds in flue gases can make the atmosphere around glass melting furnaces toxic (Inoue & Tachibana, 1971). In order to address these issues, the aim of this study is to investigate the effects of different levels of oxidizing agents such as sodium nitrate and manganese dioxide on selenium retention and glass coloration.

Material and Method

After preparing 100 grams of glass batches, all materials were thoroughly mixed to obtain a homogeneous mixture. The mixture was then melted in ceramic crucibles at 1450°C for 3 hours. Upon completion of the melting process, the glass samples were annealed to reduce internal stress. After the annealing process, the cooled glass samples were cut, their surfaces were polished, and they were made ready for analysis. The chemical composition analysis of the obtained glass samples and the Se percentages were analyzed using an X-ray fluorescence (XRF) device. The Se percentages measured in the glass samples were used to calculate the selenium retention percentages. The color parameters were determined using a UV-Vis spectrophotometer with a tungsten lamp.
In experimental studies, sodium nitrate was added within the specified range per 100 g of glass to observe its effect on selenium retention. Subsequently, manganese dioxide was added within the same range to the 100 g glass batches without sodium nitrate to observe the effect of manganese dioxide.

Findings

In experiments conducted with glass batches containing different levels of sodium nitrate, it was observed that the selenium retention rate showed a maximum increase of 83.08% within the specified range compared to experiments without sodium nitrate. Additionally, as the amount of sodium nitrate added to the glass batches

increased, the reduction state of the glass gradually decreased, and the glass became more oxidizing. Figure 2 shows the selenium retention percentages in glasses with different levels of sodium nitrate.

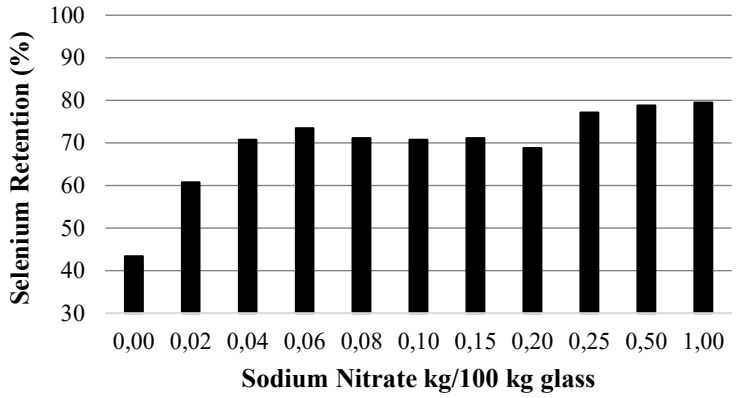

Figure 2. Selenium retention (%) in glasses with different levels of sodium nitrate.

In experiments conducted with glass batches containing different levels of manganese dioxide, it was observed that the selenium retention rate showed a maximum increase of 79.99% within the specified range compared to experiments without manganese dioxide. Similar to the series containing sodium nitrate, the reduction state of the glass decreased with increasing manganese dioxide.

Conclusion

This study investigated the effects of using different levels of sodium nitrate and manganese dioxide which are used as oxidizing agents, on selenium retention and glass coloration. Experimental studies conducted with varying amounts of sodium nitrate showed that as the amount of sodium nitrate added to the glass batch increased, a general trend of increased selenium retention was observed, although this was not a gradual increase.

However, it is known that sodium nitrate can lead to harmful nitrogen oxide emissions, causing environmental pollution. Therefore, different oxidizing agents that could enhance selenium retention and reduce harmful nitrogen oxide emissions as alternatives to sodium nitrate have been investigated. For this reason, the effect of a similar oxidizing agent, such as manganese dioxide, on selenium retention in glass was examined. In the experiments conducted, it was observed that when different amounts of manganese dioxide were added to the glass batches, selenium retention increased with the increasing amount of manganese dioxide. These results suggest that manganese dioxide could be an effective alternative for enhancing selenium retention.

In future studies, research can be conducted on other potential oxidizing agents, apart from sodium nitrate and manganese dioxide, that can enhance selenium retention in glass, ensure color stability, and reduce adverse environmental impacts. Additionally, the effects of parameters such as melting temperature on selenium retention can be examined. These studies should also include a detailed analysis of economic costs and methods for reducing the production costs of selenium-containing glass.

A Study About Tin Nanoparticles and Production of Core-shell Structure

Ayşe Zuhal Karakaş[a], Ş. Samet Kaplan[a],M. Şeref Sönmez[a]

[a] Department of Metallurgical and Materials Engineering, Faculty of Chemistry and Metallurgy, ITU Ayazaga Campus, 34469, Maslak/Istanbul
karakasay19@itu.edu.tr

Keywords: Nanoparticle, Polyol Method, Core-Shell.

Aim

This study focuses on the synthesis of nano-sized reactive tin (Sn) particles via the polyol method and the investigation of Sn/CuO core-shell structures for potential applications in low-temperature reactive bonding and soldering. Diethylene glycol (DEG) served as the solvent, polyvinylpyrrolidone (PVP) as the stabilizing agent, and sodium borohydride ($NaBH_4$) as the reducing agent. Two distinct tin precursors, tin (II) 2-ethylhexanoate and tin (II) chloride ($SnCl_2$), were evaluated to determine their influence on nanoparticle formation. The synthesis involved dissolving PVP and $NaBH_4$ in DEG at room temperature, followed by precursor addition, controlled precipitation using acetone, and subsequent washing and drying processes. The impact of $NaBH_4$ concentration and precursor selection on particle morphology and crystallinity was systematically investigated. Structural and morphological characterizations were performed via X-ray diffraction (XRD) and scanning electron microscopy (SEM). The research of Sn/CuO core-shell structures aims to enhance reaction kinetics and interfacial adhesion, thereby improving process efficiency in metal-ceramic integration for advanced microelectronic applications. In the light of this information, aim of this study is to develop nano-sized reactive particles and investigate their potential applications for low-temperature reactive bonding and soldering. The primary goal is to synthesize tin (Sn) nanoparticles using the polyol method and subsequently fabricate Sn/CuO core-shell structures. These structures are expected to enhance reaction kinetics and improve process efficiency in metal-ceramic integration. The research also focuses on optimizing process parameters such as precursor selection, reaction time, temperature, and pH, as well as evaluating the characterization of the synthesized nanoparticles.

Introduction

The term nanoscale generally comprises of the size or dimensions between 1 to 100 nanometers meaning 10^{-9} meters. Nanomaterials however, are materials have governable significant dimensions which 100nm or under 100nm. There are some basic procedures to create nanomaterials and they can be list as; "condensation from a vapor phase, precipitation from solution, chemical vapor deposition, chemical reactions (particularly reduction or oxidation), processes used to generate colloidal phases, self-assembly using surfaces, mechanical attrition" [5,6]. Increasing interest in nanomaterials through the years, substantial researches have been realized about "pure metal nanoparticles". For example, silver, palladium, copper, gold, tin, platinum. Especially, tin has very important role in microelectronic applications because it is reckoned as soldering material frequently. Tin also known as interconnection material in the area of electronics [2]. While synthesizing these nanoparticles, there are various approaches yet, wet chemical paths preferred. Particularly, (modified) polyol process is used for this purpose. While using this process many of the parameters are modifiable such as solvent or precursor's type, molecular weight or type of capping agent and concentration of so many agents [3]. The name polyol comes essentially from poly-alcohol which are acknowledged as reducing agents. In this process polyols can be listed as DEG, EG, PEG, TEG and TTEG. It should also be noted that, if the power of polyol isn't enough for the reducing then, extra reducing agent can be used [4]. Core-shell nanostructures should also be mentioned within the scope of the study. The development of core-shell nanostructures has enabled the control of various properties for use in different fields. Core-shell nanoparticles originate from two or more materials. Core-shell particles can be used in various fields like optics, electronics, biomedical, catalysis and their properties can be different from main materials. For example, core materials' properties can be improved by shell materials. So, in general, particles which has different features than each other are brought together to achieve desired properties [1].

Material and Method

In the synthesis, diethylene glycol (DEG) was used as the solvent, while polyvinylpyrrolidone (PVP) acted as a stabilizing agent. Sodium borohydride ($NaBH_4$) was employed as a reducing agent, and two different tin precursors were examined: tin (II) 2-ethylhexanoate and tin (II) chloride ($SnCl_2$). The synthesis procedure involved dissolving PVP and $NaBH_4$ in DEG at room temperature, followed by the addition of the tin precursor. The solution was stirred via magnetic stirrer, precipitated with acetone, and washed with ethyl alcohol before being centrifuged. The final product was dried at oven before characterization. This process repeated with different amounts of $NaBH_4$ to examine the effect of reducing agent and different tin precursors. In Table 1, details of the experimental parameters are given. X-ray diffraction (XRD) and scanning electron microscopy (SEM) were used to analyze the crystalline phases and morphology of the nanoparticles.

Table 1. Experiment conditions.

Experiment No	NaBH4(g)	PVP(g)	DEG (ml)	Sn Precursor
1	2	1	240	2g $SnCl_2$
2	2.5	1	240	2g $SnCl_2$
3	2	1	200	2ml Sn(II)-2ethylhexanoate
4	2.5	1	200	2ml Sn(II)-2ethylhexanoate

Findings

XRD patterns of the samples produced by the polyol method, which details are given in the materials and methods section, are given in Figure 1. As can be seen from Figure 1, looking at the XRD patterns of experiment 1 and experiment 2, it is understood that Sn could not be obtained. XRD analysis showed that samples synthesized with $SnCl_2$ contained impurities, prompting further optimization of the reducing agent and precursor concentrations. However, in the XRD patterns representing experiment 3 and experiment 4, it is understood that Sn is produced. For the samples synthesized using Sn (II) 2-ethylhexanoate, XRD analysis demonstrated single-phase Sn formation, regardless of the $NaBH_4$ concentration. However, in samples with higher $NaBH_4$ concentrations, a background signal was observed, indicating the possible presence of amorphous content. SEM analysis revealed that the Sn nanoparticles did not exhibit a spherical morphology.

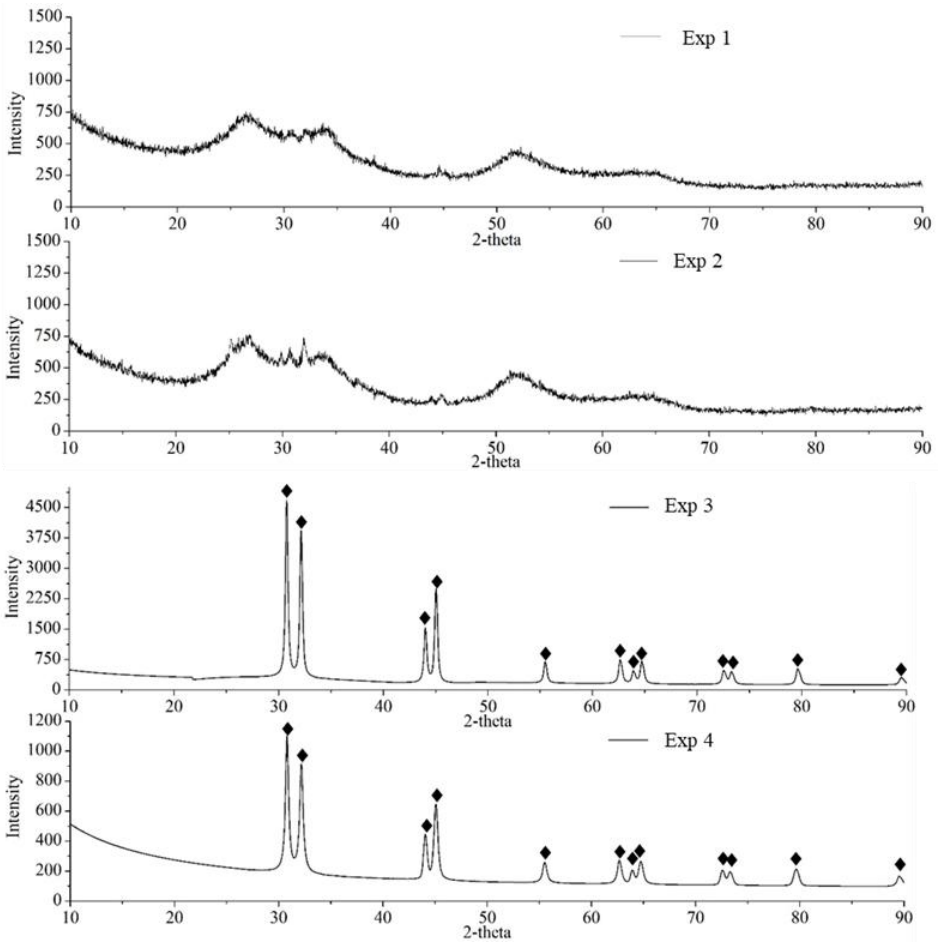

Figure 1. XRD pattern comparison of samples.

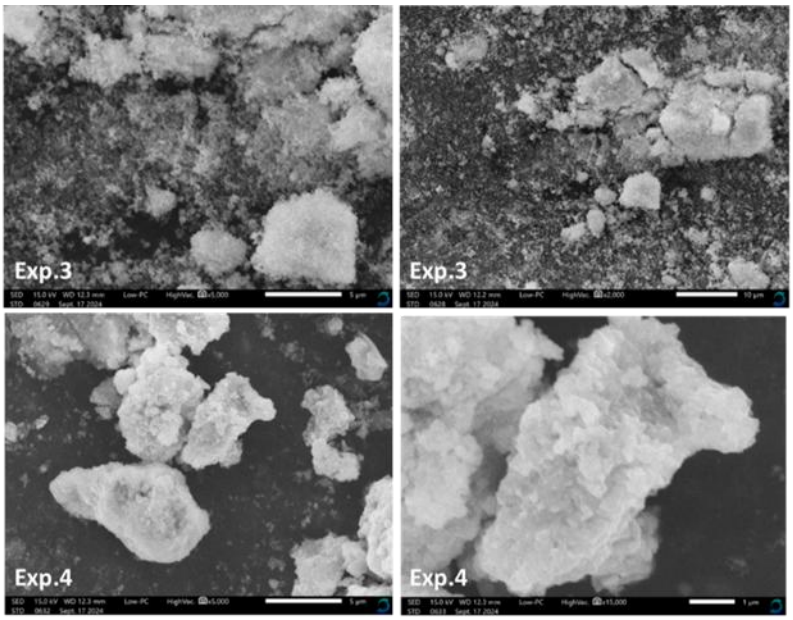

Figure 2. SEM image of experiment 3 and experiment 4.

Conclusion

The study denote that synthesized Sn nanoparticles using the polyol method, with Sn (II) 2-ethylhexanoate proving to be a more effective precursor than $SnCl_2$. It was observed that there was no significant relationship between changing the amount of $NaBH_4$ and particle formation. Future work will focus on refining reaction parameters and investigating additional characterization techniques to enhance the performance of reactive nanoparticle systems for low-temperature metal-ceramic integration

Mathematical Modeling

Symmetry Analysis on Rosenau Type Equations

Tugce Sezer [a], Cihangir Özemir [a]

[a] Istanbul Technical University, Department of Mathematical Engineering, Turkey
sezert22@itu.edu.tr

Keywords: Lie Symmetries, Rosenau Equation, Symmetry Classification.

Aim

In the field of nonlinear wave theory, the study of shallow-water wave propagation has been a major area of research for several decades. Numerous mathematical models have been developed to analyze and demonstrate the intricate dynamics of such waves. Beginning with the foundational Korteweg–de Vries (KdV) equation, a range of models, including the regularized long wave (RLW), Rosenau, and Kawahara equations, have played critical roles in describing wave propagation and interactions.

The Rosenau equation (Rosenau, 1988) was introduced to describe wave phenomena involving both dispersion and nonlinearity, particularly in contexts such as wave-wave and wave-boundary interactions. By integrating concepts from the RLW equation to more effectively represent nonlinear dispersive waves in continuous media (e.g., fluids), the Rosenau-RLW equation (Pan & Zhang, 2012) was proposed, incorporating a viscous term. This model was later extended into the generalized Rosenau-RLW equation.

To address higher-order dispersive systems, such as shallow-water waves affected by surface tension, the Kawahara equation was formulated, introducing fifth-order dispersion. Its generalized form has since found application in diverse fields, including ion-acoustic waves in plasmas and nonlinear acoustics. In an effort to unify insights from both the Rosenau and Kawahara models, the Rosenau-Kawahara equation was introduced, and subsequently generalized into the Rosenau-Kawahara equation.

Despite these developments, there has been relatively limited research focused on the Lie symmetry analysis of equations within the Rosenau family. Collectively, these partial differential equations illustrate a trend toward increasing generality and adaptability, enabling the modeling of a broader range of nonlinear wave phenomena.

Lie group analysis has become a widely used method for studying both ordinary and partial differential equations, and its application extends to difference equations, integral equations, and fractional equations as well. Central to this approach are smooth, one parameter transformations that form a Lie group, which is an algebraic structure that is simultaneously a group and a smooth manifold. The tangent space at the identity element of this manifold forms a Lie algebra, whose basis consists of vector fields that generate the symmetry transformations leaving the differential equation unchanged. If an equation remains invariant under n such transformations, it is said to possess an n-dimensional Lie algebra. The process of identifying the Lie algebra associated with a differential equation is algorithmic and applicable to any such equation.

For an ordinary differential equation of order k, the existence of a symmetry generator allows its order to be reduced by one. If the ordinary differential equation admits a $(k-1)-$dimensional Lie algebra, it may be reducible to a first-order equation. Similarly, for a partial differential equation with m independent variables, a symmetry generator enables the reduction of one independent variable. If the PDE admits an $(m-1)$-dimensional Lie algebra, it can be transformed into an ODE of the same order.

Beyond these practical advantages, especially valuable for nonlinear differential equations, which often lack general solution methods, Lie group analysis also facilitates the classification of equation families containing arbitrary functions or coefficients. In this framework, entire families of equations are analyzed and grouped based on the Lie algebras they admit. In the present study, we apply this methodology to perform a Lie symmetry classification of a Rosenau-type equation featuring a general form of nonlinearity.
In this work, we perform the analysis on a Rosenau-type equation of the form:

$$u_t + \varepsilon u_x + \alpha u_{xxt} + \eta u_{xxx} + \beta u_{xxxxt} + \gamma u_{xxxxx} + (f(u))_x = 0$$

where $f(u)$ represents a general nonlinear function. The existence and stability of solitary wave solutions to this equation have been previously investigated in (Duran & Muslu, 2024). When $f(u) = u^n$, the equation is referred to as the generalized Rosenau-RLW-Kawahara equation. Numerous exact (Tasbozan, Celik, Kurt & Akinyemi, 2024) and numerical (Wang & Dai, 2018; Wang, Cheng, & Dai, 2022) solutions have been proposed for this power-law nonlinearity case.

Material and Method

This study primarily focuses on the symmetry analysis, reductions, and exact solutions of the aforementioned equation. Adopting a group-theoretical framework, we consider the Rosenau-type equation in the form:

$$u_t + \alpha u_{xxt} + \eta u_{xxx} + \beta u_{xxxxt} + \gamma u_{xxxxx} + (g(u))_x = 0$$

Here, the term u_x from the original equation is embedded within $\big(g(u)\big)_x$. The analysis is conducted under the assumptions that $(\beta, \gamma) \neq (0,0)$ and $g''(u) \neq 0$, to ensure the presence of nonlinearity.

Findings

The Lie group analysis yields a classification of Lie algebras corresponding to various forms of the nonlinearity $g(u)$. The classification includes polynomial, logarithmic and exponential nonlinearity types. For other functional forms of $g(u)$, the equation admits a trivial two-dimensional Abelian algebra $< \partial_t, \partial_x >$. Following the exploration of optimal systems for Lie algebras, the associated reductions of the PDE to ordinary differential equations are obtained.

Conclusion

In this study, we investigated a Rosenau-type equation involving a general nonlinearity f(u). While earlier research focused primarily on the quadratic case, numerous variants have since been developed and explored from various perspectives. Building on the literature summarized in the introduction, we analyzed this class of equations using Lie group-theoretical methods.
Our symmetry classification demonstrates that, within this family of equations, the maximum dimension of the Lie symmetry algebra is three. Furthermore, we carried out reductions of each specific class to ordinary differential equations using the corresponding optimal systems of one-dimensional subalgebras.
As future work, we aim to derive exact solutions for the partial differential equation with polynomial-type nonlinearities. Additionally, we plan to incorporate numerical solutions for selected ordinary differential equations obtained through the reduction process.
The results of this work and aforementioned forthcoming investigations will attract attention of researchers working on various fields, such as wave propagation, qualitative analysis of PDEs or numerical approaches. The work also has the potential of being a guide for application of the analysis carried out to the similar families of equations.

Exploring Rayleigh Waves in Layered Media

Tugce Sezer[a], Semra Ahmetolan[a], Ayse Peker-Dobie[a], Ali Demirci[a]

[a] Istanbul Technical University, Department of Mathematical Engineering, Turkey
sezert22@itu.edu.tr

Keywords: Rayleigh Waves, Irregular Surfaces, Perturbation Methods.

Aim

The study of elastic waves in layered media with different elastic properties is an important research topic due to its applications in various engineering fields such as geophysics, seismology and metallurgy. For example, because the Earth's crust is considered a layered elastic medium that varies in stiffness and density with depth, both the free surface and the interfaces between layers may contain irregularities. These irregularities affect the reflected and refracted waves and directly affect wave propagation (Graff, 2012).

Elastic wave propagation is used in seismic research in earth sciences; In materials science, to understand the internal structure and mechanical properties of materials, to increase the durability of materials and to detect defects; In structural strength assessment, it is an important tool used to measure the durability and stability of structures. There are many studies on the propagation of elastic waves in layered media with irregular surfaces (Kuo & Nafe, 1962; Ben-Hador & Buchen, 1999; Vishwakarma & Xu, 2016; Zhang, Qin, Li & Kube, 2020; Ahmetolan, Peker-Dobie, Deliktas-Ozdemir & Caglayan, 2023). In general, analyzing the effect of irregularities on boundary surfaces on wave propagation presents mathematical difficulties. In addition, sometimes the geometry of the problem may require that the functions representing irregularities on the boundary surfaces be selected in a certain structure.

In this study, the problem of propagation of Rayleigh waves in a semi-infinite space with a layer of non-uniform thickness consisting of different homogeneous materials is examined.

Material and Method

It is assumed that the free surface is free of traction, and both displacement functions and stresses are continuous at the interface. The free and interface surfaces are treated as non-specialized functions that vary depending on the direction of propagation. The main aim of this work is to obtain the equations characterizing the propagation of such waves.

First, the formulation of the problem was made using the theory of elasticity: equations of motion and boundary conditions modeling wave propagation were obtained. Then, order problems were obtained by selecting an appropriate asymptotic perturbation method. The dispersion relation is expressed as a function of the wave's phase velocity, wave number, and wave propagation direction. In the following parts of the study, wave propagation is examined using real linear material properties and under the assumption that irregular boundary conditions exhibit periodic properties.

The spatial and material coordinates of a point in three-dimensional space are defined according to the same orthogonal coordinate system as (x_1, x_2, x_3) and (X_1, X_2, X_3), respectively. The equations of motion are

$$x_1 = X_1 + u_1^{(m)}(X_1, X_2, t), \qquad x_2 = X_2 + u_2^{(m)}(X_1, X_2, t), \qquad x_3 = X_3, \qquad m = 1, 2.$$

Here t is the time, $u_1^{(m)}$ and $u_2^{(m)}$ represent the displacements in the X_1 and X_2 directions, respectively. Here, $m = 1$ refers to the layer D_1 and $m = 2$ to the half space D_2. In the absence of body forces, the equations of motion take the following form:

$$T_{k1,k}^{(m)} = \rho_0^{(m)} \ddot{u}_1^{(m)}, \qquad T_{k2,k}^{(m)} = \rho_0^{(m)} \ddot{u}_2^{(m)} \ .$$

Here $T_{KI}^{(m)}$ represents the first Piola-Kirchhoff stress tensor and $\rho_0^{(m)}$ represents the initial density of the relevant medium.

It is assumed that the boundary of the layered half-space $X_2 = h + g_1(X_1)$ is traction free, that displacements and stresses are continuous at the interface $X_2 = g_2(X_1)$, and that displacements do not occur as $X_2 \to -\infty$. Boundary conditions are

$$N_K^{(1)} T_{KI}^{(1)} = 0 \quad on \quad X_2 = h + g_1(X_1)$$

$$u_1^{(1)} = u_1^{(2)}, \quad u_2^{(1)} = u_2^{(2)} \quad on \quad X_2 = g_2(X_1)$$

$$N_K^{(1)} T_{KI}^{(1)} = N_K^{(2)} T_{KI}^{(2)} \quad on \quad X_2 = g_2(X_1)$$

$$u_1^{(2)}, \quad u_2^{(2)} \to 0 \quad as \quad X_2 \to -\infty.$$

By substituting the explicit form of T_{Kl} into the equation of motions and the boundary conditions, while neglecting nonlinear terms, and then replacing u_1, u_2 and (X_1, X_2, X_3) with u, v and (X, Y, Z), respectively, linear equations of motion and boundary conditions are obtained.

Using an asymptotic perturbation method, an asymptotic solution is derived for the problem of linear Rayleigh waves with small but finite amplitude propagating in a layer with irregular free surfaces that vary slowly in the direction of propagation. The slow change in the boundary surfaces is represented by a small parameter $\epsilon > 0$, which measures the amplitude of the geometric change of the surfaces,

$$g_i = g_i(\epsilon X), \qquad i = 1, 2.$$

In order to distinguish between the slow and fast changing features of the waves, new variables

$$x_1 = \epsilon X\,, \quad t_1 = \epsilon t\,, \quad y = Y\,.$$

are defined. The phase variable $\theta = kX - \omega t$ is defined. Here k is the wave number and $\omega = c\,k$ is the angular velocity. The equations $\theta_{,\{Xt\}} = k_{,t} = (-\omega)_{,X} = \theta_{,\{tX\}}$ are satisfied and spatial inhomogeneity does not affect the frequency but causes a change on the wave number. In the case where the displacements are functions of $\{\theta, x_1, y, t_1\}$, the asymptotic extensions are

$$u^{(m)} = \sum_{n=1}^{\infty} \epsilon^n u_n^{(m)}(\theta, x_1, y, t_1) \qquad v^{(m)} = \sum_{n=1}^{\infty} \epsilon^n v_n^{(m)}(\theta, x_1, y, t_1).$$

Findings

The expansions are put into the equations of motion and boundary conditions and arranged according to the ϵ orders. Thus, hierarchical order problems are obtained. In this study, it is sufficient to examine the first two order problems.

The first problem has linear homogeneous equations and homogeneous boundary conditions, while the second order problem is a perturbation problem with linear non-homogeneous equations and non-homogeneous boundary conditions. By examining the first order problem, the changes of the solutions depending on the fast variables y, θ; by examining higher order problems, its dependence on slow variables will be determined. Under the assumption that $c_{1T} < c_{1L} < c < c_{2T} < c_{2L}$, the solutions for the first-order equations, including all modes, are obtained as follows:

$$u_1^{(1)} = \sum_{l=1}^{\infty} \left[A_1^{(l)} e^{-ik_{PL}y} + A_2^{(l)} e^{ik_{PL}y} + p_T A_3^{(l)} e^{-ik_{PT}y} - p_T A_4^{(l)} e^{ik_{PT}y}\right] e^{il\theta} + c.c.,$$

$$v_1^{(1)} = \sum_{l=1}^{\infty} \left[-p_L A_1^{(l)} e^{-ik_{PL}y} + p_L A_2^{(l)} e^{ik_{PL}y} + A_3^{(l)} e^{-ik_{PT}y} + A_4^{(l)} e^{ik_{PT}y}\right] e^{il\theta} + c.c.,$$

$$u_1^{(2)} = \sum_{l=1}^{\infty} \left[A_5^{(l)} e^{k_{Lv}y} + i\nu_T A_6^{(l)} e^{k_{LvT}y}\right] e^{il\theta} + c.c.,$$

$$v_1^{(2)} = \sum_{l=1}^{\infty} \left[-iA_5^{(l)} e^{k_{Lv}y} + A_6^{(l)} e^{k_{LvT}y}\right] e^{il\theta} + c.c.,$$

Here, $A_i^{(l)}$ are the first order amplitude functions with respect to $\{x_1, t_1\}$. In order to obtain the exact structures of the coefficient functions $A_i^{(l)}$ these solutions are substituted into the boundary conditions of the first-order problem.

$$W^l U_1^l = 0$$

system is obtained. Where W is the dispersion matrix and

$$U_1^l = \left[A_1^{(l)}\ A_2^{(l)}\ A_3^{(l)}\ A_4^{(l)}\ A_5^{(l)}\ A_6^{(l)}\right]^T.$$

Conclusion

Since we are working with linear Rayleigh waves in the plane, the harmonic resonance condition is not satisfied for the wave number of the fundamental wave.

$det\ det\ W^l = 0\ for\ l = 1$ and $det\ det\ W^l \neq 0\ for\ l \geq 2.$

Using $det\ det\ W^1 = 0$ the dispersion relation is obtained. Since the structure of the dispersion relation, which gives the change of free and interface surfaces, is very complex, it is not possible to calculate the phase velocity relations $c = c(k, X)$ of the waves analytically. Therefore, the graphs of the implicit functions $c = c(k, X)$ are obtained from the dispersion relation as a result of numerical calculations. In order to determine the exact variation of the coefficient functions A in the first-order solutions depending on the slow variables $\{x_1, t_1\}$, the analysis of the second-order, $O(\epsilon^2)$, problem will be continued. Numerical solutions of the dispersion relation are found using real material parameters. Thus, the effects of material parameters, wave number variation and irregularity of the boundary surfaces on wave propagation are being investigated.

Understanding Predator- Prey Dynamics Through Equilibrium State Classification

Kerime Nur Kavadar[a], Ali Demirci[a]

[a] Istanbul Technical University, Faculty of Science and Letters, Department of Mathematical Engineering, Türkiye
kavadar20@itu.edu.tr

Keywords: Equilibrium Classification, Predator- Prey Stability, Nonlinear Population Dynamics.

Aim

This study aims to analyze the stability of the logistic predator-prey model based on the Lotka-Volterra equations. By incorporating logistic growth, the research provides a more realistic representation of predator-prey interactions, considering environmental limitations. The study also seeks to classify different equilibrium states based on initial conditions and dominance relationships, ultimately offering a structured framework for stability analysis. The Lotka-Volterra system is widely used in various scientific fields beyond ecological modeling. In economics, it has been applied to model competition between firms, representing how market share dynamics evolve over time (Strogatz, 2018). The model helps predict how dominant firms maintain their position and how smaller competitors enter or exit the market. The competitive interactions between businesses can be likened to predator-prey dynamics, where dominant firms (predators) consume market share while smaller firms (prey) struggle to survive. In epidemiology, the system helps describe disease spread and interactions between infected and susceptible populations (Tang & Zhang, 2005). The predator-prey framework is particularly useful in modeling the spread of infectious diseases where the infection (predator) propagates through the population of susceptible individuals (prey). This application is crucial for understanding the dynamics of epidemics and developing control strategies such as vaccination and quarantine measures. Engineering applications include network traffic flow and resource allocation in communication systems, where the predator-prey framework captures competition for bandwidth or processing power (Zhang, Koura, & Su, 2020). In such systems, users competing for limited resources can be analyzed using similar mathematical principles. This approach is used to optimize network protocols and improve efficiency in data transmission. Additionally, in social sciences, Lotka-Volterra models are employed to study opinion dynamics, migration patterns, and conflict resolution scenarios (Berryman, 1992). Political competition, for example, can be framed as a predator-prey interaction where dominant ideologies suppress emerging ones, while in migration studies, the interaction between local and incoming populations can be modeled in a similar way. These diverse applications highlight the model's versatility in capturing competitive and cooperative interactions across multiple domains.

Material and Method

The material and method section should be written in Times New Roman font, justified-alignment and in 10-point size. The study involves a comprehensive literature review on predator-prey models, focusing on the classical Lotka-Volterra equations and their logistic extensions. The logistic predator-prey model is examined theoretically by transforming it into a dimensionless form to simplify the analysis (Murray, 2002). The reason for using a dimensionless transformation is to reduce the number of parameters and make the model easier to analyze mathematically. Stability is evaluated through local linearization techniques, particularly using the Jacobian matrix and eigenvalue analysis. This method allows for determining whether small deviations from equilibrium states grow over time (indicating instability) or diminish (indicating stability). Different classifications are proposed based on initial population conditions and species dominance, enabling a structured understanding of the system's equilibrium behavior. The approach involves identifying equilibrium points and assessing their stability using qualitative and numerical methods (Nowak & May, 2000). The equilibrium states are classified based on whether species coexistence is possible or if competitive exclusion occurs. The system's response to different parameter

values is also analyzed to understand how changes in environmental or biological conditions affect stability. To validate the theoretical findings, computational simulations are planned using MATLAB, allowing visualization of distinct stability regions. These simulations will be used to compare theoretical predictions with numerical solutions, providing additional insight into how population dynamics evolve over time. Sensitivity analysis will be performed by varying key parameters, such as growth rates and competition coefficients, to observe their impact on stability (Guckenheimer & Holmes, 2013). Additionally, bifurcation analysis will be conducted to determine how qualitative changes in the system occur as parameters are varied, offering deeper insights into critical transition points.

Findings

The findings section should be written in Times New Roman font, justified-alignment and in 10-point size. The analysis reveals that the stability of the logistic predator-prey model depends on the nature of interspecies interactions and initial population distributions. In cases of weak competition, both species can coexist, leading to an equilibrium state (Nowak & May, 2000; May, 2019). However, strong competition results in the extinction of one species. Three main dynamic scenarios are identified:

- The initially dominant species maintains its dominance, leading to a stable equilibrium where one species thrives while the other remains at a lower population level.
- The initially dominant species remains dominant but declines in population due to competitive interactions, resulting in a fluctuating or semi-stable equilibrium.
- The initially dominant species loses its dominance at equilibrium, leading to a reversal in population hierarchy over time.

These findings contribute to a deeper understanding of population dynamics, particularly regarding long-term stability under varying ecological conditions. Additionally, the numerical classification of equilibrium states provides valuable insights into how species interactions influence stability, making the model applicable to broader real-world problems such as economic market competition, epidemiological control strategies, and resource management (Guckenheimer & Holmes, 2013). The findings indicate that specific parameter conditions determine whether the predator-prey system is stable or unstable. For instance, when competition coefficients are below a critical threshold, both species can coexist without one eliminating the other. However, when competition exceeds this threshold, exclusion occurs. These insights help in designing sustainable ecosystem management strategies, economic policies, and technological systems that rely on competitive interactions (Murray, 2002). Further, the results show that external perturbations, such as environmental changes or fluctuations in resource availability, can alter the stability conditions of the system. For example, in an ecological setting, climate change or habitat destruction could shift equilibrium points and push species towards extinction. In an economic context, policy changes or technological disruptions could influence firm survival and competition patterns. By understanding these stability conditions, policymakers and scientists can make informed decisions about intervention strategies in various domains.

Conclusion

The study highlights the significance of logistic growth in predator-prey models and provides a systematic classification of equilibrium behaviors. The results confirm that species interactions and initial conditions play a crucial role in determining system stability. The logistic component of the model introduces a more realistic limitation on population growth, making it more applicable to real-world systems where unlimited growth is not possible. Future research will involve the numerical validation of theoretical findings through computational simulations and the application of the model to real-world ecological data. This approach will enhance the applicability of the logistic predator-prey model in biological and environmental studies. Additionally, the framework developed in this study can be extended to include multi-species interactions, stochastic effects, and spatial heterogeneity, making it applicable to more complex ecological and socio-economic systems. Further investigations could also explore the implications of additional nonlinearities, such as Allee effects and time delays, which can significantly influence system stability. The inclusion of stochastic elements in the model would allow

for the analysis of random environmental fluctuations and their effects on population dynamics. These extensions would provide a more detailed understanding of predator-prey dynamics in natural and artificial environments. Moreover, interdisciplinary collaborations between mathematicians, ecologists, economists, and engineers can refine the model and expand its range of applications. By incorporating more complex interactions and refining parameter estimation techniques, future studies can enhance the predictive power and practical relevance of the logistic predator-prey model in various scientific and industrial applications.

Keywords: Nonlinear Elasticity, Weak Heterogeneity, Love Waves, Thin Layer Approximation.

Aim

Elastic waves in waveguides exhibit dispersion, meaning their phase velocities depend on the wave number. Given their crucial applications in geophysics, non-destructive testing, and signal processing, dispersive elastic waves have been widely studied. In particular, the propagation of shear horizontal (SH) waves in layered media with varying elastic properties has become a key research area in engineering fields like geophysics, seismology, and metallurgy. Studies have explored the effects of linear and nonlinear material behavior, as well as inhomogeneity, on wave propagation.

Early research focused on linear wave propagation in elastic media with depth-dependent heterogeneity. Avtar, derived the dispersion relation for Love waves in a double-layered heterogeneous medium, while Kowalczyk et al. analyzed SH wave propagation in a nonhomogeneous half-space, where the shear modulus and density vary as a power function of depth. Kumari et al. studied Love-type waves in a layered isotropic structure with two heterogeneous layers over a homogeneous half-space, deriving a dispersion equation.

Recent studies have examined nonlinear wave propagation. Demirkus investigated nonlinear SH waves in a hyperbolically heterogeneous hyperelastic layer over a rigid substratum, deriving a nonlinear Schrödinger (NLS) equation to describe their self-modulation and demonstrating bright solitary SH waves influenced by heterogeneity and nonlinearity. Deliktas-Ozdemir et al. used the multiple scales method to analyze nonlinear SH wave propagation in a double-layered elastic plate with heterogeneous isotropic hyperelastic materials. Ahmetolan et al. extended this analysis to SH waves in a weakly inhomogeneous half-space with a nonlinear thin layer, deriving an NLS equation to study the effects of heterogeneity and nonlinearity.

This study explores Love wave interactions in a nonlinear homogeneous thin layer overlying a nonlinear heterogeneous semi-infinite medium. Our research extends previous work by incorporating the nonlinear material properties of the layer into the boundary conditions of the semi-infinite heterogeneous medium. Additionally, we analyze how both the layer's nonlinear properties and the medium's heterogeneity influence wave propagation.

Material and Method

First, the boundary value problem characterizing the propagation of nonlinear Love waves in a semi-infinite medium covered by a finite-thickness layer was considered. It was assumed that there are no stresses on the free surface and that both the stresses and displacements are continuous at the interface. The material of the layer was assumed to be nonlinear, homogeneous, and isotropic, while the material of the semi-infinite medium was considered nonlinear, heterogeneous, and isotropic. Using the thin-layer approximation, the following equation of motion and the boundary condition on the free surface were derived:

$$h\rho_1 \frac{\partial^2 v}{\partial t^2} - h\mu_1 \frac{\partial^2 v}{\partial X^2} + \mu_2 \frac{\partial v}{\partial Y}\left(1 + \frac{\rho_2 n_2}{\mu_2} Q(v)\right) = h\rho_1 \eta_1 \frac{\partial}{\partial X}\left\{\frac{\partial v}{\partial X}\left(\left(\frac{\partial v}{\partial X}\right)^2 + \frac{\mu_2^2}{\mu_1^2}\left(\frac{\partial v}{\partial Y}\right)^2\right)\right\} \quad on \ Y = 0 \tag{1}$$

$$\rho_2 \frac{\partial^2 v}{\partial t^2} - \mu_2 \left(\frac{\partial^2 v}{\partial X^2} + \frac{\partial^2 v}{\partial Y^2}\right) - \left(\frac{d\mu_2}{dY}\frac{\partial v}{\partial Y}\right) = \rho_2 \eta_2 \left[\frac{\partial}{\partial X}\left(\frac{\partial v}{\partial X} Q(v)\right) + \frac{\partial}{\partial Y}\left(\frac{\partial v}{\partial Y} Q(v)\right)\right] + Q(v)\left(\frac{\partial(\rho_2 \eta_2)}{\partial Y}\frac{\partial v}{\partial Y}\right) \quad , Y < 0. \tag{2}$$

$$v \to 0 \quad as \quad Y \to -\infty \tag{3}$$

Here, μ_i represents the shear modulus, ρ_i the density, and η_i the nonlinear material parameter, where $i = 1$ corresponds to the layer and $i = 2$ to the semi-infinite medium. Q is the nonlinear derivative operator. Under the assumption that the material forming the semi-infinite medium has weak heterogeneity, the material parameters are taken as follows, where $\varepsilon > 0$ is a small parameter:

$$\mu_2(y) = \mu_{2_0}(1 - \varepsilon^2 e^{dy}),\ \rho_2(y) = \rho_{2_0}(1 + \varepsilon^2 e^{dy}),\ \eta_2(y) = \eta_{2_0}(1 + \varepsilon^2 e^{fy}) \quad d, f > 0. \tag{4}$$

Applying the multiple scales method, which is an asymptotic perturbation technique, the independent variables are defined as:

$$x_i = \varepsilon^i X, \quad t_i = \varepsilon^i t, \quad y = Y, \quad i = 0,1,2. \tag{5}$$

Here, $\varepsilon > 0$ also measures the weakness of nonlinearity. The variables x_0, t_0, y are the fast variables that describe the rapid variations in the problem, while x_1, x_2, t_1, t_2 are the slow variables that characterize the slow variations. Subsequently, the displacement function v is considered as a function of these new variables, and the following asymptotic series expansion in terms of ε is applied:

$$v = \sum_{n=1}^{\infty} \quad \varepsilon^n v_n(x_0, x_1, x_2, y, t_0, t_1, t_2). \tag{6}$$

The independent variables (5) and the asymptotic expansion (6) are applied to the equations of motion and the boundary conditions. By collecting terms with similar powers of ε, a hierarchy of problems is obtained, allowing the sequential determination of v_n. Since this study focuses on the problem of nonlinear wave interactions, it is sufficient to examine the first three orders of the problem.

Findings

By analyzing the first-order problem, the variations of the solutions with respect to the fast variables x_0 and y can be determined. Examining the higher-order problems will reveal the dependence of the solutions on the slow variables. Assuming the linear phase velocity satisfies $c_1 < c < c_2$, this study considers the interaction of co-directional Love waves. Therefore, the solution of the first-order problem, assuming that harmonic resonance conditions are not satisfied, is given as:

$$v_1 = \sum_{j=a,b} \quad A_{1j}(x_1, x_2, t_1, t_2) e^{p_j y} e^{i\phi_j} + c.c., \quad p_j = k_j\left(1 - c_j^2/c_2^2\right)^{1/2}, \quad \phi_j = \left(k_j x_0 - \omega_j t_0\right). \tag{7}$$

This wave solution satisfies the dispersion relation obtained from the boundary condition:

$$-h\omega_j^2 + c_1^2 h k_j^2 + c_1^2 \gamma_0 p_j = 0, \quad j = a, b \tag{8}$$

Note that this first-order solution and the solution of the linear problem are of the same form. The only difference is that in the linear problem A_{1j} is constant, but here it is a slowly varying complex function representing the nonlinear self-modulation of a wave train. Obviously, to complete the first-order solution of the nonlinear problem, A_{1j} has to be determined. This can be achieved by examining the higher-order perturbation problems. On the other hand, the weak heterogeneity of the half space occurs in higher-order perturbation problems.

From the compatibility condition in the second-order problem, it is found that A_{1j} remains constant in a frame of reference moving with the group velocity V_{gj} of the wave. The compatibility condition in the third-order problem yields a system of equations for $A_j = k_j A_{1j}$. When the group velocities of the co-directional waves are equal to each other, i.e., $V_{g_b} = V_{g_a}$, this system will lead to the following coupled nonlinear Schrödinger (CNLS) equations:

$$i\frac{\partial A_a}{\partial \tau} + \Gamma_a \frac{\partial^2 A_a}{\partial \xi^2} + \Delta_{aa}|A_a|^2 A_a + \Delta_{ba}|A_b|^2 A_a + \Lambda_a A_a = 0 \qquad i\frac{\partial A_b}{\partial \tau} + \Gamma_b \frac{\partial^2 A_b}{\partial \xi^2} + \Delta_{bb}|A_b|^2 A_b + \Delta_{ab}|A_a|^2 A_b + \Lambda_b A_b = 0 \tag{9}$$

Here, the coefficients Γ_a and Γ_b are the linear dispersion coefficients; Δ_{aa} and Δ_{bb} are the nonlinear coefficients which describe the self-modulation of the wave packets; Δ_{ab} and Δ_{ba} are the nonlinear coupling coefficients of the cross-modulation between two wave packets and Λ_a, Λ_b are known as external potential and show the effect of heterogeneity. Thus, once solutions for A_a and A_b are derived from (9) for given initial values of the form $A_a(\xi,0) = A_{a0}(\xi)$ and $A_b(\xi,0) = A_{b0}(\xi)$, then the first-order solution v_1 can be constructed by (7).

Conclusion

In this study, the propagation and interaction of nonlinear Love waves in a nonlinear homogeneous thin layer overlying a nonlinear heterogeneous semi-infinite medium was investigated. By applying the thin layer approximation, the boundary value problem was transformed into a free-surface boundary condition for the semi-infinite medium. However, despite this transformation, the derived boundary condition still retains the linear and nonlinear material properties of the layer. Subsequently, using the multiple scales method, the obtained equations were analyzed, leading to first-order and higher-order perturbation solutions.

The compatibility conditions derived from the second and third-order problems led to a system of coupled nonlinear Schrödinger (CNLS) equations, which govern the evolution of wave amplitudes. These equations describe the nonlinear interactions of co-directional Love waves, incorporating effects of dispersion, self-interaction and cross-interaction, and the effect of the heterogeneity of the half-space. Future work will focus on the numerical solutions of the derived CNLS equations.

kucukb22@itu.edu.tr

Keywords: Time Series, EEG Classification, Machine Learning, Deep Learning, Neural Networks.

Aim

Electroencephalography (EEG) is widely used in neuroscience and medical diagnostics to analyze brain activity in clinical applications as it can help in the identification of neurological disorders and cognitive states. Classification of EEG signals plays a crucial role in the diagnosis of neurological conditions and the development of brain-computer interface (BCI) systems. The primary aim of this study is to develop and evaluate a classification pipeline based on time-frequency representations of EEG data, particularly spectrogram images, using both traditional machine learning deep learning models. This work also seeks to compare the performance of various approaches and discuss the practical implications of classification accuracy in medical applications.

Material and Method

Dataset Description

The dataset used in this study originates from a comprehensive research initiative aimed at identifying EEG-based biomarkers of genetic predisposition to alcoholism. It was compiled and made publicly available through the UCI Machine Learning Repository. EEG signals were recorded from 122 subjects, equally divided into two distinct groups: alcoholic and control. During the experiment, each participant was exposed to visual stimuli consisting of pictures selected from the standardized 1980 Snodgrass and Vanderwart picture set. These stimuli were presented in three conditions; a single stimulus (S1), two matching stimuli (S1 and S2 match), or two non-matching stimuli (S1 and S2 nonmatch). EEG recordings were collected from 64 scalp electrodes. The signals were sampled at 256 Hz over a duration of 1 second per trial, resulting in 256 data points per electrode per trial. Each subject completed 120 trials and data from each trial were stored in individual text files. These files include metadata such as subject ID (which also encodes subject group), trial type, and stimulus condition. The recorded signals were stored as four-column entries: trial number, electrode label(sensor position), timestamp (0–255) and voltage in microvolts (μV) [1].

Preprocessing

Preprocessing of the dataset required careful handling due to its size and structure. Subjects were grouped based on the prefix of their identifiers: those beginning with "co2a" or &"co3a" were labeled as alcoholic, while others were assigned to the control group. To efficiently combine trials for each subject, the Polars library was initially used for its memory efficiency and speed on large-scale tabular data. Following the merging stage, the more flexible Pandas library was preferred for further data manipulation.
Three additional columns were appended to each trial dataset to enhance the tabular structure: the subject name, group label ('a' for alcoholic 'c' for control) and the stimulus matching condition (S1-obj, S2-nomatch, or S2-match). This preprocessing was conducted separately for alcoholic and control groups to prevent memory overload. After combining all trials, the dataset reached approximately 179 million rows, necessitating optimized data management. To this end, the data was converted into the Parquet format which provided faster loading and minimized memory issues. Strategic memory handling, including kernel restarts and incremental processing was employed throughout the analysis.

After sorting each trial by timestamp, the data was reshaped using a pivot operation to format voltage values by trial and sensor. Sensor names were standardized to match the 10–20 Electrode Placement System, a widely accepted convention in EEG analysis. Three incompatible sensors labeled X, Y, and nd were excluded from further analysis to maintain EEG format integrity.

Modeling Approaches

The classification of EEG signals in this study followed a comprehensive modeling pipeline involving both traditional machine learning algorithms and advanced deep learning techniques. The process initially focused on tabular representations of the EEG data, where statistical and frequency-domain features were extracted from each of the 64 channels per trial. These features were used to train classical supervised models such as Logistic Regression, Support Vector Machines (SVM), as well as powerful ensemble methods including XGBoost, LightGBM, and AdaBoost [2].

Subsequently, deep learning approaches have been used to capture more complex spatial and temporal dynamics within EEG signals. In the first deep learning phase, 1D Convolutional Neural Networks (CNNs) were applied to tabular EEG data to extract local temporal patterns across channels. However, when the EEG signals were transformed into spectrogram images, 2D CNNs were used to exploit both spatial and frequency-based features in a visual format [3], [4]. By feeding EEG sequences into LSTM architectures, the models have been studied to effectively learn the dynamic signal transitions over time that are often crucial in brain activity interpretation [5]. In addition to CNN and LSTM models, other deep learning approaches were also examined to assess their potential contributions. For maximum accuracy and to avoid overfitting, the models were optimized through subject-based cross-validation, dropout and hyperparameter tuning. All applications were implemented in Python using libraries such as Scikit-learn, Tensorflow and Keras.

Findings

The comparative performance of the models revealed key insights into the suitability of various approaches for EEG-based classification. Among the classical machine learning algorithms, XGBoost achieved the highest accuracy on the tabular feature set, with a classification accuracy of 72.3%, outperforming LightGBM (69.1%) and AdaBoost (67.2%). The ensemble-based models demonstrated robustness to inter- subject variability and imbalanced class distributions.

However, 1D CNN significantly improved upon these results, achieving a classification accuracy of 78.3%. This highlights the strength of convolutional neural networks in handling EEG data, as they are better suited to learning spatial hierarchies and features directly from the raw data.

When transitioning to deep learning models, significant improvements were observed. The 2D CNN, trained on spectrogram images, achieved an impressive classification accuracy of 92.4%. This model benefitted from the rich time-frequency representations of EEG signals, allowing it to capture more detailed and complex features of the data compared to the classical machine learning models.

Additionally, the LSTM model applied to raw time-series EEG data achieved an accuracy of 94.9%, showcasing its ability to capture temporal dependencies that are not easily accessible to image-based models like the 2D CNN. These findings underscore that while traditional machine learning models can serve as a useful baseline, deep learning models, particularly CNN and LSTM-based architectures, offer substantial improvements in decoding cognitive states from EEG data.

Conclusion

This study presented a multi-stage pipeline for the classification of EEG signals associated with genetic predisposition to alcoholism, integrating both conventional machine learning and deep learning methods. The experimental results suggest that ensemble-based models like XGBoost can be used for structured tabular data, while deep learning models, particularly CNNs and LSTMs are highly effective in extracting meaningful patterns from raw signals and spectrogram representations.

The performance of 2D CNNs and LSTM models demonstrates the advantage of modeling both spatial-frequency and temporal dynamics of EEG signals. Furthermore, the hybrid architectures highlighted the complementarity of visual and sequential signal features with classification performance.
These outcomes indicate a strong potential for deep learning models in clinical EEG analysis, especially in early detection and diagnosis scenarios. Future work will focus on expanding the dataset, enhancing interpretability of deep models and exploring domain adaptation techniques for subject-invariant learning.

Modeling Rare Metal Market Dynamics: A Nonlinear Approach withInvestment and Geopolitical Risk

Furkan Emre Işık[a], Ali Demirci[a]

[a] Istanbul Technical University/Faculty of Science and Letters, Departmant of Mathematics, Mathematical Engineering, Turkey
isikf17@itu.edu.tr

Keywords: Bifurcation, Dynamical Systems, Nonlinear System Modeling.

Aim

The rare earth element (REE) market is characterized by complex interactions among supply, demand, price fluctuations, and geopolitical risk. These elements are essential for various advanced technologies, including electric vehicles (EVs), renewable energy systems, and defense applications. Understanding the dynamics of this market requires a robust modeling framework that captures nonlinear relationships and feedback mechanisms. The REE market is subject to disruptions due to political interventions, trade restrictions, and investment cycles, making it highly volatile. This study aims to develop and analyze a nonlinear dynamical system representing the REE market, integrating key factors such as supply from different regions, demand driven by EV adoption, price evolution, and investment inmining operations. Traditional linear models often fail to capture the nonlinear dependencies present in commodity markets, particularly when investment decisions, supply constraints, and price adjustments occur dynamically. By formulating a system of nonlinear ordinary differential equations (ODEs), this study seeks to explore the fundamental structure of market stability, equilibrium states, and bifurcation behavior. A primary objective of this research is to investigate critical thresholds that drive market instability or structural shifts. By understanding how different parameters influence market stability, policymakers and industry leaders can anticipate potential crises andtake preventive measures. This study also contributes to the broader literature on nonlinear economic systems by demonstrating how nonlinear interactions between supply, demand, and investment lead to complex market behaviors. Ultimately, the findings may provide insights into the long-term sustainability of rare earth resource management and inform strategies for stabilizing the market amid external shocks.

Material and Method

A nonlinear system of ordinary differential equations (ODEs) is formulated to model the interactions between key market components. The model introduces nonlinear dependencies to reflect real-world behavior, where investment follows a power-law response to price, supply reacts to investment in a nonlinear fashion, and demand exhibits nonlinear sensitivity to price fluctuations. Unlike standard linear economic models, this framework explicitly incorporates dynamic feedback loops that characterize the rare earth market. To analyze system behavior, equilibrium points are determined by setting the rate of change of the system variables to zero and solving for steady-state solutions. The stability of these equilibria is then evaluated through Jacobian matrix eigenvalues, where negative real parts indicate stability and positivereal parts signal instability [6]. This approach allows us to identify conditions under which market stability is maintained or disrupted. Furthermore, bifurcation analysis is performed to explore how small parameter changes can induce qualitative shifts in market behavior. Specifically, bifurcations are examined concerning geopolitical risk, price elasticity of demand, and investment sensitivity to price fluctuations. The presence of bifurcations suggests the existence of tipping points, beyond which the market transitions from a stable to an unstable state [4]. By mapping these transitions, we can assess potential risk factors leading to extreme volatility in rare earth prices. Computational simulations are used to validate the theoretical findings, providing insight into how the market evolves over time under different scenarios. Sensitivity analysis is conducted to determine the influence of key parameters, allowing us to gauge their relative importance in driving

market dynamics. This methodological approach enables a comprehensive investigation of the nonlinear characteristics of the REE market, enhancing our ability to anticipate supply crises and price fluctuations.

Findings

The analysis reveals the existence of multiple equilibria in the system, dependent on parameter values such as investment responsiveness toprice and geopolitical risk. Linear stability analysis shows that under certain conditions, the system exhibits oscillatory behavior due to the interplay between supply fluctuations and investment cycles. Moreover, bifurcation analysis identifies critical thresholds where small changes in parameters induce abrupt shifts in market stability. Key findings include:

Investment-Price Feedback Loop: Nonlinear investment response to price amplifies market volatility, leading to self-sustained oscillations or market crashes [5].

Geopolitical Risk as a Bifurcation Parameter: Increasing geopolitical risk beyond a certain threshold shifts the market from astable equilibrium to an unstable regime, where supply shortages drive exponential price increases [3].

Nonlinear Demand Suppression: High prices induce nonlinear suppression in demand, which stabilizes the system under certain conditions but exacerbates volatility under others [2].

Multiple Attractors: The system exhibits multistability, meaning different initial conditions or parameter values can lead to vastly different market outcomes (e.g., stable supply vs. crisis states) [1].

These results underscore the importance of nonlinear interactions in rare earth market dynamics and highlight the potential for sudden, unpredictable shifts due to investment behavior and geopolitical disruptions. Policy implications include the necessity for strategic investment planning and international cooperation to mitigate market instability.

Conclusion

This study demonstrates that a nonlinear dynamical system approach provides valuable insights into the behavior of the rare earth market. By incorporating nonlinear feedback loops between supply, demand, price, and investment, the model captures key features of real-world market behavior that traditional linear models fail to address. The identification of bifurcation points and multiple equilibria highlights the market's susceptibility to sudden shifts, offering a theoretical framework for anticipating disruptions. The findings emphasize the need forproactive strategies to stabilize the REE market, particularly through policies that regulate investment cycles and mitigate geopolitical risks. Further research should integrate stochastic elements and empirical validation using real-world data to refine the model's predictive capability. Additionally, incorporating external policy interventions, technological advancements, or environmental constraints could provide a more comprehensive understanding of long-term market dynamics. Ultimately, this study contributes to the broader literature on nonlinear economic modeling and offers practical insights for policymakers and industry stakeholders navigating the complexities of the rare earth market.

Evaluation of Mechanical Properties of SLM AlSi10Mg Alloy Produced with Different Production Parameters

Hasret Baş[a], Raşid Ahmed Yıldız[a]

[a] Istanbul Technical University/Science Engineering and Technology Institute,
Departmant of Mechanical Engineering, Materials and Manufacture Master of Science Program, Turkey
bash22@itu.edu.tr

Keywords: Laser Powder Bed Fusion, AlSi10Mg Alloy, Tensile Testing, Ved.

Aim

AlSi10Mg alloy, produced using LPBF technology, is frequently used today in aerospace and automotive, where high strength and lightness are preferred. According to the information from the literature, AlSi10Mg alloy with SLM had better or comparable mechanical properties than the cast AlSi10Mg alloy. In this study, the optimum parameter was selected by examining the mechanical properties of AlSi10Mg alloys produced with different parameters.

Additive Manufacturing (AM), often used for metals and known as 3D printing for polymers, has the potential to revolutionize product manufacturing through new materials and existing processes. [1] AM can also cut product development time and costs by forming process chains with other technologies, beyond just creating complex models. [2] Powder Bed Fusion (PBF) is one of seven AM methods, using a laser, heat, or electron beam to melt and fuse material into a 3D object. [3] Powder bed fusion uses laser or electron beams to melt and fuse metal or alloy powders, including methods like selective laser melting (SLM), selective laser sintering (SLS), direct metal laser sintering (DMLS), electron beam melting (EBM), and selective heat sintering (SHS). [4] For producing SLM AlSi10Mg parts, SLM is expected to be ideal for lightweight and thermal control components in aerospace and automotive, thanks to aluminum's low density and high thermal conductivity. [5,6] SLM AlSi10Mg parts are known for their high strength and low ductility. [6] SLM alloys also exhibit anisotropic mechanical properties. [6,8] In SLM-produced AlSi10Mg, mechanical properties are strongly influenced by the size and shape of eutectic Si in the microstructure. [5] Wei Li et al. [7] investigated the effect of artificial aging at different temperatures on the tensile strength and microstructure of the material. In the artificial aging processes carried out at 450, 500, 550 °C for 2 hours, a significant decrease is observed in both tensile and yield strengths of the specimens at 450 °C whist a large increase in ductility of can be observed. As temperatures increased to 500 and 550 °C, tensile and yield strengths continued to decrease, while ductility continued to increase. It has been suggested that this is due to the temperature-dependent changes in the variation in size of Si. K. Kempen et al. [8] compared the SLM-produced AlSi10Mg alloy with the conventionally cast AlSi10Mg alloy and indicated that the AlSi10Mg alloy produced by SLM exhibited higher mechanical properties than the cast AlSi10Mg alloy or were comparable. It was indicated that the reason for this is that SLM AlSi10Mg parts have a very fine microstructure and fine Si phase distribution. Alessia Teressa Silvestri et al. [9] tested and compared samples produced on different machines and in different building directions. They stated that ultimate tensile strength, yield strength, and modulus of elasticity showed different values depending on different machines, but the elongation at break was almost the same. It has been suggested that although the influence of the building direction and the equipment is evident in the diagrams, it is not possible to choose a clear production parameter in any case illustrated by the experimental work. Nevertheless, it has been stated that products with the best mechanical behaviour can be obtained and in all cases are better or comparable to samples produced with traditional technology. [8,9] In this study, laser power, scanning speed, scanning range and orientation parameters were investigated. It was investigated how the yield strength, tensile strength, elongation at break and modulus of elasticity changed with the change of these parameters.

Material and Method

Tensile tests of tensile test specimens produced using SLM Solutions powders and the Nikon SLM 500HL printer were performed in accordance with ASTM E8-09 standards. A Shimadzu Autograph machine was used as the tensile testing machine. Specimen elongation was determined using two CCD cameras (which were used as video extensometers). The test was conducted with the moving ram set at 5 mm/min, thus having an initial strain rate of 2.38×10-3 s-1. Tensile tests were performed on a total of 12 specimens, 4 specimens from the scan speed parameter and 3 samples from each of the other parameters.

The strength of Al alloys produced by additive manufacturing is notable; however, their mechanical behavior can deteriorate significantly due to process-related flaws, especially porosity, which is the most damaging. This issue arises from a non-optimized process, making the careful selection of building parameters essential to obtain a nearly fully dense final part. [10] Maverick Giovagnoli et al. [10] argued that while VED can provide a rough estimation for porosity, it is insufficient for predicting microstructure and mechanical properties, and therefore inadequate for determining the optimum processing parameters. Wayne E. King et al. [11] the occurrence of keyhole mode melting identified as a cause of porosity formation and a transition threshold for the keyhole mode determined. This keyhole transition threshold determined by a parameter called Normalized Enthalpy, which evaluates the laser power, scanning speed and beam diameter on a single scale. However, VED will be used in this study. Table 1 shows the calculated VED values according to the applied production parameters.

Table 1: Production parameters of the samples and volumetric energy density (VED) values calculated according to these parameters

Batch Name	Scan Speed (mm/s)	Hatch Spacing (µm)	Laser Power (W)	Build Direction (°)	Thickness of Layer (µm)	VED (J/mm^3)
SS 1000	**1000**	170	370	0	30	72,55
CG	**1200**	170	370	0	30	60,46
SS 1300	**1300**	170	370	0	30	55,81
SS 1400	**1400**	170	370	0	30	51,82
H 150	1200	**150**	370	0	30	68,52
H 130	1200	**130**	370	0	30	79,06
H 110	1200	**110**	370	0	30	93,43
P 350	1200	170	**350**	0	30	57,19
P 330	1200	170	**330**	0	30	53,92
P 310	1200	170	**310**	0	30	50,65
BD 35	1200	170	370	**35**	30	60,46
BD 45	1200	170	370	**45**	30	60,46
BD 90	1200	170	370	**90**	30	60,46

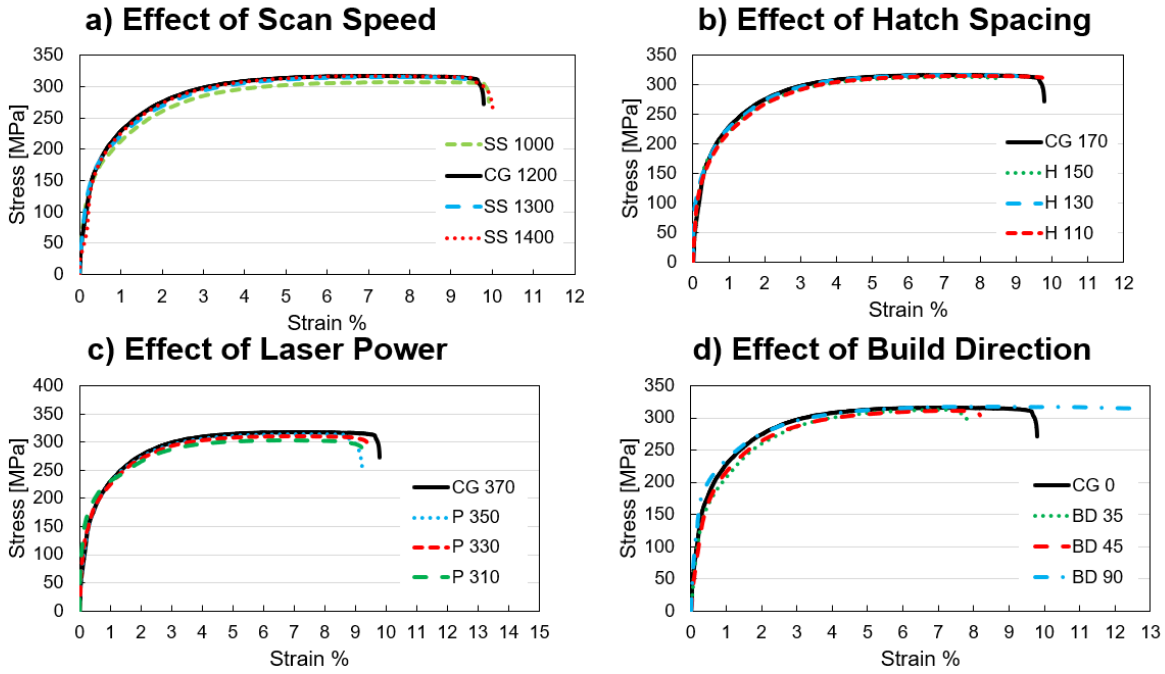

Fig 1: Effect of production parameters on mechanical behaviour.

Findings

In Fig 1(a), the effect of scanning speed on mechanical properties is investigated. As can be seen, when the scanning speed was low, the yield and tensile strengths were also relatively low compared to other scanning speeds. Because the highest VED value is reached when the scanning speed decreases and the increase in VED value increases the amount of energy given by the laser to the powder bed, causing the temperature to increase. As the temperature increases, the recoil pressure created by the molten metal vapor creates a narrow and deep melt pool called the keyhole. The keyhole is unstable and when it collapses, protective gases such as argon are trapped inside. This causes porosity and causes the yield and tensile strength to decrease. At lower VED values, the powders do not melt completely due to insufficient energy input and full bonding between layers cannot be achieved. This causes increased porosity and decreased strength. In Fig 1(b), the effect of hatch spacing was investigated. Here, it is seen that the CG specimen, which has the lowest VED value (60.46 J/mm^3) among the 4 samples, is better than the other specimens in terms of yield and tensile strength and ductility. Again, it is thought that keyhole formation causes porosity. In Fig 1(c), the effect of laser power was investigated. Here, the CG sample, which has a higher VED value (60.46 J/mm^3) than the other samples, has better mechanical properties as in other evaluations. The reason for this may be the formation of porosity due to insufficient melting at low VED value. In Fig 1(d), the effect of build direction was investigated. U. Patakham et al.
[12] stated that SLM AlSi10Mg exhibits isotropic properties when as-built and anisotropic properties after heat treatment. Shengzhao Yang et al. [13] stated that the horizontal specimen had the highest yield strength and highest elongation, the specimen with 45° orientation had the highest tensile strength, the lowest ductility was seen in the vertical specimen, and the highest ductility was seen in the vertical specimen. They attributed the low ductility and early fracture of 45° inclined samples to the high porosity rates in the contour areas. They state that the main effect in horizontal and vertical orientations arises from the alignment of the Al-Si eutectic phases. These data are consistent with our results. While the horizontally produced sample BD 90 has the highest yield and tensile strength and elongation, the samples with 35° and 45° orientation have lower yield and tensile strength. The CG sample produced perpendicularly shows mechanical properties at average values.

Conclusion

As a results, when we look at the graphics, it is seen that the BD 90 sample (produced horizontally to the table plane) has the best mechanical properties (flow strength, rupture strength, rupture prolongation). The higher breaking prolongation is important for the predictability of damage formation. However, there is no significant necking. Nevertheless, we can say that it has a higher ductility because the rupture is higher. Therefore, the best parameters are the production parameters of the BD 90 sample. However, these samples cover a lot of space on the table. And these samples can only be separated from the table by water jet and wire erosion. CG samples allow more parts production at one time and can be easily separated from the table. For BD 90 and CG samples with the same VED value (60,46 J/mm3), BD 90 sample parameters may be preferred if the ductility is very important compared to the usage area. In addition, CG sample parameters also have very good mechanical features and are preferable in terms of cost and ease of production.

Keywords: Electric Kick Scooter, Finite Element Analysis, Vehicle Dynamics, Safety, Ergonomics.

Aim

In recent years, the increasing urban population and growing traffic congestion in metropolitan areas have led to significant time loss due to prolonged vehicle idling. This inefficiency has prompted a shift toward compact, cost-effective, and environmentally friendly personal urban transportation alternatives such as bicycles, motorcycles, and scooters. Among these, electric kick scooters have gained considerable popularity due to their ease of use, portability, compact storage, and the elimination of parking requirements (Asperti et al.,2022a).

This academic study aims to investigate the dynamic behavior, ride safety, and ergonomic performance of an electric kick scooter through computational modeling and simulation. Key objectives include evaluating vehicle dynamics under various driving scenarios, analyzing rider comfort and safety, and optimizing the structural and functional aspects of the scooter.

The design of the electric kick scooter was initially developed using CAD software. Benchmarking analyses were conducted by examining the technical specifications of commercial scooter models, from which critical design parameters were derived. The propulsion system consists of a brushless DC (BLDC) hub motor mounted on the front wheel, while the battery pack is housed within the deck beneath the rider's feet. This battery compartment must be structurally robust to withstand external impacts and designed to prevent water ingress due to its proximity to the ground. Structural analyses using Finite Element Analysis (FEA) was applied to validate mechanical safety.

The electric kick scooter was designed without a suspension system; instead, damping is passively provided through tire pressure adjustments. This approach aims to absorb road-induced vibrations, particularly in the critical 1–8 Hz frequency band to which the human body is most sensitive. These vibrations significantly affect rider comfort and must be mitigated through optimized posture and minimal contact pressure.A comprehensive dynamic model of the electric kick scooter and the human body is essential to analyze the discomfort caused by vibrations and evaluate the overall riding experience. In order to analyze this situation correctly, it is aimed to benefit from mathematical modeling and vertical dynamic analysis of the rider and the electric kick scooter.

The study also considers vertical, longitudinal, and lateral vehicle dynamics. Simulations are conducted under various road conditions and loading scenarios to assess stability, maneuverability, and rider safety. The ultimate goal is to enhance ride quality, minimize injury risks,and contribute to the safe adoption of electric kick scooters as a sustainable urban mobility solution.

Material and Method

The design process of the electric kick scooter began with a comprehensive review of technical documentation provided by various existing brands through their official websites. However, due to the inaccessibility or incompleteness of certain dimensions and technical parameters, physical measurements were conducted on widely used shared mobility scooters in urban areas. These measurements were obtained using precision tools such as calipers, tape measures, and rulers, and were compiled into technical documentation to guide the design process. Based on the gathered measurements and technical data, the electric kick scooter model was created using CATIA V5, taking actual dimensions into account.

To analyze the structural durability and stress distribution of the scooter's battery compartment and the platform beneath the rider's feet, the FEA method was applied. The analyses included Von Mises stress evaluation,static displacement analysis, static strain assessment, and safety factor evaluation under maximum load-bearing conditions. Furthermore,potential impact forces to the underside compartment of the scooter were considered in the simulations. Along side static analysis, a fatigue analysis was conducted to evaluate the structural endurance of the deck. In the static analysis, virtual loads were assigned to regions susceptible to impact from the ground, particularly under the foot platform. Fig. 1 illustrates representative scenarios of the scooter encountering elevated surfaces or shallow pits. Such impacts are anticipated to cause structural deformation or damage to the battery compartment depending on the material properties and the severity of the impact.

The deck of the electric kick scooter, where the rider stands, is made of aluminum alloy 6063-T1. This material was selected due to its high strength-to-weight ratio—offering comparable durability to steel while being approximately one-third of its weight (Chandrasekhar & Deva Kumar, 2019). The parameters of the material properties of the aluminum alloy in Table 1 were used in FEA analysis.

Table 1. Properties of Aluminium Alloy 6063-T1.

Property	**Value**	**Units**
Elastic Modulus	69000	N/mm^2
Poisson's Ratio	0.33	N/A
Shear Modulus	25800	N/mm^2
Mass Density	2700	kg/m^3
Tensile Strength	150	N/mm^2
Yield Strengrh	90	N/mm^2

As the design does not include a suspension system, vibrations caused by surface irregularities are primarily absorbed and regulated through tire pressure. Therefore, various internal tire pressure levels were simulated using the FEA tool, and comparative analyses were conducted to determine the optimal tire pressure value.

Additionally, to evaluate the aerodynamic performance of the scooter design, Computational Fluid Dynamics (CFD) analyses were carried out. These simulations assessed the effects of airflow approaching the scooter from different directions, as shown in Fig. 2 . By referencing the drag coefficient, the accuracy and efficiency of the design were validated.

To investigate the dynamic interaction between the rider and the electric scooter, analyses were conducted for the vertical, longitudinal, and lateral dynamics of the vehicle. Initially, a schematic physical model representing both the rider and the scooter was developed, followed by the creation of a corresponding mathematical model. Fig. 3

illustrates the schematic representation of the dynamic system. For the vertical dynamics, generalized Lagrangian equations of motion were used as the basis for the mathematical formulation. The resulting differential equations were implemented and solved in MATLAB. Additionally, simulations of the scooter's longitudinal and lateral dynamics were performed in MATLAB, enabling virtual scenario-based modeling of its dynamic behavior.

In the final phase of the study, the electric motor and battery system of the scooter were modeled in MATLAB/Simulink. Within this framework, the mechanical and electrical components of the scooter were comprehensively defined, and system-level calculations were performed considering parameters such as motor torque, battery power, and overall system efficiency.

Findings

The load defined for the analysis was applied from the underside of the platform, since the battery is located beneath the deck platform of the electric kick scooter. The FEA included evaluations of Von Mises stress, static displacement, static strain, and the factor of safety under maximum load-bearing conditions. The results obtained from these analyses are presented in Table 2. As shown in the table, both the minimum and maximum values for each analysis type have been documented and observed to the material durability limited.

Table 2. FEA results obtained from the analysis of the force applied from below to the deck of the electric kick scooter.

Analysis Name	Method	Minimum Value	Maximum Value
Stress Analysis	Von Mises	4.283e-001 N/m^2 Node : 50,840	1.456e+007 N/m^2 Node : 75,762
Displacement	URES	0.000e-000 mm Node : 372	1.486e-002 mm Node : 31,974
Strain Analysis	ESTRN (Equivalent of strain)	3.710e-011 Node : 32,589	4.353e-004 Node : 34,306
Factor of Safety	FoS	6.180e+000	2.101e+008

The effect of crosswind loads on the lateral stability and power consumption of the electric kick scooter was investigated through aerodynamic analyses under varying wind conditions. Two primary loading scenarios were defined: forward motion under headwind (upwind) and lateral stability under crosswind conditions. For the power consumption case, the scooter was simulated traveling at a constant speed of 25 km/h against an average headwind of 15 km/h. In the lateral stability scenario, a 90-degree crosswind was applied while the scooter moved forward at the same speed, simulating a critical side-wind condition. The drag coefficients were calculated based on the projected areas perpendicular to the wind direction, with the longitudinal drag coefficient derived from the frontal area and the lateral drag coefficient from the side profile. CFD analysis was performed using the values in Table 3 to perform the flow analysis. (Acarer, Arslan, & Uyulan, 2021)

Table 3. Parameters according to wind direction (Acarer, Arslan, & Uyulan, 2021).

Parameters	Upwind Direction	Sidewind Direction
Wind Angle (degree)	0º	90º
Wind angle relative to the moving electric kick scooter(degree)	0º	50º
Aerodynamics Drag Coefficient(C_D)	0.79	0.80
Frontal Area (m^2)	0.53	0.60
Longitudinal C_D	0.79	0.60
Lateral C_D	N/A	0.74
Lateral Moment (N.m)	1	23

To represent the fundamental dynamics of the electric scooter with an onboard rider, a linear dynamic model was developed. The cooter frame was modeled as a rigid body, and its suspension was represented by equivalent elements providing vertical stiffness and damping.Tires were simplified based on their radial stiffness and damping properties. The rider was modeled as a double-series spring-damper system with vertical motion connected to the deck. The hand-arm system was modeled with greater complexity, using dual-series spring-damper systems to represent both vertical and longitudinal motions, linking the handlebar to the upper body of the rider. This comprehensive model is illustrated in Fig. 3 and offers a systematic framework for vertical dynamic analysis of e-scooters (Asperti et al.,2022b)

Fig. 4 compares the system's frequency and phase responses for the damped and undamped models. In the amplitude diagram (Figures 4.a and 4.b), the blue curve exhibits high-pass filter characteristics—attenuating low-frequency signals while allowing higher frequencies topass with less attenuation. Conversely, the red curve

behaves like a low-pass filter, transmitting low-frequency signals with less attenuation. In the phase diagram (4.c and 4.d), the blue curve shows a gradual transition from positive to negative phase, while thered curve transitions more abruptly. This indicates that damping effectively alters the system's frequency response and significantly influences its vibrational behavior.

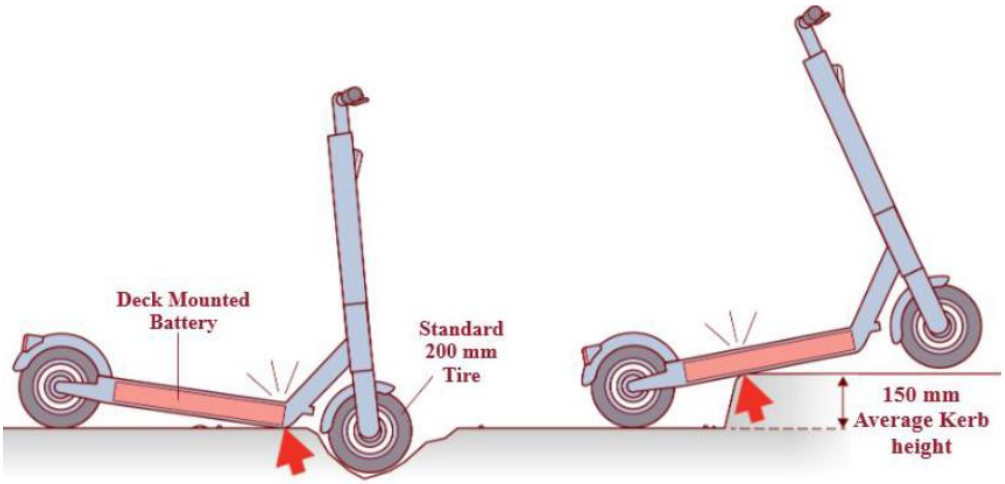

Figure 1. Some mechanical damage senarios on electric scooters.

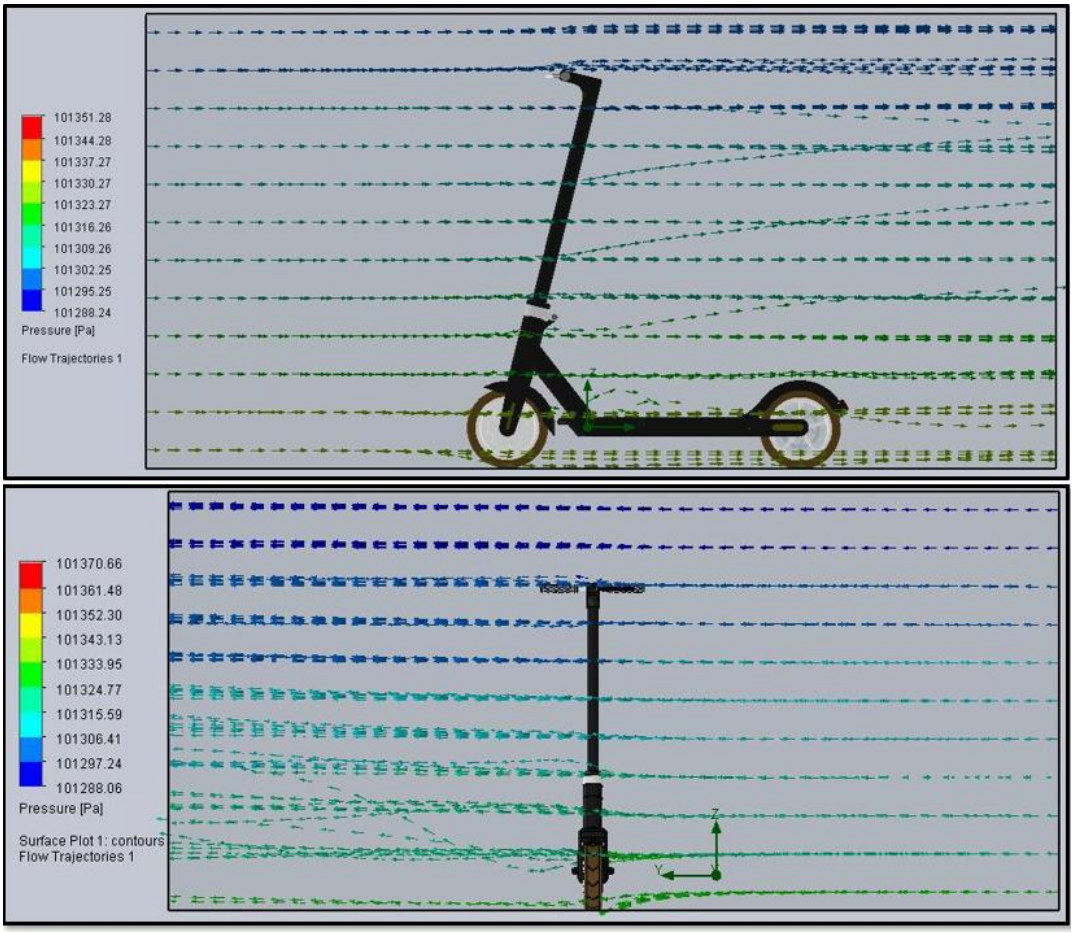

Figure 2. Flow analysis of electric scooter in different wind angle directions.

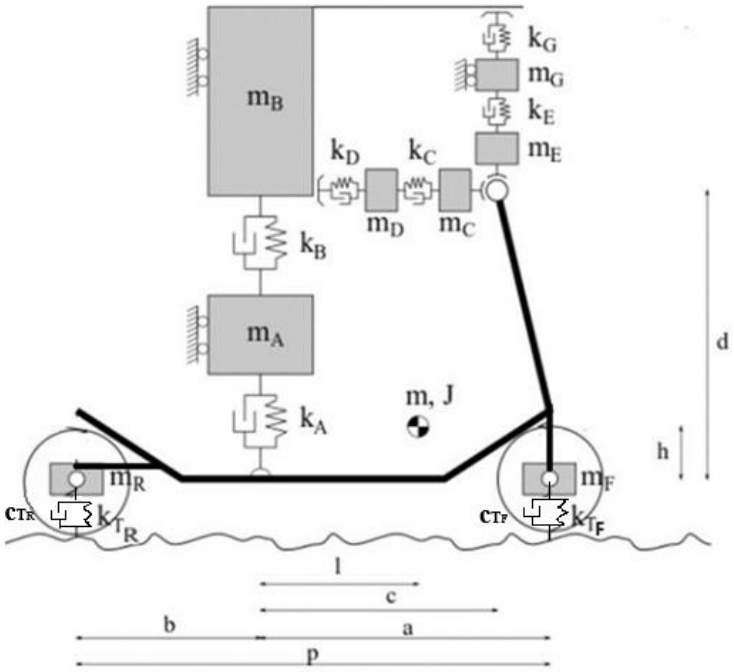

Figure 3. Biodynamic model for the rider and elektric kick scooter model without suspensions.

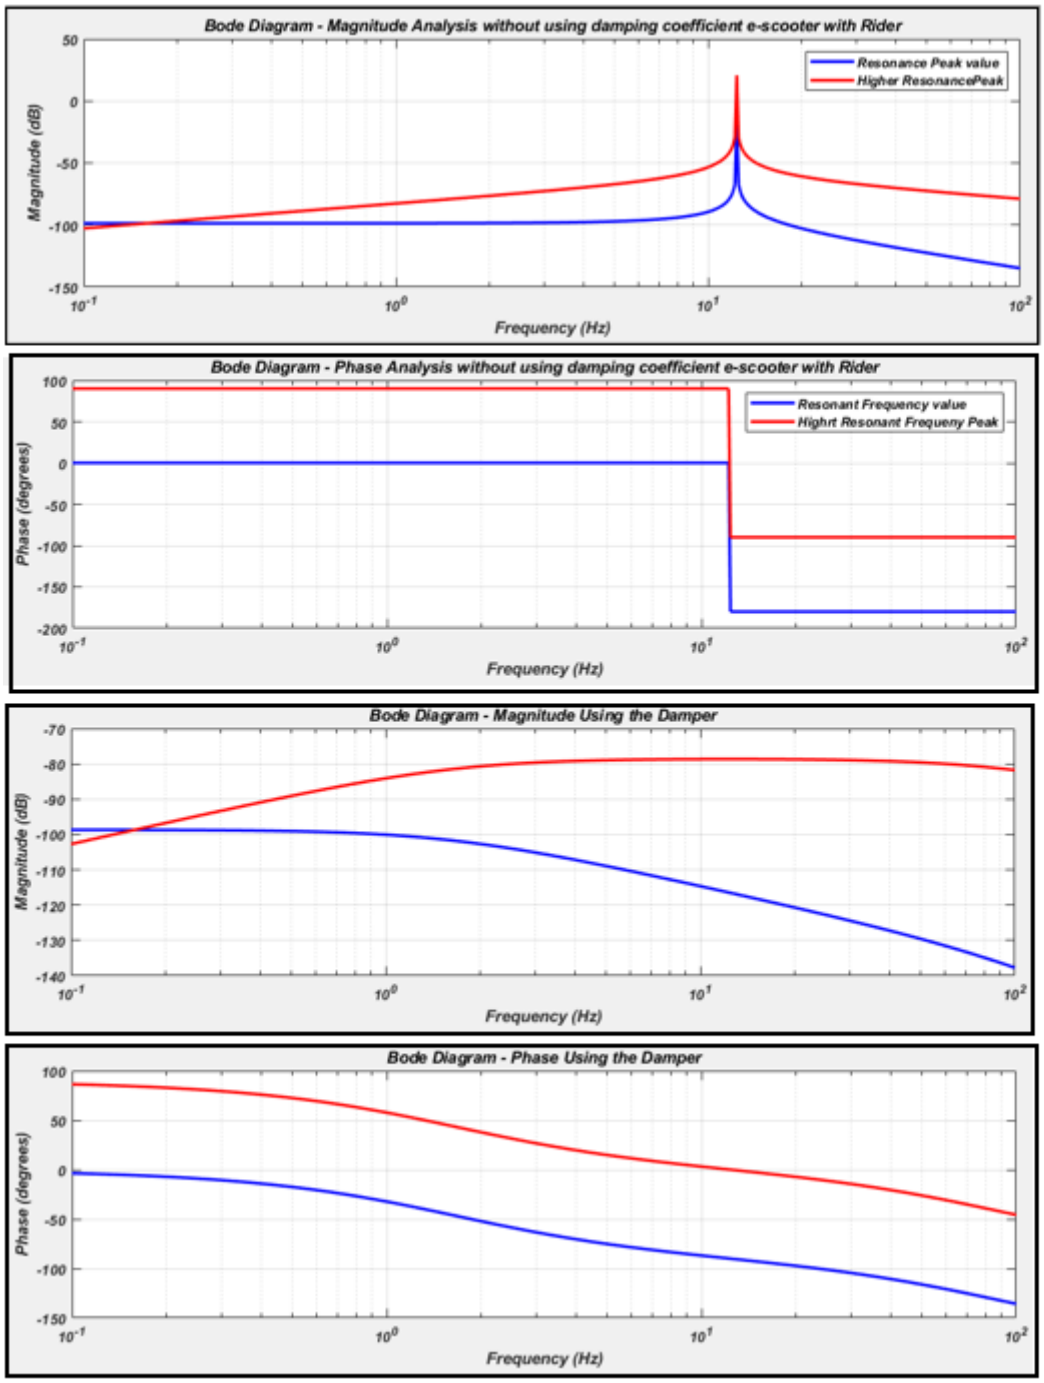

Figure 4. Frequency and phase response of the electric kick scooter system with and without damping (4.a & 4.b) illustrates the Bode magnitude and phase response of the e-scooter system without a damping component, and (4.c & 4.d) demonstrates the system's response with an implemented damping coefficient.

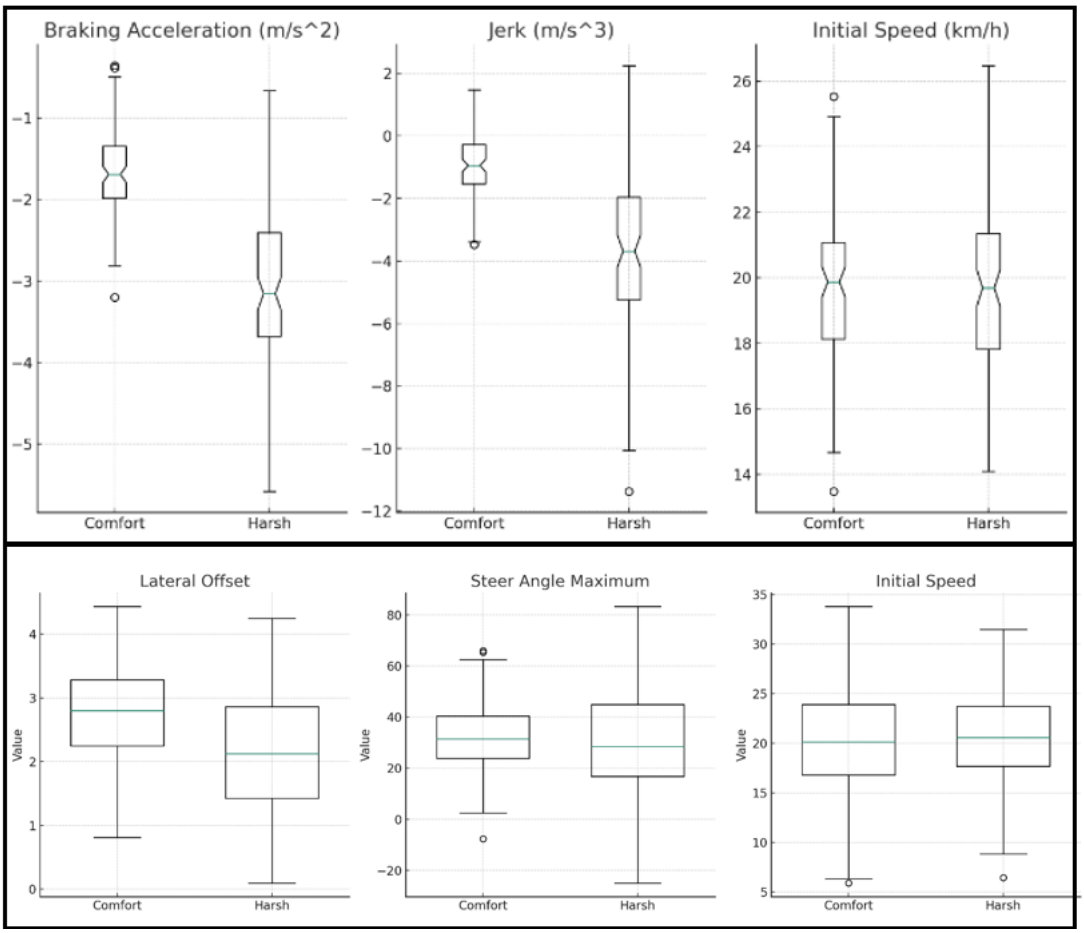

Figure 5. Comparison of braking and steering metrics under Comfort and Harsh riding conditions. (9.a) Braking acceleration, jerk, and initial speed distributions under comfort and harsh braking maneuvers, (9.b) Lateral offset, maximumsteering angle, and initial speed variations during evasive steering tasks in both riding conditions.

In the longitudinal and lateral dynamic analyses, rider performance and safety were evaluated under different maneuvering scenarios. Participants were asked to bring the scooter to a complete stop in front of a cardboard obstacle—either comfortably (relaxed braking) or abruptly (emergency braking). In two separate steering maneuvers, riders were instructed to turn either gently or forcefully before reaching the obstacle. Tasks were randomized across participants to eliminate ordering bias. Table 4 presents the comparison of braking performance under both comfort and harsh conditions. In comfortable braking, lower negative acceleration and jerk values were observed, whereas in harsh braking, both metrics increased significantly due to abrupt stopping. Initial braking speeds were comparable across both conditions.

Table 4. Comparative metrics of braking performance for the electric kick scooter during evasive maneuvers in Comfort and Harsh conditions.

Parameters	Standard Deviation	Comfort	Harsh
Acceleration (m/s^2)	M±SD	-1.70±0.60	-2.90±1.05
Jerk (m/s^3)	M±SD	-1.00±0.95	-3.20±2.70
Strain Analysis	M±SD	20.00±2.30	20.00±2.60

*M = Mean, SD = Standard Deviation

Table 5 compares lateral offset, maximum steering angle, and initial speed under both conditions. In the comfort scenario, riders maintained a greater lateral distance from the obstacle (≈2.7 m), suggesting more relaxed and safer maneuvering. In contrast, the harsh condition involved closer proximity to the obstacle and a wider distribution of steering angles, indicating more abrupt maneuvers. Additionally, the initial speed was higher in the harsh condition (≈21.5 km/h), implying that riders required quicker reaction times. These metrics are visually represented in the boxplots shown in Fig. 5, where both sets (5.a and 5.b) illustrate performance variations in braking and steering behaviors using median values and outlier data.

Table 5. Comparison of average lateral offset, maximum steering angle, and initial speeds for the electric kick scooter under Comfort and Harsh riding conditions.

Parameters	Standard Deviation	Comfort	Harsh
Lateral offset (m)	M±SD	2.75±0.80	2.10±1.00
Steer Angle Maximum	M±SD	32.60±14.50	33.70±22.00
Initial speed (km/h)	M±SD	20.00±5.15	21.50±5.00

*M = Mean, SD = Standard Deviation

Conclusion

In conclusion, this study presents a comprehensive investigation into the ergonomic design, structural integrity, and dynamic performance of an electric kick scooter, with the aim of enhancing rider safety, comfort, and vehicle efficiency under urban mobility conditions. FEA results showed that the deck-mounted battery compartment has sufficient structural strength, with a maximum Von Mises stress of 14.56 MPa and a safety factor above 2.1×10^8. Displacement and strain analyses revealed minimal deformation, ensuring platform stability during operation. The results obtained from the aerodynamic analyses performed in both upwind and crosswind scenarios highlight the

importance of taking wind-induced instability into account for safe vehicle design and control, especially when exposed to crosswind. Dynamic modeling and simulations of vertical, longitudinal, and lateral vehicle responses showed that system damping plays a crucial role in mitigating resonance effects within the 1–8 Hz sensitivity range of the human body. As illustrated in the Bode diagrams, damping effectively reduced both magnitude and phase responses, improving rider comfort. Additionally, performance evaluations in different riding conditions revealed that riders under "harsh" scenarios exhibited higher peak jerks (–3.20 ± 2.70 m/s³) and braking accelerations (–2.90 ± 1.05 m/s²) compared to "comfort" scenarios (–1.70 ± 0.60 m/s²). Steering analysis further indicated that riders in comfort conditions maintained a greater lateral clearance (2.75 ± 0.80 m) from obstacles, reflecting more stable maneuvering behavior. In conclusion, the integration of structural simulations, CFD analysis, and biodynamic modeling has provided a robust framework for evaluating the performance and safety of electric kick scooters.

Keywords: Electrification, Heavy Commercial Truck, Vehicle Modeling, Energy Efficiency, Economy.

Aim

In recent years, the environmental concerns associated with internal combustion engine (ICE) vehicles, particularly the emission of unburned hydrocarbons and harmful particulate matter from fossil fuel consumption, have significantly contributed to global pollution, climate change, and the intensification of the greenhouse effect. These adverse effects not only threaten human health but also pose a serious risk to environmental sustainability. As a solution, battery electric vehicles (BEVs) are increasingly considered a viable alternative to conventional vehicles due to their zero-emission capabilities and ability to utilize clean energy sources.

Globally, freight transportation is carried out through various modes, including road, maritime, and air transport. Among these, road transportation, facilitated by trucks and heavy commercial vehicles, plays a crucial role in maintaining supply chains and ensuring the continuity of global trade. The transition of heavy commercial vehicles to electrified systems is essential for promoting sustainable transportation with clean energy sources. In this context, the primary objective of this study is to replace the power transmission system of a diesel-powered heavy commercial vehicle with a fully battery-electric powertrain, thereby transforming the truck into a fully electric commercial vehicle. Furthermore, this study aims to conduct a comprehensive analysis of the electrified heavy commercial truck, focusing on key performance metrics such as powertrain efficiency, environmental impact, and energy/fuel economy. A comparative assessment will be performed against a similar heavy commercial vehicle equipped with an internal combustion diesel engine to evaluate these aspects under identical operating conditions. By systematically comparing electric and conventional powertrain systems, this research seeks to demonstrate the superior advantages of electrified commercial vehicles in terms of energy efficiency, sustainability, and overall performance.

Material and Method

During the electrification process, a detailed selection of an electric motor and battery cells was conducted to match the technical specifications of the conventional truck. The powertrain of the electric truck was modeled using two fundamental structures: the mechanical model and the electrical model (Giordano, 2018). Fig.1 presents the structural diagram of the electric vehicle model, visually summarizing its two key components and their interactions.

In the mechanical model, the vehicle's operating speed profile was first established, followed by the definition of key vehicle parameters to align with the selected heavy commercial truck configuration. The resistance forces acting on the truck, including rolling resistance, aerodynamic drag, and grade resistance, were formulated and integrated into the vehicle dynamics analysis. These parameters were utilized to compute the required traction force and power demand for various operating conditions. The final stage of mechanical modeling involved verifying the compatibility of the selected electric motor's technical parameters with the calculated mechanical properties. This process ensured an optimal balance of torque, power, and rotational speed, enabling the electric truck to achieve the desired acceleration and sustain efficient operation under full-load conditions. The results

obtained from the mechanical model represent the vehicle's performance and power demand. Based on these outcomes, the required electrical energy is determined and requested from the electrical model.

The electrical model was developed to ensure the compatibility of the battery pack and electric motor in delivering the required power output. Additionally, battery pack configuration—including series and parallel cell arrangements, physical structure planning, and electrical performance analysis—was conducted to establish an optimal propulsion system. Proper management of the electrification process is critical for enhancing the accuracy of dynamic analysis and modeling results, ensuring the development of a robust and efficient power transmission system.

The modelling and analysis of the electric commercial truck were conducted using MATLAB/Simulink software. In the MATLAB/Simulink environment, vehicle modelling could be performed using two fundamental approaches: forward approach method and backward approach method. In this study, the forward approach method in MATLAB/Simulink was employed to model the electric vehicle (Nakarmi, Ale, & Budhathoki, 2022). The 'Vehicle Dynamics Blockset' module available in MATLAB/Simulink provides pre-configured blocks for essential components such as the vehicle body, wheel dynamics, electric motor, battery system, Proportional-Integral (PI) controller, and drive cycle components (Kiyakli & Solmaz, 2018). By integrating these predefined components, the electric vehicle model was developed, and the parameters and results obtained from previous sections were systematically incorporated into the respective Simulink blocks. Fig. 2 illustrates the forward approach method-based vehicle model of the electrified heavy commercial truck, developed in MATLAB Simulink.

In this study, theoretical formulations were employed to assess the performance, efficiency, environmental impact, and energy/fuel economy of both the electrified heavy commercial truck and its conventional counterpart powered by an ICE. These formulations were systematically implemented in Microsoft Excel to enable an accurate comparative analysis. The electrified truck model incorporated technical parameters such as the MATLAB/Simulink analysis results, specifications of the electric motor and battery system, and resistance forces affecting the vehicle. These parameters were essential for accurately simulating the truck's real-world performance under different driving conditions. For the conventional diesel truck, engine data and experimental parameters from relevant studies were integrated into Microsoft Excel to conduct the necessary ICE calculations. This approach ensured a standardized and data-driven comparison between the electrified and conventional heavy commercial trucks. The findings derived from these calculations are presented and analyzed in the subsequent section.

Findings

The simulation process of the electric truck model in MATLAB/Simulink involved analyzing key performance indicators, including the total distance travelled (range), battery State of Charge (SoC), variations in current values, and the comparison between the reference speed and the actual vehicle speed (Nakarmi et al., 2022). These analyses were conducted to verify whether the electric motor could effectively draw sufficient energy from the battery to propel the vehicle efficiently.

By simulating the electrified commercial truck for 2000 seconds in MATLAB/Simulink using the Heavy Heavy-Duty Diesel Truck (HHDDT) driving cycle as a reference, the total distance travelled was determined to be 36.9 km. The vehicle's range, the comparison between the actual driving speed and the reference speed, and the SoC of the battery cells throughout the simulation were analyzed. The battery charge level was initially set to 90%, considering the energy consumption of the electric motor, road conditions, and system losses. After completing the predefined speed-time reference cycle, the battery's final charge level was recorded at approximately 84.5%. Additionally, the variations in current drawn from the battery over time were examined, where fluctuations in current values were observed during acceleration and deceleration periods, indicating the dynamic power demands of the vehicle.

The energy consumption and cost analysis of the electrified heavy commercial truck under both loaded and unloaded conditions were evaluated, and the results are summarized in Table 1 . Since load factor has a substantial impact on energy consumption, optimizing vehicle payload is crucial for energy efficiency. As the vehicle load

increases, the power demand from the electric motor rises, leading to a proportional increase in energy consumption per kilometer.

Operating costs for electric heavy commercial trucks depend on both unit electricity pricing and total energy consumption. In this study, calculations were performed using DC charging tariffs to determine both the per-kilometer energy cost and total cost analysis. Additionally, battery capacity and corresponding charging costs at different load conditions were assessed to estimate the charging station costs associated with the given battery capacity. All results presented in Table 1 were obtained through MATLAB/Simulink and Microsoft Excel under different loading conditions.

Table 1. Energy consumption and cost analysis of the electrified heavy commercial truck according to different load cases.

Load Condition	**Fully Loaded**	**Unloaded**
Total Energy Consumption (E_{total}) [kWh]	114,25	54,35
Total Power (P) [kW]	205,66	97,83
Electricity Unit Cost [$C_{electric}$] [TL/kWh]	12,99*	10,99**
Distance Covered in 2000 Seconds (d) [km]	36,9	36,9
Energy Consumption per Kilometer (E_{km}) [kWh/km]	3,1	1,47
Electricity Cost per Kilometer [TL/km]	40,22	16,18
Total Electricity Cost [TL]	1484,21	597,31
Battery Capacity [kWh]	374,7	374,7
Charging Station Cost [TL]	4867,22	4117,84

* DC charging tariff applies for power between 180-400 kW at a rate of 12.99 TL/kWh.

** DC charging tariff applies for power below 180 kW at a rate of 10.99 TL/kWh.

Fig. 3 presents the efficiency map of the electric motor simulated in MATLAB/Simulink under the HHDDT driving cycle. The map, developed using predefined motor speed and torque inputs, provides a visual representation of the motor's operational efficiency across different load conditions. The electric motor demonstrates a high efficiency of approximately 96% over a wide range of speeds and torque levels. Modelled as a 1-D look-up table, the map delivers real-time efficiency values based on torque and speed parameters.

The conventional heavy commercial truck utilized in this study is equipped with a 7.33-liter, 6-cylinder turbocharged diesel engine featuring an intercooler and Bosch Common Rail Injection system, capable of delivering 240 PS at 2400 rpm and 840 Nm of torque between 1200–1800 rpm (Hacıbekir, 2006). Fuel consumption and cost were evaluated at five distinct engine speeds using the same reference driving cycle and operating conditions applied to the electrified vehicle. Table 2 presents the comparative analysis of fuel consumption, total power output, and economic metrics. These results were used to assess the operational efficiency of the internal combustion engine relative to the electrified counterpart. Specific Fuel Consumption (SFC) values ranged from 199 to 214 g/kWh, with detailed evaluations conducted based on engine operating duration for accuracy.

The first graphic in Fig. 4 illustrates the relationship between SFC (g/kWh) and engine speed (RPM) under full-load conditions, providing insight into the efficiency trends of the diesel engine across various operating ranges. For the same HHDDT drive cycle, fuel consumption per kilometer was analyzed while maintaining the same driving range for accurate comparison (Pantoja Gallegos et al., 2022). Table 2 indicates that fuel consumption per kilometer decreases as engine speed increases, suggesting a more cost-efficient operation at higher motor speeds.

Table 2. Fuel consumption and economic results of the conventional diesel engine at different engine speeds and output power.

Fuel Consumption and Economics Analysis					
Engine Speed [rpm]	1200	1400	1800	2100	2400
Specific Fuel Consumption (SFC) [g/kWh]	209	201	199	205	214
Total Power [kW]	105,6	126,7	158,3	172,2	177,2
Diesel Unit Cost [TL/L]	46,62*	46,62*	46,62*	46,62*	46,62*
Distance Covered in 2000 Seconds (d) [km]	36,9	36,9	36,9	36,9	36,9
Fuel Consumption per Kilometer [L/km]	5,42	4,65	4,47	4,29	4,04

Fuel Cost per Kilometer [TL/km]	252,87	216,79	208,7	200,46	188,57
Total Fuel Cost [TL]	9331,10	7999,67	7701,22	7396,95	6954,08

* Fuel cost calculations are based on the diesel price recorded on 04/03/2025

When assessing the relationship between SFC and power output, results indicate that fuel consumption decreases up to a certain power level but increases again beyond this threshold. Second graphic in Fig. 4 demonstrates that power demand initially grows inversely with fuel consumption, but at higher power levels, fuel consumption becomes directly proportional.

Fig. 5 presents the torque vs. engine speed relationship of the diesel engine under full throttle conditions. At full throttle, the combustion chamber receives the maximum air-fuel mixture, which forces the engine to operate at maximum load. This figure provides insights into the correlation between engine torque and speed, as well as the impact of fuel consumption at full load conditions.

Heavy commercial electric trucks offer significant environmental advantages over conventional diesel trucks. With zero CO_2 emissions and lower noise levels, they contribute to reduced air and noise pollution. When powered by renewable energy sources, their carbon footprint can be nearly eliminated. Table 3 summarizes the clean energy and environmental sustainability comparison between both truck types

Table 3. Comparison of CO_2 emissions and noise pollution between heavy commercial electric truck and conventional diesel-powered counterpart.

Comparison Criteria	**Heavy Commercial Electric Truck**	**Conventional Diesel Truck**
CO_2 Emissions [g/km]	0	720-900
Noise Pollution [dB]	65	80-95

The findings of this study present a detailed comparison between the electrified heavy commercial truck and its conventional diesel-powered counterpart. The results were obtained through various computational analyses, employing separate tables and graphical representations to illustrate energy consumption and economic outcomes.

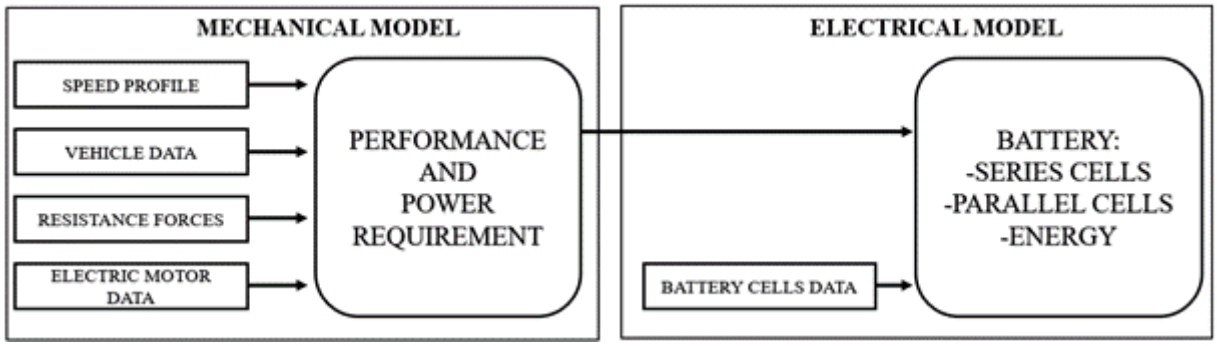

Figure 1. Battery electric vehicle model structure.

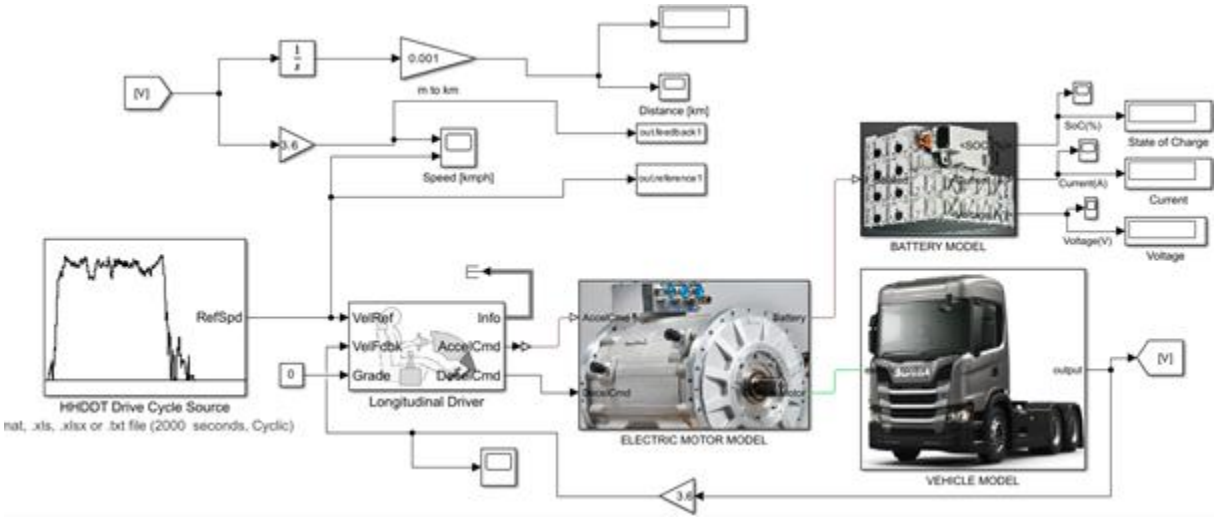

Figure 2. Modeling of the electrified heavy commercial truck with using MATLAB/Simulink.

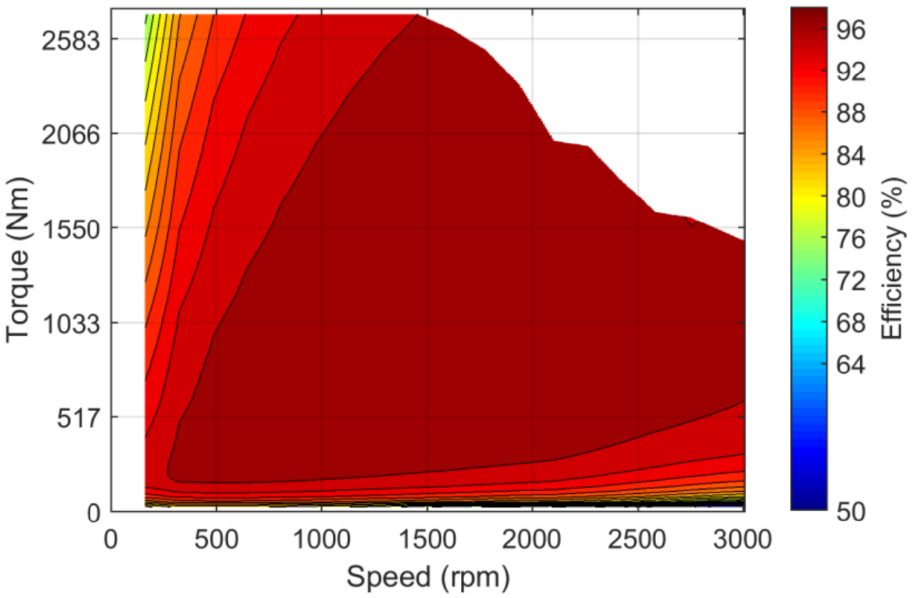

Figure 3. Operating efficiency map of the electric motor.

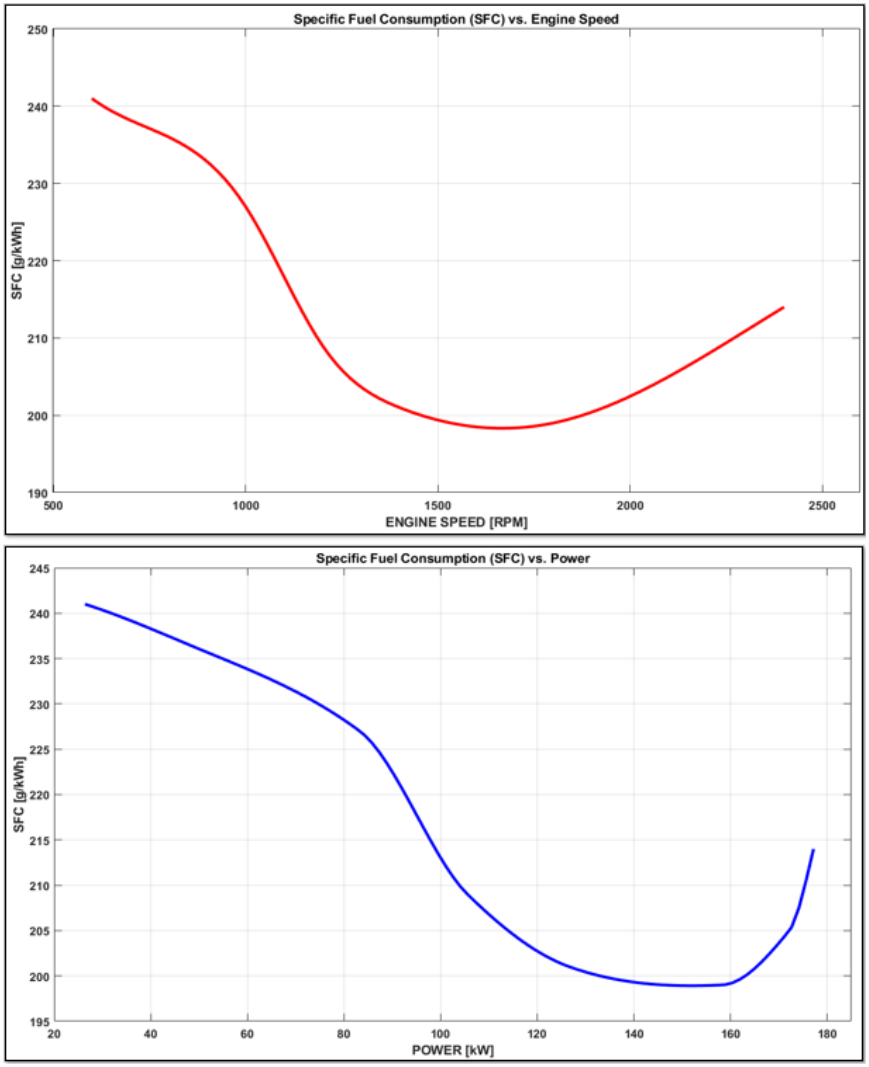

Figure 4. SFC curves of heavy commercial diesel truck based on engine speed and power.

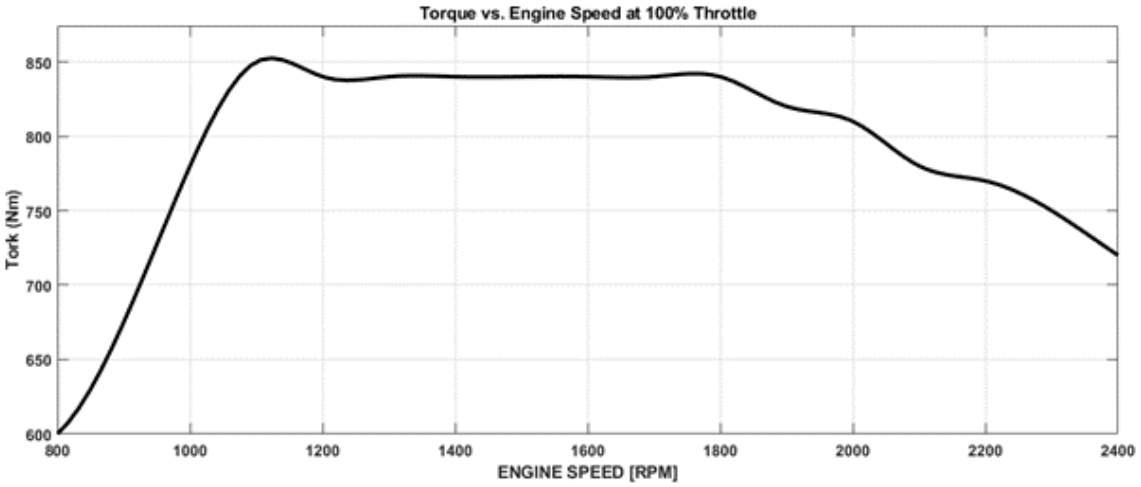

Figure 5. Torque vs. engine speed at full throttle for the diesel engine.

Conclusion

In this study, the electrification of a conventional diesel-powered heavy commercial truck was achieved by converting it into a battery-electric vehicle. Comparative analyses were conducted based on performance, efficiency, environmental impact, and economic feasibility using various calculations, simulations, and modeling processes. The results indicate that electric powertrain systems provide higher torque and power output, leading to superior vehicle performance. Additionally, the battery-electric truck demonstrated approximately 40% higher energy efficiency than its diesel counterpart due to reduced mechanical and combustion losses. In terms of environmental sustainability, it operates with 100% cleaner energy, eliminating carbon emissions, and reduces noise pollution by approximately 25%. Finally, economic analysis highlights that electric powertrains offer lower operational costs and enhanced energy efficiency, making them a more viable alternative to conventional diesel systems for heavy-duty transportation.

ANN-Based PID Tuning Mechanism For A Vehicle Control SystemConsidering Improved Path Following

Başar Zaman[a], Volkan Bekir Yangın[a], Özgen Akalın[a]

[a] Istanbul Technical University, Mechanical Engineering Department, Automotive, Türkiye
zaman22@itu.edu.tr

Keywords: ANN, Ziegler-Nichols, PID Control, Path Tracking.

Aim

There exist several control methods to improve vehicle path tracking performance [1,2] and PID control method is one of the most common strategies for an improved path tracking ability such as its usage for differential braking as a steering system back up [4]. However, conventional controller tuning methods could be very time consuming and have a lack of adaptability for varying road conditions. Therefore, artificial neural network (ANN) based tuning methods are leveraged where controller gains are adjusted in an online manner to achieve superior path tracking performance [3]. The objective of this study is to compare vehicle path tracking performance by using PID control strategy based on ANN tuning with the path tracking accuracy of the PID control strategy where the controller gains are tuned based on Ziegler-Nichols method. PID controller creates differential brake forces to follow the reference trajectory as a back-up for the steering system in case of failure. The effectiveness of differential brake forces generated via ANN over Ziegler Nichols based PID tuning method for improving trajectory tracking accuracy and vehicle stability is proved in this study. The proposed methodology is validated through a Simulink-ADAMS co-simulation, where a test vehicle performs a NATO Double Lane Change (DLC) maneuver using differential braking for steering redundancy.

Material and Method

This study employs a Simulink-ADAMS co-simulation framework to evaluate PID-based differential braking control in a NATO Double Lane Change (DLC) maneuver at a constant vehicle speed of 60 km/h. The representative scheme is given in Figure 1.

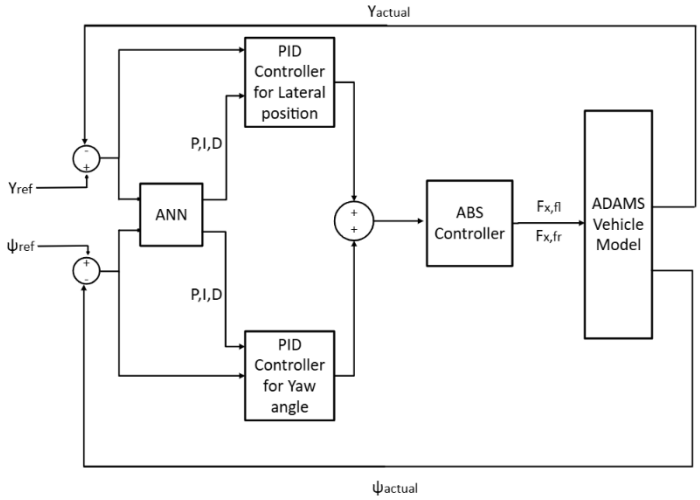

Figure 1. Controller Architecture.

The vehicle model used in this study represents the FED Alpha (Fuel Efficiency Demonstrator) vehicle. This model has been validated up to 64 kph, ensuring reliable simulation results within this speed range. The vehicle has a mass of 5482.67 kg and a wheelbase of 3.202 meters.

A dual PID control architecture used in the PID controller block. One of the PID controllers compensate for the lateral position error, another PID controller eliminates the yaw angle. Both PID controller blocks were tuned based on the offline Ziegler-Nichols method and ANN based online PID tuning and the results were compared to assess lateral position and yaw angle correlation with the reference lateral position and yaw angle values. The outputs from both PID controllers are combined to compute the necessary differential brake forces, enabling the vehicle to follow the reference trajectory while ensuring stability.

Two PID tuning methods are examined in this study. First, Ziegler-Nichols method is used for both PID controller block tunings in an offline manner. This approach involves determining the ultimate gain (K_u) and ultimate period (T_u) based on system response characteristics. PID gains are then computed using established empirical tuning formulas. However, with this method, P, I and D gains remain constant throughout the maneuver preventing adaptation for the changing path conditions. For the lateral position PID block, P, I and D gains were used as 0.07, 0.0467 and 0.0263. P, I, D gains for yaw angle controller block were 18,12 and 6.75. ANN based online PID tuning method is used for both lateral position and yaw angle PID contollers. ANN provides high adaptation to the changing path conditions and P,I,D gains are adjusted through the maneuver to minize the error between measured and reference lateral position and yaw angle values. The neural network is trained on a dataset consisting of lateral position, yaw angle outputs and corresponding optimal PID gains.

Findings

The results in Figure 2 show that the ANN-based PID tuning achieves closer adherence to the reference trajectory for both lateral position (Y) and yaw angle (ψ) than the Ziegler-Nichols method. While both controllers initially track the reference well, the Ziegler-Nichols approach exhibits higher oscillations in both lateral position and yaw angle, particularly after 5 seconds, indicating increased instability. In contrast, the ANN-based controller smooths the response, reducing overshoot and oscillations, leading to improved trajectory tracking and vehicle stability. These findings suggest that ANN-based tuning adapts more effectively to dynamic conditions, enhancing precision and robustness in path-following tasks. Also, another method to assess path tracking accuracy is to calculate Root Mean Square Error (RMSE) values for the lateral position and yaw angle. RMSE is a widely used metric for path tracking accuracy as it quantifies the average deviation between reference and actual trajectory. As RMSE becomes higher, this means higher deviation from the reference trajectory. When RMSE values for the lateral position-yaw angle for ANN and Ziegler-Nichols methods are compared; RMSE value is decreased by %2.62 in lateral position and %4.60 in yaw angle when ANN based online PID tuning is used. This result also indicates the superiority of ANN based PID tuning over Ziegler-Nichols PID tuning method.

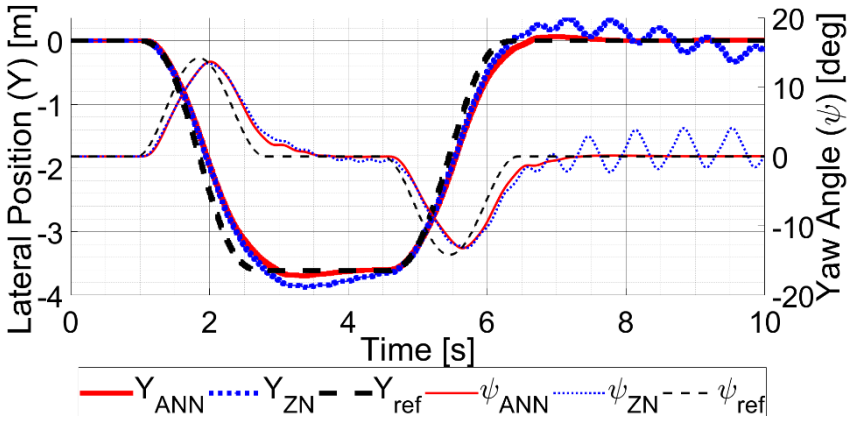

Figure 2. Path tracking performance results.

The comparison of differential brake force applications illustrated in Figure 3 between ANN-based tuning and Ziegler-Nichols (ZN) tuning highlights significant differences in control strategy and stability. The ANN-based approach applies smoother and more continuous braking forces, dynamically adjusting the left and right brake forces based on vehicle state, resulting in better modulation and reduced oscillations. In contrast, the ZN-based

method exhibits high-frequency oscillations and abrupt brake force changes, indicating a more aggressive and less stable braking pattern. The excessive fluctuations in the ZN approach may lead to unnecessary braking interventions, potentially reducing vehicle stability and comfort. These results suggest that ANN-based tuning provides better adaptability and smoother braking control, enhancing overall trajectory tracking and stability in differential braking-based steering applications.

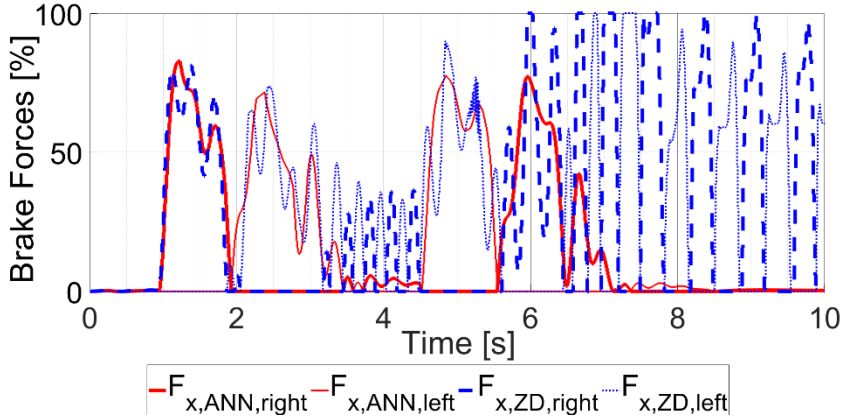

Figure 3. Brake forces generated via ANN or Ziegler-Nichols tuned PID controllers.

Conclusion

This study demonstrates that ANN-based PID tuning outperforms the Ziegler-Nichols (ZN) method in path tracking and braking control by providing smoother, more adaptive responses. The ZN-based method exhibits significant oscillations, particularly in yaw angle and lateral position tracking, due to fixed PID gains that fail to adapt to changing vehicle dynamics. The aggressive proportional control in ZN leads to overcorrections, while the absence of adaptive damping results in persistent oscillations, especially after trajectory changes. Additionally, in braking control, ZN-based tuning applies abrupt, high-frequency brake force variations, potentially reducing vehicle stability. In contrast, the ANN-based approach dynamically adjusts PID gains, leading to improved stability, reduced overshoot, and better trajectory adherence. These findings highlight the effectiveness of AI-driven control strategies in autonomous and safety-critical applications, where adaptive tuning enhances robustness, stability, and performance under varying conditions.

Combustion Model Analysis on Validation Purpose of a Spark Ignition Engine

Akay Delihasan[a], Ahmet Yapmaz[a], Barış Doğru[a]

[a] Istanbul Technical University, Department of Mechanical Engineering, Automotive Division, Turkey
delihasan@itu.edu.tr

Keywords: Engine Combustion Model, Mass Fraction Burned, SI Engine.

Aim

The aim of this study is to build up one-dimensional (1-D) model for a spark ignition (SI) engine at a part load condition by using SI Wiebe combustion model. The most realistic results could be obtained by an experimental study, but it takes time and if a system capable of precise measurement established is expensive. The problem could be defined with universally valid expressions and equations with a theoretical study. However, analytical solutions often rely on simplifying assumptions, reducing accuracy. A mathematical model for any physical system should be developed and is needed to be solved using a numerical method which is faster and cheaper than other methods in most cases. It is referred to as verification when the mathematical model is numerically solved. But the developed mathematical model may not accurately represent the system, so this does not necessarily mean that the problem has been solved correctly. The key point is to develop the correct mathematical model for the physical system, solve it accurately, and compare it with experimental data to validate it, ensuring that the model aligns with the real-world behaviour. This is the validation process. The originality of this study lies in attempting to create a more accurate simulation of the previous modelling study based on experimental data, in other words a further investigation on former 1-D simulation model. A 1-D model has been used since it provides quick insights into overall engine performance and fuel consumption. It is significantly faster and cheaper with reduced computational cost than three-dimensional modelling [1].

Material and Method

Internal combustion engine (ICE) operated vehicles have been mostly used at part load conditions rather than at high load conditions where their overall efficiency levels reach the maximum. Therefore, it has much more importance to focus on part load efficiency improvement of ICEs. A throttle valve is used in intake line of a conventional SI engine in order to control the air quantity suctioned into the combustion chamber. Wide-open throttle (WOT) conditions match with full load operation conditions where maximum amount of air has been taken into the combustion chamber in order to generate nominal power output. Throttle valve has been opened less at part load conditions in comparison to WOT conditions since power requirement is less, resulting in an increase of pumping losses and a reduction in overall efficiency [2,3]. In experimental stage of this research, a four-cylinder SI engine has been operated with conventional gasoline fuel at steady state part load conditions including 1800 rpm engine speed and 3 bar brake mean effective pressure (BMEP) where throttle valve angle is 14°, corresponding to 15.5% opening area of WOT position. Test-bench experiments have been carried out at Istanbul Technical University Automotive Engine Laboratory. The test-bench engine is water cooled to control engine temperature and also fuel is injected into the intake port to control air-fuel ratio in stoichiometric one in a sensitive way. The SI research engine specifications are given in Table 1.

Table 1. SI research engine specifications.

Feature	Value
Stroke Volume	1820 cm^3
Bore x Stroke	85 x 80 mm
Compression Ratio	9:1
Intake Valve Opening	16˚CA bTDC
Intake Valve Closing	40˚CA aBDC
Exhaust Valve Opening	40˚CA bBDC
Exhaust Valve Closing	16˚CA aTDC

Mass fraction burned (MFB) could be considered as a ratio between released combustion energy of burned fuel and the total combustion energy at the end of combustion. Rassweiler and Withrow conducted a study which states in summary that pressure rise percentage aligned with the burned charge percentage by weight during combustion [4].

Idealized SI engine combustion assumes constant volume heat addition into the combustion chamber at TDC as well-known in Otto Cycle [5]. However, actual combustion processes occurring in SI engines need a time interval between spark plug activation and combustion termination. Heat release curve of SI engines resembles an S-shape profile and modelled with Wiebe combustion as shown in equation 1.

$$x_b = 1 - e^{-a\left(\frac{\theta-\theta_0}{\Delta\theta}\right)^{m+1}} \quad \text{(Equation 1) [1]}$$

"x_b" is the MFB, "θ" is the crank angle, "θ_0" is the start of combustion, "$\Delta\theta$" is the burning duration, "m" is shape factor, and "a" is efficiency factor. The combustion rate of the fuel-air mixture starts at a low-level right after the spark discharge, rises to its highest point roughly halfway through the combustion process, and then gradually declines to nearly zero by the end of combustion. As could be seen in Figure 1, the flame-development stage corresponding to MFB0-MFB10 interval is the crank-angle range from spark discharge to when a notable fraction of the cylinder mass has been burned. The rapid-burning stage characterized by MFB10-MFB90 interval is the crank-angle range in which the main portion of fuel is burned. The burning completion stage indicates the last part of combustion process [5,6].

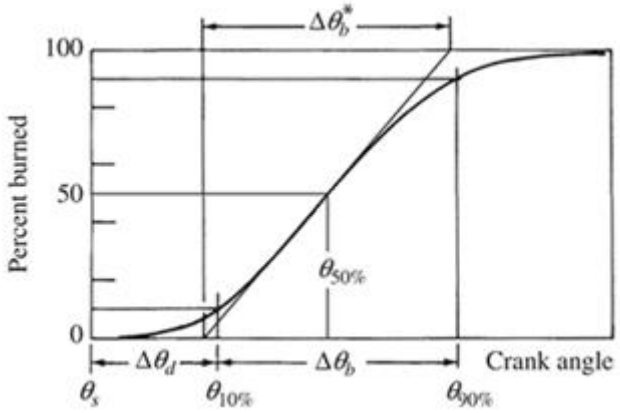

Figure 1. Combustion stages in SI engines on mass fraction burned vs. crank angle curve [6].

In order to fix the combustion curve in means of approximate MFB10 and MFB90 points via crankshaft angle, the 50% burn time is preferred rather than ignition time since it aligns closely with peak pressure as seen in Figure 2, making it a useful starting point [7]. In the experimental study, the peak firing pressure (PFP) value is considered

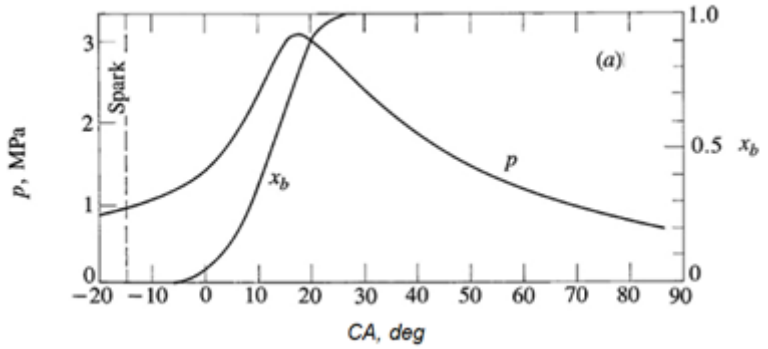

Figure 2. Cylinder pressure and mass fraction burned vs. crank angle curve of an SI engine [6].

close to the crank angle corresponding to the MFB50 point in the SI Wiebe combustion model. In the Wiebe function used in the combustion model, the parameter expressed as $\Delta\theta$, which defines the MFB0 to MFB100 range in terms of crank angle, is manipulated to ensure that the MFB50 point is close to the PFP.

Findings

Pressure vs. crank angle graph of experimental and simulation results conducted by Doğru et al. [8] is given in Figure 3.

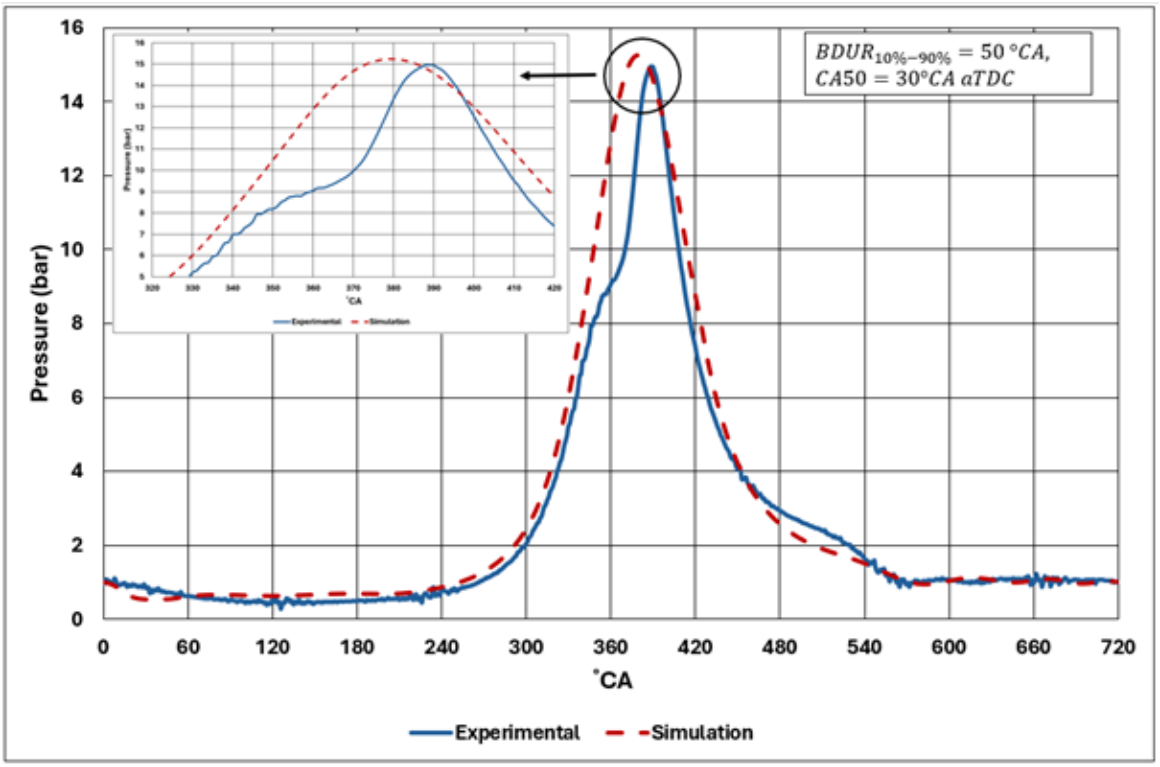

Figure 3. Pressure vs. crank angle curve of experimental and simulation study.

The crank angle at which the highest pressure obtained is closer to the TDC and PFP value is higher than that in the experimental ones although this difference could be accepted with a good accuracy since the percent errors are

below 2.5% as could be seen in Table 2. In former simulation study, burning duration between MFB10 and MFB90 was taken to be 50˚CA, and MFB50 crank angle was set to 30˚CA aTDC.

In 1-D engine modelling approach, the consistencies between the PFP, the timing of PFP, and the net indicated mean effective pressure ($IMEP_{NET}$) values signify a high degree of modelling accuracy and reliability. The results of former simulation study raised a research question of whether a more realistic simulation model could be developed for validation purpose. PFP value and the crank angle at which it is obtained are strongly dependent on the burning duration and the crank angle at which MFB50 value is reached. Numerous optimisation attempts have been carried out by adjusting the crank angle parameters associated with the combustion duration and MFB50 values. In this study, these two parameters have played a critical role on integrating a robust combustion model in order to match a better validation agreement against the experimental data in comparison to the former simulation model.

Pressure vs. crank angle graph of experimental and optimized simulation results is given in Figure 4. As a result, the peak pressure value and the corresponding crankshaft angle at which it occurs have been obtained in a better agreement against the experimental results. The accuracy of PFP magnitude and timing as crankshaft angle has been calculated are below 1% as seen in Table 2. The results demonstrate that a better combustion model approach has been developed compared to former simulation results. In the optimized simulation study, burning duration between MFB10 and MFB90 was taken to be 40˚CA, and MFB50 crank angle was set to 30˚CA aTDC.

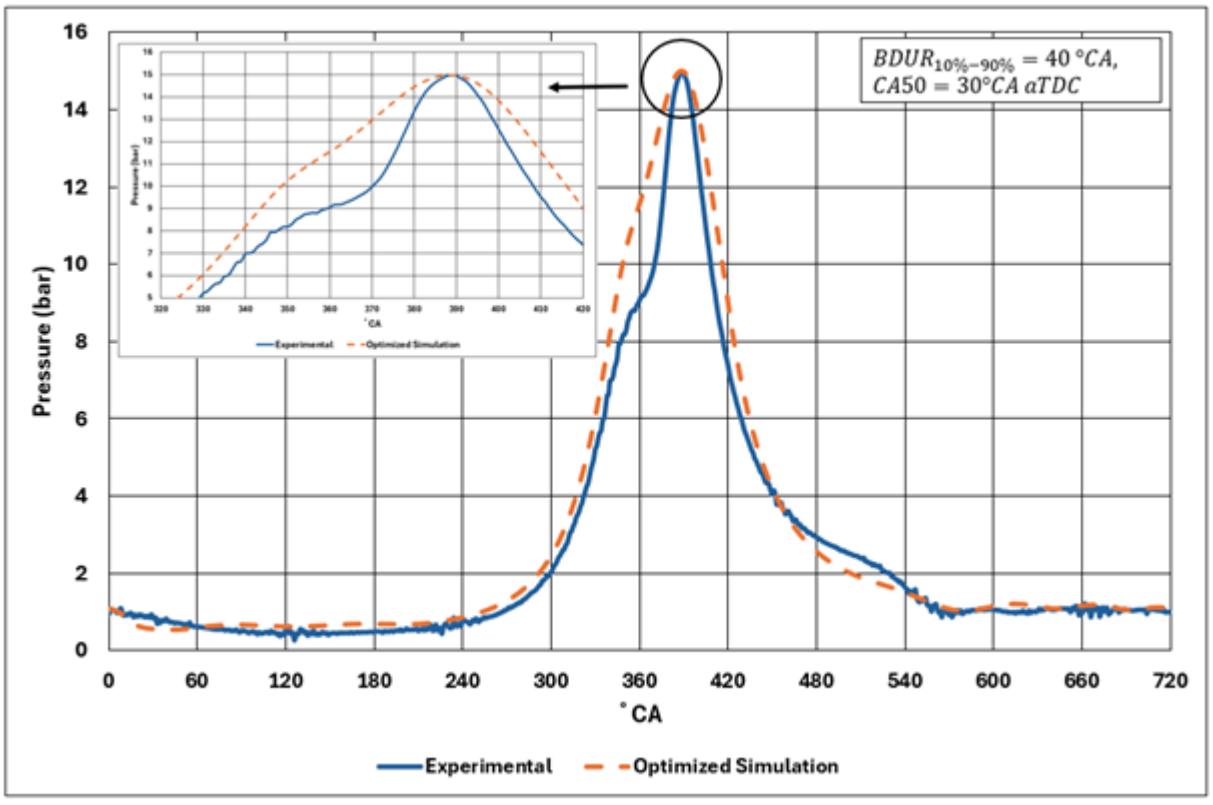

Figure 4. Pressure vs. crank angle curve of experimental and optimized simulation study.

The accuracy of $IMEP_{NET}$ finding decreases from 2% to 0.5%. The pressure levels at compression stroke after intake valve closing (IVC) point have been observed higher than that in experimental data for both simulations.

Table 2. Comparison of experimental, simulation and optimized simulation results.

@1800 rpm, 3 bar BMEP	$IMEP_{NET}$	P_{max}	θ_{Pmax}	BSFC
	(bar)	(bar)	(˚CA)	(g/kWh)
Experimental	3.75	14.96	389.0	477
Simulation	3.68	15.02	379.3	471
Error (%)	-1.87	0.40	-2.49	-1.26
Optimized Simulation	3.77	14.99	388.4	473
Error (%)	0.53	0.20	-0.15	-0.84

Conclusion

A 1-D model of a gasoline-fuelled engine was re-simulated. Validation was performed at one test point of 1800 rpm and 3 bar BMEP based on the Wiebe combustion framework. The optimized simulation results, achieved by adjusting the crankshaft angle values for combustion duration and MFB50, indicate a much better agreement against experimental data with respect to maximum cylinder pressure, PFP crank angle, and $IMEP_{NET}$ output. $IMEP_{NET}$, P_{max}, θ_{Pmax}, and BSFC were calculated with less than 1% error. It is more appropriate to use 40˚CA for MFB10-MFB90 burning duration rather than 50˚CA without adjusting MFB50 crank angle of 30˚CA. As a future study, the factors contributing to the pressure values being higher than those obtained experimentally during the compression phase should be examined and corresponding inconsistencies should be eliminated. Simulation studies are going to be extended for a matrix including different low load and engine speed ranges.İ

Multi-Objective Aerodynamic Shape Optimization of Helicopter Nose

Yiğit Can Özdemir[a], Sertaç Çadırcı[a]

[a] Istanbul Technical University, Faculty of Mechanical Engineering, Department of Mechanical Engineering, Türkiye
ozdemiry22@itu.edu.tr

Keywords: Helicopter Nose, Aerodynamic Interaction, Download Drag, Parasite Drag, Aerodynamic Shape Optimization.

In this study, multi-objective aerodynamic shape optimization of helicopter nose is performed in order to enhance helicopter performance. As a result, 500 design points are obtained and the influence of each design parameter on the objectives is numerically shown. The study suggests that download drag is governed by certain geometric features of the helicopter nose. With shape optimization, approximately 14% and 1% enhancements are achieved in download drag and parasite drag, respectively.

Aim

Helicopters are rotorcraft that take off and land vertically, hover and fly forward, backward, and sideways. Performance criteria for helicopters are based on both hover and forward flight performances so helicopter airframe designs must be made considering efficient flight in these two different flight conditions.

During the design process of a helicopter, there is a strong phenomenon as an interaction between the main rotor and the airframe which emerges especially during hovering and at low forward flight speeds. Because of the downwash of the helicopter's main rotor, download drag occurs on the helicopter's body towards the ground. The download drag depends on the downwash velocity of the main rotor and the helicopter's airframe geometry. Download drag has an impact on many performance parameters such as helicopter's payload weight and efficiency of hovering [Bagai and Leishman, 1992] [Leishman and Bi, 1990] [Bramwell, 1966] [Renaud, 2008] [Venegoni, 1977]. Total drag in forward flight produced by a helicopter is the sum of the parasite drag, induced drag, and profile drag. Parasite drag is a type of aerodynamic drag caused by non-lifting parts of the helicopter. It includes the skin-friction drag and pressure drag associated with nose, fuselage, engine cowling, rotor hubs, landing gears and empennage. Parasite drag increases with the square of the airspeed so after a certain airspeed, parasite drag becomes the dominant source for total drag. Parasite drag has an impact on many performance parameters like helicopter's maximum attainable forward speed, range and fuel consumption [Venegoni, 1977] [Keys and Wiesner, 1975] [Leishman, 2006]. Helicopter nose geometry is part of an airframe which affects an aircraft's flight performance. It is the part that needs to be worked on due to the complex structure and limited design space, especially for a helicopter.

The design and optimization of aerodynamic components is challenging due to the large number of design variables; thus, different strategies have been developed to overcome these challenges. The different strategies include adjoint optimization methods, surrogate models, hybrid routines that combine lower- and higher-fidelity evaluations and feature-extraction approaches based on dimensionality reduction techniques [Tejero, 2023].

In this study, multi-point, multi-objective aerodynamic shape optimization of helicopter nose is performed in order to reduce the download drag and the parasite drag to enhance the performance of the helicopter.

Material and Method

CFD based aerodynamic shape optimization is performed by coupling Siemens NX, Star CCM+ and HEEDS. Parameters are determined to create different cross-sections in the three-dimensional domain. While determining the parameters, it is aimed to reduce computational cost and save time with a minimum number of parameters and to scan different geometries, to ensure that these geometries are aesthetically smooth and manufacturable at the same time.

A simple helicopter geometry is generated to be used in this study. Helicopter geometry, main rotor disk and the nose part to be optimized are illustrated in Figure 1.

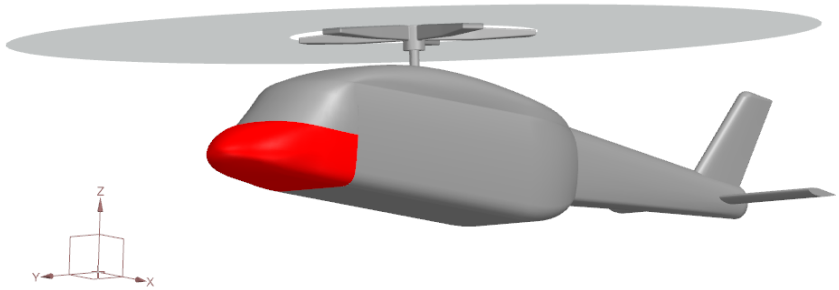

Figure 1. Geometry of the helicopter and main rotor disk.

Parametric design is performed with Siemens NX CAD software. Figure 2 shows the design parameters of interest in the study. The first parameters are x- and z-positions in the domain of Point 1 and Point 2. Their y-position is constant, and the z-position of Point 2 is always the same z-position of Point 1. Thus, there are three parameters arising from these two points. Another parameter is the angle between the ground and Line 1. It has a tangential relationship with the middle curve. By changing the angle of Line 1, the slope of the upper surface of the nose changes. The curve depth is another parameter affecting the curvature of Curve 1. Finally, a further parameter is the height of Line 2 from the ground. In total, there are six parameters to control the geometry of the helicopter's nose.

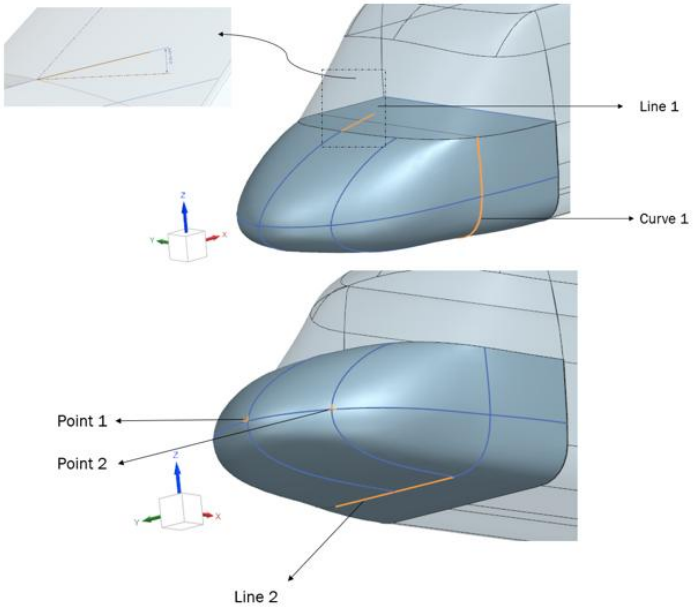

Figure 2. Design parameters of the helicopter nose.

Grid generation and CFD analyzes are performed using Star-CCM+, a commercial CFD software. To obtain reliable results from CFD analyzes, computational domain with high-quality mesh is significant. A mesh independence study is carried out to accurately calculate force- and moment- coefficients. Therefore, results are compared with T625 helicopter test results. As a result, high-density polyhedral mesh with approximately 9 million elements is selected to continue which is illustrated in Figure 3. The boundary layer zone consists of prism cells where wall functions are employed in the calculations.

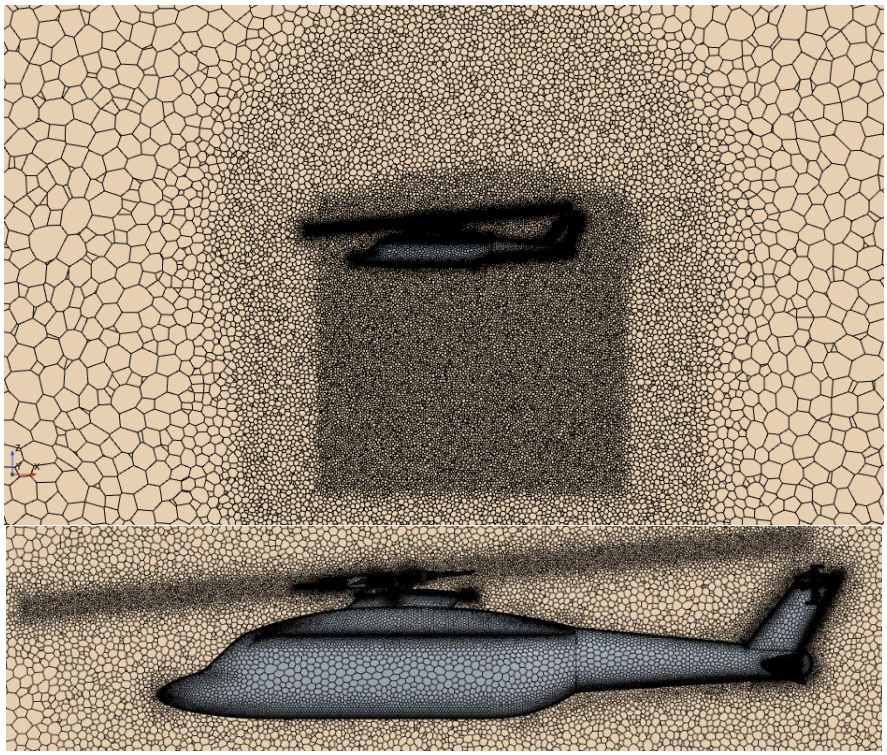

Figure 3. Mesh Structure.

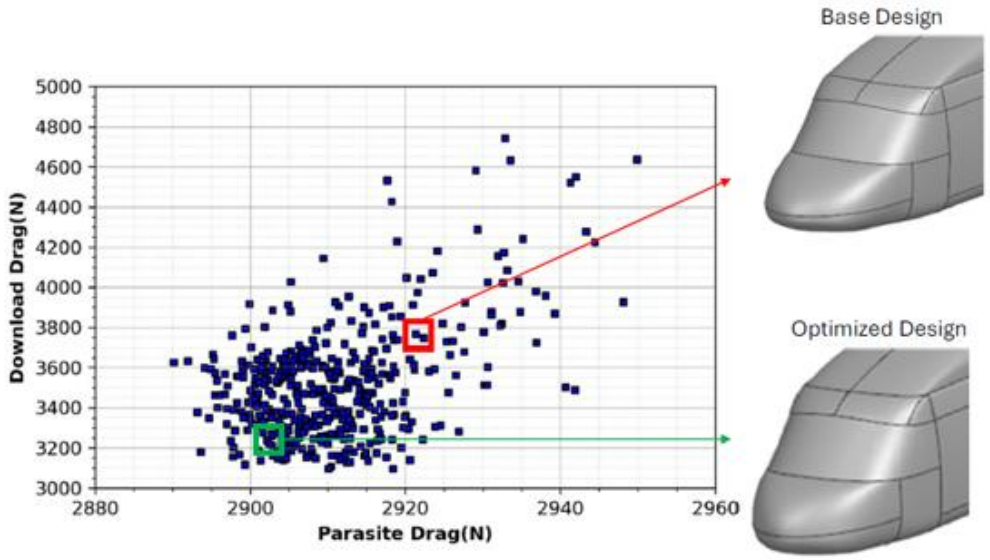
Among RANS-based turbulence models, the SST k-ω turbulence model is preferred. The flow is assumed to be at steady-state and implicit density based coupled solver is used. In order to simulate main rotor flow, Virtual Disk Model of Star-CCM+ is employed. For optimizing the nose of the helicopter, HEEDS software's Multi-Objective SHERPA algorithm is applied. MO-SHERPA (Multi-Objective SHERPA) is a modified version of the algorithm SHERPA for multi-objective Pareto search. It uses a non-dominated sorting scheme to rank designs but shows differences from NSGA-II and NCGA algorithms [Chase, 2009]. The objectives are selected and evaluated according to different flight conditions which are hover flight and high-speed forward flight. Download drag must be minimized to enhance hover performance, parasite drag must be minimized to enhance forward flight performance and the minimum volume requirement of the nose must be satisfied.

Findings

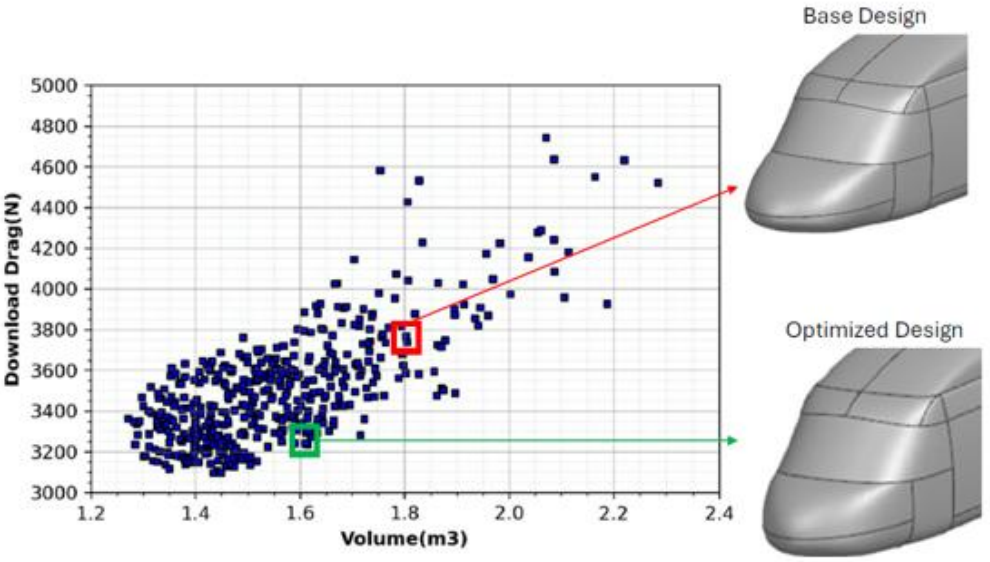
The relations between different design objectives are obtained from HEEDS and suitable alternatives are evaluated in terms of hover flight performance, forward flight performance, nose volume, smoothness and manufacturability. As can be seen in Figure 4, parasite drag is not significantly affected by the nose geometry. It is observed that there is a tradeoff relation between download drag and volume of the helicopter nose. As the volume of the nose decreases, i.e. the projection area becomes smaller, download drag decreases, as can be seen in Figure 4.

The download drag is reduced from 3773 N to 3238 N. With this decrease, a 14% improvement is achieved for download drag. For parasite drag, there is no great improvement, but parasite drag is reduced from 2923 N to 2902 N which means nearly 1% improvement is achieved. The new design is selected to meet the 1.6 cubic meter volume requirement; thus, the volume is decreased from 1.8 cubic meter to 1.61 cubic meter.

Figure 5 shows that static pressure contours around the baseline and the optimized design during hover flight. There is a remarkable decrease in high-pressure and low-pressure regions above and below the front of the airframe. So, it causes download drag to reduce.



a) Baseline and optimized design in design space.



b) Baseline and optimized design in download drag versus volume plot.

Figure 4. Design space.

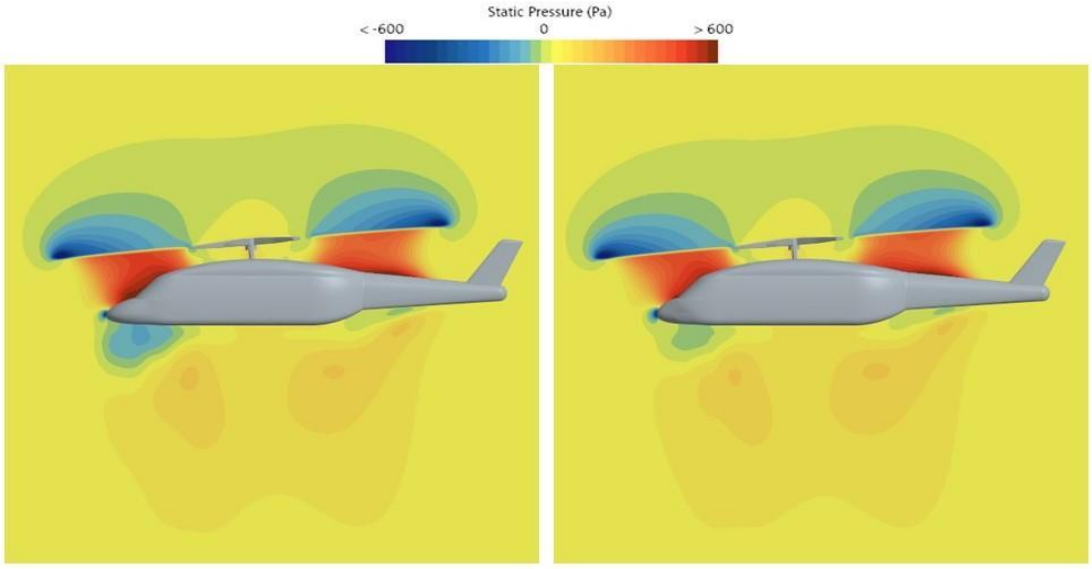


Figure 5. Static pressure contours during hover flight.

Conclusion

Hover and forward flights have a significant role in helicopter performance. It is aimed to reduce the download drag and parasite drag without compromising the stability on the pitch axis by optimizing the nose shape. Design parameters are selected to scan different geometries in a wide range. Virtual disk model is employed to consider the aerodynamic interaction between the main rotor and the airframe in a cost-effective way. One of the best performing alternatives selected from the optimization results are compared with the baseline nose design. It is observed that the nose geometry has a greater effect on the download drag than on the parasite drag. With proposed shape optimization, approximately 14% and 1% improvements are achieved in download drag and parasite drag, respectively.

Analysis of Effects of Tip Clearance on Axial Pump Performance

Mehmet Deniz Pacaci[a], Levent Ali Kavurmacioglu [b]

[a] Istanbul Technical University Graduate School, Heat-Fluid, Turkey
[b] 2Istanbul Technical University, Mechanical Engineering Department, Turkey
pacaci@itu.edu.tr

Keywords: Tip Clearance, Axial Pumps, Hydraulic Efficiency, Tip Leakage Vortex.

Aim

Axial pumps are widely used in different industries such as marine, energy and different applications and require different installation and maintenance specifications. Tip clearance distance is the distance between blade and casing which is necessary for thermal expansion and safety; but it creates leakage flow and mechanical losses and it has a significant effect on hydraulic performance and cavitation formation of axial pumps. Tip leakage vortex can be optimized and made parametric using numerical methods. Several investigations have been conducted in this field to observe tip vortex evolution and its characteristics [1-2].
Tip vortex mainly triggered by pressure difference between pressure and suction sides of the blade. High pressure triggers flow separation and results in tip leakage from pressure side to suction side. This reverse flow forms tip leakage vortex on hydraulic machines. Tip leakage vortex can be observed experimentally and numerically. Thus, clearance distance can be optimized. Lin Z. et. al. suggests that while many axial pump CFD studies have focused on tip vortex flow characteristics for a certain tip clearance; Shen J. et. al. focused to observe effects of tip clearance distance on tip vortex flow.
Within the scope of this study, effects of different tip clearance distances have been investigated for an axial pump numerically.

Material and Method

An industrial axial pump blade has been selected for this study and numerical analysis have been conducted within the scope of this study. Parameters have been selected as follows: fluid is water. Total number of rotor blades of pump are four, 3D model is prepared as 90° rotational periodic.

Song X. Et. al. suggests 157 m^3/s flow rate.

Blade hub diameter is 100 mm and tip diameter is 240 mm. Two different tip clearances are analyzed. First distance is 2 mm; second distance is 4 mm. Shroud diameters are different per tip clearances; first shroud diameter is 244 mm; second shroud diameter is 248 mm.

Zhang H. suggests that angular velocity is 152 rad/s.

Average static pressure at outlet is assigned as 0 kPa.

In addition to general mass and momentum conservation equations, Reynolds-averaged Navier-Stokes (RANS) equations can provide a general and specific information for formation of tip leakage vortex [1].

For turbulence, shear stress transport is used.

Three different domains have been designed for this investigation: inlet, rotor and outlet. Rotor length has been selected as 180 mm; length of inlet and outlet domains has been selected as 180 mm and 900 mm, respectively. All domains have been designed 90 degree rotational periodic. This has been demonstrated in Fig. 1 Design configuration of flow domain.The material and method section should be written in Times New Roman font, justified-alignment and in 10-point size.

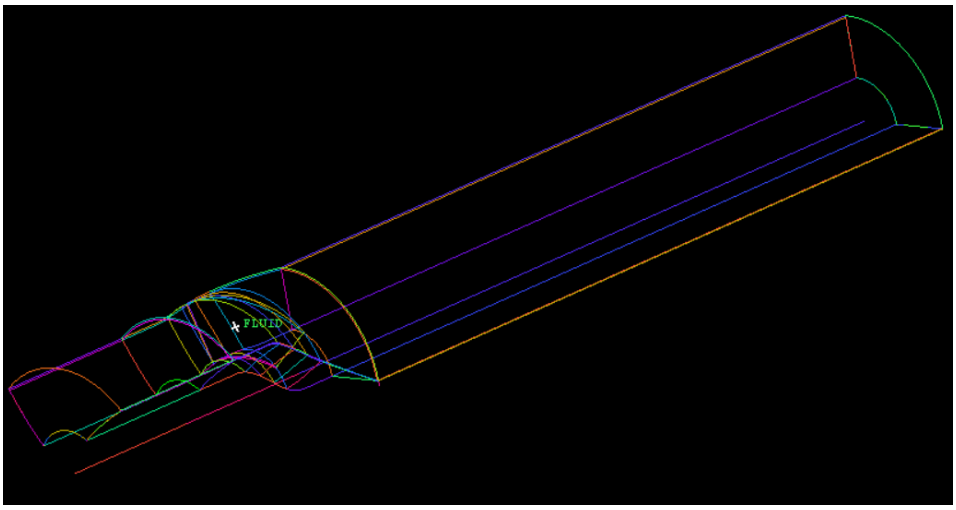

Figure 1 : Design configuration of flow domain.

In this study, numerical investigations have been conducted by using Ansys 2023 R1. Specifically, Icem CFD has been used for meshing; CFX-Pre, CFX Solver Manager and CFD Post have been used for analysis and post processing.

All geometry has been blocked and structured mesh has been used. It's been stated that to handle problems related with structured grid for complex geometries, block-structured CFD methods have been developed as Versteeg H.K. and Malalasekera W. suggest to cope with different difficulties related with structured grid.

Mesh has been generated for two different domains per tip clearances, 2 mm and 4 mm respectively. This is demonstrated in Fig. 2: Rotor mesh view sample (with 2 mm tip clearance).

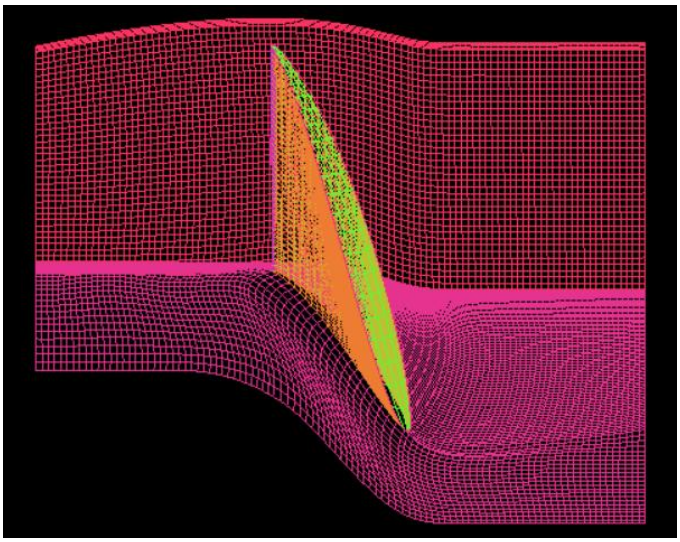

Figure 2 : Rotor mesh view sample (with 2 mm tip clearance).

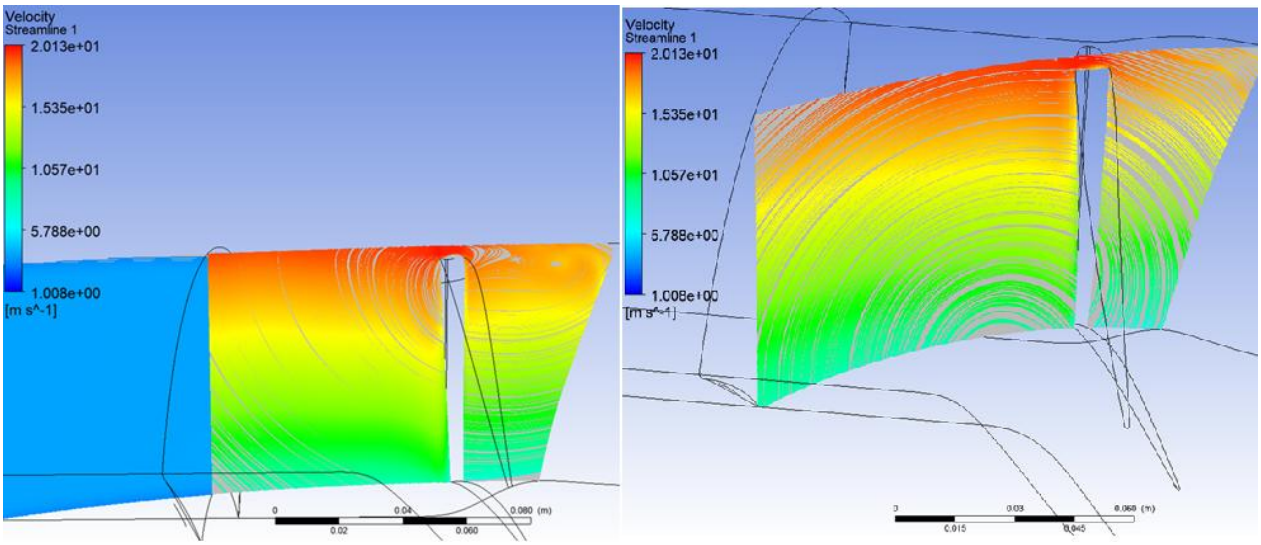
During the mesh generation process, hexahedral elements were used in all regions to accurately resolve especially near wall regions. Multiple mesh topologies were generated and highest mesh quality was carefully monitored. Boundary layer grid has been designed for small y+ values. Due to stability and quality considerations, the highest-quality mesh was selected for the simulation; quality issues limited the use of alternative meshes. During the CFX analysis, the development of the normal moment on the blade surface was tracked, and the mesh was also observed based on its ability to capture consistency.

In first mesh setup, hexagonal elements have been used with total 976.089; in second mesh, total element number is 1.403.700.

The turbulence model SST has been selected.
In CFX Solver Manager, stability and convergency are observed per normalization of normal moment affecting on blade as well as different RMS values.

Findings

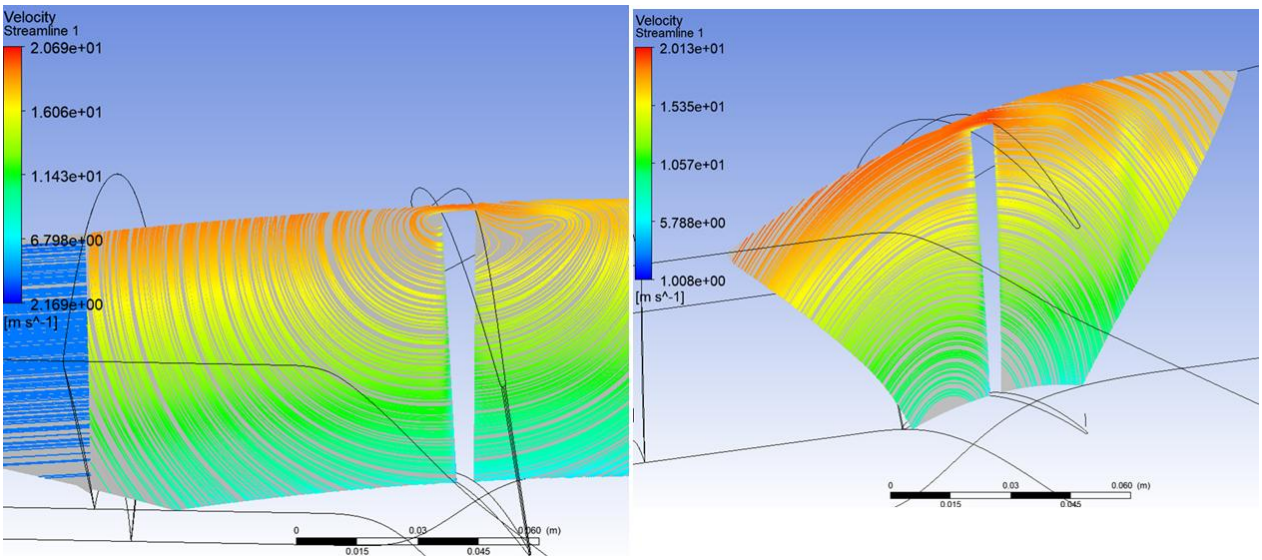
After completion of analysis of both cases, results have been compared to each other by graphics. Cross sections have been taken from leading edge, middle of blade and trailing edge sides. It's been observed that flow directions are quite different from each other. 2 mm tip clearance resulted in reverse flow on concave side nearby leading edge and major vortexes on both leading edge pressure side and trailing edge suction side. In 4 mm tip clearance case, higher velocity values have been calculated; again there are reverse flow but tip vortex has only been observed on trailing edge side. This has been demonstrated in Fig. 3.



(a) (b)

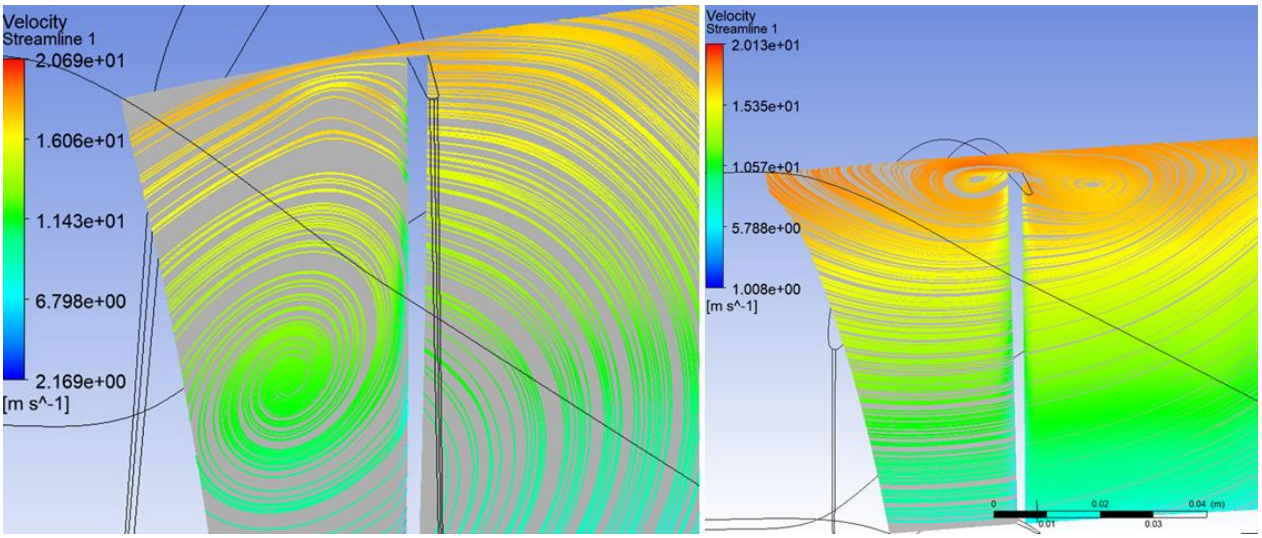
Figure 3 : Streamlines on cross section view near leading edge (a) 2 mm tip clearance, (b) 4 mm tip clearance on right side).

Streamlines on cross section view near leading edge (2 mm tip clearance on left side; 4 mm tip clearance on right side), Fig.4 Streamlines on cross section view of middle of the blade (2 mm tip clearance on left side; 4 mm tip clearance on right side), and in Fig. 5 Streamline graphics on cross section view near trailing edge (2 mm tip clearance on left side; 4 mm tip clearance on right side)



(a) (b)

Figure 4 : Streamlines on cross section view of middle of the blade, (a) 2 mm tip clearance, (b) 4 mm tip clearance on right side).



(a) (b)

Figure 5 : Streamline graphics on cross section view near trailing edge, (a) 2 mm tip clearance on left side, (b) 4 mm tip clearance on right side.

Results have been demonstrated in Table 1 Calculation results of both analysis. Torque, power, efficiency, total head, total pressure ratio have been reviewed for these tip clearance distances. In addition, pressure distribution in whole domain in streamwise direction has been reviewed and pressure coefficient (C_p) on blade surfaces has been checked for both cases; C_p distribution graph has been taken as sample in Fig. 6.

Table. 1 : Calculation results of both analysis.

Results	2 mm tip clearance distance	4 mm tip clearance distance
Torque (one blade row) ($kg.m^2/s^2$)	3.14	3.02
Power (all blades) ($kg.m^2/s^3$)	477.5	458.6
Efficiency	0.657	0.647
Total Head (m)	0.81	0.77
Total Pressure Ratio (Out/In)	10.7	13.7

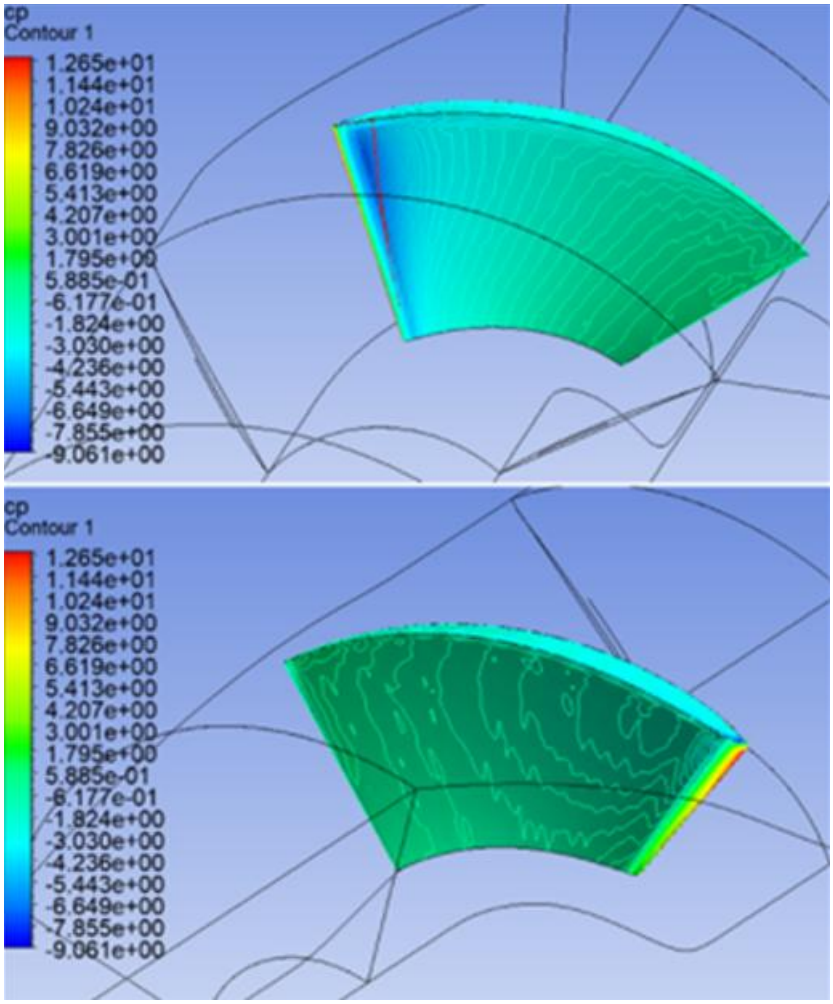


Figure 6 : Cp distribution on blade surfaces for 4 mm tip clearance.

Conclusion

It's been observed that low tip clearance results in higher head and efficiency. Higher tip clearance results in higher pressure difference, thus, higher noise is expected. Lower tip clearance is a better design solution than higher.
Tip leakage vortex core trajectory can be adjusted and changed by tip clearance. However, vortex position may still vary dramatically in different regions on blade. Tip clearance has significant effect on topology of flow separation, tip leakage vortex and other possible vortexes.

Finally, it may have also been concluded that tip clearance shall be adjusted according to other characteristics such as stack axis thickness, trailing edge thickness etc. on the outermost surface of the blade. Passive control methods such as winglet, squaler tip can be also applied to blade geometry.

Aerodynamic Performance Enhancement of a 27-Inch Apc Propeller Through Geometric Modifications

Mehmet Emin Arslan[a], Sertaç Çadırcı[a]

[a] Istanbul Technical University, Department of Mechanical Engineering, Türkiye
arslanme16@itu.edu.tr

Keywords: Airfoil Thickness, CFD simulation, Propeller design, Static Pitch, Twist Angle.

This study aims to improve the aerodynamic performance of a 27-inch APC propeller through modifying geometric design parameters, including static pitch, twist angle, and airfoil thickness distributions. Computational Fluid Dynamics (CFD) simulations at multiple operating conditions demonstrate that certain aggressive twist adjustments yield notable efficiency gains, while thickness changes can reduce aerodynamic performance at higher advance ratios. A validated CFD framework supports these findings, providing a balanced view of the trade-offs between propeller thrust, and propeller efficiency. The results offer valuable design guidance for propellers requiring optimal performance across a broad operational envelope.

Aerodynamic efficiency of a propeller is crucial for the performance of aerial vehicles. As these vehicles become more prevalent, propellers play a growing role in delivering efficient thrust. Early design choices significantly influence both efficiency and flight endurance (Chen et al., 2020), underscoring the importance of propeller optimization. Researchers have employed optimization algorithms combined with CFD or semi-empirical approaches to refine blade twist and chord for improved efficiency (Sedelnikov et al., 2024). In an earlier study, a fast vortex-lattice aerodynamic tool was integrated with a subsonic point-source noise model to optimize twist, chord, and sweep, thereby showing that adjusting the twist angle can simultaneously enhance efficiency and reduce noise (Miller & Sullivan, 1985). Meanwhile, a calculus-of-variations approach demonstrated that although the best twist distribution varies with operating conditions, a single twist angle configuration can still achieve near-optimal performance across different flight phases (Dorfling & Rokhsaz, 2014). Overall, these investigations highlight those well-considered geometric modifications can deliver gains in thrust generation and energy efficiency. However, there remains a gap in understanding how combined modifications of twist angle and airfoil thickness distribution may further improve propeller performance.

Aim

The aim of this study is to improve the aerodynamic performance of a 27-inch APC propeller by modifying its geometric parameters. Three main parameters are considered: static pitch, twist angle distribution and airfoil thickness distribution across the blade span. The goal is to increase overall efficiency across a range of operating conditions. A baseline design, referred to as the Standard 27×13 Propeller, was derived from the vendor's published geometry data of the 27×13E model (APC Propellers.). From this baseline geometry, several static pitch variants were created by adjusting the pitch values in the geometry data. In the twist and thickness distribution studies, four levels of modification were investigated.

Material and Method

The computational domain was sized relative to the propeller diameter D as shown in Figure 1. The appropriate domain size was determined regarding both the radial and axial extents. Once further enlargement showed no significant effect on thrust or torque, the domain boundaries were deemed adequate (Lopez Mejia et al., 2017). To save computational time and conduct cost-effective simulations, the Multiple Reference Frame (MRF) technique was chosen instead of a sliding mesh approach. In the MRF method, rotating and stationary zones are treated in a steady-state manner, reducing computational overhead (Gullberg & Sengupta, 2011). At the inlet of the computational domain, uniform velocity is employed. At the outlet of the computational domain pressure outlet

boundary condition is specified for incompressible flow assumptions. The symmetry boundary condition is defined in the farfield region of the domain (Kyaw & Jinming, 2021).

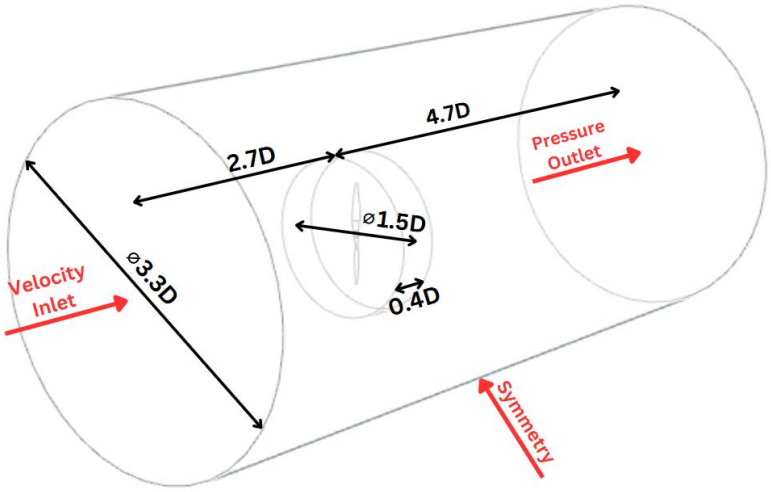

Figure 1. Computational domain setup and boundary conditions.

The mesh configuration, illustrated in Figure 2, features local refinements near the blade surfaces and in the wake region. A mesh independence analysis was performed by progressively refining the grid and monitoring variations in thrust and torque. Once additional refinement produced negligible changes in these parameters, it was concluded that the selected mesh resolution adequately captured all relevant flow physics. As a result, it was shown that a mesh consisting of 2.5 million elements was sufficient to approach the thrust value provided by the vendor with an approximate relative error of 5%. Among all tested turbulence models in the turbulence sensitivity analysis, realizable k-ε model with standard wall functions was shown to be the most favourable turbulence model in terms of computational savings and matching with the vendor's performance data.

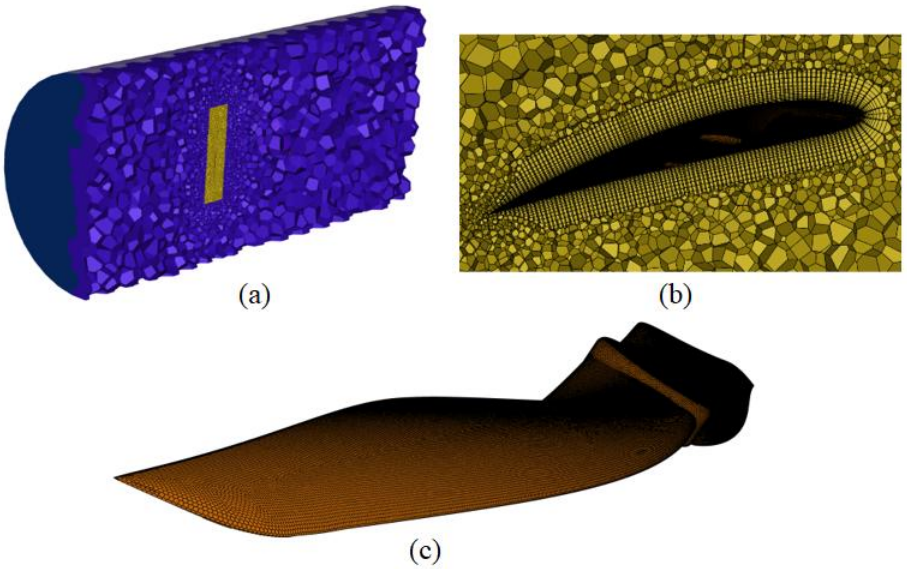

Figure 2. Illustration of mesh arrangements: (a) general mesh section, (b) close-up view of mesh layers around the airfoil, and (c) propeller surface mesh.

Various blade configurations have been derived from the baseline geometry and modifications have been conducted to parametrically investigate the effect of the blade geometry on the aerodynamic performance indicators. From the baseline geometry, static pitch variants (7, 10, 16, and 19 inches) were generated by adjusting

pitch values as shown in Figure 3.a. To determine the blade twist angle at any radial station, the local twist angle was calculated using the formula $\beta(r) = \left(\frac{P}{2\pi r}\right)$ (Giljarhus et al., 2022) where P denotes the pitch length. All simulations were conducted at a constant rotational speed of 3000 RPM, covering inlet velocities corresponding to advance ratios (J) ranging from approximately 0.1 to 0.6. The thrust and torque outputs were then represented by the thrust coefficient (C_T) and the power coefficient (C_P), respectively and then plotted as the efficiency versus advance ratio.

Using the verified setup, the effects of modifications in twist distribution and thickness distribution were investigated. For the studying the effect of the twist angle, four variants—A1, A2, B1, and B2—were derived from the Standard 27×13 Propeller. In the A-series, the twist angle was reduced at the root and gradually increased toward the tip, whereas in the B-series the twist angle was increased at the root and then decreased toward the tip. In both approaches, the twist at 75% of the blade span was held constant to preserve the propeller's nominal pitch reference point as shown in Figure 3.b.

For the thickness study, another four variants—again labelled as A1, A2, B1, and B2—altered the airfoil thickness distribution across the blade span using two strategies. In the Uniform Thickness approach (A-series), thickness was reduced at the root and slightly increased at the tip, while preserving the baseline thickness value at 75% of the blade span. In the Tapered Thickness approach (B-series), airfoil thickness was increased at the root and reduced at the tip, maintaining the same mid-span thickness as the baseline. The variations of the airfoil thickness along the blade span for both approaches is shown in Figure 3.c. All CFD simulations using the modified geometries were evaluated in terms of the efficiency, an estimated aerodynamic indicator was computed calculated as JC_T/C_P (Dantsker et al., 2022).

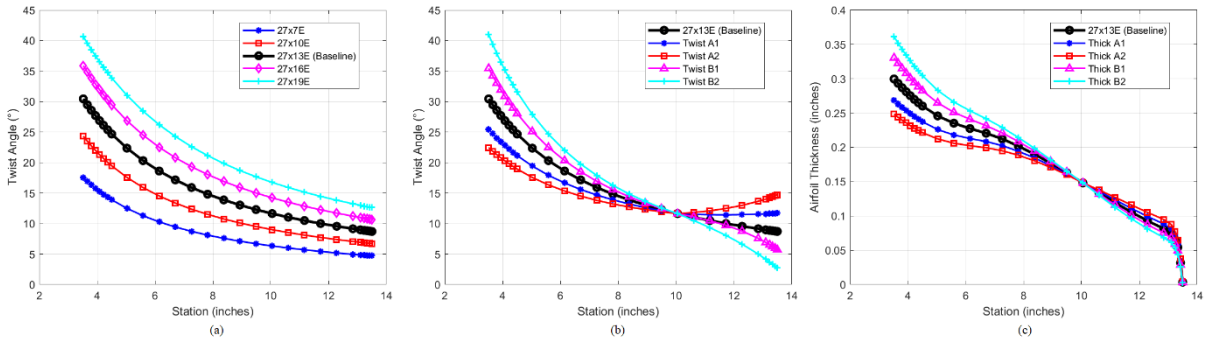

Figure 3. Distribution of propeller parameters along the blade span: (a) Static pitch variants, (b) Twist-modified variants, and (c) Thickness-modified variants.

Findings

The static pitch study identified the Standard 27×13 Propeller as offering the best compromise among variants (7, 10, 16, and 19 inches), balancing performance at different freestream speeds as shown in Figure 4.a. At low to moderate advance ratios, the 27×13 Propeller displayed relatively high efficiency alongside solid thrust output, which made it a logical choice for further shape optimization.

In the twist study, the propeller's baseline efficiency declined as the advance ratio J increased typical behavior for a fixed-pitch propeller. At low J values, the efficiency of all modified twist-angle variants was almost indistinguishable from the baseline. However, as J advanced into moderate and higher regimes, the performance differences became more evident. In particular, the aggressive twist variants (B1 and B2) sustained a noticeable increase in estimated efficiency compared to the baseline, especially at $J \approx 0.5$ as it can be seen in Figure 4.b. Even at $J \approx 0.6$, where overall efficiency typically drops, the B1 and B2 configurations maintained a higher efficiency compared to the baseline. In contrast, the mild twist variants (A1 and A2) provided only small efficiency gains at high advance ratios.

At low and moderate J values, all modified airfoil thickness-variants exhibited efficiency levels comparable to the baseline. However, at higher advance ratios, these modifications yielded a drop in the efficiency compared to the

baseline configuration. As Figure 4.c shows, at $J \approx 0.6$, the baseline geometry demonstrated an efficiency of roughly 0.50, whereas the thickness-modified variants dipped to approximately 0.42, indicating a slight performance penalty at higher speeds. This result suggests that any structural benefits gained from adjusting the blade thickness distribution may come at the cost of decreased aerodynamic efficiency at moderate to high advance ratio values.

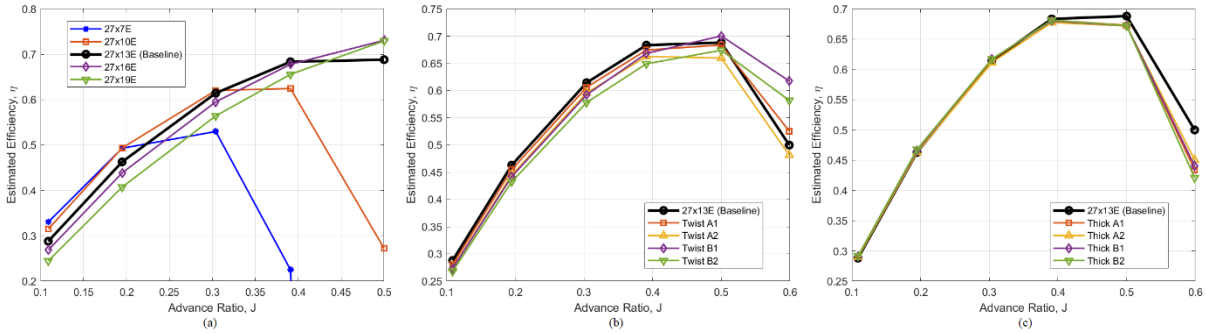

Figure 4. Efficiency comparison of (a) static pitch variants, (b) twist modified variants, and (c) thickness modified variants.

Conclusion

This study demonstrates that modifiying a 27-inch APC propeller's geometry can lead to substantial enhancements in aerodynamic efficiency. Among the static pitch variants, the 13-inch pitch was chosen for detailed exploration based on its balanced performance across varying speeds. The twist study shows that more aggressive modifications (B1 and B2) yield notably higher efficiency at increased advance ratios, making them especially advantageous for high-speed applications. By contrast, airfoil thickness modifications—whether uniform or tapered—cause a modest reduction in efficiency at higher advance ratio, even though they may offer structural or manufacturing benefits. Future research may incorporate structural and acoustic analyses to yield a fully optimized propeller design that meets all operational requirements.

Process Optimization of Polymer Melt Impregnation Systems by Extrusion Method

Mehmet Usta[a], Aliihsan Koca[a], Mustafa Doğu[b]

[a]Istanbul Technical University, Mechanical Engineering Department, Heat - Fluid Program, Turkey
[b]Mir Innovation And Technology Center, Turkey
ustam16@itu.edu.tr

Keywords: CFD, Composite, Extrusion, Impregnation, Polymer.

Aim

The primary objective of this study is to optimize the polymer melt impregnation process through a combination of experimental and numerical methods. Specifically, the research aims to: Investigate the effects of key extrusion parameters—including temperature, pressure, and screw speed—on impregnation efficiency. Validate experimental results with Computational Fluid Dynamics (CFD) simulations to gain insights into the flow dynamics and polymer-fiber interactions within the extruder. Determine the impregnation ratio of the composite using high-resolution microscopy images processed with ImageJ, thereby establishing a direct correlation between processing conditions and impregnation quality. Provide comprehensive guidelines for optimizing polymer-based composite production for enhanced industrial applications.

Materials and Methods

This study employs a variety of polymer matrices, including polypropylene (PP), polyethylene terephthalate (PET), and polyamide (PA), which are widely used in composite manufacturing due to their versatile properties. Polypropylene (PP) is a thermoplastic polymer known for its chemical resistance, low density, and cost-effectiveness, commonly used in automotive parts and packaging. Polyethylene terephthalate (PET) is recognized for its strength, dimensional stability, and moisture resistance, making it ideal for textiles, packaging, and engineering components. Polyamide (PA), or nylon, offers high mechanical strength, temperature resistance, and abrasion resistance, commonly used in automotive, aerospace, and electrical industries.

To enhance the mechanical properties, reinforcing fibers such as glass fibers and carbon fibers are incorporated into the composite material. Glass fibers provide significant improvements in tensile strength, impact resistance, and durability. They are cost-effective and widely used in various applications, from construction to automotive parts. Carbon fibers are included for their exceptional strength-to-weight ratio, high stiffness, and fatigue resistance. These fibers are ideal for high-performance, lightweight structures in industries such as aerospace and automotive. Carbon fibers also offer superior thermal conductivity, chemical resistance, and dimensional stability, further enhancing the properties of the composites.

The combination of these polymers and reinforcing fibers results in composite materials with a balanced mix of mechanical, thermal, and chemical properties, making them suitable for a range of demanding applications. The selection of these materials allows for optimizing composite performance for specific uses.

Figure 1. Experimental Setup.

In the continuous fiber-reinforced filament production line, the equipment is arranged in the following sequence: creel, spreading system, extruder, impregnation die, cooling system, and puller. In the process, carbon fibers are unwound from the creel system and passed through the spreading system. The spread fibers are then guided into the impregnation die, where they are combined with molten polymer. The process uses a Gülnar-brand single-screw extruder with a screw diameter of 16 mm, an L/D ratio of 30, and a production capacity ranging from 0.1 to 1 kg/hour. After being coated with polymer in the impregnation die, the fibers exit the die in cylindrical form and pass through an air-cooling system. The movement of the filaments along the production line is ensured by the puller unit.

The polymer melt impregnation process is performed using a single-screw extrusion system. In this system, the polymer melt and fibers are combined under controlled conditions. Various extrusion die profiles, heating zone configurations, and screw speed settings are investigated to assess their impact on impregnation efficiency. The study also examines the role of shear forces and residence time inherent to single-screw systems, as these factors critically affect fiber wetting and dispersion.

To quantitatively evaluate the impregnation quality, high-resolution optical microscope images were captured at magnifications of 2x, 3x, 5x, and 10x. In addition, Scanning Electron Microscope (SEM) images were obtained at higher magnifications of 144x, 800x, and 5000x to enable more detailed microstructural characterization. These images reveal the distribution and penetration of the polymer within the fiber bundles. All captured images were analyzed using the ImageJ software, which allowed for the calculation of the impregnation ratio—i.e., the percentage of the fiber surface that is effectively wetted by the polymer matrix. This combined optical and electron microscopic evaluation provides a comprehensive insight into the microstructural quality of the composite and facilitates a direct correlation between processing parameters and impregnation outcomes.

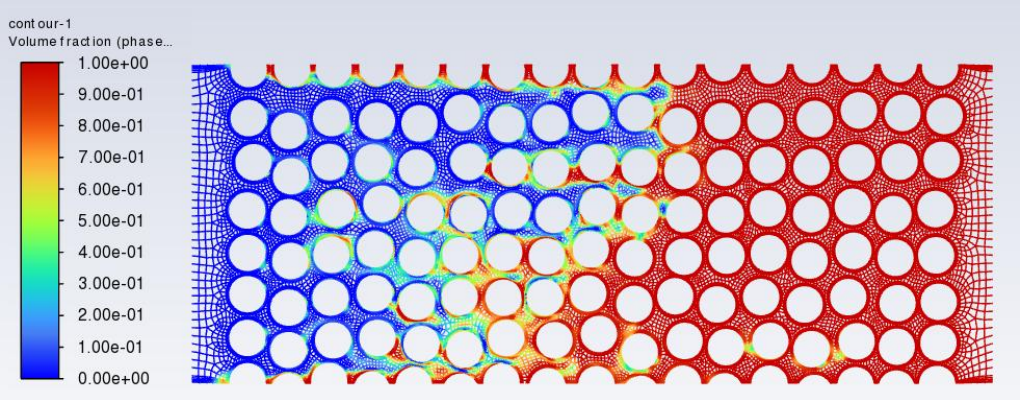

Figure 2. 2D CFRP Analys.

The figure shows the volume fraction contour of a 2D carbon fiber-reinforced polymer (CFRP) cross-section subjected to a pressure of 90 kPa for 10 seconds. The distribution of fiber content within the matrix is visualized, illustrating the impregnation efficiency under these process conditions.

CFD simulations were employed to model the complex interactions between the polymer melt and reinforcing fibers during the extrusion process. The simulations focused on predicting the flow dynamics, temperature distribution, and the effect of shear forces on fiber impregnation. As illustrated in Figure 2, a two-dimensional cross-sectional model of a die for PA6 (polyamide 6) was constructed to analyze the flow behavior of the polymer melt among circular fiber bundles. Under conditions of 90 kPa pressure and 220°C temperature, the polymer was simulated to flow between the fiber tows, aiming to achieve effective impregnation of the fiber bundle.

Figure 2 shows the volume fraction contours of the polymer phase within the fiber architecture. The color gradient—from blue (0% volume fraction) to red (100% volume fraction)—illustrates the progression of polymer penetration across the fiber domain. The blue region on the left indicates the inlet where the polymer begins to infiltrate, while the red region on the right shows areas where the polymer has fully impregnated the fiber bundle. This visual clearly demonstrates how polymer flow develops spatially and highlights regions of incomplete impregnation, which is crucial for evaluating processing effectiveness. These numerical results were then compared with experimental data—including the impregnation ratios determined from microscopy—to validate the process and identify the optimal processing conditions.

Findings

The CFD simulations provided valuable insights into the flow behavior within the extruder. The numerical models accurately predicted the distribution of the polymer around the fibers, confirming that an optimal range of extrusion parameters leads to improved impregnation efficiency. The analysis identified that maintaining an extrusion temperature in the range of 220–260°C, along with an appropriate combination of screw speed and pressure, maximizes fiber impregnation. These simulation results were in close agreement with the experimental observations, thereby confirming the reliability of the numerical model.

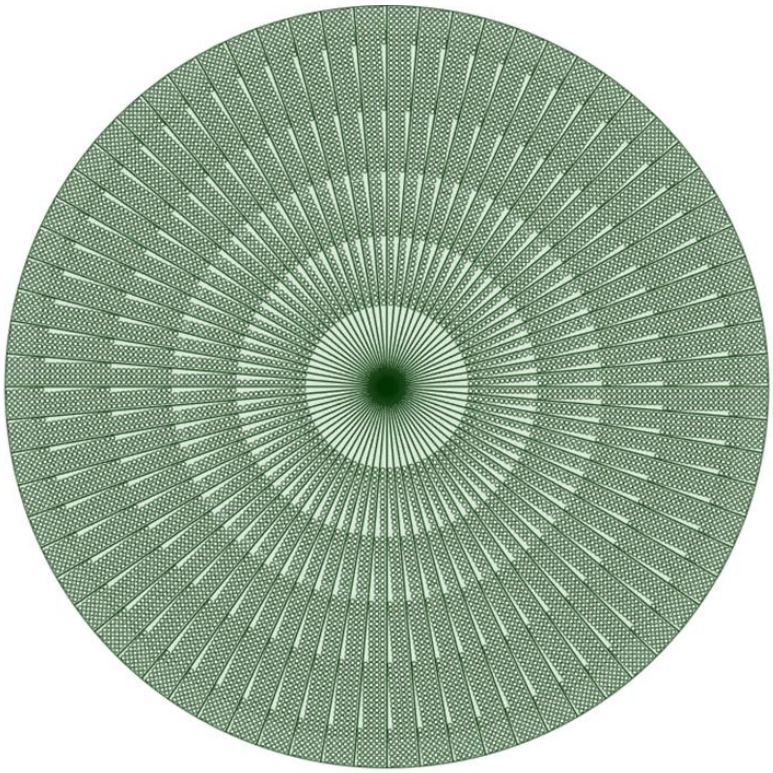

Figure 3. Fiber Bundle "Illustration of a fiber bundle containing 12,000 fibers, each with a diameter of 7 micrometers."

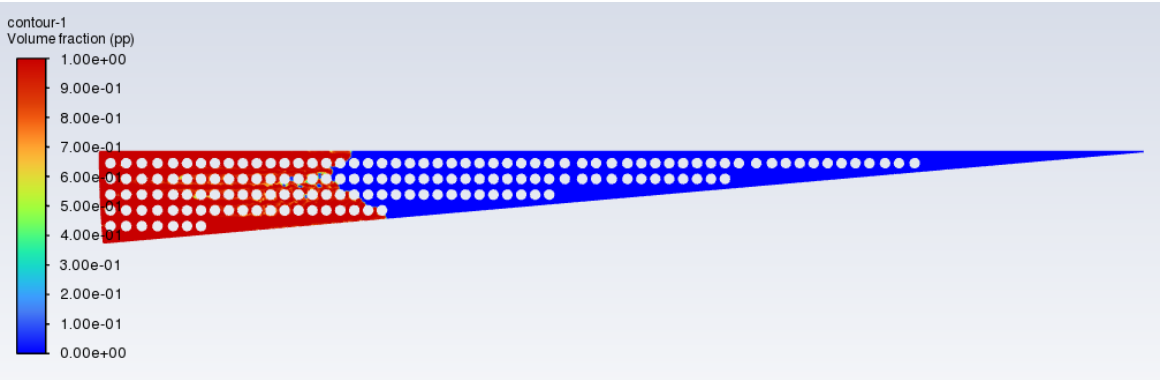

Figure 4. 5-degree circular fiber bundle ''5-degree circular fiber bundle and corresponding volume fraction contour."

The CFD simulations offered valuable insights into the flow behavior and impregnation dynamics within the extrusion die. Figure 3 illustrates a full fiber bundle consisting of 12,000 individual fibers, each with a diameter of 7 µm. This bundle was subjected to impregnation under conditions of 90 kPa pressure and 220°C temperature for 10 seconds. Due to the complexity and size of the model, the entire circular fiber bundle was divided into 72 equal sectors, each representing a 5-degree slice, to enable a more manageable simulation. As shown in Figure 4, a 5-degree segment of the circular bundle was modeled, where the polypropylene polymer enters from the arc boundary and advances between the fibers toward the center. The contour visualization of the volume fraction reveals how effectively the polymer permeates through the fiber matrix along the radial direction.

Additionally, earlier CFD results (as seen in the first image) highlight the interaction of polymer flow with the fibrous structure in a 2D planar section. The red-to-blue gradient in the volume fraction contour clearly indicates the progressive infiltration of the polymer, supporting the assessment of impregnation efficiency. The tapered

domain in the second image demonstrates how fiber spacing and orientation influence flow uniformity and impregnation performance under extrusion-driven conditions.

Overall, the simulations confirmed that an optimal range of processing parameters—particularly maintaining the extrusion temperature between 220°C and 260°C, combined with controlled pressure and screw speed—enhances the impregnation quality. These results closely align with experimental observations, validating the accuracy and reliability of the numerical model for predicting fiber–polymer interactions in industrial-scale manufacturing setups.

Table 1. Mesh Independence Analysis.

MESH INDEPENDENCE ANALYS			
	MESH1	MESH2	MESH3
EDGE SIZING(M)	0,0000003	0,0000002	0,0000004
ELEMENT SIZING(M)	0,0000005	0,0000004	0,0000006
METHOD	ALL TRIANGLE	ALL TRIANGLE	ALL TRIANGLE
NODES	66694	112510	44677
ELEMENTS	119519	204607	78782
VOLUME FRACTİON	0,42	0,42	0,40

Mesh independence analysis is a validation step performed in finite element (FEM) or computational fluid dynamics (CFD) simulations to ensure that the results are not dependent on the mesh density. In this analysis, the variation of the solution is examined as the number of elements (mesh quality) increases. If the results no longer change significantly beyond a certain mesh density, the solution is considered mesh-independent. However, if the results continue to vary, a finer mesh or a different meshing method may be required. In the graphical representation, the X-axis represents the mesh number, while the Y-axis shows the simulation result (e.g., volume fraction). As the mesh number increases and the results stabilize, it indicates that an appropriate mesh density has been achieved.

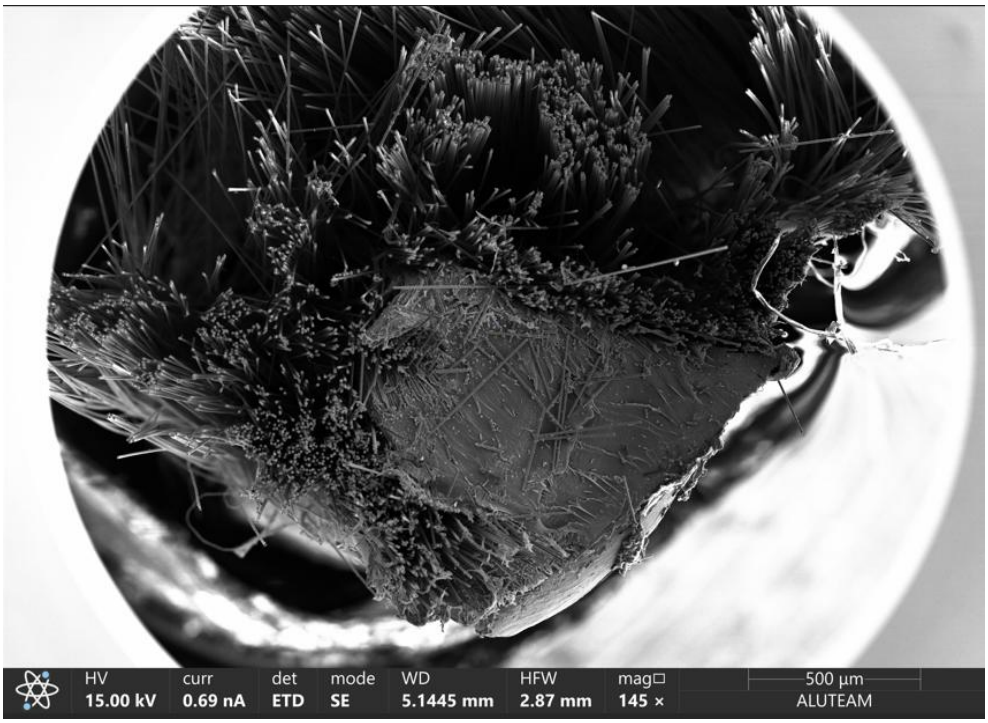

Figure 5. Section 1 fiber bundle SEM images 145X.

The high-resolution microscope images—captured at magnifications of 2x, 3x, 5x, and 10x and SEM images taken at 144x, 800x, and 5000x, were analyzed using ImageJ to quantitatively evaluate the impregnation quality of the composites. This multi-scale imaging approach enabled the visualization of polymer distribution and penetration into the fiber bundles with exceptional detail. The analysis revealed that samples processed under optimized conditions exhibited significantly higher impregnation ratios, reflecting more effective wetting of the fiber surfaces by the polymer matrix. These observations were further supported by the microstructural evidence from SEM, which highlighted improved polymer-fiber interface integrity. The enhanced impregnation quality directly correlates with the observed improvements in both mechanical and thermal properties, emphasizing the importance of precise process control in composite manufacturing.

Conclusion

Table 2. Impregnation Ratios and Fiber Counts for Three Different Cross-Sections.

Parameter	Unit	Section 1	Section 2	Section 3
High-Density Region	count / 10,000 μm²	100	60	120
Medium-Density Region	count / 10,000 μm²	87	40	100
Low-Density Region	count / 10,000 μm²	74	30	73
Average Fiber Count	count / 10,000 μm²	87.00	43.33	97.67
Total Area (via ImageJ)	μm²	1,432,955.67	2,912,031.39	1,325,414.93
Total Area (via Equivalent Radius R)	μm²	1,431,938.25	2,896,404.48	1,327,833.00
Calculated Total Fiber Count	count	12,467	12,619	12,945
Impregnated Area (via ImageJ)	μm²	340,216.34	1,187,561.72	691,207.54
Impregnation Ratio	-	0.24	0.41	0.52
Number of Impregnated Fibers	count	2,960	5,146	6,751

Table 3. Impregnation Rate and Number of Impregnated Fibers for General Average.

General Average	Value
Average Impregnation Rate	0.39
Average Number of Impregnated Fibers	4,952

This study successfully integrates experimental analysis and CFD simulations to optimize the polymer melt impregnation process in single-screw extrusion-based composite manufacturing. The findings demonstrate that precise control of processing parameters significantly enhances the mechanical and thermal properties of the final composite materials. In particular, the integration of high-resolution microscopy analysis to determine the impregnation ratio offers a robust method for evaluating and correlating the microstructural quality with processing conditions.

Additionally, experimental results obtained from three separate fiber bundle cross-sections, with 46 measurements in total (as shown in Figure 5, magnifications of 144x), revealed that the impregnation ratio, calculated using the ImageJ software as the ratio of the impregnated area to the total area, yielded an average experimental impregnation rate of 0.39. It was also observed that, out of 12,000 fibers, 4,952 were impregnated, as shown in Tables 2 and 3. Furthermore, the impregnation ratio calculated for the 5° fiber bundle in Figure 4, based on the same method using ImageJ, was found to be 0.42. This result, in combination with the experimental findings, indicates a strong correlation between the experimental and simulation-based impregnation rates (0.39-0.42), demonstrating the reliability of the simulations.

Future research should focus on extending these methods to more complex fiber architectures and alternative polymer matrices, potentially incorporating artificial intelligence for further process optimization. Overall, this study provides valuable insights that can drive the development of high-performance, efficient, and reliable composite manufacturing processes for industrial applications.

gurle17@itu.edu.tr

Keywords: Closed Circuit Cooling Tower, Computational Fluid Dynamics (CFD), Heat and Mass Transfer, Multiphase Analysis, Staggered Tube Arrangement.

Aim

In this study, a two-dimensional Computational Fluid Dynamics (CFD) model has been developed to understand the counterflow air-water interaction in a closed-loop cooling tower of the packaged type. During the modeling process, a multiphase flow method and the SST k-ω turbulence model were integrated. Additionally, the shear force term and water evaporation were incorporated to determine the circular distribution of the falling film flow and specific humidity fields.

This study analyzes thermal parameters such as flow behavior, specific humidity, water and air temperatures, air velocity, heat transfer coefficient, saturation temperature, and mass transfer rate in a staggered tube arrangement. Simulation results showed that mass transfer rate increased with higher air velocity, which indicates improved performance. Also revealed that the heat transfer coefficient on the spray side exhibits an exponential increase with rising air velocity. However, results indicates that the heat transfer between the water film and the outer tube surface is not adequately captured in the 2D model. A 3D design is necessary to reveal regions where the water does not always contact the tube surface.

The main aim of this study is to investigate a two-dimensional Computational Fluid Dynamics (CFD) model to better understand the counter-current air-water interaction and thermal behavior in a packaged-type closed-circuit cooling tower (CCCT). The objectives of the study include investigating the key parameters such as flow behavior, specific humidity, water and air temperature, air velocity, heat transfer coefficient, saturation temperature and evaporation rate. Additionally, the study integrates the Mixture multiphase method and SST k-ω turbulence model to simulate the air-water interface and counter-current flow across the staggered tube bundle using Fluent software. The CFD results are validated by comparing the heat transfer coefficient between the water film and the outer surface with experimental data. Ultimately, this research aims to provide a deeper understanding of the complex mechanisms governing heat and mass transfer in CCCTs and to contribute to the optimization of cooling tower design and operational parameters.

Material and Method

A two-dimensional CFD model was developed using the mixture multiphase method combined with the Shear Stress Transport (SST) k-ω turbulence model to simulate counter-current air-water interactions in a closed-circuit cooling tower. The computational domain was discretized using a fully structured quadrilateral mesh containing over 50,000 elements to ensure high-resolution accuracy in capturing flow and heat transfer behavior, as shown in Figure 1. Only the last row of coils was considered with water directed toward the center of the pipe to achieve a uniform film distribution and observe the evaporation dynamics.

Simulations were performed using ANSYS Fluent, incorporating additional physics such as water vapor diffusion and advection to capture humidification and heat-mass transfer more effectively. To enable evaporation below the saturation temperature, a UDF was written and integrated into the Evaporation - condensation Lee model responsible for mass transfer. An explicit formulation was used with a volume fraction cutoff value of 1e-6. Since the dispersed model tends to overpredict the evaporation rate compared to practical observations, the interface modeling was set to Sharp/Dispersed and the drag coefficient model that provided the best convergence was the Symmetric model.

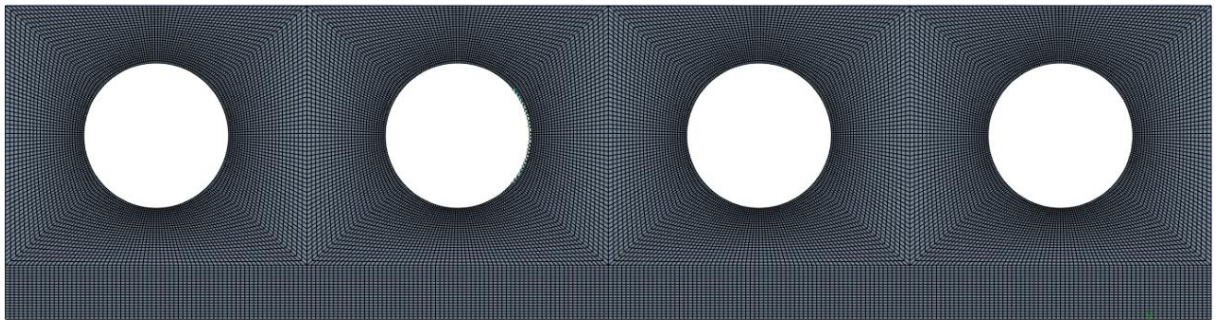

Figure 1. The mesh structure of computational domain generated by Ansys Fluent**.**

Surface tension force modeling was based on the Continuum Surface Force (CSF) approach, with wall adhesion set at 90°. The slip velocity was modeled using the Manninen et al. approach. For pressure-velocity coupling, the Coupled method was employed. Boundary conditions included varying air velocities of 0.01 m/s, 0.5 m/s, 1 m/s, 1.5 m/s, with a constant water inlet velocity of 1 m/s. The process air conditions and initial temperatures were set according to experimental measurements.

To support the numerical approach, an experimental study was conducted using a CCCT equipped with 10 rows of staggered serpentine tubes under real atmospheric conditions. During testing, inlet and outlet air temperatures were recorded to evaluate the cooling performance of the system. The heat transfer coefficient between the falling water film and the outer tube surface was determined using empirical correlations and resistance-based calculations. These experimentally obtained values were then used to validate the CFD model by comparing the numerical results with measured data, ensuring that the simulation accurately captured the air-water interaction and coupled heat-mass transfer processes within the cooling tower.

Findings

A mesh independence study was conducted with models between 50,000 to 100,000 elements, and the resulting outlet specific humidity showed variations within a ±10% error margin, confirming the reliability of the mesh, as shown in Figure 2.

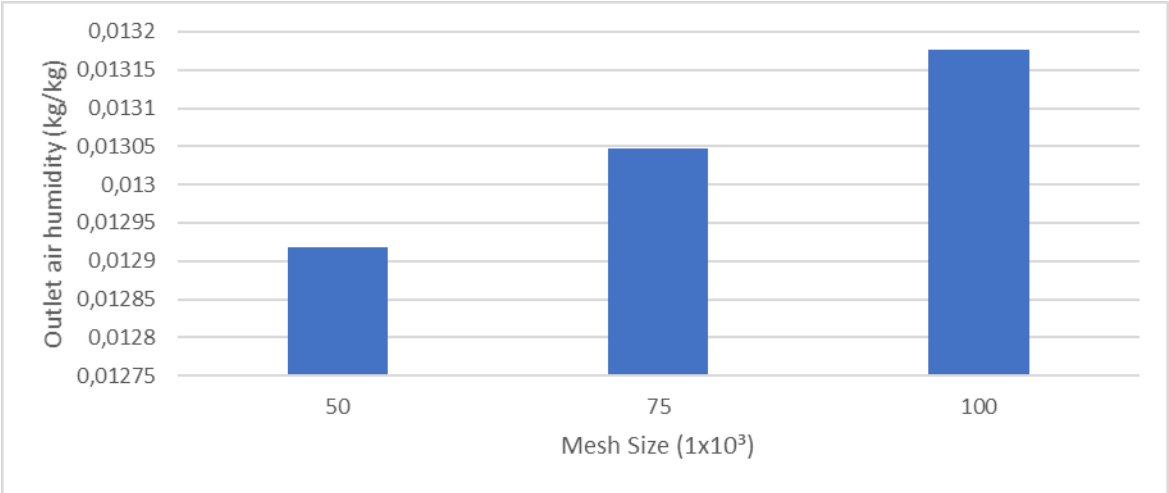

Figure 2. The mean value of outlet air humidifies under three quadrilateral mesh sizes.

The air velocity varied from 0 to 1.5 m/s in the widest section of the tower and increased in narrower sections due to contraction effects. As the air velocity increased, the water film began to thin at the bottom of the tube. Similarly, as the air velocity increases, the spray film heat transfer coefficient, outlet air specific humidity and mean mass transfer rate also increase. These trends are presented in Figure 3.

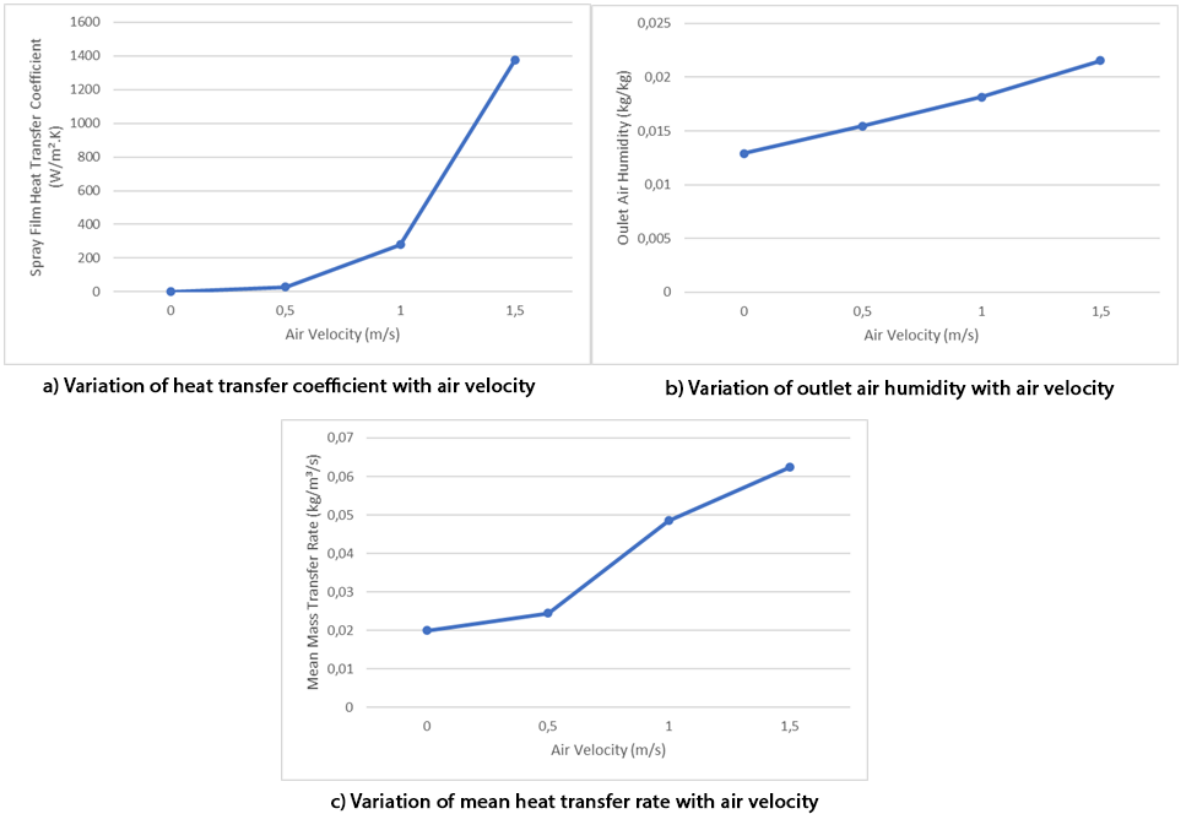

Figure 3. Variation of Different Parameters with Air Velocity: (a) Heat Transfer Coefficient, (b) Outlet Air Humidity, (c) Mean Heat Transfer Rate.

At an air velocity of 1.5 m/s, the specific humidity obtained from the simulation was 0.021 kg/kg, whereas the experimental value was 0.019 kg/kg, indicating that the simulation result is approximately 10% higher. The contours of temperature, specific humidity, and mass transfer rate with respect to air velocity are presented in Figure 4.

In terms of experimental data, the dry and wet bulb temperatures of inlet air were recorded as 29.02°C and 19.73°C, respectively. The process water entered the tower at 34.88°C and was cooled to 25.90°C at the outlet. Data were averaged over one hour under steady-state conditions to ensure accuracy. The range and approach values were calculated as 6.97°C and 6.17°C, respectively, as shown in Figure 5. Based on appropriate thermal resistance calculations, the spray heat transfer coefficient was determined to be 752.07 W/m²·K. The total evaporation loss observed in experiment was 0.8 m³/h. However, spray heat transfer coefficient was found to be around 1400 W/m²·K based on the simulation results.

Figure 4. Variation of different parameters around the serpentine tubes depending on the air velocity.

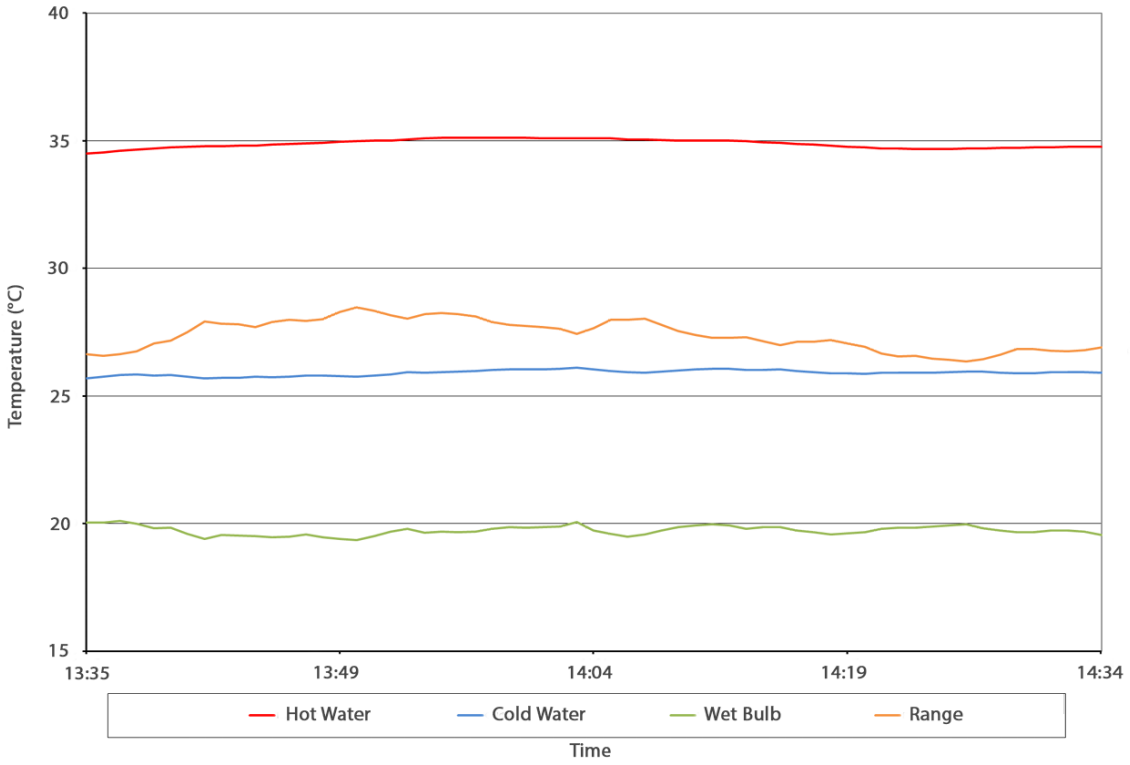

Figure 5. Variation of hot water, cold water, wet bulb temperature, and range over a 1-hour period in the cooling tower.

Conclusion

This study successfully developed a 2D CFD model employing the Mixture multiphase method and SST k-ω turbulence model to analyze counter-current air-water interaction in a closed-circuit cooling tower. Simulation results showed different agreement with experimental findings, with the heat transfer coefficient exhibiting an error margin of approximately +100%, which indicates that the heat transfer between the water film and the outer tube surface is not adequately captured in the 2D model. A 3D design is necessary to reveal regions where the water does not contact the tube surface. These non-wetted areas would reduce the local heat transfer coefficient, leading to a more realistic, non-uniform water film distribution, unlike the uniform assumption inherent in 2D simulations. Temperature contours of the spray water indicated progressive heating, and the simulated mass transfer rate increment aligned well with increasing air velocity. With dry and wet bulb inlet air temperatures recorded at 29.02°C and 19.73°C, and process water cooling from 34.88°C to 25.90°C, the system demonstrated a 6.97°C range and 6.17°C approach. Overall, this study provides valuable insights into heat and mass transfer mechanisms in CCCTs and offers practical guidance for understanding design and enhancing thermal performance in industrial cooling applications.

A Novel Approach for Robust Identification and Characterization of Mechanical Shock Loads for Structural Durability Assessment

Doğukan Elibol[a], Mesut Kırca[a]

[a] Istanbul Technical University, Faculty of Mechanical Engineering, Solid Mechanics Programme, Türkiye
elibol16@itu.edu.tr

Keywords: Accelerated Structural Durability Tests , Acceleration Data Processing , Automotive Low Cycle Fatigue , Mechanical Shock Loads , Shock Load Extraction.

Aim

Advancements in mechanical engineering have improved structural durability by enabling lighter, stronger designs through innovations in computational analysis and fatigue prediction (Akbaba et al., 2022). Fatigue is classified into high-cycle fatigue (HCF) and low-cycle fatigue (LCF). HCF results from repeated small load cycles, while LCF occurs under higher stress amplitudes, leading to rapid failure (Chen et al., 2014; Jimenez, 2018).
Accurate load spectrum determination is critical, particularly for high-inertia automotive components like battery systems and fuel tanks, which experience mechanical shocks from sudden accelerations, potentially causing LCF failures (Prueter, 2021; Wang, 2023). Testing such components in electrodynamic shakers using real-world acceleration data is expensive and complex. Accelerated fatigue testing replicates long-term damage under controlled conditions, but precise load spectrum determination is essential to prevent overengineering or premature failures (Chen et al., 2014; Sisemore et al., 2017).
This study investigates the accelerated testing of vehicle structural components affected by impact-induced Road Load Data (RLD). Road conditions like potholes and speed bumps generate shock based loads, contributing to most of the total damage (Kubo, 2018). Examples of such roads are illustrated in Figure 1. Predicting these loads is essential for shaker tests. However, extracting them from RLD acceleration data is complex. Shock loads that are embedded within gaussian stationary signals, require isolation and transformation into simplified waveforms (half-sine, damped-sine) for efficient testing. This approach improves test acceleration, cost reduction, and practical implementation.

Figure 1. Shock induced roads.

Mechanical shock loads in the automotive industry exhibit both deterministic and stochastic characteristics depending on their source. Deterministic shocks occur under controlled conditions (Frajnković, 2018), while stochastic shocks occur from real-world irregularities (Manouchehry Nya, 2019; Billal, 2015; Zhou, 2023). These loads are transient, non-stationary and non-ergodic (Özga, 2023), which makes frequency-domain methods such as FFT, STFT, and PSD unsuitable (Abdullah, et al., 2009). Figure 2 shows randomly distributed shock profiles

from repeated measurements on the same vehicle, road, and maneuvers, showing the stochastic nature of mechanical shock loads.

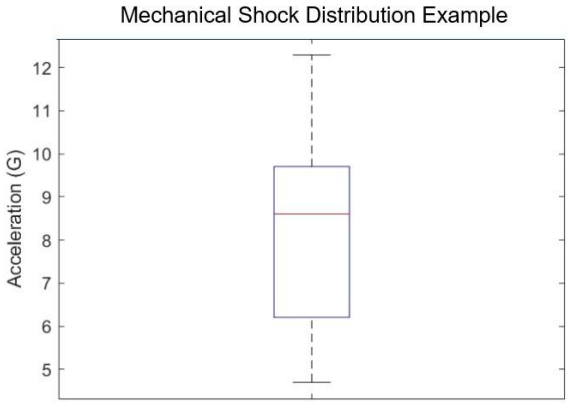

Figure 2. Mechanical shock distribution example.

Many studies fail to capture the stochastic, non-stationary nature of shock loads, particularly in vibration embedded signals (Rouillard, 2024). Time-domain methods typically apply a threshold, but they require case-specific adjustments and rather than transforming, they only crop the signal (Kırbaş, 2023). Statistical filtering techniques like moving crest factor, RMS, and kurtosis similarly lack sufficient simplification and require extensive tuning (Lepine, 2018). Shock Response Spectrum (SRS) is widely used but struggles with multiple shocks in a signal, lacks precise time and phase information, and can be overly conservative (Alexander, 2018). Rainflow based block load methods capture load distribution but not frequency and phase, making them suitable only for quasi-static conditions. (Halfpenny, 2006). Some advanced studies apply machine learning algorithms to detect mechanical shock loads (Gorges, 2019). While effective, these approaches add complexity, struggle with generalization, and increase computation time.

This study presents a data processing method for autonomously detecting mechanical shock loads in acceleration signals without separate tuning. It efficiently identifies LCF shock loads, determines impact timing, frequency, and waveforms, and supports multiple test conditions. Simplified signals enable easier implementation for electrodynamic shakers.

Material and Method

Structural products used in the automotive industry are mostly made of aluminum or steel materials (Trzepieciński, 2024). Validations were conducted on a steel specimen using finite element analysis for design verification. Table 1 presents its mechanical properties, and Figure 4 shows its visual representation. The specimen, subjected to inertial loads, was driven by RLD data with shock loads, and resulting stress values were analyzed. Transient dynamic analyses were performed in Abaqus and Ansys Mechanical. Original and processed RLD profiles were applied separately, and stress history was compared (Fig. 5). Fatigue analyses were conducted using nCode and Femfat. The proposed multi-step method was implemented using nCode and Matlab softwares.

Table 1. Specimen mechanical properties**.**

Material	Structural Steel
Thickness	4 mm
Weight	0.22 kg
Hanging Weight	5 kg
Bending Natural Frequency	42 Hz
Material Damping Ratio	2%

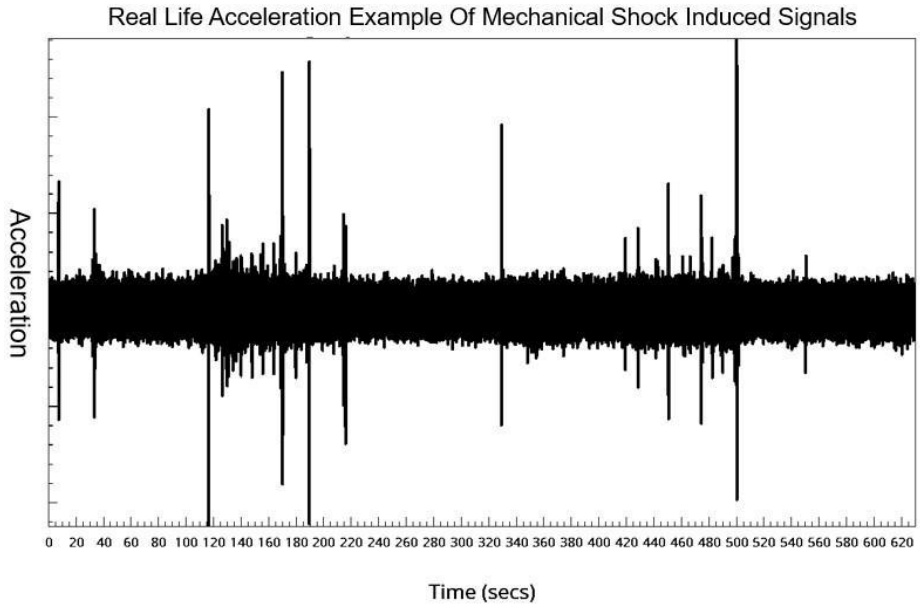

Figure 3. Acceleration measurement example.

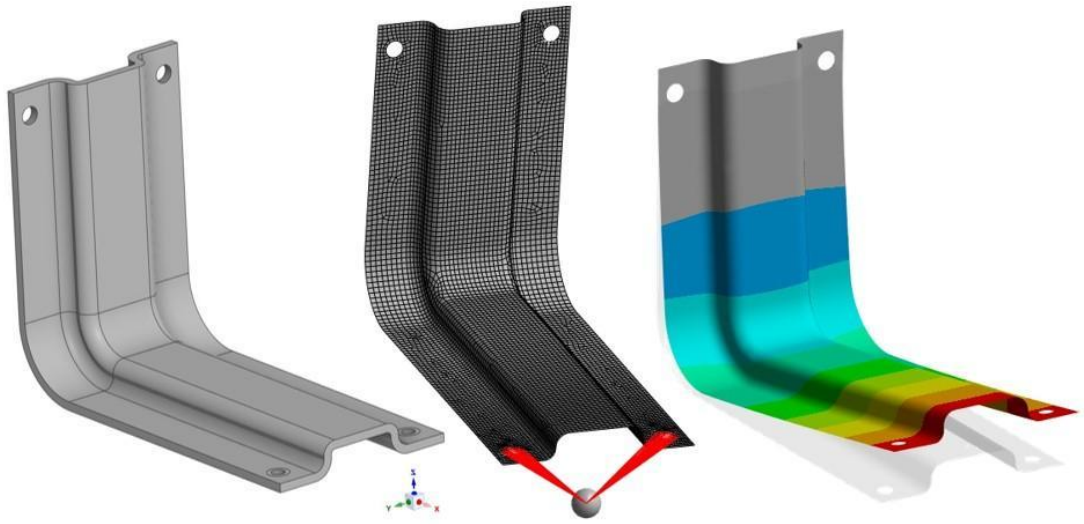

Figure 4. 3D & FE model of the specimen and the dominant mode shape.

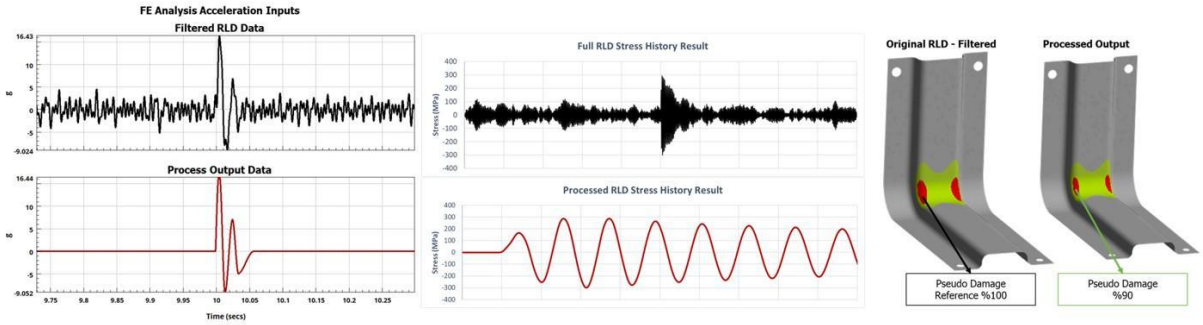

Figure 5. Stress history & fatigue damage comparison.

Used excitation loads are real acceleration data obtained from an actual automotive proving ground, including road profiles such as potholes and curb strikes (Fig.1). Additionally, synthetic road data, were generated. Synthetic road data was generated using a full-car dynamic model (Figure 6), a common approach in validation studies (Rouillard, 2024).

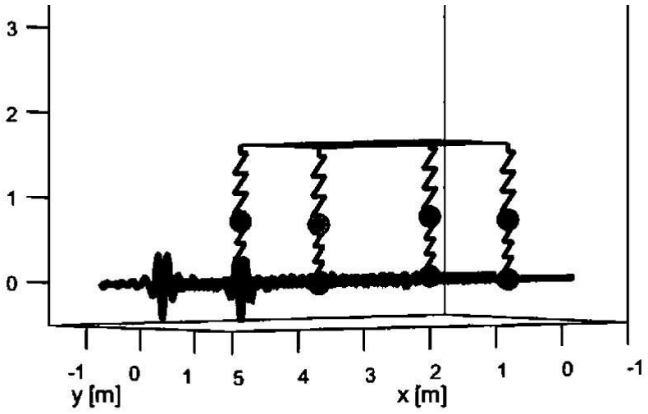

Figure 6. Full car model.

Figure 7 demonstrates the step-by-step process of the proposed method on a sample RLD. After collecting acceleration data, the first step is filtering and adjusting the sample rate to 2048 Hz for consistency. Filtering (2–250 Hz) removes noise, non-damaging loads, and unrealistic trends. The data is then segmented into 1-second transient windows and adjusted to oscillate around a zero mean (mean removal).

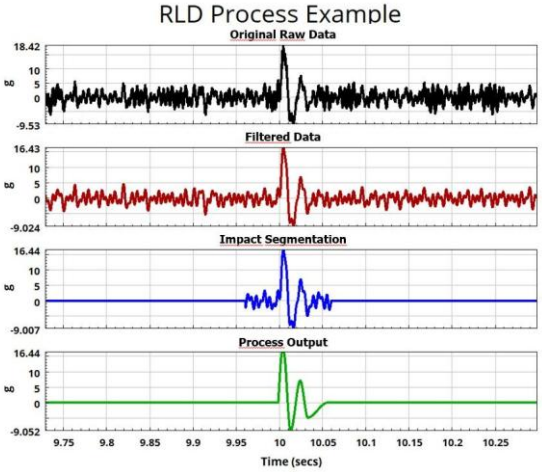

Figure 7. Proposed method's transformation example.

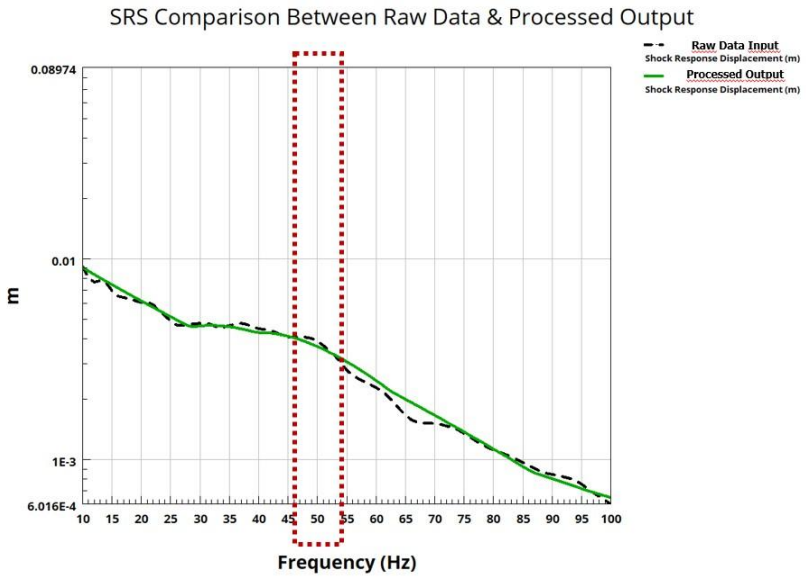

Figure 8. SRS comparison & validation.

The next step is the parametric identification of potential impact regions in the data. Repeated studies on both real and synthetic data have demonstrated that segments containing loads above 3.5 standard deviations correspond to impact events. All other windows are zeroed out, effectively isolating the segments where impacts are expected. Next, zero-crossing points of the first derivative are identified, retaining only these points to detect reversals. However, due to random loads at multiple frequencies, the data remains complex. To refine it, reversal points are further processed using statistical parameters in Table 2.

Table 2. Statistical parameters**.**

Ideal Sampling Rate	Min. 2048 Hz
Filtering Bandwidth	2-250 Hz
Mean Removal	Every 1024 Data Points
Impact Parameter	<3.5 Standard Deviation
Impact Period	Between 5-100 ms
Range Gate Factor	1.4
Width Factor	3
Allowable Width	Range/Width Factor
Allowable Range	Range/Range Factor
Waveform Factor	Peak/Valley Ratio

Reversal points closer than the minimum period are removed, reversal points farther apart than the maximum period are retained and points with a vector length shorter than the defined width parameter are eliminated, while longer ones are kept.

During this process, backward checks are conducted to ensure that no peaks or valleys are lost. If any are missing, the data is readjusted. As a result of these steps, impact regions within the zero-valued sections are successfully identified.
For datasets with multiple impacts, separate rainflow analyses are conducted for each segment. If transformed correctly, each window contains one impact, having only start, end, peak, and valley points. Finally, shock amplitudes are verified, discarding those below the predefined range (Table 2).

The rainflow analysis at this stage accurately provides amplitude and frequency values, while the ratio of data points determines its waveform. For further inspection or storage, the data is resampled to a 2048 Hz sampling rate using Makima interpolation.
Makima interpolation is an improved version of Akima spline interpolation, designed to prevent excessive oscillations and ensure smooth curve fitting. It is particularly effective for time-series data and irregular datasets, providing stability against sudden changes (Akima, 1970).
The proposed method does not require manual corrections or parameter adjustments at any stage. Unlike simple downsampling, which may lose exact amplitude information, this method preserves high-frequency variations, ensuring that no significant peak is overlooked. All parameters have been formulated based on the statistical properties of the data and fine-tuned through hundreds of trials to ensure accuracy.

Finding

The proposed method operates without needing additional tuning across real and synthetic road signals. A dataset of 100 synthetic RLDs was processed, and its accuracy is shown in Table 3.

Table 3. Proposed method's performance**.**

Impact Detection Accuracy	Amplitude Detection Accuracy	Frequency Detection Accuracy
93%	95%	85%

Finite element analyses have shown that the maximum stress amplitude responses of the original RLD and the simplified RLDs are highly comparable (Fig.5). In fatigue analyses, it was found that using the stress data obtained through the proposed transformation and the original RLD yielded highly similar damage results (Fig.5)
Based on these findings, the proposed method is found to be applicable in the load spectra generation. For further validation, a Shock Response Spectrum (SRS) analysis was conducted. In the expected damage frequency ranges, the new profile produced similar displacement responses to the original RLD (Fig. 8). However, unlike direct SRS-based shock profiles, this method captures real frequency, phase, and amplitude data while accounting for repeated varying loads, making it more accurate and less conservative.

Conclusion

Defining the load spectrum is key to avoiding conservatism or early failures in accelerated fatigue testing. This study extracts shock loads from RLD, creating simplified profiles to enhance vehicle fatigue assessments.
Mechanical shock loads in automotive applications are stochastic, transient, and non-stationary. Many RLD studies fail to capture these loads accurately, especially in vibration embedded signals. Frequency domain methods are inapplicable, some time-domain methods crop data without simplification, SRS struggles with overlapping shocks, and rainflow analysis alone ignores shock timing and frequency. AI/ML methods enhance detection but add complexity and high computational costs.
This study presents an autonomous method for extracting mechanical shocks from acceleration signals. It automates filtering, sampling, impact detection, segmentation, and simplification while preserving frequency and amplitude, requiring no manual tuning and closely matching the original RLD.

Finite element validations were conducted in Abaqus and Ansys Mechanical, while fatigue assessments employed nCode and Femfat softwares. Synthetic and actual measurement signals were tested. Comparison, including SRS validation, showed the method's accuracy, efficiency, and scalability, benefiting automotive fatigue assessment.

Keywords: Finite Element Method, Hydrogen Embrittlement.

Aim

The rising trend in hydrogen technologies along with net-zero emission goals has accelerated research on the phenomenon of hydrogen embrittlement, which describes a condition where materials experience premature failures or a shift in mechanical behavior from ductile to brittle due to the presence of hydrogen in metallic materials. Due to its small atomic size, hydrogen diffuses into the interstitial lattice sites of metallic materials, as well as into intergranular sites such as dislocations and grain boundaries. Accumulation in these regions alters the mechanical behavior of metallic materials, making it more susceptible to brittle failure [1].
The stress distribution, exposed hydrogen environment, temperature, applied strain rate and microstructure of the material are all known to affect hydrogen embrittlement susceptibility. As expected, the probability of hydrogen-induced failure increases with increasing applied stress, hydrogen concentration and microstructural impurities [2,3]. Besides, the slow strain rate tests reported in the literature indicate that hydrogen-induced failure stress dramatically decreases at very low strain rates, without exception. Some of the reported test results indicate fractures occurring even within the elastic region due to high hydrogen concentration in the material [4,5]. There are a couple of hypotheses proposed for the hydrogen embrittlement mechanism over several decades:

- Hydrogen-Enhanced Decohesion Model (HEDE)
- Hydrogen-Enhanced Localized Plasticity (HELP)
- Absorption Induced Dislocation Emission (AIDE)
- Hydrogen-Enhanced Strain Induced Vacancy (HESIV)

HEDE is based on the weakening of interatomic bonds among iron atoms due to their interaction with hydrogen ions. It is accepted that the hydrogen-induced fracture starts with fracture initiation gap formation [2]. The HELP asserts that the hydrogen concentration in both interstitial sites and trap sites increases the dislocation activity. As a result, premature failure occurs due to a reduction in the stress required for dislocation movement [2,6]. The AIDE model proposes that the adsorbed hydrogen weakens the atomic bonds and leads the formation of dislocation centers, which then propagate under reduced stress due to the presence of hydrogen [2,6]. The latter hypothesis, HESIV, depends on enhanced internal vacancy formation and agglomeration due to mobile hydrogen within the material [7]. The consensus in the literature is that the interactive effect of these proposed mechanisms leads to the hydrogen-induced fracture in metallic materials [8].
There are numerous approaches available in the literature to model the hydrogen diffusion and failure limits of the materials. Phase-field approaches, finite element and finite difference methods are utilized to model hydrogen diffusion from the micro to the macro scale [1, 9-12]. By coupling hydrogen diffusion and mechanical models, both the effect of the stress-state on hydrogen concentration distribution and the effect of this distribution on fracture limit can be investigated. The cohesive zone modeling approach is widely preferred in the literature for this purpose [13-16]. Besides, some studies have implemented statistical approaches to evaluate failure probability [17, 18]. Moreover, both statistical and machine learning approaches, trained with experimental data, have also been developed to predict hydrogen-induced fracture [19, 20].

Although many approaches have been published in the literature, there is still a need for a solid approach that is suitable for utilization in industrial practice for predicting the failure limit and designing reliable engineering systems [21]. In this study, an experimental stress-dependent critical hydrogen concentration curve was integrated into a coupled hydrogen diffusion and mechanical finite element model to predict the failure limit of a specimen under various loading conditions. This approach aims to enable accurate material selection for engineering systems and to address the lack of a practical modeling framework in the existing literature. A 3D model framework is required to address industrial problems and to ensure practicality. However, a 2D model framework is needed to prove the proposed methodology and to validate 3D model framework. The method and preliminary results of the developed 2D model are briefly described in the following sections. A 3D model and the alteration of plastic deformation behavior due to the presence of hydrogen will be further investigated in future work.

Material and Method

A coupled thermal and mechanical finite element model framework was developed using the heat transfer analogy to calculate hydrogen mass transport [1, 10, 11]. Isotropic work hardening during plastic deformation was modeled using a power law, as shown in Equation 1 [22].

$$\sigma = \sigma_y(1 + \frac{E\varepsilon_p}{\sigma_y})^n \tag{1}$$

Here, n is the hardening coefficient, and ε_p is the plastic strain. The coupling term, gradient of hydrostatic stress, is calculated by means of the accordingly selected shape functions, global and isoparametric coordinate transformations and the coordinates of integration points [10, 23]. The model accounts for hydrogen concentration accumulated in interstitial lattice sites as well as traps such as grain boundaries, dislocations, and carbide interfaces. However, for the sake of simplicity, only dislocation sites were considered in the preliminary simulations. The variation of dislocation density with respect to plastic strain is evaluated using the relation proposed by Kumnick and Johnson [24]. The experimentally determined failure stress versus critical hydrogen concentration curve was implemented into the model, and failure was tracked based on the ratio between the actual stress and the critical stress derived from the current total hydrogen concentration, as shown in Equation 2.

$$R_f = \frac{\sigma_{actual}}{\sigma_{critical}} \tag{2}$$

Here, R_f is the indicator to track the failure in the model framework.
The experimental data for AISI 4135 steel, illustrated in Figure 1, were implemented into the UMAT and UMATHT subroutines to calculate the failure indicator ratio [25].

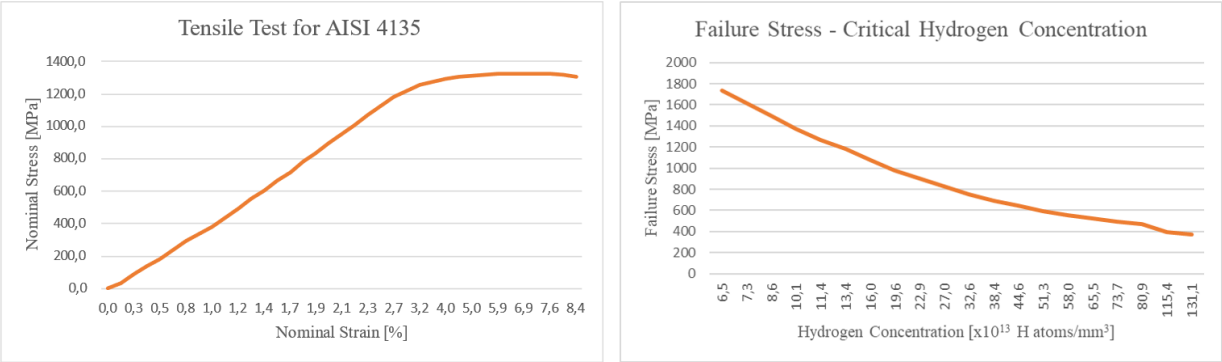

Figure 1. Experimental curves for AISI4135 steel [25].

The general model framework developed in Abaqus is given in Figure 2.

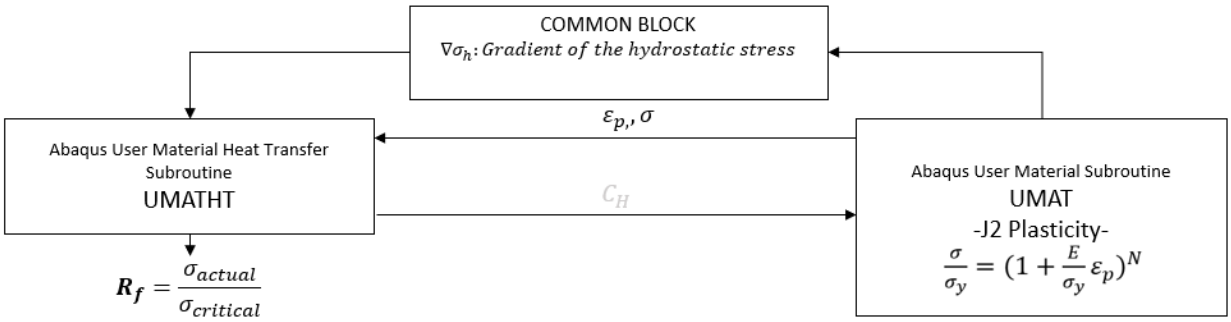

Figure 2. Model framework developed in Abaqus.

Findings

Most tensile tests in the literature are conducted using pre-charged and coated notched specimens. A coating is applied to the specimens to prevent hydrogen desorption and to maintain the hydrogen concentration at its initial level during the tests. Therefore, the simulation was done with a predefined hydrogen concentration ($2.6x10^{12}$ atoms/mm^3), assuming the specimen is insulated, and using a displacement rate of 4 μm/s. The parameter set used in the simulation are given in Table 1.

Table 1. Parameter set used in the simulation.

Parameter	Value
Initial concentration [atoms/mm^3]	2.6E+12
Diffusion coefficient (Surface film coef. = Conductivity) [mm^2/s]	2.01E-07
Dislocation density [sites/mm^3]	8.3E+13
Dislocation binding energy [Nmm/mol]	5.86E+07
Young's Modulus [MPa]	45000
Poisson Ratio	0.3
Initial Yield Strength [MPa]	1181
Work-Hardening Exponent	0.009

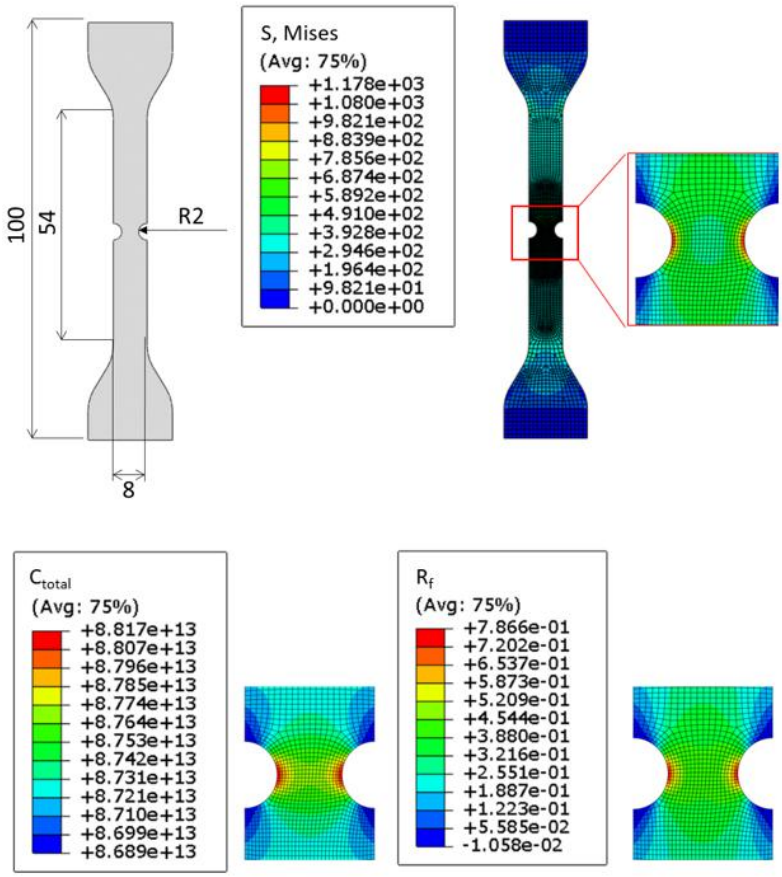

Figure 3. Simulation results.

Simulation results, Figure 3, show that even if the sample is insulated, hydrogen redistribution within the specimen is consistent with stress distribution, leading to increased local concentrations in these critical areas. This finding is significant in terms of its consistency with modeling studies available in the literature. In addition, the preliminary results indicate that the experimental dataset has been successfully integrated into the code. Immediately after the transition to the plastic region, the failure ratio R_f increases to around 0.8, which can be considered critical.

Conclusion

A 2D finite element model framework was developed in the Abaqus environment, and an experimental curve for AISI 4135 steel was integrated to assess the failure limit, aiming to fill the gap for a practical and accurate tool. The preliminary results are in good agreement with the findings available in the literature, and the developed model structure is sufficiently mature for further implementations and validation of 3D model framework which will be developed in future works as described in the introduction.

Keywords: Homogenization, Re-entrant Auxetic, Lattice Structures, Modal FEM Analysis.

Aim

Additive manufacturing is increasingly utilized across various industries, including aerospace, automotive, robotics, and biomedical fields [2]. Lattice structures and auxetic materials are gaining considerable attention due to their exceptional mechanical properties, particularly their potential for superior energy absorption capacity [3]. Auxetic materials exhibit a counterintuitive behavior due to their negative Poisson's ratio; they contract orthogonally under compressive force, leading to densification of the material near the applied load. This unique property also causes them to expand transversely when stretched axially, offering significant advantages in various applications [1-3]. This interest has led to the development of lightweight materials and structures for high energy absorption, such as honeycomb configurations and auxetic materials featuring re-entrant or anti-tetra-chiral core geometries [3].

Recent advancements in additive manufacturing have increased the internal geometric complexity of new designs, thereby enhancing efficiency. However, directly modeling these intricate geometries numerically requires significant computational resources. Predicting the mechanical properties of these components through finite element modeling (FEM) instead of physical testing is essential for saving both cost and time [1]. Due to the extensive geometry preparation, meshing, and computational time required for lattice structures, various methods have been explored to accurately predict mechanical properties.

To address these challenges, the use of equivalent media with average or effective mechanical properties has become common practice to reduce computational time while maintaining accuracy in FEM analysis. One effective method for modeling complex geometries is the homogenization approach. Numerical homogenization evaluates effective material properties by utilizing energy equivalence between explicit (full-scale) shown in Figure 1. and implicit (simplified) geometries shown in Figure 2. This approach allows for the modeling and analysis of complex geometries through implicit unit cells with effective material properties, rather than explicit unit cells with isotropic material, simplifying numerical models and reducing meshing and solve time [1]. Homogenization integrates multi-scale functionality, allowing effective properties derived from microscale unit cells to be applied in subsequent analyses and components of complex geometries at larger scales progressively. The homogenization method requires the periodicity of minimum unit cells in all applicable directions. Specifically, periodic boundary conditions must be imposed on the structural boundaries.

This study proposes using the homogenization method for one of the most common types of lattice structures: re-entrant auxetic. Comparative modal analyses were performed for both explicit (full-scale) FE model with isotropic material and implicit (simplified) finite element (FE) model with homogenized material. The first ten mode shapes were extracted from both models and compared in terms of mode shapes and natural frequencies. The results demonstrated that homogenization can be successfully applied to sandwich composite structures with auxetic re-entrant core without significantly compromising accuracy [1]. The implicit (simplified) FE model predicted natural frequencies with a difference range of less than 5% compared to the explicit (full-scale) FE model across all mode shapes.

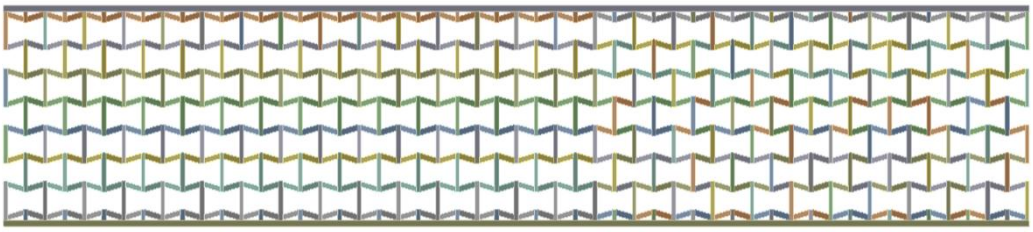

Figure 1. Explicit (Full-Scale) FE Model.

Figure 2. Implicit (Simplified) FE Model.

Material and Method

For this study, the re-entrant type of auxetic structure geometry (shown in Figure 3) was chosen for numerical simulation. This type of auxetic structure is characterized by a periodic arrangement of unit cells with negative angles, resulting in its negative Poisson's ratio behavior. Auxetic behavior involves transverse expansion under tension and contraction under compression. In the re-entrant type structure, this behavior is achieved through the bending or stretching of diagonal ribs under tensile loads [2].

Finite element model (FEM) for an auxetic re-entrant structure was developed using Ansys Workbench 2020 R2. To determine the equivalent material properties of the solid bodies, homogenized material properties were obtained using the Ansys Material Designer module. The unit cell, or the smallest representative volume element (RVE), corresponding to this structure is shown in Figure 3. An RVE can be defined as the smallest volume of a material that accurately represents the effective material properties [1].

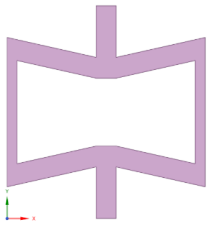

Figure 3. 1x1 Unit cell in X and Y directions.

Isotropic material properties, such as Young's modulus of elasticity and Poisson's ratio, for the explicit (full-scale) FE model were derived from tensile testing conducted during this study. Additionally, the material density was measured using the same tensile test coupons.

Modal analysis was conducted on both the explicit (full-scale) FE model and the homogenized (simplified) FE model. A free-free boundary condition was applied, allowing the lattice structure to move freely at its boundaries during the analysis. The primary advantage of using free boundaries is the elimination of the effects of boundary conditions [1]. The natural frequencies and corresponding mode shapes were obtained from the modal analysis. The first ten mode shapes were considered for comparison.

In Material Designer, anisotropic analyses were initially performed, revealing that the structure exhibited orthotropic symmetry behavior based on the resultant stiffness matrix. Consequently, orthotropic analyses were utilized in Material Designer [1].

Subsequently, sensitivity studies were conducted to better understand how the homogenized material properties change in various scenarios. The impact of extrude length in the Z direction was examined across five different cases, ranging from the original extrude length (100%) to 5% of the original length. Additionally, the effect of the number of unit cells stacked in the X and Y directions was analyzed across eight different cases, starting from a 1x1 unit cell configuration to an 8x8 unit cell configuration. Lastly, a mesh size convergence study was performed by conducting a series of simulations with eight different mesh sizes, and the results of the mesh convergence study are presented in Figure 4.

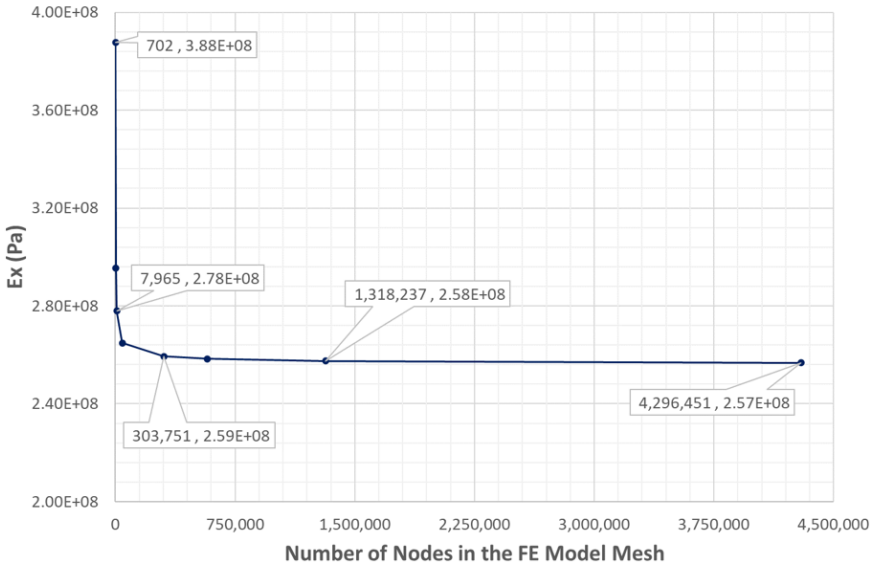

Figure 4. Meshconvergence study for the elasticity modulus in the X direction (E1, Ex).

Following the homogenization of the auxetic re-entrant structure, the stiffness matrix was obtained, along with Young's modulus of elasticity, shear modulus of elasticity, and Poisson's ratio in the X, Y, and Z directions [1].

When comparing the meshing of both the homogenized (simplified) FE model and the explicit (full-scale) FE model, there is a significant reduction in meshing time and the total number of elements and nodes, despite both models utilizing fine and structured hex meshing with SOLID185 elements throughout. The homogenized FE model consists of 337,125 nodes and 311,808 elements. In contrast, the explicit FE model contains 1,185,500 nodes and 897,600 elements. This reduction in nodes by approximately 3.5 times greatly decreases the time required for FE meshing and model preparation, ultimately leading to faster solve times. Therefore, during this study, the modal analysis solve time for the homogenized FE model was approximately 43 times shorter compared to the solve time for the explicit FE model.

Total deformation with respect to the first five mode shapes for both the explicit (full-scale) FE model and the homogenized (simplified) FE model are shown in Figure 5. The natural frequencies for the first ten mode shapes are provided in Table 1. It is evident from Table 1. that there is a very good correlation between the implicit and explicit models for the first ten mode shapes of the auxetic re-entrant lattice structure. Comparison of the natural frequencies based on the implicit and explicit models for the first ten mode shapes (Table 1) reveals that the maximum error is less than 5% in all cases. Additionally, it is observed that the implicit model resulted in lower natural frequencies in all cases [1].

Mode Shape Number	Explicit (Full-Scale) FE Model with Isotropic Material	Implicit (Simplified) FE Model with Homogenized Material	Difference%
1	 **Frequency = 342 Hz**	 **Frequency = 335 Hz**	**-2.1%**
2	 **Frequency = 425 Hz**	 **Frequency = 414 Hz**	**-2.5%**
3	 **Frequency = 624 Hz**	**Frequency = 606 Hz**	**-2.9%**

10	1528.1	1462.1	-4.3%

Findings

This study examined the efficiency of applying a homogenization method to re-entrant auxetic structures. Through homogenization, orthotropic material properties were calculated. Modal analyses were conducted, extracting the first ten mode shapes from both explicit and implicit models. The results were compared in terms of mode shape, maximum deformation, and natural frequency. Figure 5. illustrates the total deformation for the first five mode shapes of the re-entrant auxetic explicit and implicit FE models, while the natural frequencies for the first ten mode shapes are provided in Table 1.

The main findings are as follows:

- There is a very good correlation between the ten mode shapes derived from the explicit and implicit models.
- The maximum natural frequency difference between the explicit and implicit models is 4.3%, with all other differences being less than 4%.

Conclusion

The key conclusions are as follows:

- Utilizing the homogenization method simplifies the numerical model and reduces its size. This leads to a significant reduction in FE modeling effort and computational solve time, making the homogenization method highly effective, time-efficient, and computationally efficient while maintaining acceptable accuracy.

- It identifies and addresses potential needs related to analytical methods for complex geometrical structures.

This study investigated the feasibility of applying a homogenization method to re-entrant auxetic core structures. Future research will focus on the experimental validation of the numerical results.

Keywords: Auxetic re-entrant structure, Crush force efficiency, Energy absorption, Metamaterial, Parametric investigation.

Aim

Auxetic structures, widely recognized as a class of metamaterials, are known for exhibiting extraordinary mechanical properties that distinguish them from conventional materials. These structures possess a unique characteristic: a negative Poisson's ratio, which means that they expand in all directions when stretched, as opposed to most materials that contract perpendicular to the direction of applied force. Along with this, auxetic materials also demonstrate negative linear compressibility, meaning that they become stiffer when compressed, and negative thermal expansion coefficients, indicating that they contract when subjected to increases in temperature. These peculiar properties make auxetic structures highly advantageous in a wide array of industrial applications, where energy absorption, impact resistance, and durability are critical [1].

Among the various practical applications, auxetic structures have gained significant attention in industries such as automotive, construction and aerospace engineering, where their ability to absorb energy efficiently makes them ideal candidates for use in crash boxes, impact protection systems, and blast-resistant materials. For instance, in the automotive industry, auxetic materials can be incorporated into vehicle safety structures to enhance crashworthiness by improving their energy absorption capacity during collisions. Similarly, in the construction and defense sectors, auxetic metamaterials are increasingly being explored for blast-resistant applications due to their ability to withstand high-impact forces and mitigate damage during explosions. As a result, the development of auxetic materials has opened new opportunities for the design of advanced, high-performance structures that can withstand extreme conditions while minimizing damage [2,3].

The crushing behavior and energy absorption characteristics of various types of auxetic metamaterials have been extensively studied in the literature. Researchers have investigated how the auxetic behavior of these materials influences their mechanical properties, such as strength, stiffness, and energy dissipation, when subjected to external forces.

In the current study, the mechanical properties of re-entrant auxetic structures, which are fabricated using additive manufacturing techniques from Inconel 718 material, are thoroughly examined under axial compressive loads. The focus of this investigation is to understand how changes in the geometric parameters of the re-entrant unit cells affect the overall mechanical behavior of the structure. The re-entrant structure, which is a specific type of auxetic material, is particularly interesting due to its ability to maintain enhanced strength when subjected to in-plane compressive loads, which are often encountered in real-world applications.

Material and Method

Before proceeding with the analysis of geometric parameters, a validation study was carried out to ensure the accuracy of the finite element simulations. To validate the accuracy of the FEM analyses performed in this thesis geometry presented in the Figure 1, the boundary conditions in the FEM model were adjusted to align with the stress-strain curve obtained from the reference test study [4].

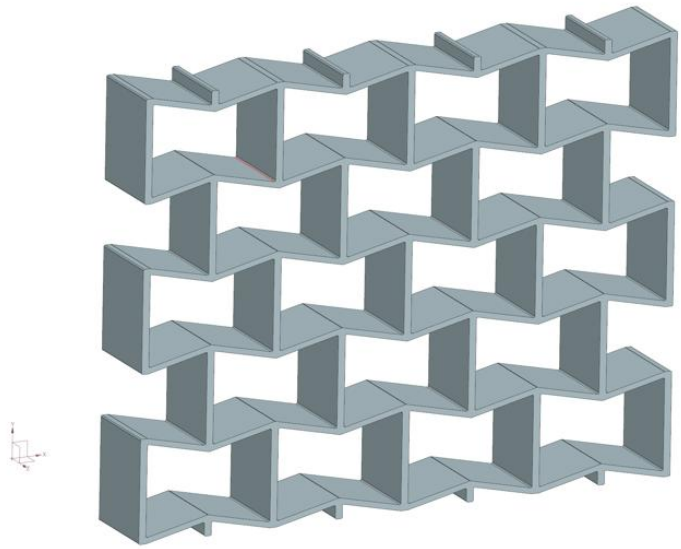

Figure 1. FEM model geometry.

In the reference study [4], the same test was conducted three times on the identical geometry, yielding consistent results which are illustrated in Figure 2. The FEM analysis in this work also produced similar results, thereby confirming the validity of the model which is presented in Figure 3.

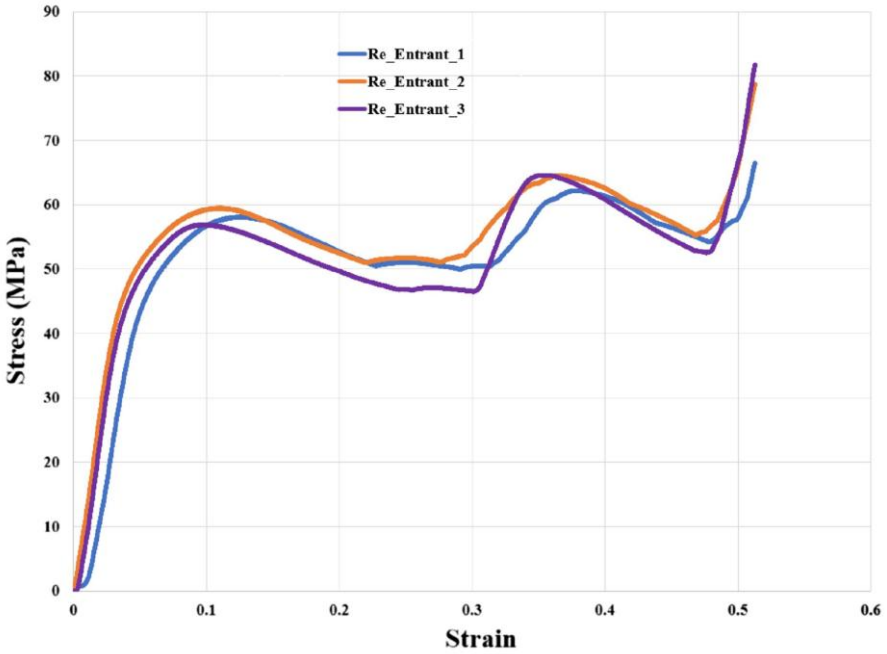

Figure 2. Reference test study stress vs strain results [4].

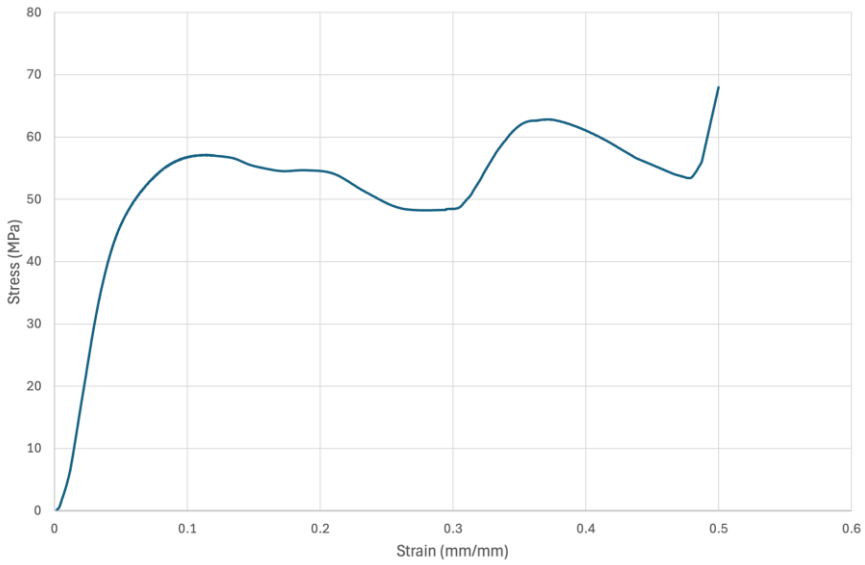

Figure 3. In this current thesis study stress vs strain results.

In the reference study [4], Quasi-static compression tests were carried out using an Instron 5985 universal testing machine (Instron Inc., Norwood, MA, USA) with a constant crosshead velocity of 0.5 mm/min. In these tests, the bottom crosshead was held stationary while the top crosshead moved towards the bottom. The specimens were compressed until the displacement of the top crosshead reached 40 mm.

For the FEM analyses validation study, the COMSOL Multiphysics finite element software program [5], was utilized to examine the influence of design parameter variations on the mechanical properties of the structure. The finite element model consisted of a bottom plate of the core structure, which was fully constrained in all directions. The top plate, however, underwent axial compressive displacement until a total displacement of 40 mm was reached with a constant crosshead velocity of 0.5 mm/min, while the other directions of the bottom plate remained fixed. The material employed in this analysis, INCO 718 powder whose chemical composition is shown in Table 1, has a density of 8190 kg/m³ and a Poisson's ratio of 0.294 [6].

Table 1. Chemical Composition of Inconel 718 [4].

Element	Ni	Cr	Nb	Mo	Ti	Mn	Si	Al	Fe
Wt %	53.00	18.50	5.00	3.00	0.66	3.00	0.35	0.35	Bal

The validation study compared the simulation results with those from previously published studies in the literature, ensuring that the boundary conditions, material properties, loading scenarios, and other parameters were defined correctly for further analysis. This validation provided a solid foundation for the subsequent investigation of the re-entrant structure's mechanical properties.

The study then focused on several critical mechanical properties of the re-entrant structures, including yield strength, energy absorption (EA), specific energy absorption (SEA), mean crush force (MCF), and crush force efficiency (CFE). These properties were assessed for eight different geometries of re-entrant structures, with various geometric parameters which are illustrated in Figure 4. The geometric parameters are wall cell lengths, heights, angles, and wall thicknesses being systematically varied. The goal was to determine how these factors influenced the material's overall behavior under axial compressive loading, particularly focusing on its ability to absorb energy and resist deformation.

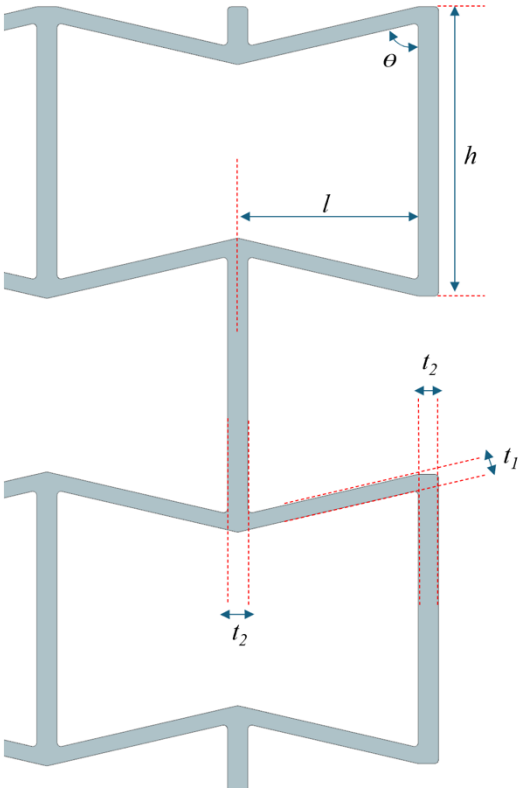

Figure 4. Geometric design parameters.

Finite element analysis results were used to evaluate and compare the absorbed energy at different strain levels, as well as the toughness of the re-entrant structures. The force-displacement curves obtained from these simulations were converted into stress-strain curves, which were then analyzed using curve fitting functions in MATLAB [7]. This allowed the researchers to determine absorbed energy and toughness values for each configuration, as well as provide insights into how the geometric parameters influenced the overall mechanical performance of the structures.

Findings

In this study, a comprehensive investigation was conducted to evaluate the mechanical behavior of re-entrant auxetic structures manufactured from Inconel 718 using additive manufacturing techniques. A validated finite element model was first established by aligning simulation results with experimental data from a reference study [4], ensuring the accuracy and reliability of the subsequent analyses. Following this validation, a detailed parametric study was carried out to assess the influence of key geometric parameters—including unit cell angle, length, height, and wall thickness—on critical mechanical properties such as energy absorption (EA), specific energy absorption (SEA), mean crush force (MCF), and crush force efficiency (CFE). Eight different geometries were systematically examined under axial compressive loading, providing insights into how design modifications affect the structural performance and energy absorption capabilities of auxetic materials. This work not only confirms the sensitivity of auxetic behavior to geometric tuning but also provides a framework for optimizing such structures in engineering applications requiring enhanced compressive performance.

The results demonstrated that increasing the wall thickness of the unit cells significantly enhanced all considered performance metrics. Thicker walls improved load-bearing capacity and facilitated greater energy dissipation, resulting in higher EA and SEA values, as well as increased MCF and more efficient force distribution as indicated by improved CFE. In contrast, an increase in the unit cell length led to reductions in structural stiffness and energy absorption capabilities, thereby diminishing all four mechanical indicators. Similarly, increasing the unit cell height contributed to reduced stability under compression and lowered the structure's energy absorption

performance. Additionally, enlarging the internal re-entrant angle weakened the auxetic effect, which in turn resulted in a decrease in EA, SEA, MCF, and CFE. These trends clearly illustrate the sensitivity of mechanical performance to geometric configurations, affirming that even small changes in design parameters can substantially impact the structural integrity and energy absorption behavior of auxetic materials.

Conclusion

In conclusion, this study provides valuable insights into the relationship between the geometric parameters and the mechanical properties of re-entrant auxetic structures. By altering key design factors such as wall length, height, thickness, and angle, it is possible to optimize the performance of these materials for specific engineering applications. These findings contribute to the ongoing development of auxetic metamaterials, which are expected to play an increasingly important role in industries that require high-energy absorption and exceptional mechanical performance, such as automotive, aerospace, construction and defense.

Hybrid Optimization Method for I-Section Beams: A Comparative Study with Detailed FEM

Ahmet Aktaş[a], Hacı Abdullah Taşdemir[a]

[a]Istanbul Technical University Faculty of Mechanical Engineering, Department of Solid Mechanics, Türkiye
aktasahm16@itu.edu.tr

Keywords: FEA, I-beam, Optimization.

Aim

I-section beams have been fundamental components in structural engineering for over a century, frequently employed in ship interiors and decks, aircraft wings and fuselage structures, helicopter airframes and tail sections, as well as large structural frameworks, bridges, and building frames. These beams are commonly preferred over other cross sectional geometries due to their lighter weight and higher load carrying capacity. The main objective of this study is to develop an advanced optimization tool for I-section beams by merging established analytical and empirical methods from the literature with numerical approaches. This method integrates various failure modes (such as buckling, crippling, and stress-based failures) to ensure a minimum weight design that meets the required strength, based on user defined loads and geometric parameters (thickness, width, length). Initially, a load finite element model (LDFEM) model is constructed for the entire structure to rapidly estimate the loads acting on the beam of interest. These LDFEM derived loads are then used as input for the optimization process. The results obtained from this tool are compared with those from a detailed finite element model (DFEM) of the relevant structure, thereby allowing an assessment of the error margin in preliminary design. DFEM has a much finer mesh and includes smaller structural elements. It provides an accurate evaluation of the actual load distributions and stress patterns to assess the accuracy of the preliminary LDFEM based estimates. Through this integrated approach, the study aims to evaluate how accurately beam sizing can be performed prior to the use of high accuracy DFEM analyses. This will establish a practical and cost effective methodology suitable for preliminary design iterations.

Material and Method

The methodology of this study begins with the construction of a simplified LDFEM to determine the force distributions acting on an I-section beam. The loads obtained from this model are then input into a hybrid sizing method that integrates both analytical and empirical formulas to select a safe (Reserve Factor (RF) ≥ 1) and lightweight design from various geometric configurations. The optimal cross sectional dimensions identified by this method are then applied to a more accurate DFEM model and analysed under the same loading conditions. The DFEM stress results of the beam are compared with the applied stress values calculated using the LDFEM based loads which is showing how close the design of the simplified model is to reality and the extent of any associated error. This approach provides a quick, cost-effective solution at the initial design stage, while allowing the accuracy of the method to be verified against higher accuracy DFEM data.

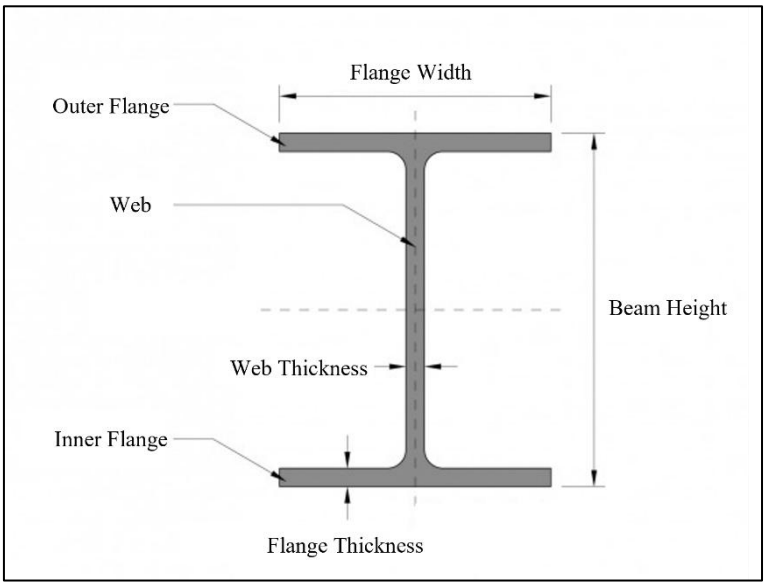

Figure 1. Illustration of an I-Section beam showing principal regions and dimensions.

Hybrid Sizing Method

The method performs optimization by separately evaluating the outer flange, inner flange, and web regions of an I-section beam. Potential failure modes in the inner and outer flanges include Johnson or Euler buckling, crippling and both compressive and tensile yielding. Under compressive loads, long-column behavior is assessed using Euler's buckling approach (Abbott, 2017), whereas short columns are analyzed with Johnson's method (Abbott, 2017). Crippling is calculated using an empirically derived formula (Flabel, 1997), taking into account material properties, flange width, flange thickness, and boundary conditions. In addition, the minimum and maximum stresses in the flange are compared against the material's compressive and tensile yield strengths, provide a strength evaluation in conjunction with the stability checks. For the web region, the method considers compressive and shear buckling failures (Gerard, 1957). The effect of the opening hole on the web on reducing the strength was taken into account by using the formula obtained by numerical methods (Wang, 2009). The approach assumes linear-elastic, isotropic material behaviour for all beam components, and web thickness, length, and height serve as key optimization parameters. From these analyses, the resulting RF is computed for each failure mode, and any design maintaining RF ≥ 1 across all modes is considered acceptable. Among these valid configurations, the tool identifies the lightest option as the optimum solution.

LDFEM

The LDFEM model is a numerical approach that uses relatively large mesh elements and omits certain detailed subcomponents. This strategy significantly reduces the modeling effort and preparation time, allowing for a rapid estimation of the load distributions acting on one or more beams. Because the LDFEM employs coarser elements and does not account for all structural details, the predicted loads may deviate from those obtained through more refined simulations. The extent of this deviation can be determined by constructing a DFEM model, which adopts finer mesh resolution and includes additional structural elements for greater accuracy. The loads derived from the LDFEM are subsequently utilized as inputs to the hybrid sizing method's analytical and empirical formulas, enabling an efficient preliminary evaluation of the beam design.

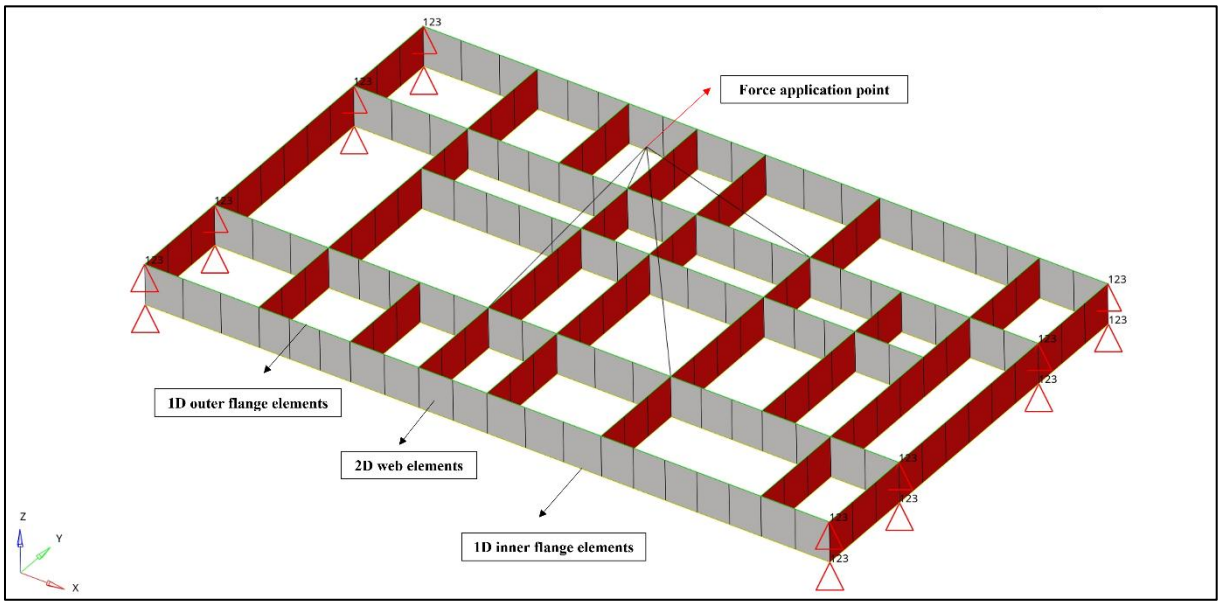

Figure 2. Illustration of the LDFEM.

DFEM

The DFEM model offers a far more comprehensive representation of the structure by including fasteners, angles, straps, and other small scale components that are omitted in the LDFEM. In contrast to the larger mesh elements used for the LDFEM, the DFEM may employ significantly finer discretization (for instance, a 5 mm element size), capturing localized stress concentrations and load paths with greater accuracy. In this study, a DFEM was developed to evaluate how closely the LDFEM reflects the true load flow through the structure, particularly under the same boundary conditions and applied forces. Constructing the DFEM is a more resource intensive and time consuming process due to its higher level of detail and denser mesh. Consequently, one of the goals of this work is to determine the extent of potential error introduced when using the LDFEM derived loads in the hybrid sizing method. By comparing the DFEM results with those from the LDFEM based analysis, it becomes possible to assess the balance between modeling simplicity and accuracy, thereby clarifying how reliable the preliminary load estimates from LDFEM can be in a detailed design context.

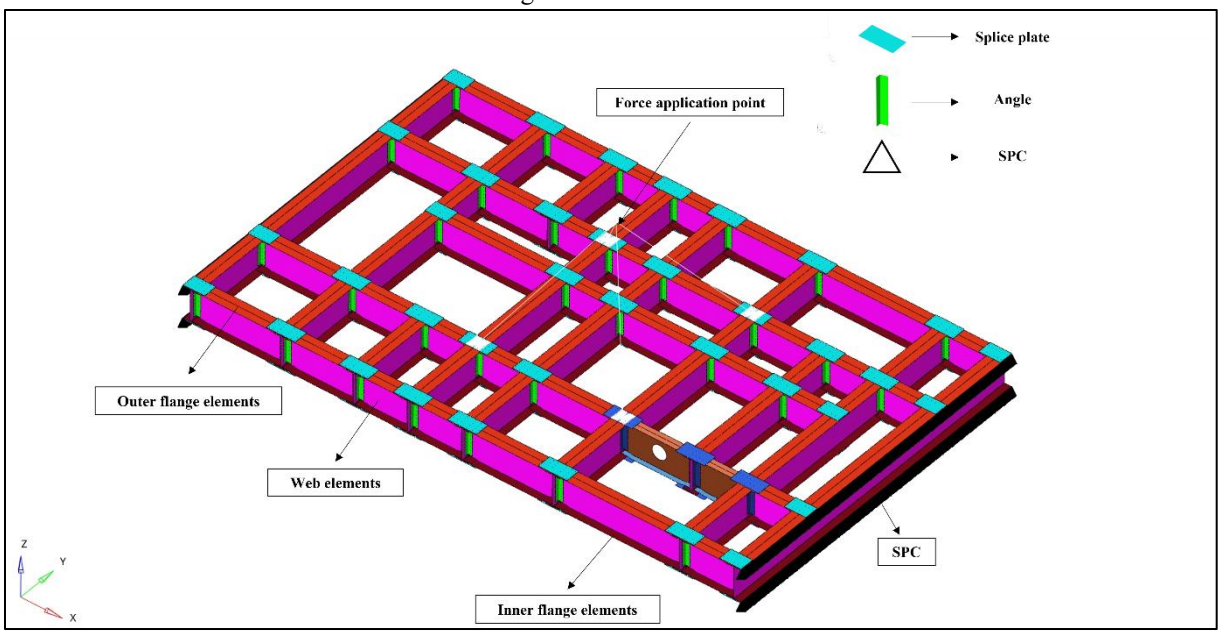

Figure 3. Illustration of the DFEM.

Findings

A hybrid optimization tool was used to determine the optimum dimensions of an I-section beam made from 2024 T42 Clad Aluminum. For the flange regions, the algorithm evaluated 19 thickness values, 21 widths and 61 lengths (24,339 total combinations), while the web section considered 19 thickness values and 11 widths (209 combinations). Initially, the outer flange was 2.5 mm thickness and 80 mm width, the inner flange was 3.0 mm thickness and 80 mm width, and the web thickness was 3.0 mm. After optimization, the outer flange was reduced to 0.8 mm thickness and 50 mm width, the inner flange to 1.0 mm thickness and 50 mm width, and the web to 2.0 mm thickness. This redesign reduced the overall beam weight from 1,536 g to 591 g, a 61% reduction. Under these conditions, the critical RF were 1.15 for tension yield in the outer flange, 1.05 for crippling in the inner flange and 1.34 for shear buckling in the web.

To validate the LDFEM approach, the DFEM model was constructed with approximately 462,000 elements, compared to the 574 element LDFEM. Under the same loading conditions, the DFEM predicted loads that differed on average by about 15% from the LDFEM based estimates. The outer flange and web showed slightly higher loads in the DFEM, while the inner flange showed a slight lower load. At local stress concentrations, such as flange-web intersections, the differences were more significant. But the overall error remained close to 15%. Given the significant computational savings, these results suggest that the hybrid sizing method is sufficiently accurate for preliminary sizing with DFEM serving as a reliable final check for critical regions and safety margins.

In addition, the hybrid approach provides a quick and reasonably accurate solution at the initial design stage, particularly for large or complex structures. After this initial stage of sizing, the optimized dimensions can be used in the DFEM for comprehensive verification. In cases where the structure has fewer detailed parts and more basic loading conditions, the hybrid method alone can provide reliable results without the need for DFEM.

Conclusion

This study has presented a hybrid optimization method for I-section beams, combining analytical and empirical formulas with the LDFEM to speed up the initial sizing process. By systematically evaluating a wide design space and maintaining a positive RF, the hybrid optimization method ensures that the beam design remains both lightweight and structurally safe. The method reduced the beam weight by 61% compared to a baseline configuration, while ensuring safety against multiple failure modes. A subsequent comparison with the DFEM showed that the average discrepancy in the load was approximately 15%, which is acceptable for early stage design decisions. Although certain localized regions, such as flange-web intersections, displayed higher differences, the overall accuracy of the hybrid approach was sufficient for guiding preliminary design in large or complex structures. From an engineering standpoint, the proposed methodology offers significant computational savings relative to creating a fully detailed model at every iteration. Designers can achieve rapid, near optimal configurations before turning to more detailed DFEM analyses. In simpler applications, where loads and structural details are less complex, the hybrid method may serve as an effective standalone solution. In more critical cases, a final DFEM check provides a detailed assessment of stress distributions and local stability. Future work could expand the hybrid approach by introducing additional failure modes and exploring alternative formulas or methods for failure calculations. The method could also address multiple or asymmetric cutouts in the web and investigate the inclusion of ribs on the web during the optimization process.These developments would further extend the suitability of the method for use in a wide range of engineering applications.

Structural Optimization of LPDC Aluminum Wishbone for Sheet Metal Design in Rear Suspension System for Electric C-SUV Vehicles

Alparslan Erdirençelebi[a]

[a]Istanbul Technical University, Mechanical Engineering Departmant, Solid Mechanics Program, Turkey
erdirencelebi17@itu.edu.tr

Keywords: Aluminium Wishbone Design, Automotive Suspension Technology, Design for Durability, Sheet Metal Wishbone Design, Strcutural Optimization.

Aim

Electric C-segment SUVs face pressure to reduce manufacturing costs while meeting performance targets. This study aims to replace a low-pressure die-cast (LPDC) aluminum rear suspension wishbone in a independent rear suspension with a cost-effective sheet metal design using S550 high-strength steel. The motivation is to leverage the lower material and production costs of stamped steel without sacrificing critical performance attributes. The wishbone must maintain wheel alignment and stability under load, enabling proper camber and toe characteristics during cornering and braking (Reimpell, Stoll, & Betzler, 2001). Aluminum control arms are lightweight, reducing unsprung mass and benefiting handling and ride quality (Reimpell et al., 2001). However, cast aluminum components entail high material and processing costs (Nagarjuna & Devaki Devi, 2012). In contrast, stamped steel arms are inexpensive and commonly used in cost-sensitive vehicle models (Nagarjuna & Devaki Devi, 2012). The objective is to achieve significant cost reduction by switching to an S550 steel sheet metal wishbone, while ensuring the new design meets or exceeds the original's performance constraints. Key performance criteria include: (1) Stiffness retention – the new arm must preserve suspension kinematics, keeping camber and toe change within acceptable limits under load; (2) Durability – it must endure proof and extreme loads without failure and offer adequate fatigue life; (3) Packaging – the geometry must fit within the existing suspension architecture and clear surrounding components. By focusing on structural optimization of the wishbone's design, the study targets a solution that balances weight, strength, and cost, thereby improving manufacturing feasibility for mass-production EVs without undermining vehicle dynamics or safety.

Material and Method

The design methodology integrates material selection, computational optimization, and rigorous simulation analysis. Material Selection: S550 steel was chosen for its high strength (yield strength on the order of 550 MPa) and good formability, allowing thinner gauges to be used to counteract its higher density relative to aluminum. Although steel is roughly three times heavier than aluminum per unit volume, its Young's modulus is also about three times higher (≈210 GPa vs. 70 GPa), which aids stiffness. The baseline LPDC wishbone is an aluminum alloy (e.g., AlSi7Mg) part whose geometry and performance served as a starting reference (Nagarjuna & Devaki Devi, 2012). Design & Optimization: A design space was defined based on the packaging envelope of the original arm. A topology optimization approach was employed to conceive an initial load-efficient shape for the sheet metal design, given the existing hard points and space constraints. This optimization prioritized material distribution for maximizing stiffness-to-weight ratio, yielding a conceptual geometry that could meet the load paths of the suspension. Using this as a guide, a detailed CAD model of a sheet metal wishbone was developed. The design consists of stamped steel sections seam-welded into a closed-cross-section control arm, providing bending and torsional rigidity comparable to the cast arm. Throughout the design process, manufacturing constraints were imposed (minimum bend radii, stamping draw depth limits, weld accessibility) to ensure the concept is production-feasible.
Finite Element Analysis (FEA): The candidate steel wishbone design was subjected to extensive FEA to evaluate structural performance. Stiffness Analysis: Quasi-static stiffness tests were simulated by applying representative

loads at knuckle connecting hardpoints and measuring the resulting deflection between the hardpoints. The compliance directly correlates with camber and toe changes. The optimized steel arm achieved equivalent stiffness to the aluminum arm, owing to the higher elastic modulus of steel and an optimized boxed geometry, thereby preserving wheel alignment characteristics under load. Strength and Durability: FEA was conducted for extreme load cases such as pothole strikes and curb impacts (proof loads). The steel design remained within the elastic range under these loads, with von Mises stresses below the yield threshold, indicating no plastic deformation or cracking. Fatigue life estimation was performed using an amplitude-based approach: load spectra from road load data or standards were applied to assess if the design would survive the required number of cycles. Since steel exhibits an endurance limit (a stress amplitude below which infinite life is possible), the design was iterated until all stress hotspots were reduced under this limit or had acceptable life. Weld regions were given special attention in fatigue analysis, using appropriate weld fatigue factors. Comparative Evaluation: After optimization and analysis, the steel wishbone's performance was benchmarked against the original aluminum component. Prior research (Fuchs & Salmon, 2011) demonstrated that a well-designed lightweight steel control arm can achieve equivalent structural performance to an aluminum arm at lower cost, a finding corroborated by our results. Similarly, multidisciplinary optimization studies (e.g., Heo, Kang, Lee, & Choi, 2013) guided the refinement of our design to meet all targets. The final design underwent a design for manufacturability review with tooling engineers to confirm that the sheet metal forming and welding processes are feasible at scale (Yu, Jia, & Huang, 2021). The outcome of this methodical approach is an optimized S550 steel wishbone design that satisfies the mechanical performance requirements while significantly reducing

Findings

The feasibility study confirms that the sheet metal S550 steel wishbone can successfully replace the LPDC aluminum wishbone without compromising suspension performance. In static stiffness analyses, the steel design demonstrated comparable camber and toe stiffness, meaning it maintains wheel alignment under cornering and braking loads essentially as well as the aluminum arm (Fuchs & Salmon, 2011). This ensures that vehicle handling dynamics and tire wear characteristics remain consistent. The higher elastic modulus of steel contributed to maintaining rigidity, even though the part's mass is higher (Reimpell et al., 2001). Durability results indicate that the optimized steel arm meets or exceeds the required fatigue life. The combination of a robust design and steel's favorable fatigue endurance properties (having an endurance limit) resulted in a component that can endure repetitive road loads over the vehicle's service life without crack initiation. In fact, steel control arms are known for their ability to withstand heavy loads and impacts; our design shows no signs of localized weakness under peak loads, and the stress distribution is smooth, minimizing potential fatigue hot spots. Packaging and weight: The new wishbone fits within the same geometric envelope as the original, with minor modifications in shape to accommodate the stamping process (such as flanges and ribs). All clearances to other suspension links, brake components, and the chassis are maintained. The weight of the steel arm is unavoidably higher than the aluminum arm; however, through careful optimization of thickness and shape, the weight increase was kept as low as feasible. The final design's mass is only marginally higher, a small trade-off for a substantial cost reduction. This added unsprung mass is considered acceptable for a C-SUV EV, especially given that battery weight often dominates and the slight increase has negligible impact on overall vehicle efficiency. Finally, the cost advantages are significant: the material cost per arm is lower due to steel's lower price per kilogram and the near-net-shape forming that minimizes waste. Production costs per piece drop thanks to faster cycle times in stamping (once tooling is in place) compared to casting and the elimination of extensive machining operations. While exact figures are proprietary, the automaker can expect a notable reduction in suspension system cost, contributing to a lower overall vehicle cost (Nagarjuna & Devaki Devi, 2012).

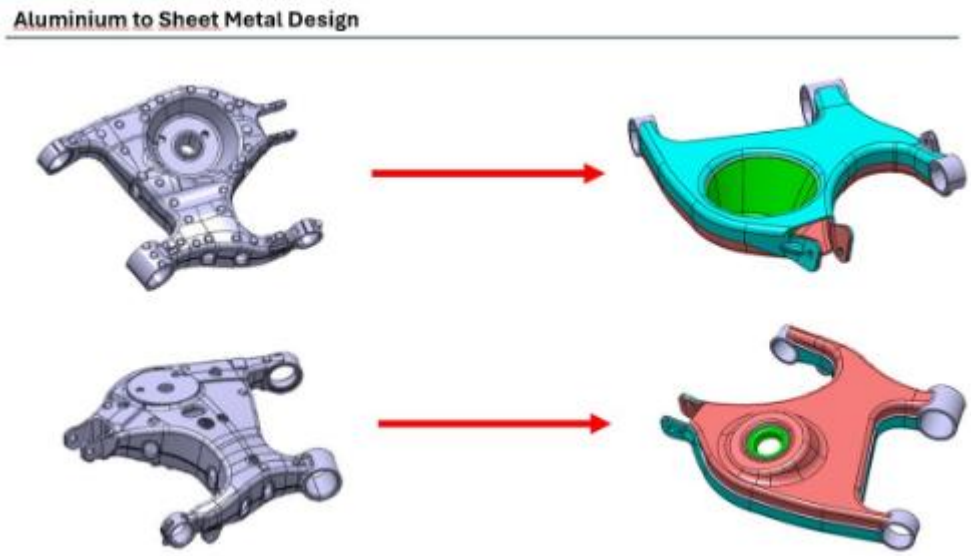

Figure 1. Aluminium to Sheet Metal Wishbone Design.

Conclusion

This work demonstrates a successful material and design substitution in an EV rear suspension component, yielding both economic and engineering benefits. The optimized S550 sheet metal wishbone achieves equivalent stiffness and durability performance to the original LPDC aluminum wishbone, validating that critical parameters such as camber compliance, toe stiffness, and fatigue life are preserved. The transition to a steel design offers a substantial cost reduction, aligning with the cost targets for mass-market electric SUVs without impairing vehicle dynamics or quality. Crucially, the redesign was accomplished with minimal impact on weight and no compromise to fit or function – a testament to the efficacy of structural optimization techniques in chassis component development. From a manufacturing standpoint, the new design leverages high-volume production methods (progressive stamping, automated welding) that promise reliable quality and cycle times, thus enhancing production efficiency (Yu et al., 2021). The implications of this work extend beyond the specific part: it showcases a systematic approach to re-engineering existing components for better cost-performance balance, which can be applied to other aluminum-to-steel conversions in the vehicle (Reimpell et al., 2001). Overall, replacing the aluminum rear wishbone with an optimized steel assembly is found to be practical and beneficial, delivering cost savings and maintaining performance. This contributes positively to the manufacturing feasibility and sustainability of the EV's design. The outcome supports the broader strategy of using the right material in the right place – employing aluminum where ultra-lightweight is paramount and using advanced high-strength steels where cost-effectiveness can be achieved without detriment to performance (Nagarjuna & Devaki Devi, 2012). As electric C-SUV platforms continue to mature, such optimization efforts will be key to balancing range, performance, safety, and cost. The success of this project encourages further exploration of material optimization in automotive suspensions, reinforcing that innovative design can unlock the potential of traditional materials in modern EV applications.

Post-Buckling Behavior of Metallic Panels

Taha Çimen[a], Ata Muğan[a]

[a] Istanbul Technical University, Mechanical Engineering, Solid Mechanics Program, Turkiye
ciment17@itu.edu.tr

Keywords: Buckling, Post-Buckling, Post-Buckling Strength, Secondary Buckling Load.

Aim

The primary aim of this thesis is to investigate the effect of plastic strain on the critical buckling load of panels subjected to reloading. When plasticity occurs during the post-buckling stage of thin-walled structures, their stiffness is altered, which in turn influences their buckling resistance. However, the extent of this reduction and its implications on structural performance remain insufficiently explored.

Numerically, finite element simulations are performed in Abaqus to evaluate the impact of plastic strain accumulation on the critical buckling load. A total of 18 different models are created for numerical analysis, considering two different materials. The panel dimensions are varied with side lengths of 500 mm, 650 mm, and 750 mm, while the thickness is set to 2 mm, 3 mm, and 4 mm for each case.

By comparing the critical buckling loads of plastically deformed and undeformed panels, this research aims to quantify the reduction in buckling resistance due to prior plastic deformation. The findings will contribute to a deeper understanding of post-buckling behavior in engineering structures and provide guidelines for design improvements and failure prevention in load-bearing applications.

Material and Method

The finite element analyses were conducted via software ABAQUS to simulate panels under shear load. To create FE models, S4R elements, which are shell elements with reduced integration, were utilized. The used shell elements have 5 integration points. In ABAQUS, nodes of S4R elements have 6 DOF with three rotational and three translational. Also, the 30x30 mesh was selected as the minimum required mesh after the mesh convergence study.

In Figure 1, the used boundary condition that provides clamped edges and pure shear loading is given. It can be seen that the edges of the plates can move freely in both directions. In order to compare and validate the numerical findings with the data that is theoretically accessible, the clamped boundary condition was used.

Figure 1. Boundary Condition of FE Model.

The used panel material in this thesis is AL-5754 alloy and ST-37. The data used to define materials were taken from stress-strain graphs found in literature [1], [2].

The calculation of the critical buckling load of the panel that has plastic strain is conducted in five steps:

- The Linear Buckling Analysis (Eigenvalue Extraction)

First, the eigenvalues and eigenmodes of the panel were calculated using a linear buckling analysis step, which employs the Lanczos eigen solver. The boundary condition was applied as shown in Figure 1, and 1 N is applied as a shell edge load.

- The Nonlinear Post-Buckling Analysis (Static Riks Method)

After obtaining the eigenmodes, the panel was analysed using a Static Riks analysis step to determine its post-buckling capacity. Although the same boundary conditions as in the linear buckling analysis were applied, the magnitude of the shell edge load was determined based on the panel's eigenvalue. In this step, the first eigenmode of the panel, shown in Figure 2, is introduced as an initial imperfection using the *IMPERFECTION command. The imperfection magnitude is set to t/100, where 't' is the panel thickness.

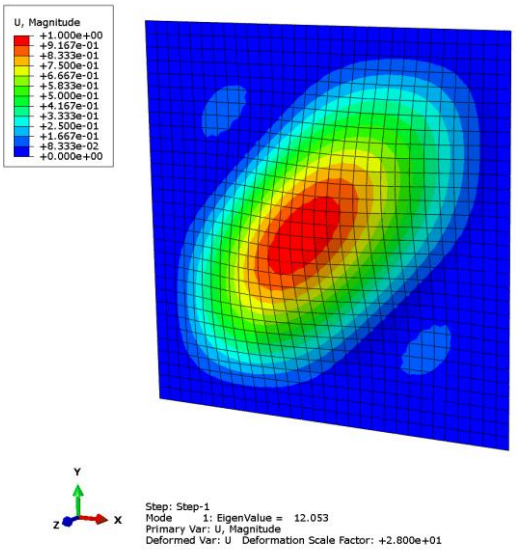

Figure 2. First Eigenmode of Panel.

The introduction of an initial imperfection is essential for this type of analysis, as it enables the structure's post-buckling behavior to be captured, allowing the ultimate load (V_u) to be determined. Without an imperfection, the model may not progress beyond the buckling bifurcation point, preventing an accurate post-buckling load-displacement response from being obtained.

- Defining Plastic Strain After Post-Buckling

To evaluate the secondary buckling load of the panel, the different levels of plastic strain such as 25%, 50%, 75%, and 100% developed in the post-buckling stage were separately transferred to new models using the *PREDEFINED FIELD function. This ensures that the residual plastic strains and deformations from the previous post-buckling analysis are correctly applied as the initial state in the new analysis.

- Strain Relaxation Step

Since both elastic and plastic strain are developed while reaching the ultimate load, an additional static step was introduced to allow the elastic stain to relax, leaving only the plastic strain in the model. This step was created using same boundary condition, but external load was not applied.

- Secondary Buckling Load Calculation

After completing the strain relaxation step, a linear buckling analysis was conducted again on the plastically deformed panel to determine its new critical buckling load.

Findings

In this study, the finite element (FE) analyses were conducted for eighteen different panel configurations made from AL-5754 alloy and ST-37, with varying dimensions and thicknesses. The panel sizes and thicknesses were chosen to ensure that plastic strain would occur under the ultimate (post-buckling) load, thereby allowing the evaluation of the effect of plastic strain on the linear buckling load.

- Linear Buckling Analysis

The linear buckling analysis was performed to calculate the critical buckling loads (V_{cr}) and associated mode shapes used to define initial geometric imperfections in the post-buckling analysis. The results and panel dimensions can be found in Table 1. It is revealed that the critical buckling load increases significantly with increasing panel thickness, due to the bending stiffness scales with the cube of thickness. Thus, even when in-plane dimensions remain constant, thicker panels exhibit greater resistance to buckling.

Table 1. The Critical Buckling Loads of Panels.

Materials	F_{CR}^{FEM} (N)	Materials	F_{CR}^{FEM} (N)
AL57-500x2	15117.5	ST37-500x2	45056.0
AL57-500x3	50980.0	ST37-500x3	151940.0
AL57-500x4	120695.0	ST37-500x4	359745.0
AL57-650x2	11631.75	ST37-650x2	34667.8
AL57-650x3	39238.55	ST37-650x3	116948.0
AL57-650x4	92943.5	ST37-650x4	277017.0
AL57-750x2	10082.25	ST37-750x2	30048.0
AL57-750x3	34014.0	ST37-750x3	101377.5
AL57-750x4	80587.5	ST37-750x4	240172.5

- Post-Buckling Analysis

For the investigation of structural performance beyond the critical point, nonlinear post-buckling analyses were conducted using Static Riks method. The post-buckling loads (F_u), corresponding shear plastic strains (ε) are given in Table 2.

Table 2. The Ultimate Buckling Loads of Panels.

Materials	F_U (N)	Materials	F_U (N)
AL57-500x2	34619.1	ST37-500x2	82452.5
AL57-500x3	75144.5	ST37-500x3	180808.6
AL57-500x4	132161.0	ST37-500x4	334562.9
AL57-650x2	35825.8	ST37-650x2	84589.4
AL57-650x3	76907.6	ST37-650x3	183608.4
AL57-650x4	133838.6	ST37-650x4	321339.7
AL57-750x2	36699.4	ST37-750x2	86237.7
AL57-750x3	77892.0	ST37-750x3	185520.8
AL57-750x4	134581.1	ST37-750x4	324232.9

The results show that there is a clear dependence between thickness and post-buckling load. It can be concluded from Table 2 that thinner panels and lower elastic modulus causes lower the ultimate buckling load, while the thicker panel and higher elastic modulus causes higher F_u values.

- Secondary Buckling Analysis

In this section, the secondary buckling behavior of the panels was investigated. This analysis was conducted using plastic strains in the post-buckling stage. To study the effect of plastic strain on the critical buckling load during reloading, four levels of plastic strain were applied: 25%, 50%, 75%, and 100% of the total plastic strain that occurs at the ultimate buckling load.

The secondary buckling loads and percentage of reduction of critical buckling load of AL-5754 alloy and ST37 panels for different plastic strain levels are presented in Figure 3, Figure 4 and Figure 5. The results show that the buckling resistance is reduced in occurrence of plastic strain for all panel configurations due to the critical buckling load decreases as the applied plastic strain increases.

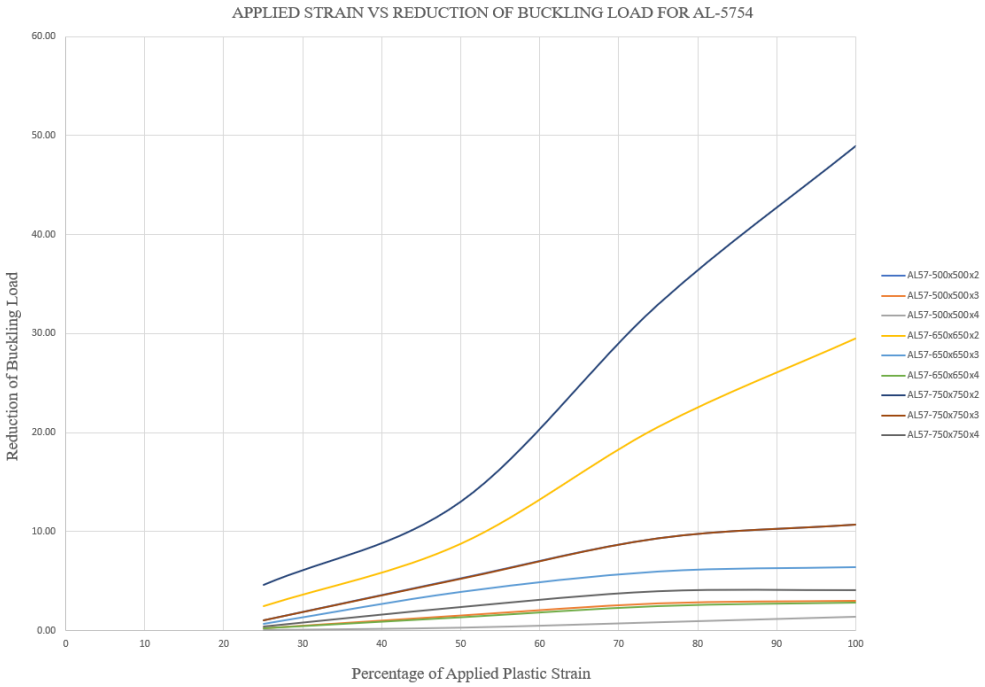

Figure 3. Applied Strain vs Reduction of Secondary Buckling Load for AL-5754.

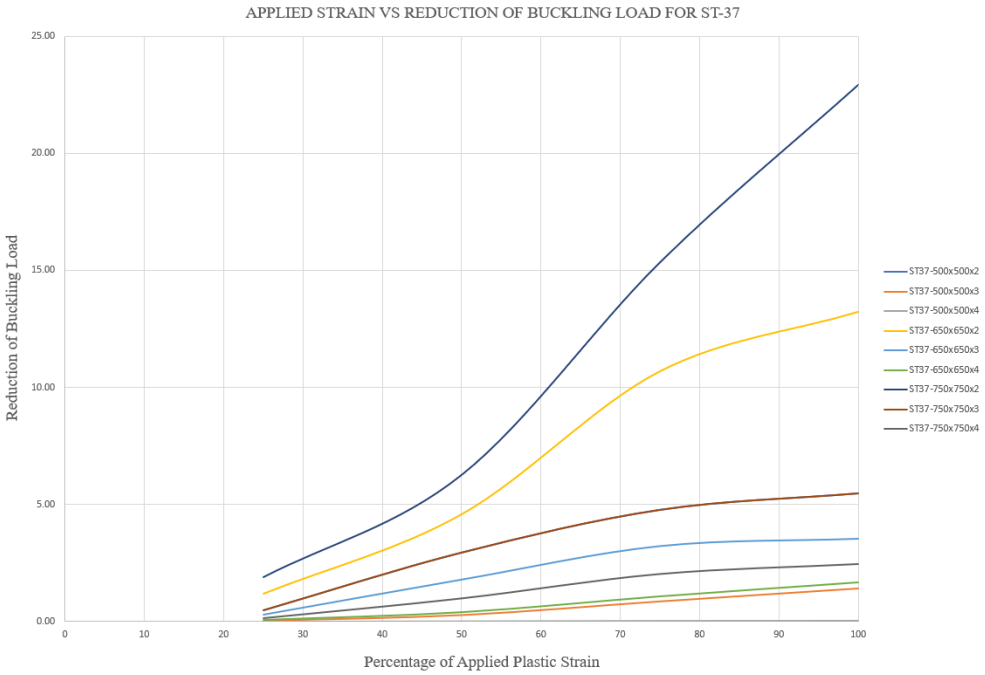

Figure 4. Applied Strain vs Reduction of Secondary Buckling Load for ST-37.

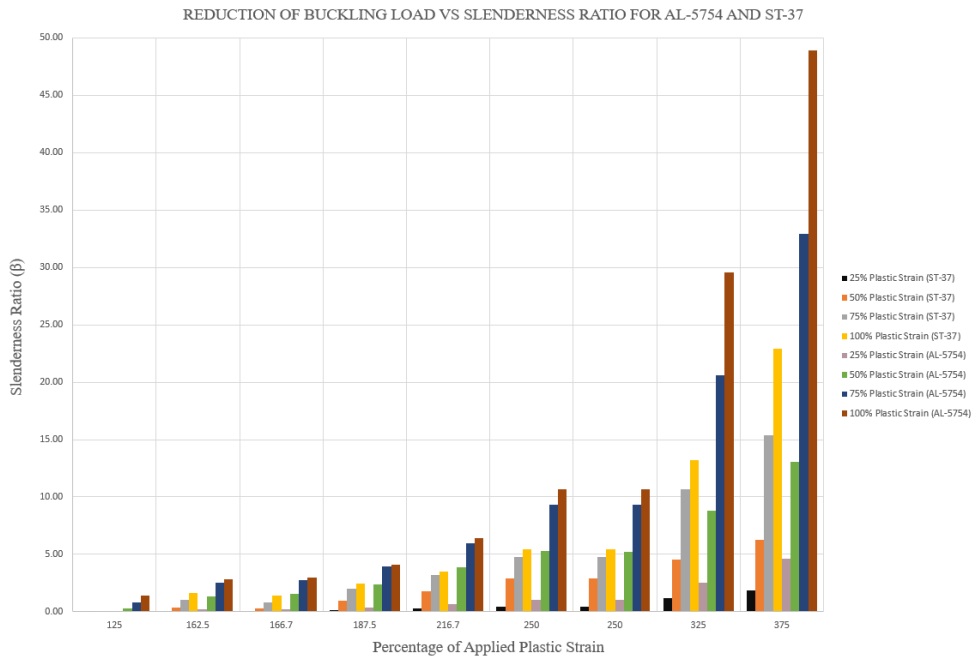

Figure 5. Slenderness Ratio (β) vs Applied Strain for AL-5754 and ST-37.

At low slenderness ratios, both AL-5754 and ST-37 show very small reductions in buckling load, even under 100% plastic strain. This indicates shorter and thicker panels are more resistant to plastic strain. However, as the slenderness ratio increases, the reduction becomes much higher especially for AL-5754.

Moreover, it can be seen from the figures that the reduction of buckling load is calculated the same for the 750X750X3 mm and 500X500X2 mm panel configurations. The common property of these panels is their slenderness ratio and post-buckling reserve, which directly affect the percentage reduction in buckling load.

While the reduction for ST-37-500×500×2 panel configuration increases gradually from 0.5% at 25% strain to 5.5% at 100%, the AL-5754 panel of the same size shows 1.03% at 25%, and 10.7% reduction is calculated when 100% plastic strain is applied, which means that the aluminium panels loses their stiffness than steel plates under the same conditions.

ST-37-500×500×3 panel shows only 1.4% reduction at 100% strain, while the reduction of secondary buckling load of AL-5754 reaches more than twice as much, which is 3.02%. In 500×500×4 panels, there is almost no reduction for the ST-37 panel, while AL-5754 still shows a larger reduction under 100% plastic strain. The calculated reductions are 0.008% and 1.4% for the AL-5754 and ST-37, respectively. These results clearly show that thicker steel panels are nearly unaffected, while aluminium still loses some strength.

The difference becomes even clearer as the slenderness ratio increases. The reductions of 650×650×2 panels are calculated as 13.2% and 29.5% at 100% strain for the ST-37 and AL-5754, respectively. These reductions are decreased with increasing thickness. However, the aluminium panels always show higher reduction compared to steel panel even in same slenderness ratio. For example, 3.5% and 6.4% values are calculated for 650×650×3, and 1.6% and 2.9% values are calculated for 650×650×4 panel configurations for ST-37 and AL-5754 materials, respectively.

The biggest difference is seen in 750×750×2 panels, where the ST-37 panel reduces by 22.9%, but AL-5754 drops sharply by 48.9%, showing that thin and large aluminium panels lose nearly half of their buckling strength under full plastic strain. In the 750×750×3 configuration, ST-37 shows 5.5%, while AL-5754 shows 10.7%. Even in 750×750×4 panels, ST-37 shows 2.4% and AL-5754 has 4.07%.

These values show that ST-37 steel is more resistant to buckling strength reduction after plastic strain, especially in thicker or shorter panels. In contrast, AL-5754 panels are more sensitive and can lose a significant part of their capacity, especially when thin and slender.

Conclusion

In this study, the effects of plastic strain on the critical buckling behavior of slender panels under in-plane shear loading were investigated. Both numerical analysis and experimental study were used to understand influence of plastic strain, developed in the post-buckling stage, on the critical buckling load during reloading.

The results showed that as plastic strain increases, the secondary buckling load decreases. This effect becomes more significant in panels with higher slenderness ratios and smaller thicknesses. In general, slender and thin panels are more sensitive to plastic strain, while thicker and shorter panels preserve most of their buckling strength.

When different materials were compared, ST-37 panels performed better than AL-5754 panels in terms of resistance to plastic strain. For example, at 100% plastic strain, the AL-5754 panel with a slenderness ratio of 375 showed up to 48.9% reduction, while the ST-37 panel of the same size showed only 33% reduction.

Among the materials, panels made from ST-37 show the least sensitivity to plastic stain especially for panels with 4 mm thickness, which maintain nearly their full buckling capacity with less than 2% reduction.

The findings confirm that both material selection and geometric properties (slenderness ratio and thickness) have a strong influence on secondary buckling load of panel and their post-buckling performance. For structural applications where panels may undergo plastic deformation and be reloaded, ST-37 is a more reliable material for designs requiring high stability and load-carrying capacity after buckling. especially in shorter and thicker forms. This makes ST37 a good choice for structures that may experience overloading or reloading conditions.

Weight and Volume Optimization of Two Stage Wolfrom Planetary Gear Mechanism

Kadir Kanat[a], Ali İmre Aydeniz[a], Cevat Erdem İmrak[a]

[a] Istanbul Technical University, Mechanical Design Program, Türkiye
kanat18@itu.edu.tr

Keywords: Fine Sizing, Gear System, Optimization, Particle Swarm Optimization, Wolfrom Planetary.

Aim

Wolfrom planetary mechanisms are gear systems used in all, especially in the aviation and energy industries. It is a compact power transmission system with five different gears. It also appears in the literature as systems without planet carriers (carrierless system). Its advantages include the possibility of concentric operation, high transmission ratio and durable systems. Due to having two different internal gear groups and the large number of gear groups, these are systems that operate with high cost and low efficiency. Due to the operation of 5 different gear groups (Figure 1.) and the use of coaxial planetary shafts, low tolerances and profile shifting operations in gears are frequently encountered situations in these mechanisms.

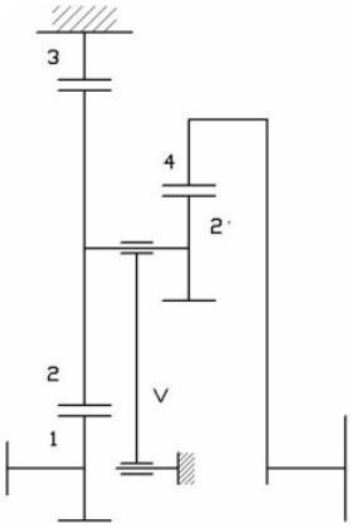

Figure 1. Wolfrom Planetary Mechanism System Design.

The aim of the study is to design a gearbox with minimum volume and weight that will provide the desired torque and speed requirements at the output of a Wolfrom planetary mechanism. The results of the used optimization method and gear commercial software (KissSoft) will be compared. In this system, also called the two stage planetary mechanism, in order to provide power transmission, the planetary gear groups must operate in different pitch circles. This situation also shows that the assembly conditions must be taken into consideration when designing. In addition, one of the design criteria is to use small gears in order to provide the minimum volume and weight that we aim for. For this, profile shifting must be done in order to obtain the minimum number of gears without experiencing undercutting situations. In particular, positive profile shifting was done due to the number of teeth falling below 17 in planetary gears. In this way, gear strength was tried to be provided with minimum gears. The parameters to be optimized are determined as the number of teeth, module, tooth thickness, pressure angle, material and material quality, and center distance.

Material and Method

In the first stage of the study, "Fine Sizing" optimization was performed for the center planet group via KissSoft software. The main purpose of "Fine Sizing" optimization is to give value ranges for certain variables in gear groups and to determine constants. With the determined values, all mountable macro geometry iterations that can occur in the gear group have emerged. With "Fine Sizing", both the internal gear mesh and the external gear mesh are optimized for planetary (Figure 2.). While performing planet modeling, variable values were determined as module in the range of 1.5-2.5, center distance between 45-55, tooth width in the range of 5-20, profile shift ratio between -0.6 and 1. As fixed values, pressure angle was determined as 20 degrees and profile shift ratio of internal gear was determined as 0. It was also considered that the study was an easy-to-produce mechanism rather than a simulation. The reason why the profile shift ratio of internal gear was taken as 0 is that the critical role in planet strength calculations is in the planet and sun gears and the profile shift ratio of internal gear has no connection with the profile shift ratio between planet and sun gear. In addition, the effects of the change in the number of planets on gear strength were observed.

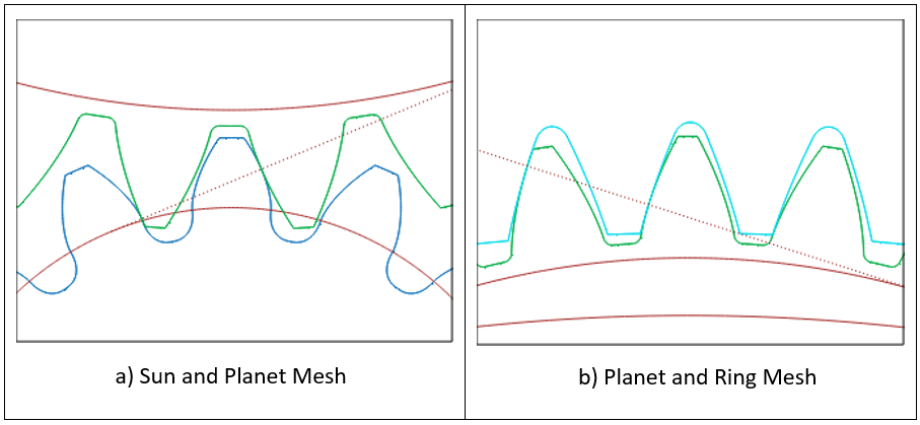

Figure 2. Wolfrom Planetary Mechanism Gear Profiles.

In the second stage of the study, "Particle Swarm Optimization" (PSO) method was used for volume optimization of two-stage Wolfrom type planetary gear system. Planetary gear systems are widely used in modern engineering applications with their high efficiency and compact structure features. Volume optimization is of great importance in terms of these systems taking up less space and reducing material costs. In the study, it was aimed to design the system in minimum volume by considering the geometric and mechanical design parameters of the gear stages. In the optimization process, it was aimed to obtain the most suitable gear dimensions within the framework of the determined constraints (such as strength, durability, and construction limitations). PSO optimization was coded. The inputs for the Wolfrom planetary gear mechanism were determined as the same data as in the "Fine Sizing" process. Gear strength control was performed according to gear bending and pitting. The module parameter was determined as a result of the hertzian pressure of the gear surface (pitting) and gear root bending. In addition, factors such as dynamic load factor, application factor and form factor (K_A, K_V etc.) were used when determining the module.

Findings

During the studies and literature review, it was seen that the most important issue while designing a two-stage wolfrom mechanism was planetary macro geometry design. The concentric operation of the planetary gears in two stages shows that the difference in the number of teeth between the internal gears should be equal to the difference in the number of teeth between the planets or a maximum of two. It was observed that gear pairs could operate with positive profile shifting in the case of a maximum difference. In addition, since it is a carrierless system design, it was concluded that crowning should be applied as micro geometry on gear surfaces due to the bending that will occur in the planetary gear shafts. Crowning aims to spread the Hertz pressure surface on gear surfaces to the middle of the tooth width. Also, a systematic approach was put forward to keep the gear ratio constant. As

seen in the gear ratio formula, there are five different gear tooth numbers. This formula should also be taken into consideration when making the optimization.
The internal gear and planet meshes in two stages were also checked according to the interference conditions. The optimization conditions were checked according to the minimum gear numbers. In places where there will be interference, it was determined as a suggestion to reduce the addendum coefficient of the internal gear. Reducing the addendum coefficient of the internal gear without reducing the contact ratio below 1 prevents interference, if any.

Conclusion

As a result, the PSO study and "Fine Sizing" results were evaluated. In the incoming results, while the volumes of the Wolfrom planetary mechanisms were close to each other, similar results were obtained in the number of gears. In the "Fine Sizing" results, the optimum result was obtained by the elimination method. While elimination was made, the minimum root safety and minimum flank safety factors were taken as 1.1 for each gear and the values below were eliminated (Figure 3.). In addition, the results where the undercut and contact ratio were below 1 were eliminated. Among the remaining results, the gear set that met the minimum volume and weight conditions and complied with the gear strength criteria was selected. The PSO algorithm has attracted attention by providing a faster solution compared to traditional methods. The weights of the gearboxes formed after approximately 200 different iterations in the created algorithm were compared (Figure 4.). This algorithm has operated an iterative process to find the optimum parameter combination under certain constraints in gear design. The results obtained have shown that while a significant reduction of 13.5% was achieved in the total volume of the gears, basic requirements such as strength and durability were met. It has also been observed that the optimization performed with the "KissSoft Fine Sizing" yielded similar results in terms of volume. During the optimization, the compliance of parameters such as the contact ratio with the limit values was checked and the design life was increased. As a result, this study has contributed to establishing a balance between lightness and durability in gear design. In particular, the optimization of parameters such as surface contact stress and contact ratio increased the performance of gear systems. In addition, the results obtained have revealed that the PSO algorithm is an effective method in gear optimization.

Examining the Impact of Groove Profiles and Dimensional Parameters on Shear Pin Strength

Mehmet Ozan Yitim[a,b], Cevat Erdem İmrak[a], Adem Candaş[a]

Keywords: Shear Pin, Design Optimization, Stress Concentration, Correlation.

Aim

As mechanical design engineers, the whole design process needs to follow the right path for some main purposes such as cost, maintainability, manufacturability, accessibility, toughness/endurance, etc. Therefore, to maintain the balance between two key objectives such as strength and safety, it is necessary to deliberately leave certain weak points (such as shear pins) in the design, especially in structures working under uncertain and high loads. Shear pins can be considered as safety pins. This study focuses on the shear pin design process and the investigation of geometric optimization of the shear pins.

Shear pins are widely used in mechanical, aerospace, and structural engineering applications where controlled failure mechanisms are required. The failure of a shear pin occurs primarily due to shear stress exceeding the material's yield strength. However, the presence of grooves (Fig. 1a, 1b) and variations in diameter and thickness can alter stress distribution, influencing both the pin's load-bearing capacity and fatigue life.

Figure 1. a) Various types of shear pins, b) Parts of a shear pin.

Despite existing research on shear pin design, a systematic optimization framework incorporating geometric parameters remains underdeveloped. This study aims to fill this gap by employing Finite Element Analysis (FEA) to achieve the optimal geometric design result.

Material and Method

The study begins with an examination of the most prevalent shear pin geometries used in widely applied shear pin designs. The classical designs usually comprise straight cylindrical pins with single or multiple grooves to control failure points [1]. These designs lack uniform stress distribution leading to abrupt material fatigue and fracture. Therefore, this study employs Finite Element Analysis (FEA) and experimental testing to establish stress concentration factors for different groove configurations [2]. By varying parameters such as groove depth, width, and curvature, this research proposes a method to determine the optimal groove geometry for predictable and controlled failure at specified loads. The geometric parametric study examines various groove types, namely V-notch, U-notch, and rounded-notch grooves.

The primary shear mechanism examined in this study is the double shear pin mechanism (Fig. 2). Double-plane shear mechanisms are widely used in various applications, particularly in structures subjected to high loads from

torsional, transverse, or axial forces. For instance, transverse loads on beam members generate bending moments, while in certain safety applications, shear pins help distribute these moments and absorb excessive loads to minimize damage to critical structural components. The fundamental formula for single-plane shear capacity is given as follows,

$$\tau_{s.shear} = \frac{F}{A_{shear}} \quad (1)$$

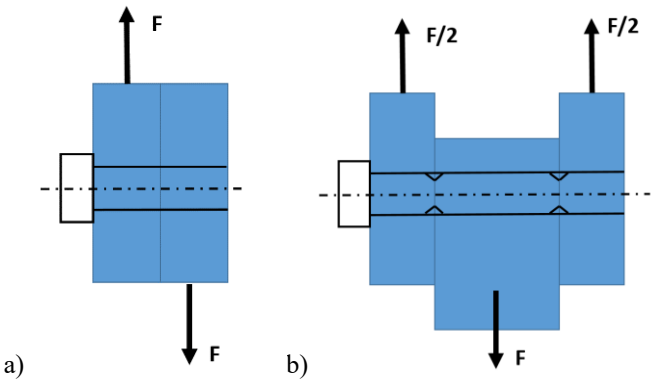

Figure 2. a) Single shear loads and b) Double shear loads acting on the pin.

The double shear mechanism is analyzed using both analytical methods and the Finite Element Method (FEM), as well as experimentally [3]. After all calculations and evaluations, a single correlated and verified model is obtained. Once verification is complete, all remaining design options are evaluated using FEA solutions. To differentiate groove designs, key parameters such as shear diameter, nominal diameter, width, and groove shape are considered for optimal design selection. For finite element analysis, the most suitable mesh parameters have been determined. Mesh convergence method was studied first for describing the most suitable FEA method. Quadratic Hex 3D elements (SOLID186) were chosen for bulk material on pin, because they are sufficient for our case with respect to displacement and stress calculation accuracy, as well as computation cost. To find the best mesh sizing, mesh convergence study was done, with details shown in Fig. 3 and Table 1. Example pin geometry and mesh study has been done, 1mm of element size will adequate for the application.

Table 1. Mesh convergence iterations.

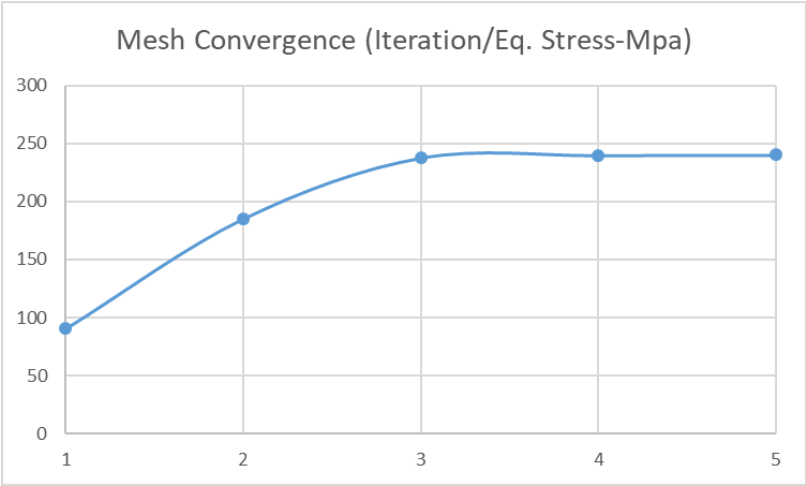

Table 2. Mesh convergence iteration element and node numbers.

	Element Size (mm)	Equivalent Stress 2 (MPa)	Change (%)	Nodes	Elements
1	4	90.3		933	458
2	2	185.3	68.9	5632	3240
3	1,2	237.9	24.9	31921	20683
4	1	239.6	0.71	58363	38596
5	0.8	240.1	0.001	91804	62900

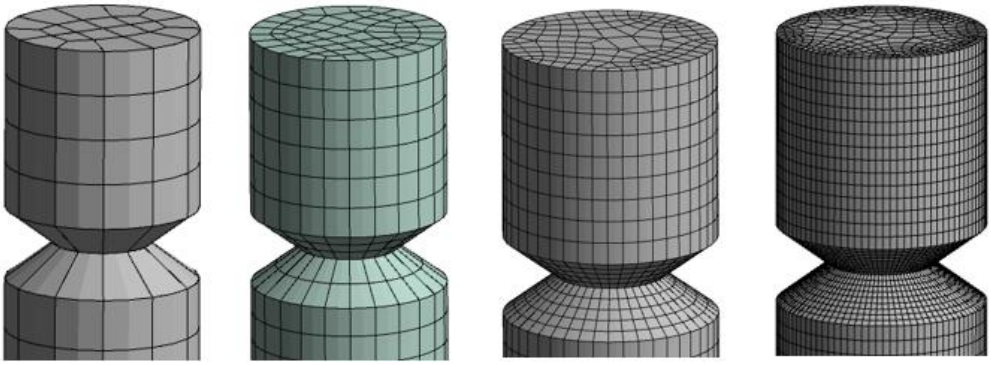

Figure 3. FEA mesh details.

Finite element models are obtained as load applied on the pin middle surface radially and distributed linearly, the both ends of the pin have been fixed for 6 degrees of freedom as deformable condition, and linear static analysis has been done on this pin only FE model as shown in Fig. 4. The stress results taken on max stress plane on the pin and maximum radial displacement values have been read from middle surface of the pin. The boundary conditions are presented in Fig. 5 [4].

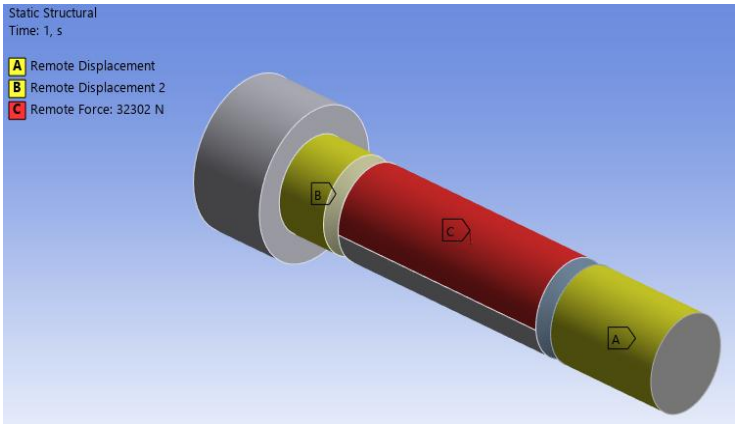

Figure 4. FEA boundary conditions for V shape groove pin.

Findings

The cross-sectional geometries of grooves in shear pins have a significant impact on strength. In this regard, the V-notch, U-notch, and rounded-notch profiles to be examined and compared in this study are shown in Fig. 6.
In addition, material spectral and mechanical shear tests have been done. Results are, the material of the sample pin specified as free cutting steel that the yield stress has been given below, also the 32kN of radial load considered as shear yield of the pin. The further analysis processes have been carried out by guide of this results.

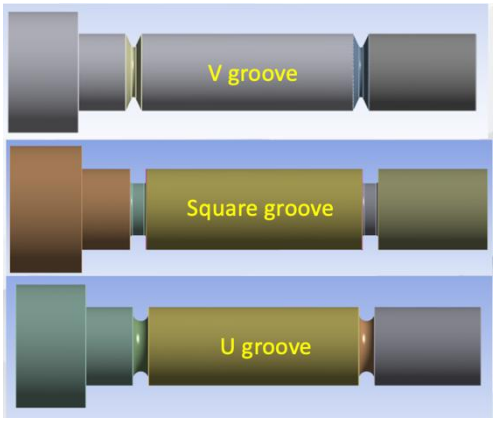

Figure 5. CAD models of different groove profiles.

The initial FEA analysis and design process have been done using the same procedure given in [5,6]. The model has been prepared with linear free cutting steel material (1.0727) and loaded by displacement from the very middle section of the pin. The pure shear condition has occurred and the material carries the load till it reaches the yield point (440 MPa).

After test-analysis corelation studies [6], the further analysis have been done fort he comparison between different shaped grooves. 3 main mechanical results are taken as the comparison criterias. Radial shear stiffness of the pin, maximum stress ocurred on shear plane and average stress ocurred on groove section. The result tables as shown below.

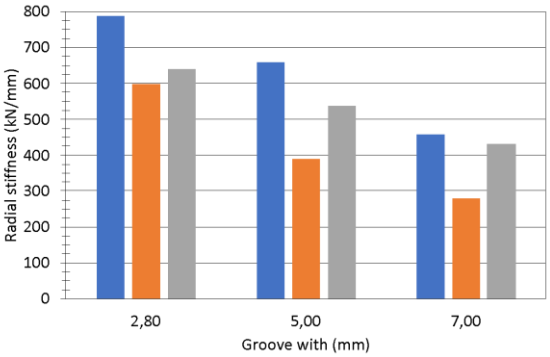

Table 3. Radial stiffness comparison.

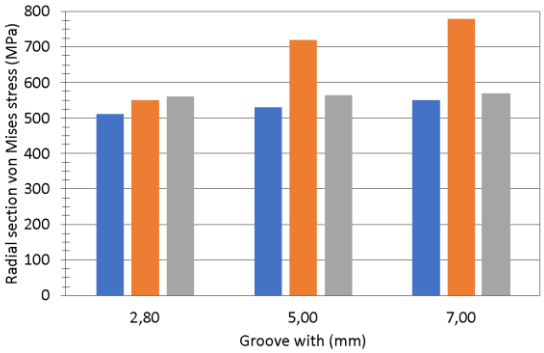

Table 4. Maximum stress ocurred on shear plane.

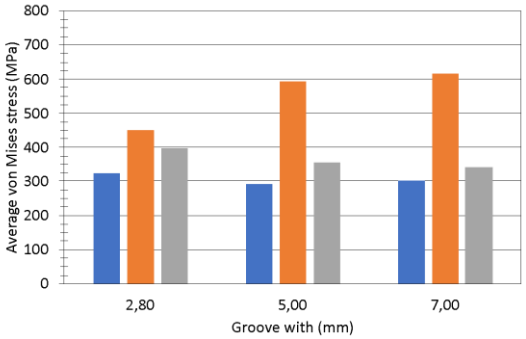

Table 5. Average stress on groove section.

Conclusion

By this study, at first, engineering routines was tried to cover from the beginning sequentally, design, analytical aproaches, FE analysis ann mechanical test for calidation. Correlation techniques used and physical & analytical studies overlapped.
At the and, material strength is highly dependent on shear pin groove geometrical properties,

Increasing the groove width effected the results as, changing the stress tensor from shear dominant to bending side, so that the pin's shank areas also started to carry bending loads, by most of the cases the stress levels got higher and overall radial stiffness of the pins got lower too, but for V and U grooves the average stress on groove area gots smaller an the reason of this can be expressed as above.
Also the groove profile type effected the both stiffness and stress levels directly as seen on the analysis, V groove got better results on most of the cases, this results cause thought as, the material stock in the groove profile is higher on V groove, so that the stiffness on groove got higher.

Keywords: Single Stage Spur Gearbox, Gear Modifications, Gear Noise, Müller Method.

Aim

Spur gears are widely used in power transmission applications due to their high torque carrying capacity and low energy losses. The most common use is gearbox. Gearboxes are intermediate equipment that provides torque-speed conversion between the motor and the machine in industrial applications. While it generally increases the motor torque according to the needs of the machine it will drive, it reduces the motor speed to the machine operating speed. Thus, it is a solution in applications requiring low speed and high torque where the direct motor cannot be used.

Today, due to the increase in competition conditions and the improvement of design and manufacturing conditions depending on the development of technology, the demand for gearboxes that can carry high torque per unit volume and have a minimum sound level is increasing day by day. Especially with the spread of electric vehicles, the sound level of gearboxes that provide torque-speed conversion between the electric motor and the wheel has become important in terms of driving comfort. In addition, gearboxes that are lighter in terms of energy efficiency and can carry high torque in smaller volumes have become inevitable for electric vehicles. Without changing the main gear parameters (macro geometry), torque carrying capacity can be significantly increased with micron-level modifications made to the profile and the noise level can be reduced thanks to the reduction of transmission error and homogeneous gear contact. Thus, it is possible to produce quieter gearboxes that can carry higher torque in the same volume.

Material and Method

In this study, a gearbox with single-stage spur gear will be examined (Figure 1). Deformations in the gear, shaft and bearings supporting the gear under load will be calculated using analytical methods using the FVA Workbench program. The pressure distribution on the gear surface will be analysed and the noise level will be found. According to the ISO6336:2019 (Calculation of load capacity of spur and helical gears) norm, KHβ (load distribution factor) and gear flank surface safety (SH) and gear tooth root safety (SF) will be calculated. Considering all the deformations and the pressure distribution on the gear surface, lead crowning and helix angle modifications will be applied in the gear width direction. After finding the optimum KHβ and lead crowning and helix angle modification values that provide homogeneous surface pressure distribution, sound optimization will be carried out.

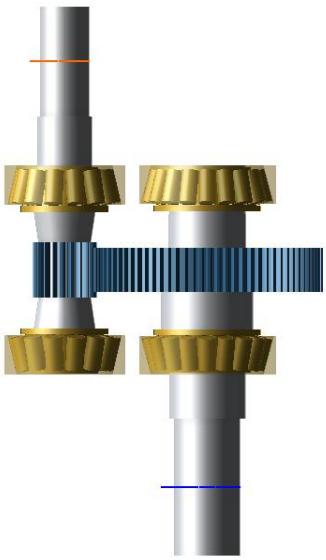

Figure 1. Single Stage Spur Gearbox Model.

According to the SIGG (Schwab, Ishikawa, Güntsch, Göpfert) approach, long and short tip relief modifications will be found in sound optimization. The SIGG approach is an analysis method developed to reduce transmission error (TE), improve load distribution and reduce vibration level in gear systems. This approach, which is especially used in precision and high-performance gear applications, focuses on optimizing the tip relief amount. According to the SIGG model, applying a controlled modification at the starting point and exit point of tooth contact improves the contact dynamics of the gear and provides a more stable operation. In this way, the noise and vibration levels in gear systems decrease significantly, while the load distribution becomes more homogeneous. The short and long tip relief modifications obtained thanks to this approach will be applied to the gears to reduce sudden pressure increases at the root and tip of the gear, thus achieving a more homogeneous transition and reducing the sound level.

The Müller method will be used in calculating the sound level (Equation 1). In gear systems, the tooth load level and excitation level are directly related to the forces generated at the point where the gears come into contact with each other. According to the study conducted by Müller (1991), these levels can be expressed as the weighted sum of the adjusted amplitudes of the engagement forces. In other words, when the gears rotate, forces of a certain magnitude occur when the teeth come into contact with each other. These forces change over time and cause vibrations at certain frequencies. While the tooth load level expresses the magnitude of these forces, the excitation level indicates the potential of these forces to create vibration and noise. The method described by Müller involves evaluating these forces with certain weighting coefficients instead of directly adding them. Thus, it becomes possible to more accurately estimate how much vibration and noise the gears will produce during operation. This approach is especially important in terms of vibration analysis and evaluating the acoustic performance of gear systems. Such models are used to design quieter and more efficient gear systems. In our study, the sound level produced by the unmodified gear will be determined with the Müller method and the sound level will be tried to be reduced by applying different tip relief modifications.

$$L_{Fz} = 10.lg\left[\frac{1}{(\omega_0.F_0)^2}\sum_{i=1}^{k}(i.\omega_z.F_i)^2\right] dB$$

Equation 1. The Tooth Excitation Level by Müller (**Müller, R.** (1991).

In this study, the gearbox with a 130mm axis distance was examined. The gear module was 2.5mm, the teeth number of pinion was 21, and the teeth number of wheel gear was 83. In the gearbox with a 3.95 gear ratio, the

pressure angle was 20° and the profile shift coefficient were 0.3391 and -0.3391, respectively. The pinion tip diameter was Ø59.2mm, its width was 44mm, the wheel gear tip diameter was Ø210.8mm, and its width was 40mm. Tapered roller bearings were used to be mounted without clearance on the input and output shafts. Heat-treated 21NiCrMo2 case-hardened steel with a surface hardness of 58-62HRC and a material quality of MQ was used as gear material. In the analysis to be performed under load, the gearbox input power was 55kW and the input speed was 1500rpm.

Findings

In the first stage, for unmodified gears, the load distribution factor was found to be KHβ: 1.13 according to Method B using the ISO6336:2019 norm. Accordingly, gear safety values were calculated as SH: 1.04 and SF: 1.54. These gear safety values provide the minimum safety values SH≥1.0 and SF≥1.4 required in the norm. With the help of FVA Workbench software, the effect of deformations occurring in all parts including gear, shaft and bearing on the pressure distribution on the gear surface during gear contact was examined. When the pressure distribution was examined, it was seen that a maximum of 1634MPa Hertzian pressure occurred on the gear surface (Figure 2). This value is above the allowable contact stress (σHlim) value of 1500MPa defined in the ISO6336-5 (Part 5: Strength and quality of materials) norm. σHlim is the maximum stress value that gears can withstand against repeated loading without surface fatigue damage such as pitting. In this case, according to the calculation made according to ISO6336 norm, the gears are safe, but according to the maximum stress value resulting from analytical calculation considering deformations, they are unsafe.

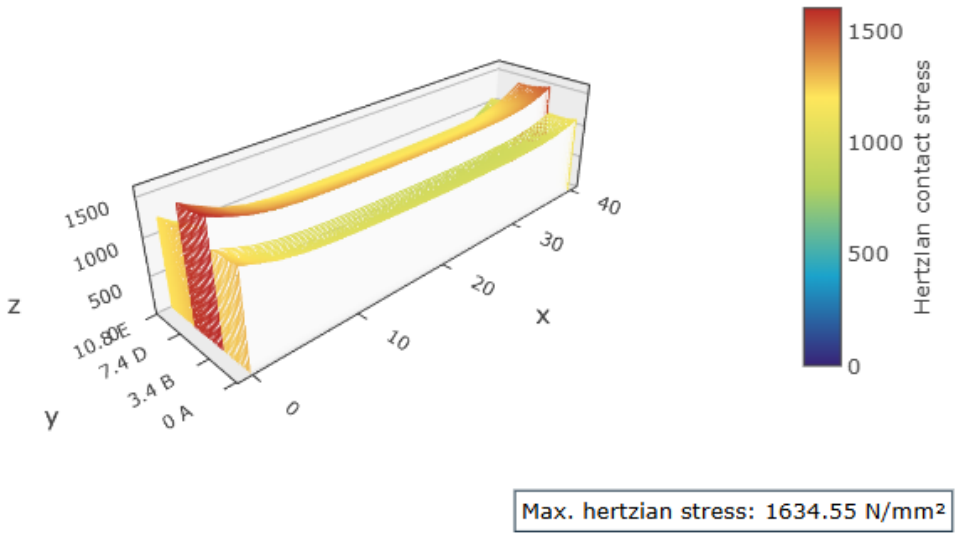

Figure 2. Hertzian Pressure Distribution on The Unmodified Tooth Surface.

In the second stage, lean crowning and helix angle modification were applied on the pinion tooth surface to reduce the maximum stress. As a result of the analyses made according to both rotation directions, +3µm helix angle modification was applied on the right surface of the tooth, -4µm helix angle modification was applied on the left surface of the tooth and +7µm lean crowning was applied on both tooth surfaces. After the optimization process, KHβ was improved to 1.03. In this way, gear safeties increased to SH: 1.09 and SF: 1.66 values. The pressure distribution on the tooth surface was became more homogeneous and the maximum pressure value was reduced from 1634MPa to 1406MPa (Figure 3). Thus, the maximum pressure value remained below the limit value of σHlim:1500MPa defined in the ISO6336-5 norm.

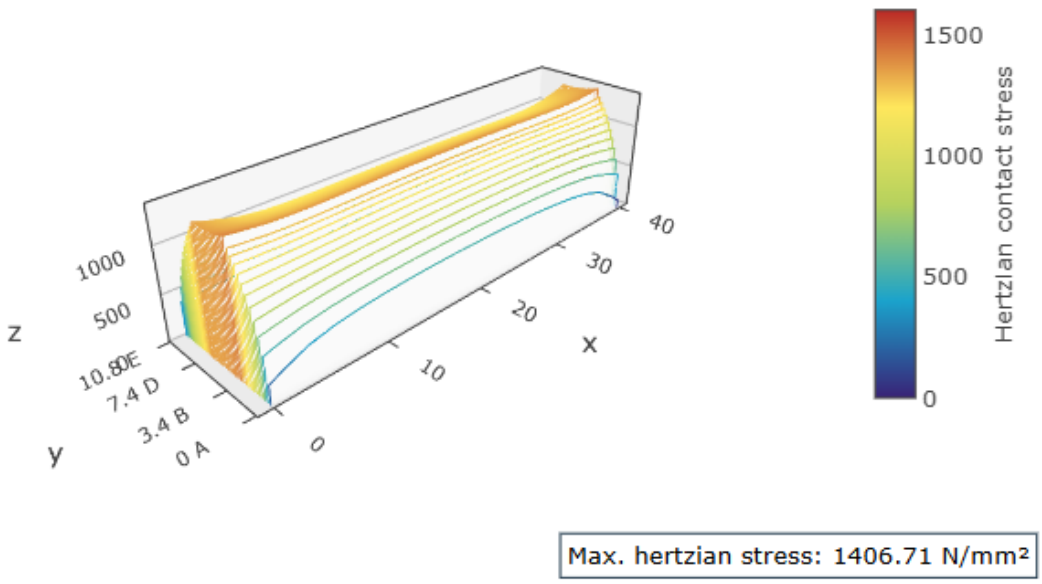

Figure 3. Hertzian Pressure Distribution on The Modified Tooth Surface.

In the third stage, the sound optimization was examined. The short and long tip relief values suggested by the SIGG method were applied to the tooth profile. In both short and long type, the amount of tip relief is C_αa:20µm. The starting point of the tip reliefs are Ø57.4 mm and Ø209.3 mm, respectively, in the short tip relief and the pinion and wheel gear. In the long tip relief, the starting point of the tip reliefs are Ø55.6 m and Ø207.7 mm, respectively, the pinion and wheel gear. In the calculations made after applying the tip relief modifications, the transmission error value decreased slightly from 11.32µm to 11.26µm when the short tip relief was applied and decreased significantly to 6.49µm when the long tip relief was applied. When the pressure distribution on the tooth surface was examined, a transition from low pressure to high pressure was achieved from the tooth root and tooth tip regions towards the tooth centre. The gear excitation levels before and after the tip relief were compared using the Müller method. While the gear excitation level was 42.50 dB in the unmodified gear, this value decreased slightly to 42.07 dB when short tip relief was applied and decreased significantly to 35.75 dB when long tip relief was applied.

Conclusion

In conclusion, gearbox with a single-stage spur gear was examined, and the effect of deformations in the gearbox components under load on gear contact was investigated. Various modifications were applied to improve the increase strength and reduce the noise level (Table 1). When the gear safeties were checked for the gear without modification, it was determined that the tooth root and flank safeties were sufficient according to the ISO6336 norm, but the maximum surface pressure formed on the tooth surface due to deformation was approximately 9% above the allowed value. In this case, it was seen that the ISO6336 norm alone was not sufficient in gear safety calculations and that deformation calculations made with the help of advanced software should also be taken into account. It was observed that gear modifications made at the micron level (lean crowning and helix angle modification) improved the gear safeties and reduced the maximum surface pressure value by 14% below the allowed limit value. Additionally, it was determined that lean crowning, helix angle modification and short tip relief modifications were insufficient in reducing the noise level, and that when long tip relief was applied, the noise level was significantly reduced by 16%. As a result, it has been determined that gear modification have a great effect on high torque, low noise level gearbox designs that will meet today's expectations.

Table 1. Output Parameters.

	ISO6336:2019 without modification	Lead Crowning + Helix angle modification	Lead Crowning + Helix angle modification + Short Tip Relief	Lead Crowning + Helix angle modification + Long Tip Relief
KHβ	1,13	1,03	1,03	1,03
SH	1,04	1,09	1,09	1,09
SF	1,54	1,66	1,66	1,66
Max. Pressure [Mpa]	1634	1406	1406	1406
Transmission Error [μm]	11,32	11,27	11,26	6,49
Excitation Level [dB]	42,50	42,48	42,07	35,75

Semi-Analytical Investigation of Nonlinear Tuned Mass Dampers Using the Multi-Term Harmonic Balance Method

Okan Çengel[a], Osman Taha Şen[a]

[a] Istanbul Technical University, Department of Mechanical Engineering, Machine Dynamics, Vibrations and Acoustics, Turkiye
okancengel98@gmail.com

Keywords: Nonlinear Tuned Mass Damper, Harmonic Balance Method, Passive Control Device.

Aim

A Tuned Mass Damper (TMD) is a passive control device widely used to mitigate vibrations in structures by targeting a specific excitation frequency. However, when the excitation frequency varies, especially near the primary system's natural frequency, a linear TMD may not effectively suppress vibrations. To address this limitation, incorporating nonlinear elements into the TMD's coupling path can broaden the frequency band over which it effectively reduces vibrations, thereby limiting the primary structure's vibration amplitude across a wider range of excitation frequencies (Den Hartog, 1985).

Applications of nonlinear TMDs include reducing structural responses to seismic vibrations (Sadek et al., 1997), mitigating wing loads in aerospace engineering (Kwok & Samali, 1995), and suppressing vibrations in cutting tools during turning operations (Lee et al., 2001). Moreover, nonlinear TMDs have been applied in various engineering fields. In civil engineering, they are used to control vibrations in structures subjected to unpredictable forces such as earthquakes and wind loads. For example, the installation of TMDs in skyscrapers and bridges has proven effective in mitigating vibrations and enhancing structural stability (Webster & Vaicaitis, 1992). These studies aim to optimize TMD parameters to enhance vibration reduction performance, acknowledging that real-world applications often involve inherent nonlinear characteristics due to large displacements or the use of limiting devices.

In summary, nonlinear TMDs offer a robust solution for vibration control across various applications by extending the effective frequency range and improving the resilience of primary structures against variable excitation forces. In this study, the nonlinear TMD problem will be solved using the semi-analytical multi-term harmonic balance method (MHBM). Results will be presented in the frequency domain to investigate the performance of the system while systematically varying the system's parameters. This approach will provide insights into how changes in parameters affect the effectiveness and robustness of the nonlinear TMD, ultimately guiding the optimization of design parameters for enhanced vibration control.

Material and Method

Sen and Singh (2018) investigated the mechanism of energy transfer between two subsystems interconnected by a nonlinear elastic element, where the external force excitation is applied solely to the mass component of the second oscillator. In contrast, the current study applies force excitations simultaneously to both mass components, with nonlinear couplings present both between the ground and the first mass, and between the two masses.

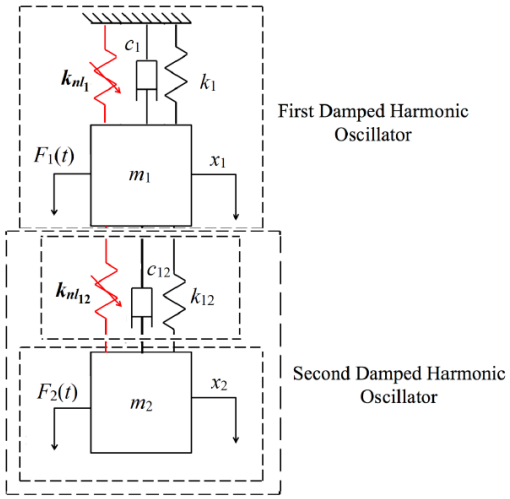

Figure 1. 2-DOF nonlinear vibration absorber system.

The nonlinear elastic elements are modeled by assuming cubic-type nonlinearities. The nonlinear equations governing the dynamic behavior of the system depicted in Figure 1 can be expressed as follows:

$$m_1\ddot{x}_1 + (c_1 + c_{12})\dot{x}_1 + (-c_{12})\dot{x}_2 + (k_1 + k_{12})x_1 + (-k_{12})x_2 + k_{nl_1}{x_1}^3 + k_{nl_{12}}(x_1 - x_2)^3 = {F_1}^S + {F_1}^D \sin\sin(wt + \varphi_1) \quad \#(1)$$

$$m_1\ddot{x}_2 + (-c_{12})\dot{x}_1 + c_{12}\dot{x}_2 + (-k_{12})x_1 + k_{12}x_2 + k_{nl_{12}}(x_2 - x_1)^3 = {F_2}^S + {F_2}^D \sin\sin(wt + \varphi_2) \quad \#(2)\#\ \#$$

To simplify these governing equations, the following dimensionless parameters are introduced:

$$\mu = \frac{m_2}{m_1} \quad \gamma = \frac{c_{12}}{c_1} \quad \lambda = \frac{k_{12}}{k_1} \quad w_n = \sqrt{\frac{k_1}{m_1}} \quad \xi = \frac{c_1}{2m_1 w_n} \quad \alpha_1 = \frac{k_{nl_1}{x_0}^2}{k_1} \quad \alpha_{12} = \frac{k_{nl_{12}}{x_0}^2}{k_1} \quad \tau = w_n t \quad X_1 = \frac{x_1}{x_0} \quad X_2 = \frac{x_2}{x_0} \quad x_0 = \frac{{F_1}^S}{k_1} \quad \#(3a-n)$$

$$\sigma = \frac{{F_2}^S}{{F_1}^S} \quad \varepsilon_1 = \frac{{F_1}^D}{{F_1}^S} \quad \varepsilon_2 = \frac{{F_2}^D}{{F_2}^S}$$

Thus, the dimensionless nonlinear governing equations become:

$$X_1'' + [2\xi(1+\gamma)]X_1' + (-2\xi\gamma)X_2' + (1+\lambda)X_1 - \lambda X_2 + \alpha_1 X_1^3 + \alpha_{12}(X_1 - X_2)^3 = 1 + \varepsilon_1 \sin\sin\left(\frac{w}{w_n}\tau + \varphi_1\right) \quad \#(4)$$

$$\mu X_2'' + (-2\xi\gamma)X_1' + (2\xi\gamma)X_2' - \lambda X_1 + \lambda X_2 + \alpha_{12}(X_2 - X_1)^3 = \sigma + \varepsilon_2 \sin\sin\left(\frac{w}{w_n}\tau + \varphi_2\right) \quad \#(5)$$

where, $X_i' = \frac{dX_i}{d\tau}$ ve $X_i'' = \frac{d^2X_i}{d\tau^2}$

The MHBM is employed to obtain the steady-state response of the nonlinear system subjected to harmonic excitation. For simplicity, the governing equations (Eqs. 4-5) are reformulated in the spatial domain by introducing a linear transformation of the independent variable, $\theta = \omega\tau$. Thus, derivatives with respect to τ are redefined in terms of θ, yielding the following nonlinear equations in the θ-domain:

$$\omega^2\frac{d^2X_1}{d\theta^2} + [2\xi(1+\gamma)]w\frac{dX_1}{d\theta} + [-2\xi\gamma]w\frac{dX_2}{d\theta} + (1+\lambda)X_1 - \lambda X_2 + \alpha_1 X_1^3 + \alpha_{12}(X_1 - X_2)^3 = 1 + \varepsilon_1 \sin\sin\left(\frac{\theta}{w_n} + \varphi_1\right) \quad \#(6)$$

$$\mu\omega^2\frac{d^2X_2}{d\theta^2} + (2\xi\gamma)w\frac{dX_2}{d\theta} + [-2\xi\gamma]w\frac{dX_1}{d\theta} - \lambda X_1 + \lambda X_2 + \alpha_{12}(X_2 - X_1)^3 = \sigma + \varepsilon_2 \sin\sin\left(\frac{\theta}{w_n} + \varphi_2\right) \quad \#(7)$$

The dimensionless dependent variables X_1 and X_2 are approximated by truncated Fourier series expansions, where N_h denotes the number of harmonics retained:

$$X_1(\theta) = a_{1,0} + \sum_{n=1}^{N_h} a_{1,2n-1}\, sin\, sin\,(n\theta) + a_{1,2n} cos(n\theta) \#(8a)$$

$$X_2(\theta) = a_{2,0} + \sum_{n=1}^{N_h} a_{2,2n-1}\, sin\, sin\,(n\theta) + a_{2,2n} cos(n\theta) \#(8b)$$

The assumed solutions (Eqs. (8a) and (8b)) are discretized as $X_1 = \Gamma a_1$ and $X_2 = \Gamma a_2$ where Γ is the discrete Fourier transform matrix, and a_1 and a_2 represent the unknown Fourier coefficient vectors for variables x_1 and x_2. The matrix Γ is defined as:

$$\Gamma = [1\ sin\, sin\,(\theta_0)\ \ cos\, cos\,(\theta_0)\ \cdots\ sin\, sin\,(N_H\theta_0)\ \ cos\, cos\,(N_H\theta_0)\ 1\ sin\, sin\,(\theta_1)\ \ cos\, cos\,(\theta_1)\ \ldots\ sin\, sin\,(N_H\theta_1)\ \ cos\, cos\,(N_H\theta_1)\ \vdots\vdots\vdots\ddots\vdots \\ \vdots\ 1\ sin\, sin\,(\theta_{N-1})\ \ cos\, cos\,(\theta_{N-1})\ \cdots\ sin\, sin\,(N_H\theta_{N-1})\ \ cos\, cos\,(N_H\theta_{N-1})\ ] \#(9)$$

where N is the number of discrete points.

Furthermore, the non-dimensional governing equations (Eqs. (6-7)) are written in discrete form as:

$$R_1 = w^2\Gamma D^2 a_1 + [2\xi w(1+\gamma)]\Gamma D a_1 + (-2\xi\gamma w)\Gamma D a_2 + (1+\lambda)\Gamma a_1 - \lambda\Gamma a_2 + \alpha_1(\Gamma a_1)^3 + \alpha_{12}(\Gamma a_1 - \Gamma a_2)^3 - \Gamma - \left(\frac{\theta}{w_n} + \varphi_1\right) \#(10)$$

$$R_2 = \mu w^2\Gamma D^2 a_2 + [2\xi w]\Gamma D a_2 + (-2\xi\gamma w)\Gamma D a_1 + \lambda\Gamma a_2 - \lambda\Gamma a_1 + \alpha_{12}(\Gamma a_2 - \Gamma a_2)^3 - \Gamma\sigma\left(\frac{\theta}{w_n} + \varphi_2\right) \#(11)$$

where D is the differential operator. The differential operator matrix is defined as:

$$D_{(2N+1)x(2N+1)} = [0\ 0\ 0\ \cdots\ 0\ 0\ 0\ 0\ -n_1\ \cdots\ 0\ 0\ 0\ +n_1\ 0\ \cdots\ 0\ 0\ \vdots\vdots\vdots\ddots\vdots\ 0\ 0\ 0\ \ldots\ 0\ -n_N\ 0\ 0\ 0\ \ldots\ +n_N\ 0\ ] \#(12)$$

Note that Eqs. (10) and (11) constitute a set of coupled nonlinear algebraic equations. Therefore, the unknown coefficient vectors a_1 and a_2 are determined by minimizing the residue functions:

$$R_1 = w^2 D^2 a_1 + [2\xi w(1+\gamma)] D a_1 + (-2\xi\gamma w) D a_2 + (1+\lambda) a_1 - \lambda a_2 + \alpha_1\Gamma^+(\Gamma a_1)^3 + \alpha_{12}\Gamma^+(\Gamma a_1 - \Gamma a_2)^3 - 1 - \left(\frac{\theta}{w_n} + \varphi_1\right) \#(13)$$

$$R_2 = \mu w^2 D^2 a_2 + [2\xi w] D a_2 + (-2\xi\gamma w) D a_1 + \lambda a_2 - \lambda a_1 + \alpha_{12}\Gamma^+(\Gamma a_2 - \Gamma a_2)^3 - \sigma\left(\frac{\theta}{w_n} + \varphi_2\right) \#(14)$$

Here, Γ^+ denotes the pseudo-inverse of the discrete Fourier transform matrix. The residue minimization is iteratively performed using the Newton-Rapson method, where $\eta = [\ a_1\ a_2\ w]^T$ and $R = [\ R_1\ R_2\ ]^T$ represent the vectors of unknowns and residues, respectively, and i indicates the iteration number:

$$\eta_{i+1} = \eta_i + J_i^{-1} R_i \#(15)$$

Note that the excitation frequency ω is also treated as an unknown in the Newton-Raphson procedure, allowing clearer analysis of the system's dynamics at turning points on the frequency response curve. Additionally, the Jacobian matrix J in Eq. (15) is defined as follows:

$$J = \left[\frac{\partial R_1}{\partial a_1}\ \frac{\partial R_1}{\partial a_2}\ \frac{\partial R_1}{\partial w}\ \frac{\partial R_2}{\partial a_1}\ \frac{\partial R_2}{\partial a_2}\ \frac{\partial R_2}{\partial w}\right] \#(16)$$

Using the residue minimization outlined in Eq. (15), Eqs. (13) and (14) are solved iteratively for chosen parameters values. The subsequent step involves systematically examining the performance of the nonlinear tuned mass damper (TMD) system by varying key system parameters. Specifically, the following scenarios will be analyzed:

Influence of Linear Stiffness (λ): The performance of the nonlinear TMD system will be evaluated by varying the linear stiffness parameter. The aim is to understand how changes in linear stiffness influence the overall dynamic response and effectiveness of vibration suppression.

Linear Primary System Coupled with a Nonlinear Secondary System: The primary system maintains linear characteristics, while the secondary system exhibits nonlinear behavior. Frequency response curves and system performance metrics for these cases will be presented.

Nonlinear Primary System with Varying Secondary System Nonlinearity: Here, both the primary and secondary systems exhibit nonlinear characteristics. The nonlinearity parameter for the primary system remains fixed, while the secondary system's nonlinearity is varied.

Findings

Influence of Linear Stiffness (λ):

Table 1. Relative linear stiffness effect on X_1 and X_2 displacements.

Case	N_h	N	μ	γ	λ	ξ	σ	α_1	α_{12}	ε_1	ε_2
1	80	200	0.05	0.2	0.05	0.005	$\frac{\mu}{\mu+1}$	0.01	0.01	0.1	0
2	80	200	0.1	0.2	0.1	0.005	$\frac{\mu}{\mu+1}$	0.01	0.01	0.1	0
3	80	200	0.2	0.2	0.2	0.005	$\frac{\mu}{\mu+1}$	0.01	0.01	0.1	0

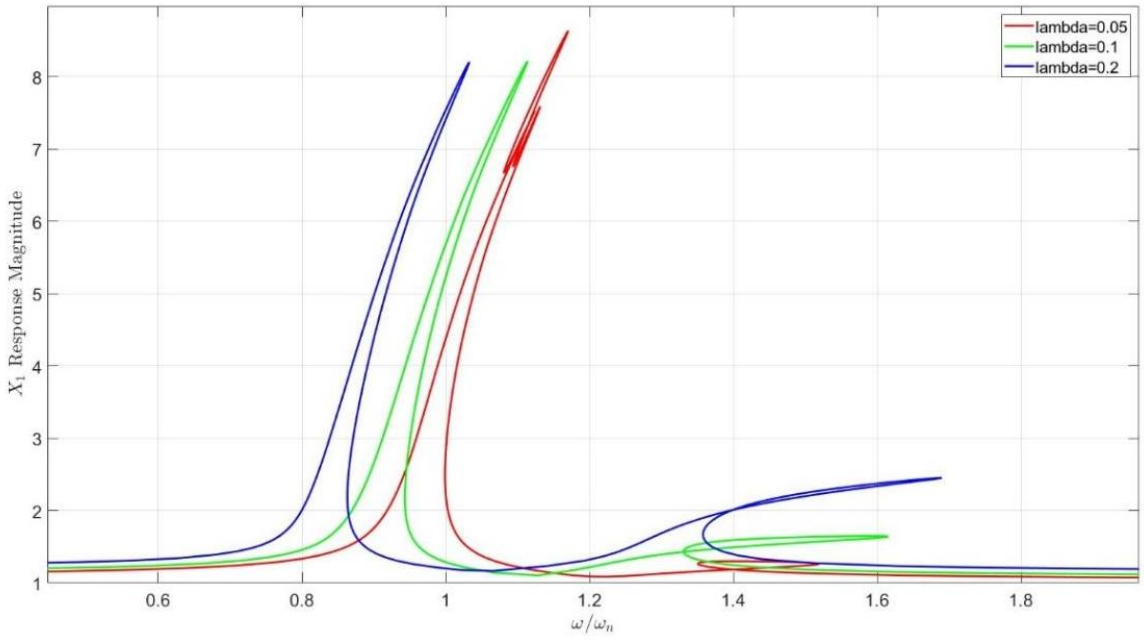

Figure 2. Frequency response curves showing the effect of linear stiffness(λ).

The results indicate that as the linear stiffness parameter(λ) decreases, the second natural frequency of the system shifts downward. However, the presence of hardening type nonlinearities ($\alpha_1 > 0$, $\alpha_{12} > 0$) restricts a significant leftward shift in the frequency response curves near the second natural frequency. This suggests that while adjusting λ influences the system's frequency characteristics, the nature of the nonlinear elements plays a crucial role in shaping the system's dynamic response. The frequency response analysis further reveals that at lower values of λ, the system experiences a more pronounced frequency shift, affecting vibration mitigation performance.

Linear Primary System Coupled with a Nonlinear Secondary System:

Table 2. System parameters for the linear primary system and nonlinear secondary system analysis.

Case	N_h	N	μ	γ	λ	ξ	σ	α_1	α_{12}	ε_1	ε_2
1	80	200	0.2	0.2	0.2	0.005	$\frac{\mu}{\mu+1}$	0	0	0.1	0
2	80	200	0.2	0.2	0.2	0.005	$\frac{\mu}{\mu+1}$	0	0.001	0.1	0
3	80	200	0.2	0.2	0.2	0.005	$\frac{\mu}{\mu+1}$	0	0.005	0.1	0

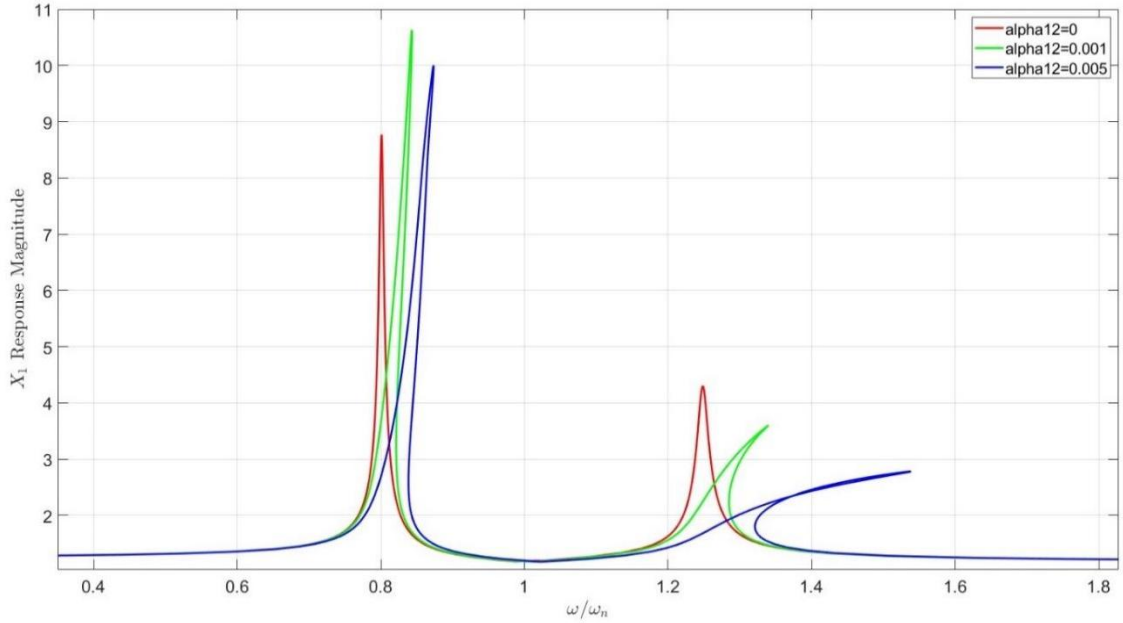

Figure 3. Frequency response curves for the linear primary and nonlinear secondary system.

When the primary system remains linear while the secondary system exhibits nonlinear characteristics, the frequency response curves indicate that increasing nonlinearity in the secondary system effectively reduces the vibration amplitudes of the primary system at specific excitation frequencies. This highlights the potential of nonlinear TMDs in improving vibration mitigation by redistributing energy within the system. The nonlinearity enhances damping behavior by introducing additional energy dissipation mechanisms, reducing the amplitude of forced vibrations.

Nonlinear Primary System with Varying Secondary System Nonlinearity:

Table 3. System parameters for the nonlinear primary system with variable secondary system nonlinearity.

Case	N_h	N	μ	γ	λ	ξ	σ	α_1	α_{12}	ε_1	ε_2
1	80	200	0.2	0.2	0.2	0.005	$\frac{\mu}{\mu+1}$	0.001	0	0.5	0
2	80	200	0.2	0.2	0.2	0.005	$\frac{\mu}{\mu+1}$	0.001	0.001	0.5	0
3	80	200	0.2	0.2	0.2	0.005	$\frac{\mu}{\mu+1}$	0.001	-0.001	0.5	0

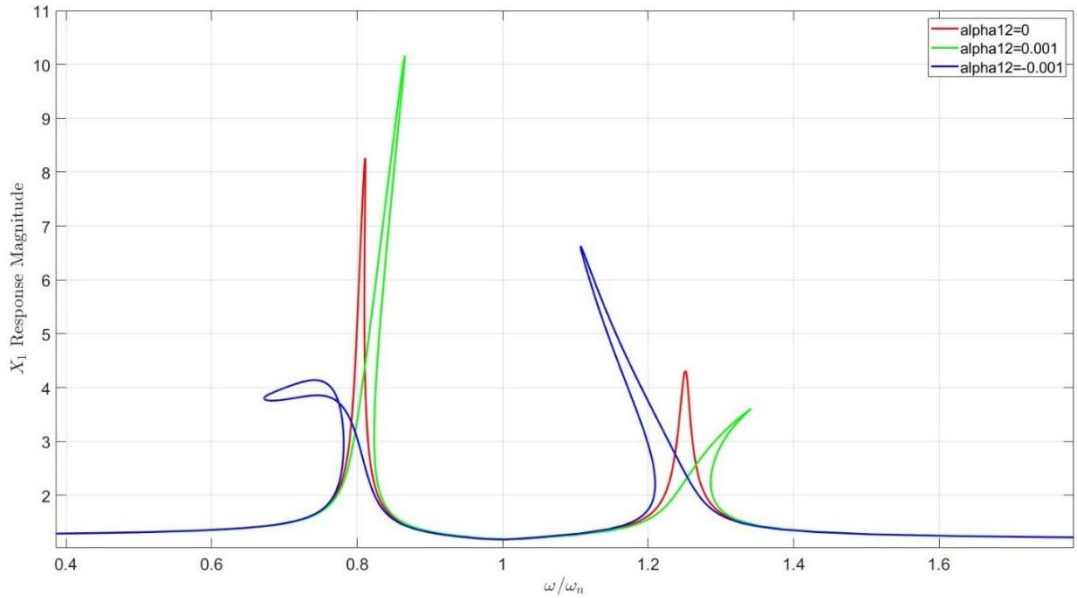

Figure 4. Frequency response curves for the nonlinear primary system with variable secondary system.

For cases where both the primary and secondary systems exhibit nonlinear behavior, different levels of nonlinearity in the secondary system lead to notable variations in the frequency response. The introduction of a softening-type nonlinearity ($\alpha_{12}<0$) results in saturation effects near both natural frequencies, particularly in the lower frequency range. This behavior suggests that appropriately tuning the nonlinearity of the secondary system can enhance the system's resilience to external excitations. The results demonstrate that strong nonlinear couplings influence frequency shift patterns and energy exchange mechanisms within the system.

Conclusion

This study presents a semi-analytical investigation of a nonlinear TMD system using the MHBM. By systematically varying key parameters, including linear stiffness and nonlinearity levels, the study explores their impact on vibration suppression effectiveness.

The results highlight that introducing nonlinearity in the secondary system extends the operational bandwidth of the TMD, improving its ability to mitigate vibrations across a wider frequency range. The findings also

demonstrate that a hardening-type nonlinearity prevents excessive shifts in response curves, while a softening-type nonlinearity introduces saturation effects that influence the overall system behavior. Moreover, when both the primary and secondary systems exhibit nonlinearities, complex frequency interactions emerge, emphasizing the importance of careful parameter selection in nonlinear TMD design.

Overall, the study provides valuable insights into the dynamics of nonlinear TMDs, offering a foundation for optimizing their design in various engineering applications, including civil structures, aerospace components, and machining systems.

Future work may focus on experimental validation and the exploration of additional nonlinearity types to further refine the theoretical understanding of nonlinear vibration control.

Keywords: Whole-Body Vibration (WBV), Crash Dummies, Ride Comfort, Finite Element Analysis (FEA), Biomechanical Response.

Aim

Ride comfort has become a key parameter in modern vehicle design, directly influencing user, health, satisfaction and the competitiveness of vehicles in the market. Among the many factors affecting ride comfort, whole-body vibration (WBV) is of particular concern, as it impacts occupant health and perception during vehicle operation [1].

Traditional methods for assessing WBV exposure have largely relied on multibody dynamics (MBD) human body models [2] and direct human testing [3]. However, the ethical concerns surrounding the use of real human subjects and limits in vibration experiments have made it impractical to conduct large-scale or controlled studies. As a result, numerical methods involving MBD human body models have been widely adopted to simulate and analyze WBV effects. Despite their advantages, correlating these models with real-world conditions remains a challenge.

To overcome this limitation, crash dummies—whose biomechanical characteristics are designed to represent human responses—have emerged as a viable alternative for WBV studies. Notably, the finite element (FE) models of crash dummies, which are extensively validated for safety testing, can also be applied to comfort studies. These FE models enable the simulation of detailed vibration responses in various body regions, making crash dummies a valuable tool for WBV analysis [4].

Material and Method

Methodology

This study utilizes FE simulations (LS-Dyna) to assess the potential of using crash dummies, specifically 50th percentile male THOR dummy, for whole-body vibration (WBV) evaluations in vehicles. The methodology integrates dummy models seated on a passenger seat subjected to short-duration shock inputs in x, y and z directions. The vibration responses from key body regions (chest, head, and pelvis) are then analyzed and compared with natural frequency ranges from ISO 2631[5] and the literature.

CAE Model

The case is simulated on a generic passenger seat, with a shock input applied that simulates a vehicle passing over an obstacle as shown in Figure 1. The shock duration is approximately 1 second, and the data based on measurement from seat pad of a vehicle. The seat and the dummy models are based on finite element models for LS-Dyna.

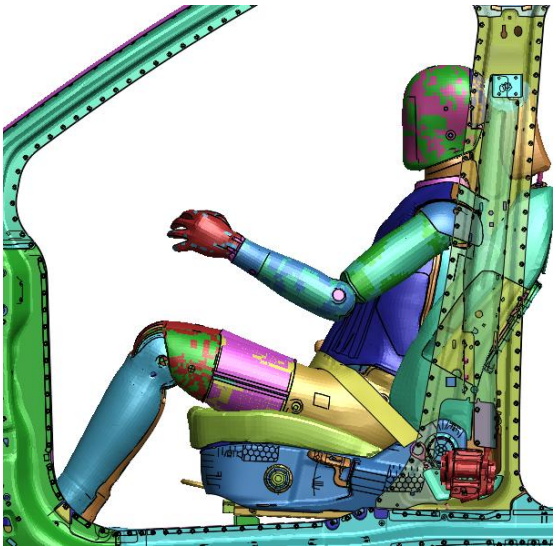

Figure 1. CAE Model Setup.

Dummy Model Characteristics

The dummy model is represented in detail using FE modeling techniques that capture the biomechanical properties of the human body. The THOR dummy model includes precise representations of key body regions, such as the chest, head, and pelvis etc. with corresponding material properties and damping characteristics. These models are validated against experimental crash test data to ensure their responses to crash pulses—such as force, acceleration, and deceleration—are accurate. Since crash dummy FE models are already validated through crash tests, their biomechanical response to impact forces is well-established, ensuring their reliability in simulating human-like responses in dynamic crash conditions. This validation supports their use in vibration studies, where their behavior under dynamic loads can be effectively extrapolated to WBV assessments.

Data Acquisition

The simulation involves applying the shock input to the dummy seated on a vehicle body. Vibration response data for critical body regions, including the chest, head, and pelvis, are recorded and processed. These responses are characterized by peak accelerations and frequency components, which are extracted from the recorded signals. The data is processed at a sampling rate of 1000 Hz to ensure high fidelity and accuracy in the vibration measurements.

Findings

The dynamic response assessment of the THOR dummy under whole-body vibration (WBV) conditions was conducted using a finite element (FE) model in LS-DYNA. The analysis revealed distinct resonance behaviors across different body regions. Figure 3 shows that in the Z-axis, significant resonance peaks were detected around 4–5 Hz, closely matching seated human body natural frequencies reported in previous studies [1]. Additionally, a peak was observed around 25 Hz in the head-Z axis, which aligns well with documented axial resonance frequencies of the human head [1]. In Figure 2, X-axis response showed peaks between 2-8 Hz, corresponding to seat-back oscillations, in agreement with findings from [4]. Since the THOR dummy was tested with an inclined backrest, the higher frequency response in the -X direction aligns with findings in the literature, suggesting that seatback inclination significantly influences WBV response and perceived discomfort. This indicates that the increased peaks in the -X direction at frequencies above 10 Hz are likely due to the altered dynamic response of the human body when the backrest is inclined, leading to a shift in resonance behavior. the equivalent comfort contours shift the maximum sensitivity to higher frequencies [1].

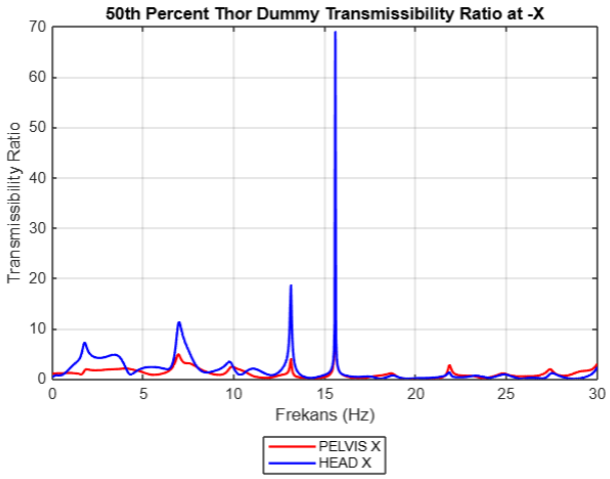

Figure 2. Transmissibility Ratio at -X Axis.

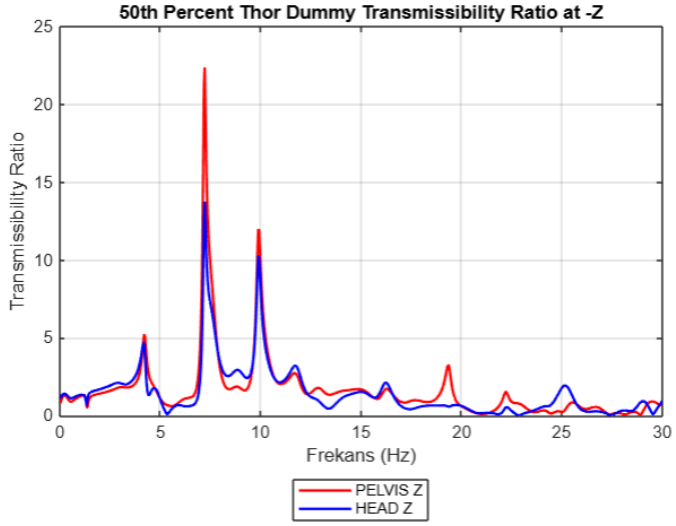

Figure 3. Transmissibility Ratio at -X Axis.

Conclusion

This study investigated the feasibility of using crash test dummies for whole-body vibration (WBV) assessments in vehicles. By subjecting a THOR dummy to shock-induced vibrations caused by a vehicle passing over an obstacle in LS-DYNA, dynamic response characteristics were analyzed and compared with known human body natural frequencies from the literature. The results demonstrated that the dummy exhibits distinct resonance peaks in frequency ranges consistent with human biomechanical responses, particularly in the pelvis and head regions. In the Z-axis, where vertical vibrations dominate, resonance peaks were observed around 4–5 Hz, aligning well with established WBV natural frequencies for the seated human body [1]. Similarly, X-axis responses exhibited resonant behavior in 2 Hz, corresponding to lateral human body vibrations in the -x direction, aligning with previous studies [5]. 8 Hz peak in -X direction may be occurred due to contribution of excitation in -Z axis resonant area. Also, strong peaks around 13–15 Hz. indicate the influence of the inclined seat position. Additionally, the head-Z axis response showed a peak around 23 Hz, which is consistent with the axial resonance frequency of the human head referred as 25Hz [1].

Overall, the findings suggest that advanced crash dummies can serve as viable surrogates for WBV analysis in vehicle environments. Their ability to replicate fundamental biomechanical responses indicates potential

applicability in ride comfort evaluations, seat design optimizations, and vibration exposure studies. Further refinement of dummy stiffness parameters and damping characteristics could enhance their fidelity for WBV-specific research, making them a valuable tool for automotive ergonomics and occupant comfort studies.

Comparison of Time and Frequency Domain Approaches for Fatigue Life Estimation Using the Finite Element Method

Ahmet Fatih Turhan[a], Osman Taha Şen[a]

[a] Istanbul Technical University, Faculty of Mechanical Engineering, Department of Mechanical Engineering, Türkiye
turhana21@itu.edu.tr

Keywords: Dirlik Method, Fatigue, Finite Element Analysis, Frequency-Domain, Time-Domain.

Aim

Fatigue, defined as the progressive and localized structural damage caused by repeated or fluctuating stresses, is one of the most critical failure modes in components subjected to cyclic or random dynamic loading. Over time, numerous fatigue life estimation methods have been developed typically classified into time-domain and frequency-domain approaches. Time-domain fatigue analysis applies the entire load history step by step, yielding explicit cycle-by-cycle stress or strain data for damage accumulation (Matsuishi & Endo, 1968). Conversely, frequency-domain approaches offer significant computational efficiency by relying on the power spectral density of the load, rather than simulating each time step (Dirlik, 1985).

Extensive research underscores both the strengths and potential limitations of these contrasting methodologies. The rainflow cycle counting algorithm, widely regarded as the standard in time-domain fatigue analysis, remains a cornerstone due to its precise capture of load reversals (Lee, Barkey & Kang, 2012). Conversely, Dirlik's method exhibits robust performance in numerous frequency-domain applications, though it can underestimate fatigue damage under certain conditions — especially when the loading features prominent periodic components, multiple resonance peaks, or significant non-Gaussian behavior (Quigley & Lee, 2012). Notably, Quigley and Lee (2012) observed that Dirlik's approach fell short by up to 30% for certain automotive components, while other researchers reported instances where it predicted more damage in broadband or narrowband scenarios (Benasciutti & Tovo, 2004). Likewise, Ragan & Manuel (2007) found notable discrepancies whenever the excitation departed from purely stationary or broadband assumptions, underscoring the influence of modal interactions and geometric factors on final fatigue life estimates. Furthermore, Demirkaya & Tüfekci (2020) carried out a study with a difference of up to approximately 58 times between time domain and frequency domain fatigue lives.

Despite their considerable advantages in computational efficiency, the accuracy of frequency-domain methods in predicting fatigue life remains uncertain. This study aims to evaluate the fatigue life predictions obtained from frequency-domain analyses by comparing them against time-domain fatigue analyses, which are considered the reference standard.

Material and Method

In this study, the core input data consisted of an acceleration–time signal and its frequency-domain equivalent as a power spectral density signal, both of which were synthetically generated rather than recorded from a physical test. A MATLAB script was used to produce white noise acceleration data, ensuring adequate coverage of the frequency range up to 2048 Hz. This same script then applied a Fast Fourier Transform to convert the acceleration–time signal into its corresponding power spectral density. Both datasets are shown in Figure 1. Consequently, the same loading was characterized in two ways — directly as a time history and as a PSD — for subsequent finite element analyses.

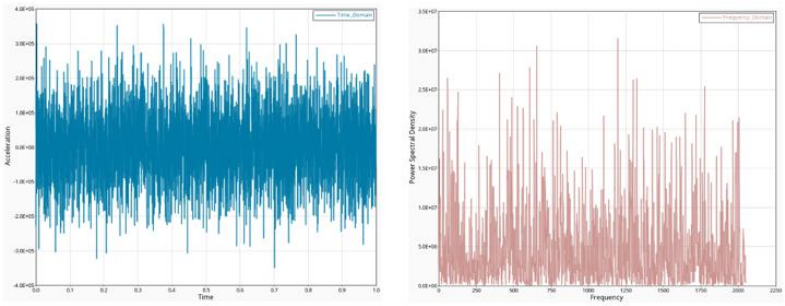

Figure 1. The acceleration-time data in the time domain and its corresponding Power Spectral Density (PSD) representation in the frequency domain.

All numerical simulations were carried out using OptiStruct, with identical finite element meshes, boundary conditions, and linear-elastic material models. The geometric dimensions of the models used are shown in Figure 2 and Figure 3. In the Notched Plate model, the linear material properties were defined as E = 70 GPa, Poisson's ratio = 0.3, and a density of 1.85×10^{-9} ton/mm³, while in the L-Plate model, E = 207 GPa, Poisson's ratio = 0.3, and a density of 7.88×10^{-9} ton/mm³ were used. While the number of elements of Notched Sample is 25,071, the number of elements of L-Plate is 15,991. Shell elements were preferred during the study due to the low computational cost. The only difference was whether the loading was applied transiently in the time domain or as a random vibration in the frequency domain, loading was applied in the z direction in both models. To evaluate and compare the responses before proceeding to fatigue life calculations, the Transient Dynamic statistics over time results were compared with the Random Vibration RMS over frequencies (3-sigma) outputs, examining both contour plots and numerical values to ensure consistency in overall stress distributions and magnitudes. Since there were no physical test data for correlation, the Transient Dynamic (time-domain) simulation served as the reference results throughout the study.

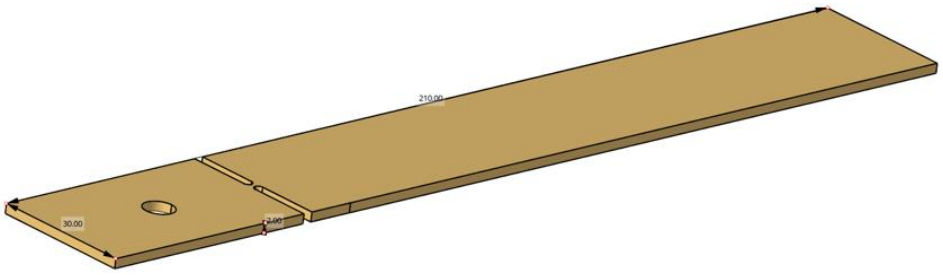

Figure 2. Geometric dimensions of the Notched Sample.

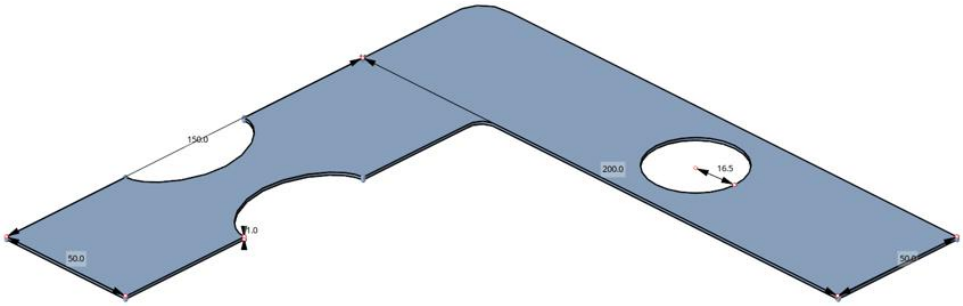

Figure 3. Geometric dimensions of the L-Plate.

Once the mechanical responses from each analysis were verified, fatigue life predictions were performed in Altair HyperLife using a conventional stress-based (S–N) approach that does not account for nonlinear or plastic deformations. Since direct correlation with a physical test was not targeted, the S-N curve to be used in fatigue analysis was obtained using the Estimate from UTS input method. In HyperLife software, the SN curve was created

by estimation method with UTS = 1000 MPa for L-Plate and UTS = 500 MPa for Notched Sample. In the frequency-domain route, the Dirlik method was used to convert the PSD-derived RMS stresses into an equivalent damage estimate, and average stress effects are neglected, as it is desirable not to affect the results under investigation. By combining these steps - synthetic load generation in MATLAB, separate transient and random vibration analyses in OptiStruct, and subsequent fatigue life assessment in HyperLife - the study aimed to compare fatigue analyses performed in the frequency domain with fatigue analyses performed in the time domain, which is considered as a reference.

Findings

Analyses were conducted on both the Notched Sample and the L-Plate using time-domain (Transient Dynamic) and frequency-domain (Random Vibration) methods, applying the same finite element meshes and boundary conditions to ensure comparability. In the Notched Sample, the time-domain Transient Dynamic analysis — using the acceleration–time input in OptiStruct — yielded a peak statistical stress of 600.110 MPa at element ID 5441. By contrast, the PSD-based random vibration simulation reported an RMS over frequencies (1-sigma) stress of 185.527 MPa at the same critical element. Notably, multiplying the 1-sigma result by three (3-sigma) brings the stress to approximately 556.580 MPa, which is in close agreement with the time-domain outcome of 600.110 MPa. An examination of the stress distributions presented in Figure 4 reveals that both methods produce identical contour patterns. In both analyses, the element with ID 5441 is identified as the most critical one. Fatigue life calculations for the Notched Sample employed a synthetic S–N curve derived via the "Estimate from UTS" method with UTS = 1000 MPa. In the time domain, the notched specimen achieved 21,177 cycles, whereas the Dirlik-based fatigue analysis in the frequency domain yielded 22,726 cycles — about a 7.315% increase over the Transient Dynamic result.

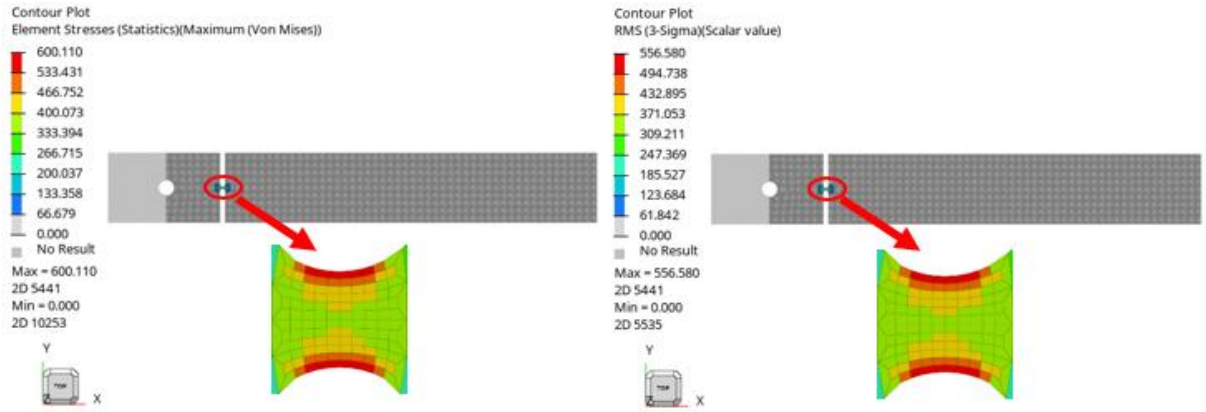

Figure 4. Time-domain (transient dynamic) and frequency-domain (random vibration) analysis results for the Notched Sample.

A similar pattern emerged for the L-Plate model. With the same acceleration–time signal in a Transient Dynamic simulation, the highest stress — 314.359 MPa — arose at element ID 26776. The corresponding Random Vibration analysis gave a 1-sigma RMS stress of 96.430 MPa, and its 3-sigma equivalent 289.289 MPa again closely matched the time-domain statistical peak of 314.359 MPa. Despite the minor differences in the stress distributions shown in Figure 5, both methods exhibit very similar contours and identify the element with ID 26776 as the most critical one. Fatigue predictions, using an S–N curve estimated with UTS = 500 MPa, resulted in 52,137 cycles for the Transient Dynamic case versus 55,477 cycles when the Dirlik method was employed on the PSD data exhibiting a 6.406% higher value.

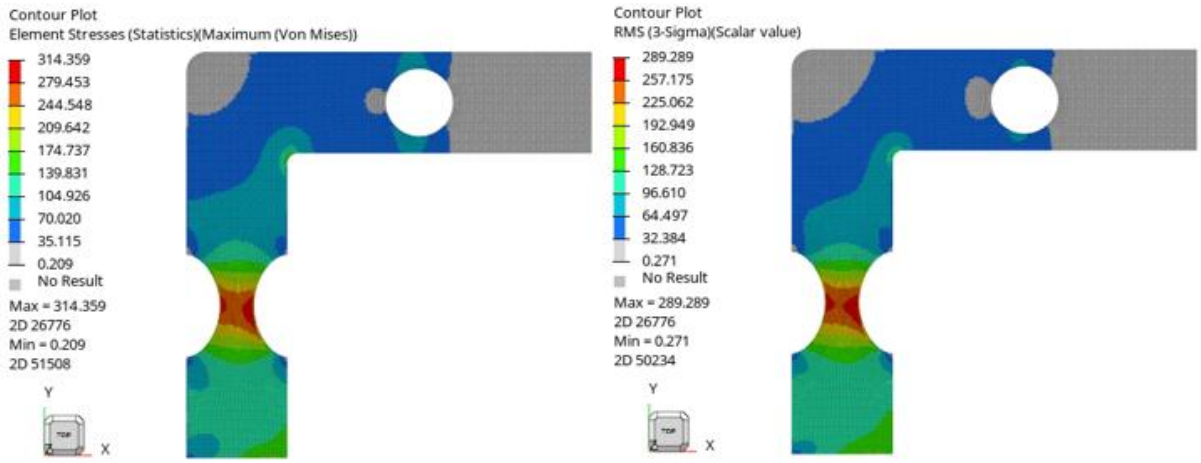

Figure 5. Time-domain (transient dynamic) and frequency-domain (random vibration) analysis results for the L-Plate.

According to results shown in Table 1, fatigue life predictions in the frequency domain tend to be slightly higher than fatigue life predictions in the time domain; this observation is consistent for both geometries. This highlights how spectral fatigue methods, especially the Dirlik approach, can slightly overestimate service life compared to direct cycle-by-cycle analysis and highlight the need to account for this slight life difference when choosing PSD-based fatigue predictions in future studies.

Table 1. Comparison of time-domain vs. frequency-domain results.

Model	Transient Dynamic Stress (MPa)	Random Vibration Stress (MPa)	Time-Domain Fatigue Life (cycles)	Frequency-Domain Fatigue Life (cycles)	Difference in Fatigue Life (%)
Notched Sample	600.110	556.580	21,177	22,726	+7.315%
L-Plate	314.359	289.289	52,137	55,477	+6.406%

Conclusion

In this study, fatigue life predictions from time domain (Transient Dynamics) and frequency domain (Random Vibration) simulations were compared under synthetic acceleration-time data and its frequency domain counterpart, PSD data loading using Notched Specimen and L-Plate geometries. Since direct physical test data was not available, the time domain Transient Dynamics results served as the reference against which the frequency domain (PSD-based) simulations were compared.

Fatigue life estimates generally aligned well across methods but revealed a consistent offset, with the Dirlik-based frequency-domain calculations yielding around 7% higher life for the Notched Sample and about 6% for the L-Plate. This difference highlights the known tendency of spectral fatigue methods to slightly overestimate service life compared to direct cycle-by-cycle counting. While this margin is relatively small, it remains a meaningful distinction for design and safety considerations. Quigley & Lee (2012) also reported that Dirlik's method fell short by up to 30% for certain automotive components, reinforcing the notion that modeling details and the nature of the load input can significantly impact the accuracy of frequency-domain predictions.

In a similar study in the literature Demirkaya and Tüfekci (2020), a difference of up to approximately 58 times in fatigue life results obtained from time and frequency domains was observed. However, in the present study, the deviation remained modest, below 10%, highlighting that frequency-domain methods can produce fatigue life predictions in close agreement with time-domain solutions if the input signals and modeling assumptions are well-defined.

The fatigue analyses in the study were conducted using the S-N method under uniaxial loading; however, the results may vary under multiaxial loading conditions and low-cycle fatigue applications. Moreover, although the effects of mean stress were neglected in this study, the difference between time-domain and frequency-domain fatigue life predictions may become more pronounced in studies where the mean stress effect is considered.
Overall, the findings underscore that PSD-based simulations reliably track the same damage trends as time-domain analyses but may slightly overestimate the number of cycles to failure. The results demonstrated that, in both geometries, the same element was identified as the critical location under random loading, indicating that neither domain approach missed the underlying stress hot spots. Considering the computational advantages of random vibration analyses, these methods can be highly valuable for early design iterations or broad parametric assessments. However, if accurate or conservative life predictions are paramount, supplementing PSD-based results adjusting with a suitable safety factor is recommended especially in scenarios where the final design decision hinges on the precise fatigue limit.

Analytical Investigation of Modal Curvatures of Damaged Beams

Ozan Ürel[a], Uğurcan Eroğlu[a]

[a]Istanbul Technical University, Mechanical Engineering, Solid Mechanics, Turkey
ozanurel52@gmail.com

Keywords: Beam Theory, Closed-Form Solutions, Damage, Vibration.

Aim

Monitoring of dynamic parameters such as natural frequency, mode shapes and modal curvature is a frequently preferred method for structural damage detection since it provides information about the general condition of the structure. The effectiveness of structural health monitoring and damage detection applications based on the study of dynamic behavior has been demonstrated by various studies conducted in different fields [1]. In mechanical engineering, there are several studies on post-earthquake condition assessment of structural systems ranging from rotors and shafts to structural systems related to aircraft engineering, and in civil engineering for historical buildings, long-span bridges and high-rise structures [2-6].

Various parameters such as mathematical modeling of the structure and damage, quality of measurement data and data processing methods play an important role in accurate and reliable damage detection [7]. The study of modal characteristics that are least affected by measurement errors and uncertainties that may occur under different operating conditions plays an important role in improving the accuracy of structural health monitoring [8-10].

The practicality of measuring and analyzing natural frequencies has led to the use of this parameter in frequency calculations of damaged structural systems [11-16], as well as the prediction of damage by analyzing the changes in natural frequencies [17-23]. The fact that the natural frequency changes caused by damage can be affected by external factors negatively affects the reliability of the results obtained as a result of a damage estimation study to be carried out by measuring natural frequencies. The use of modal curvatures is a good option for the study, as they are less affected by the adverse effects of environmental conditions and have shown successful results in research on the investigation of various structural systems [24,25,26]. Nevertheless, in the case of damage over large areas, the fact that it affects structural properties in areas where damage is not present and the use of a dense sensor for high accuracy damage detection indicates that extensive research is needed to increase the applicability of modal curvatures [27-29].

Earlier studies based on the use of natural frequencies to match the data obtained in the process of structural damage detection with mathematical models used co-frequency curves [30-34]. The fact that obtaining a single solution in this method is only valid for the ideal case has led researchers to use optimization methods that include a multi-point search method. Examples of solution algorithms that include this method are genetic algorithms [7,35,36,37,38], differential evolution algorithm [39,40,41] or many similar algorithms and hybrid techniques [42-46]. It can be seen that these methods can produce a good solution under ideal conditions, but when various uncertainties begin to occur in the measurement conditions, the solution may be unacceptably inaccurate. Accordingly, it is possible to reach the desired parameter by using an appropriate algorithm by removing the noise that may occur during data collection and processing. "Beamforming algorithms" will be used in this study. Beamforming is a technique that uses the channel information at the transmitter to appropriately weight the transmitted signals and make them more compatible with the channel conditions. It is widely used in areas such as signal strength enhancement in wireless networking, radar systems and medical monitoring. It is a suitable method for estimating damage located far away from sensors. However, it has been preferred in damage detection studies in structural mechanics.

In this study, a solution method for the damage detection problem is presented by analyzing the modal curvature changes in beam-type structural elements. In the future, it is aimed to improve the study with Bartlett and Minimum Variance Distortionless Response (MVDR) techniques, which are beamforming algorithms. It is aimed to compare

the inferences made by using the modal curvatures of the bending vibrations of damaged beams with conventional methods and to reveal the advantages of the beamforming algorithms used in this investigation.

Material and Method

1-Dimensional Beam Model

In 3-dimensional Euclidean space ($\mathbb{R}3$), the geometry formed by planes with double axes of symmetry, always connected to a line of length L at its geometric centre, represents the bar to be investigated in this study. In this case, the line is called the axis of the bar and the plane perpendicular to this axis is called the cross-section of the bar. The Oxyz Cartesian coordinate set to be used to describe the position of any point on the bar is described in such a way that the z-axis is located along the bar axis and the xy-axes are located along the principal directions of the bar section. With the assumption of small displacement and deformation, the deformed state of the bar is described by the displacement of the points on the bar axis and small rotations of the bar section. For forces and force couples in the plane only, the deformed bar axis will remain in its plane and the sections with area A will rotate only about its axis. This deformation state is called 'simple bending'. Deformation of the bar when only vertical (along the y-axis) displacements are considered,

$$\gamma = \frac{dv}{dz} + \Omega\,, \qquad \chi = \frac{d\Omega}{dz} \quad \#(\,SEQ\ Denklem\ \backslash *\ ARABIC\ 1)$$

are described by the expressions. In the case where shear deformation is neglected and there is a linear relationship between bending moment (M) and curvature, assuming Hooke's material, the kinematic expressions take the following form,

$$\frac{dv}{dz} = -\Omega\,, \qquad \frac{d\Omega}{dz} = \frac{M}{EI} \quad \#(\,SEQ\ Denklem\ \backslash *\ ARABIC\ 2)$$

Here EI indicates the bending stiffness of the sections about the x-axis. Assuming that each bar piece will be in equilibrium in the deformed state, the relations between the cross-sectional effects and external loads are as follows,

$$\frac{dV}{dz} = -q\,, \qquad \frac{dM}{dz} = V \quad \#(\,SEQ\ Denklem\ \backslash *\ ARABIC\ 3)$$

Where V is the shear force in the sections and q is the distributed load in the y-axis direction. According to d'Alembert's Principle, which states that the structure will be in equilibrium under the effect of external loads and inertia forces at all times,

$$q = -\rho A\ddot{v} \quad \#(\,SEQ\ Denklem\ \backslash *\ ARABIC\ 4)$$

Here, ρ is the density of the bar. With the assumption that the motion is a harmonic motion with angular frequency and the following nondimensionalisations,

$$\underline{v} = \frac{v}{L}, \underline{z} = \frac{z}{L}, \underline{V} = \frac{VL^2}{EI}, \underline{M} = \frac{ML^3}{EI}, \omega^{-2} = \frac{\omega^2 L^4 \rho\, A}{EI} \quad \#(\,SEQ\ Denklem\ \backslash *\ ARABIC\ 5)$$

the equations of motion of the analysed bar can be formulated as follows,

$$\frac{dy}{d\underline{z}} = Ay, y = \{\underline{v}\ \underline{\Omega}\ \underline{V}\ \underline{M}\}^T, A = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 0 & -\omega^{-2} & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}, \underline{z} \in [0,1] \quad \#(\,SEQ\ Denklem\ \backslash *\ ARABIC\ 6)$$

the solution of this set of equations is known in terms of the principal matrix (transfer matrix or matrix) and initial values as follows,

$$y(z) = Y(z, z_0)y(z_0), A_{ij}\ \epsilon^{\sim}, Y(z, z_0) = exp\ exp\ [(z - z_0)A] \quad \#(\ SEQ\ Denklem\ \backslash *\ ARABIC\ 7)$$

As also practised in the literature, accepting z0=0 will simplify the expressions of the principal matrix. In this case, the non-zero elements of the principal matrix are as follows,

$$Y_{11} = \frac{1}{2}\left[cos\ cos\left(\sqrt{\omega}z\right) + cosh\ cosh\left(\sqrt{\omega}z\right)\right]; Y_{12} = \frac{-1}{2\sqrt{\omega}}\left[sin\ sin\left(\sqrt{\omega}z\right) + sinh\ sinh\left(\sqrt{\omega}z\right)\right];\ Y_{13} = \frac{Y_{12}}{\omega^2};$$

$$Y_{14} = \frac{1}{2\omega}\left[cos\ cos\left(\sqrt{\omega}z\right) - cosh\ cosh\left(\sqrt{\omega}z\right)\right]; Y_{21} = \frac{\sqrt{\omega}}{2}\left[sin\ sin\left(\sqrt{\omega}z\right) - sinh\ sinh\left(\sqrt{\omega}z\right)\right]; Y_{22} = Y_{11}; \quad \#(\ SEQ\ Denklem\ \backslash *\ ARABIC\ 8)$$

$$Y_{23} = -Y_{14}; Y_{24} = -Y_{22}; Y_{31} = \omega^2 Y_{12}\ ; Y_{32} = \omega^2 Y_{23}\ ; Y_{33} = \omega^2 Y_{11};\ Y_{34} = \omega^2 Y_{23};$$
$$Y_{41} = \omega^2 Y_{14}\ ;\ Y_{42} = -\omega^2 Y_{13}\ ; Y_{43} = -Y_{23}; Y_{44} = Y_{11}$$

In order to find the 4 unknown initial values, a total of four boundary conditions are written, two for each end. The conditions used are as follows,

Cantilever; $\nu = 0, \Omega = 0$
Simply supported; $\nu = 0, M = 0$
Free end; $V = 0, M = 0$

Here; ν is translations, Ω is rotation, V is shear force and M is moment. This set of algebraic equations, homogeneous in terms of initial values, is the set of equations from which the characteristic equation for the solution of natural frequencies is obtained. For non-zero solutions of the initial values vector, the operator applied to it must be singular. Natural frequency values are obtained with this condition, which appears as an equation with infinite root and requires numerical solution. The set of algebraic equations for a bar with fixed supports at both ends, which will also be analysed in its damaged form, is expressed as follows,

$$H(\omega)y(0) = 0,$$

$$H(\omega) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \frac{cos\ cos\sqrt{\omega} + cosh\ cosh\sqrt{\omega}}{2} & \frac{\sqrt{\omega} - cosh\ cosh\sqrt{\omega})}{2} & 0 \\ -\frac{sin\ sin\sqrt{\omega} + sinh\ sinh\sqrt{\omega}}{2\sqrt{\omega}} & \frac{\sqrt{\omega} + sinh\ sinh\sqrt{\omega})}{2} & 0 & \frac{sin\ sin\sqrt{\omega} - sinh\ sinh\sqrt{\omega}}{2\omega^{\frac{1}{2}}} \\ \frac{sin\ sin\sqrt{\omega} + sinh\ sinh\sqrt{\omega}}{2\sqrt{\omega}} & 1 & \frac{cos\ cos\sqrt{\omega} - cosh\ cosh\sqrt{\omega}}{2\omega} & \frac{cos\ cos\sqrt{\omega} - cosh\ cosh\sqrt{\omega}}{2} \end{bmatrix} \quad \#(\ SEQ\ Denklem\ \backslash *\ ARABIC\ 9)$$

For a non-zero solution,

$$det\ det\ H(\omega) = 0,\ \ sin\ sin\sqrt{\omega}\ sinh\ sinh\sqrt{\omega} = 0 \quad \#(\ SEQ\ Denklem\ \backslash *\ ARABIC\ 10)$$

must be satisfied,

$$\omega = n^2\pi^2, n\ \epsilon\ Z^+ \quad \#(\ SEQ\ Denklem\ \backslash *\ ARABIC\ 11)$$

is obtained. The expression obtained is substituted into equation (9) and the initial values are obtained in a parameter dependent form. Based on dimensionless values,

$$\langle \nu, \nu \rangle = \int_0^1 \quad \nu^2 dz = 1 \quad \#(\ SEQ\ Denklem\ \backslash *\ ARABIC\ 12)$$

when the mass normalization defined as follows, the vector of initial values for these boundary conditions is obtained as follows,

$$y(0) = \sqrt{2}n\pi\ \{0\ \ 1\ \ -n^2\pi^2\ \ 0\}^T \quad \#(\ SEQ\ Denklem\ \backslash *\ ARABIC\ 13)$$

Damage Model for 1-Dimensional Structures

It is possible to model a potential damage as a reduction in bending stiffness in a certain part of the beam. In this case,

$$A = \begin{bmatrix} 0 & -1 & 0 & 0 & 0 & -\omega^2 & 0 & 0 & 0 & 0 & 0 & 1 & \frac{1}{1-\varepsilon\eta(z)} & 0 & 0 \end{bmatrix} \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 14)$$

To express the reduction in bending stiffness, Ciambella et al. [26] proposed a piecewise polynomial. A precise expression of this function can be written by relating the increase in strain energy around the crack tip to the variation along the axis of the bar and the increase in flexibility caused by this energy increase. In all cases it is known that this will be maximum at the crack location and will converge to zero as one moves away from the crack. The use of a piecewise function increases the computational effort as it implies that the solution will also be piecewise. Instead, a continuous function will be used in this study. If the properties that the function describing the decrease in bending stiffness must satisfy are described,

$$\eta(z) \epsilon\ [0,1], \forall z\ \epsilon\ [-\delta + z_c, \delta + z_c], \eta(z_c) = 1$$

$$\eta(z) = 0, \forall z\ \epsilon \notin [-\delta + z_c, \delta + z_c] \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 15)$$

Here zc is the centre of damage and δ is the area of damage. Here zc is the centre of damage and delta is the area of damage. In accordance with these descriptions, the normal distribution function can be used as,

$$\eta(z) = exp\left[\frac{-(z-z_c)^2}{\beta}\right] \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 16)$$

According to the parameter ε, which describes the magnitude of the damage and is assumed to be small, if the perturbation expansion is performed around ε=0, i.e. the undamaged state,

$$y = y_0 - \varepsilon y_1, \omega^2 = {\omega^2}_0 - \varepsilon {\omega^2}_1, A = A_0 - \varepsilon A_1$$

$$A_0 = \begin{bmatrix} 0 & -1 & 0 & 0 & 0 & -{\omega^2}_0 & 0 & 0 & 0 & 0 & 0 & 1 & \frac{1}{1-\varepsilon\eta(z)} & 0 & 0 \end{bmatrix}, A_1 = [0\ -1\ 0\ 0\ 0\ -{\omega^2}_1\ 0\ 0\ 0\ 0\ 0\ 1\ \ -\eta(z)\ 0\ 0\ ] \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 17)$$

The sub-index '0' describes the quantities derived for ε=0, while the index '1' the value of the derivative of the function with respect to the parameter at ε=0. When these expansions are placed in the differential equation set, the zeroth and first order equations and their solutions are as follows,

$$\frac{dy_0}{dz} = A_0 y_0, \frac{dy_1}{dz} = A_0 y_1 + A_1 y_0$$

$$y_0 = Y_0(z, z_0)\ y_0(z_0) \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 18)$$

$$y_1(z) = Y_0(z, z_0)\ y_1(z_0) + Y_0(z, z_0) \int_{z_0}^{z} \quad Y_0(z_0, \xi) A_1 y_0(\xi) d\xi\ ,$$

The solution of the zeroth order equation is the solution of the undamaged beam. The first order equations, on the other hand, contain inhomogeneities consisting of the zeroth order solution. This is always encountered in the perturbation method. The boundary conditions written to find the initial values of the zeroth order solution will give a set of homogeneous algebraic equations as follows,

$$H(\omega_0)\ y_0(z_0) = 0 \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 19)$$

The expression is similar to equation (9). For the first order, a non-homogeneous set of algebraic equations with the same (singular) operator is obtained.

$$H(\omega_0)\ y_1(z_0) = b(\omega_1) \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 20)$$

The non-homogeneous part of this set depends on the first order natural frequencies, i.e. the effect of damage on the natural frequency. Since the operator applied to the unknown vector is singular, the solution of this equation can only be found if the Fredholm compatibility condition is satisfied [49].

$$a^T b(\omega_1) = 0, a \in R^4, H^T(\omega_0) = 0 \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 21)$$

When the first order natural frequency obtained from this condition is used in Eq. (17), the natural frequencies of the damaged bar are obtained. In addition, if the unknown initial values from equation 20 are solved with this frequency change, the field functions describing the motion of the beam are obtained. This allows the modal curvatures described by the second derivative of the vertical displacement to be calculated under appropriate normalization. Since the first-order solution is linearly independent of the zeroth-order solution, this normalization is done by using the expression,

$$\langle v_0, v_1 \rangle = 0 \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 22)$$

This expression, also known as 'intermediate normalization' in perturbation technique, means that the projection of the modal strain energy of the zero-order solution onto the total solution is 1. This can be compared to the fact that the projection of two unit vectors whose directions are very close to each other can also be assumed to be equal to 1.

Findings

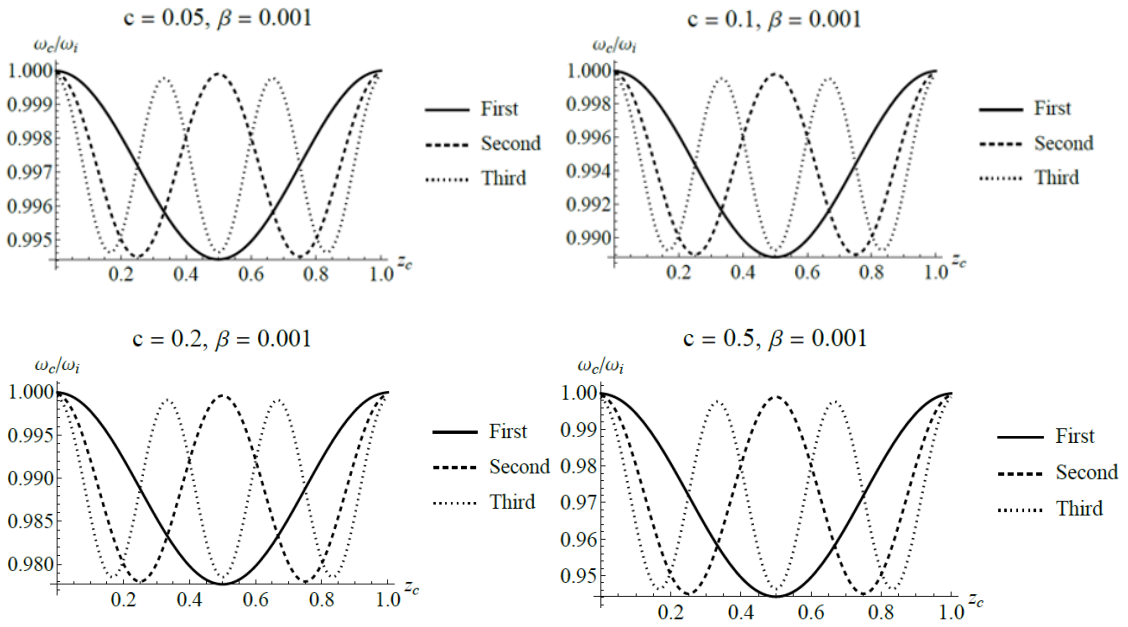
Simply Supported Damaged Beams

In this section, the case of damage to a simply supported bar, for which the zeroth order solution (undamaged case) is known, is analyzed. For this problem, the vector a described by Eq. (21) is found as follows,

$$a = a\,\{-(-1)^n\ n^2\pi^2\ -(-1)^n\ n^2\pi^2\ 1\}^T, n \in Z^+ \quad \#(SEQ\ Denklem\ \backslash *\ ARABIC\ 23)$$

From this, the first order frequency expression describing the decrease in natural frequency is obtained as follows,

$$\omega^2_1 = \frac{1}{4} n^{\frac{9}{2}}\sqrt{\beta}n^4 e^{-\pi n(\pi\beta n+2iz_c)}\{2\left(erf\left(\frac{1-z_c}{\sqrt{\beta}}\right)+erf\left(\frac{z_c}{\sqrt{\beta}}\right)\right)e^{-\pi n(\pi\beta n+2iz_c)}+erfc\left(\frac{z_c-i\pi\beta n}{\sqrt{\beta}}\right) \quad \# \ +erfc\left(\frac{i\pi\beta n-z_c+1}{\sqrt{\beta}}\right)$$
$$-e^{4i\pi n z_c}\left(erf\left(\frac{-i\pi\beta n-z_c+1}{\sqrt{\beta}}\right)+erf\left(\frac{z_c+i\pi\beta n}{\sqrt{\beta}}\right)\right)-2\}\ (24)$$



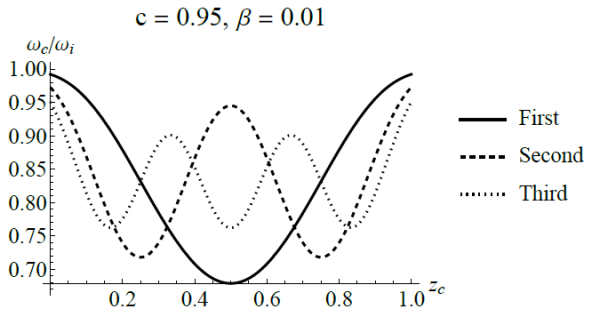


Figure 1. Effect of severity of the damage on the first 3 natural frequencies of a damaged bar with two end hinges.

The damage width parameter β = 0.001 was assumed constant and the effect of crack location on the first three natural frequencies was analyzed and the obtained frequency plots are shown in Figure-1. The comparison was made for five different damage magnitudes, c = 0.05, c = 0.1, c = 0.2, c = 0.5 and c = 0.95. In the graphs, the horizontal axis indicates the damage location (zc), while the vertical axis indicates the ratio of the damaged bar frequency to the undamaged bar frequency (ωc/ωi). According to the results, it can be seen that the shape of the curves expressing the natural frequencies in the first three modes does not change with increasing damage magnitude, but the natural frequency ratios decrease.

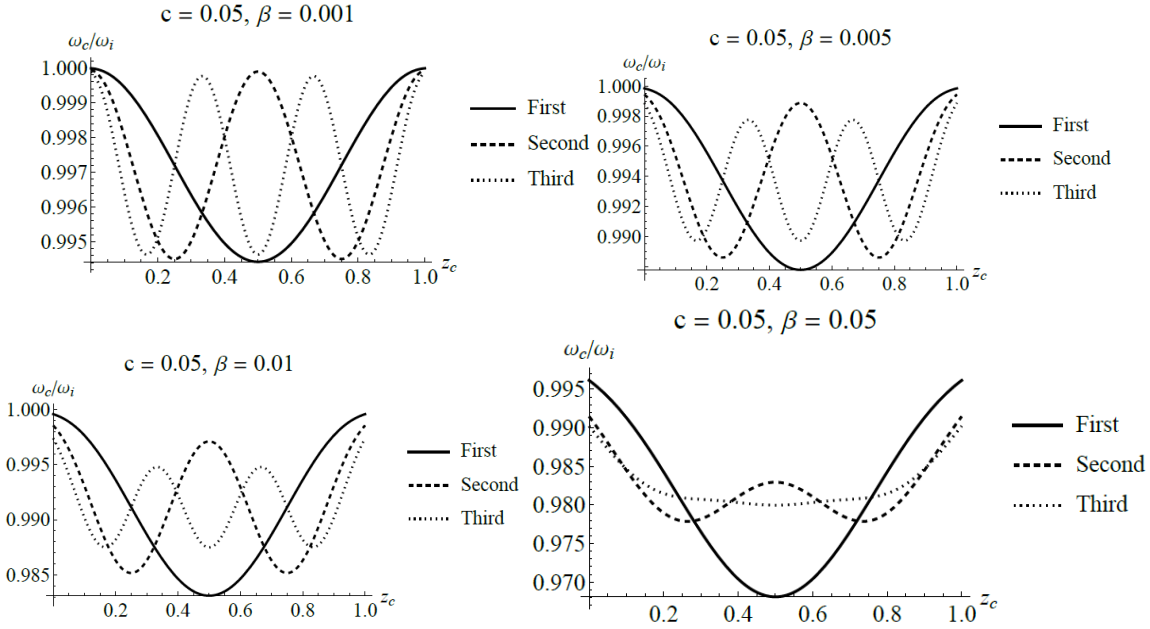

Figure 2. Effect of crack width on the first 3 natural frequencies of a damaged bar with two end hinges.

The damage magnitude parameter c = 0.05 was considered constant and the effect of crack width on the first three natural frequencies was analysed and the frequency graphs obtained are shown in Figure-2. It is observed that the natural frequency values decrease with the increase of the parameter expressing the damage width and the curves of the second and third modes tend to resemble the curve of the first mode and it can be said that the higher modes are more affected by this increase.

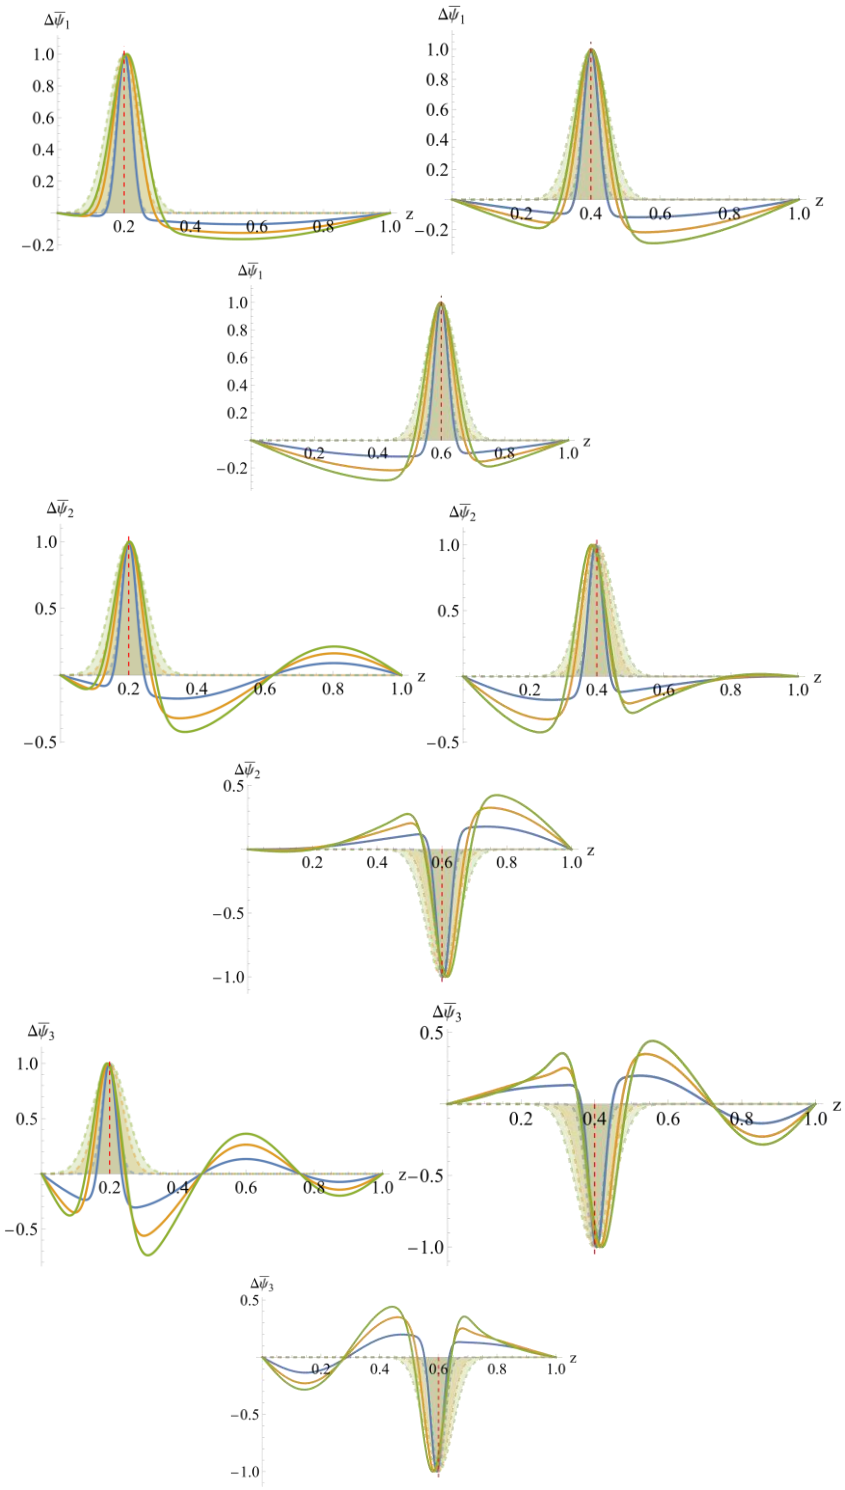

Figure 3. Modal curvature changes of the first three modes for 3 different damage locations and 3 different damage widths (blue, yellow, green: b = 0.001, 0.003, 0.005).

For three different damage locations (zc = 0.2, 0.4, 0.6) and three different damage widths (β = 0.001, 0.003, 0.005) the changes in the modal curvatures of the beam (ΔΨ) were plotted. It was observed that as the value of the parameter 'β', which represents the damage width, increases, the modal curvatures of the first three modes spread over a wider area in the relevant damage zone. In addition, the effect of the damage width on the mode shape can

be followed by plotting the function that characterises the decrease in flexural stiffness depending on the damage width parameter on the graph. Based on the graphs, it is seen that there is a peak in modal curvatures in the damage zone, but there are also extremum points outside the damage zone. If measurements are made at these points, it may be evaluated that the damage is around the extremum points. This increases the risk of error in determining the actual location of the damage. In addition, due to the symmetry of the investigated system, it can be said that the change in the mode shapes is the same in case of damage in symmetrical regions.

Conclusion

In the part of the study up to this stage, a solution to the problem of damage detection in beams was presented by analyzing modal curvature changes in beam type structural elements. According to the results obtained, it can be said that monitoring the changes in modal curvatures gives successful results in determining the damage parameters. The function $\eta(z)$ describing the damage and the proposed closed form solution are the unique parts of the study. In the future, it is aimed to improve the solution with Bartlett and MVDR techniques, which are beam forming algorithms. It is aimed to compare the inferences made by utilizing the modal curvatures of bending vibrations of damaged beams with conventional methods and to reveal the advantages of the beamforming algorithms used in this research.

Nonlinear System Identification of a 2-DOF Gimbal System

Batuhan Kalkan[a], Ayhan Kural[a]

Keywords: Gimbal Nonlinear Modelling, Identification, Friction.

Aim

Gimbal systems are used to keep the payloads they carry at a certain stabilization accuracy under the disturbing effects caused by the movement of the platforms they are placed on (Hilkert, 2008). These systems are especially preferred in military applications for the tasks of recognizing and tracking targets in the line of sight thanks to the electro-optic systems they carry as payloads. Control algorithms must be developed to meet the motion control and stabilization requirements in gimbal systems. In order for control algorithms to be applied successfully, dynamic models similar to the real system must be obtained. There are many parameters that need to be known in order to create a dynamic model of gimbal systems. Even if these parameters are determined from the design or datasheets, there may be major differences between the obtained model and the real system. For this reason, after the production of gimbal systems, system identification application is performed and dynamic models of the system are created. In this way, control algorithm development studies can be carried out in a computer environment without the need for a real system.
In this study, linear and nonlinear dynamic models of the azimuth axis of a 2-dof gimbal system were created in order to meet the motion control and stabilization requirements of the sight system in the gun turret of a land vehicle.

Material and Method

In this study, there is a DC motor, encoder and gyrocope on the azimuth axis of the gimbal system. Electrical energy is converted into mechanical energy by the current command applied to the DC motor and the system is moved. The current controller of the DC motor is controlled by a driver. The gyroscope gives the angular speed of the gimbal system relative to the ground. The angular speed coming from the gyroscope is used as a feedback signal in the speed control algorithm. Nonlinear friction and unbalance models are developed with the angular position coming from the encoder and the angular speed data produced from this angular position. Figure 1 shows a visual of the gimbal system used in a similar study (Lee et al., 2020).

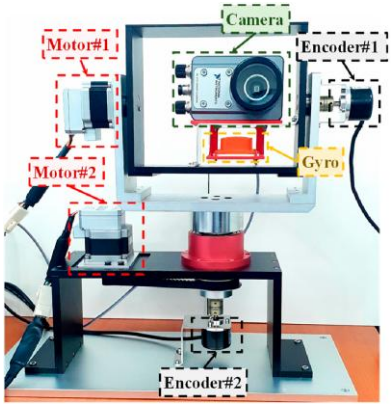

Figure 1. A sample of 2-dof gimbal system design (Lee et al., 2020).

The gimbal system is modeled as a single input and single output with current input and angular speed output. The block diagrams of the model are shown in Figure 2 below. The nonlinear dynamic model of the gimbal system consists of the motor model, inertia, friction model, unbalance model and gyroscope model (Özçelik et al., 2022). The current control loop is designed by the digital motor driver thanks to the PWM (Pulse Width Modulation) in the motor model. In the tests conducted with the current controller, it was seen that it works ~100% correctly (Tezgelen, 2020). The gimbal system designed for current input and angular speed output is shown by the following Equation 1 by the linear transfer function. W(s) represents the angular speed output, I(s) represents the current input, Kt represents the motor torque constant, J represents the inertia of the system and B represents the friction of the system.

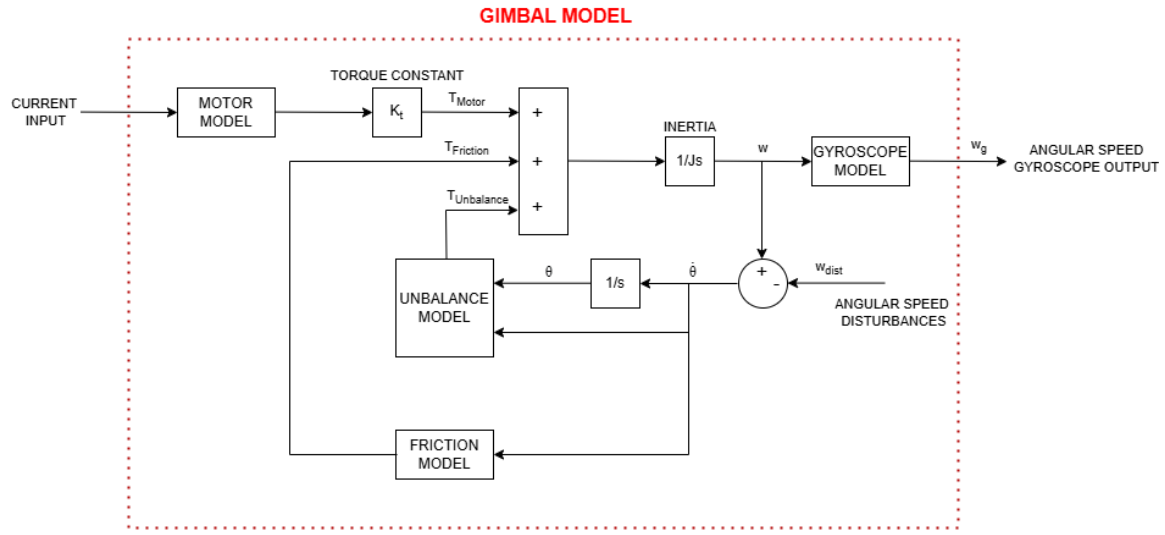

Figure 2. Block diagrams of gimbal system.

Equation 1 Transfer function of gimbal system

$$\frac{W(s)}{I(s)} = \frac{1}{\frac{Js}{K_t} + \frac{B}{K_t}}$$

FRF (Frequency Response Function) wave was applied to the gimbal system as current input and angular speed outputs were obtained from the gyroscope (Özdoğan, 2016; Olsson, 1998). The targeted bandwidth of the gimbal was determined as 8 [Hz] and for this reason, system identification was performed up to 25 [Hz]. In order to create the FRF signal, a sine sweep signal was created from 1 [Hz] to 25 [Hz] with 0.25 [Hz] increments and each frequency value was repeated 16 times in order to reveal the dynamics of the system (Çetinyol, 2023; Eroğlu, 2023). The FRF signal design is shown in figure 3 below. The FRF signal created at 2.4 [A], 3 [A], 3.6 [A], 4.2 [A] and 4.8 [A] current amplitudes was applied to the system.Transfer functions were obtained using the System Identification Toolbox in Matlab. Real Data is the angular speed data obtained from the gyroscope after the current commands applied to the real system. Estimation Data is the angular speed data obtained by applying the current commands applied to the real system separately to the transfer function obtained as a result of system identification. The formula in Equation 2 below was used to calculate RMS Accuracy.

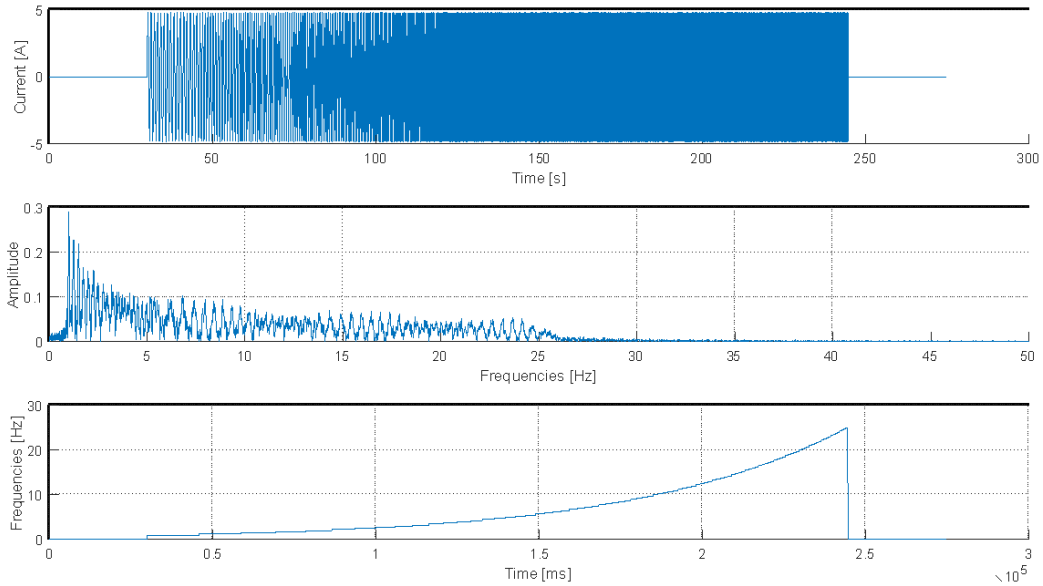

Figure 3. Sine sweep signal design.

Equation 2 RMS Accuracy

$$RMS\ Accuracy = \left(1 - \frac{rms(RealData - EstimationData}{rms(RealData)}\right) * 100$$

Table 1 below shows the RMS Accuracy, J/Kt and B/Kt values calculated as a result of the system identification applications. It was observed that the test result with an amplitude of 4.8 [A] had the highest system identification success and the J/Kt value was accepted as the inertia of the system and the B/Kt value was accepted as the friction of the system to be used in the linear system model.

Table 1. Results of System Identification.

Test No	Amplitude [A]	RMS Accuracy Linear System Identification	J/Kt	B/Kt
1	2.4	79.1433	0.0186	0.1552
2	3	82.3678	0.0187	0.1259
3	3.6	85.1759	0.0183	0.0917
4	4	86.6240	0.0183	0.0751
5	4.8	88.3800	0.0182	0.0649

Since the friction in gimbal systems can vary depending on the direction and speed of the movement, nonlinear models were created. As a result of literature research, it was observed that the modeling success of gimbal dynamic models increased with the addition of the Lugre friction model (Olsson, 1998; Sincar, 2015; Mashayekhi et al., 2022). The Lugre friction model parameters consisting of pre-slip and sliding phases were calculated with tests performed on the Azimuth axis (Sisu, 2023; Yang et al., 2016).

Unbalance is divided into two as static and dynamic unbalance. Since the axis of the flank does not shift to one side in any way when it is released, static unbalance is zero. Dynamic unbalance can vary depending on the angular position and angular speed. The unbalance effect was examined by rotating the axis of the flank at different speeds. After the curve fitting studies, it was seen that the change in the unbalance current depending on the angular position in the axis of the flank was too low to be considered significant. The unbalance model was created by creating the unbalance current polynomial depending on the angular speed (Poyrazoğlu, 2017; Çetinyol, 2023).
Figure 4 below shows a gyroscope model. Since the bandwidth of the gyroscope used was very high, a lowpass filter was not used (Tezgelen, 2020). Angular speed data from the gyroscope was recorded without giving any command to the gimbal system. The gyroscope noise was calculated by taking the standard deviation of this angular speed. The gyroscope delay was determined in the optimization studies of the dynamic model of the system designed in Matlab/Simulink (Baskın et al., 2017).

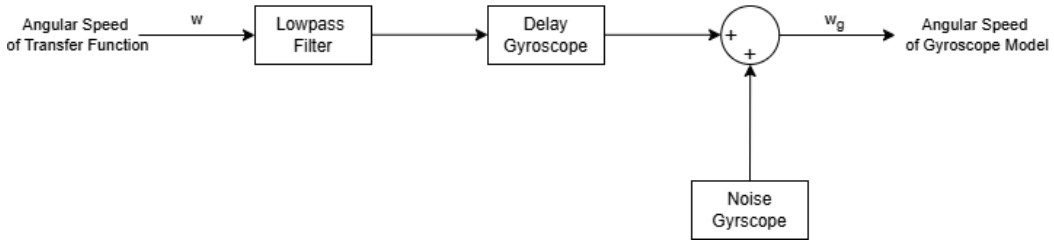

Figure 4. Gyroscope modelling representative.

The dynamic model in this study was implemented in MATLAB/Simulink using a fixed-step discrete solver (with no continuous states) at a sampling frequency of 1000 [Hz].

Findings

In Matlab/Simulink, sine sweep current waves with different amplitudes used for system identification were applied as input to both linear and nonlinear dynamic models of the gimbal system's azimuth axis, and the angular speed values in the gyroscope model were obtained (EstimationData). After the sine sweep current waves with different amplitudes applied to the real system were applied, the angular speed values read from the gyroscope were compared (RealData). According to Table 2 below, it is seen that the success of the linear system model decreases by half at different amplitudes, while the success of the nonlinear gimbal model is high at different amplitudes.In Figure 5 below, the similarity between the response of the real system and the response of the simulation model to the sine sweep signal with a current amplitude of 4.8 [A] is calculated to be approximately 95%.

Table 2. Comparison of Linear and Nonlinear Modelling.

Test No	Amplitude [A]	RMS Accuracy Linear Modelling	RMS Accuracy Nonlinear Modelling
1	2.4	46.3199	85.6004
2	3	61.2113	87.4529
3	3.6	78.5073	92.6000
4	4	85.3936	94.2643
5	4.8	88.3749	95.0356

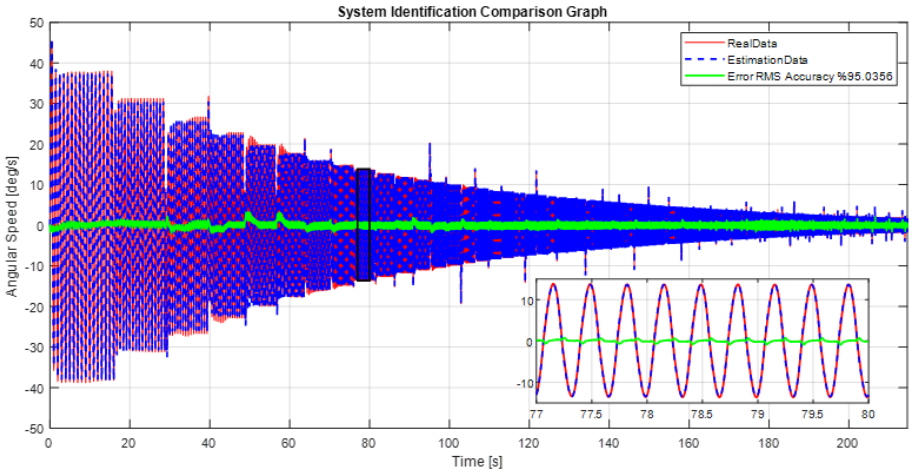

Figure 5. Comparison of Real and Simulation systems.

Conclusion

As a result of this study, linear and nonlinear gimbal system dynamic models were created in Matlab/Simulink. Current commands consisting of sine sweep waves with different amplitudes were applied to these simulation models and angular speed data were obtained. The same tests were performed on the real system and angular speed data were obtained from the gyroscope. It was observed that linear modeling could be applied quickly, but modeling success was low. It was observed that nonlinear modeling could take time because nonlinear parts needed to be created with controlled tests, but modeling success was high. In future studies, control algorithms can be developed in a simulation environment without real system.

Keywords: Ballistic Missile , Flight Path Prediction , Range Estimation , Trajectory Analysis.

Aim

The primary objective of this study is to analyze the trajectory and acceleration characteristics of a medium-range ballistic missile through detailed design and simulation. By accurately modeling the missile's dynamic behavior during each phase of flight, the study aims to generate comprehensive trajectory data. This information is essential for the development of ballistic missile-specific tracking algorithms and the precise prediction of impact points, contributing to the enhancement of missile defense systems and overall strategic planning.

Material and Method

This research employs a two-stage propulsion system consisting of three major phases: an initial thrust stage, a sustained thrust stage, and a free-flight (coasting) stage. The missile adheres to conventional aerodynamic design principles, featuring an axially symmetric cylindrical body with a conical nose and swept-shaped fins, ensuring optimized aerodynamic performance. The missile's total initial mass is 22,000 kg, with a tapered fin structure at both the tail and intermediate stages to enhance stabilization during flight and reduce aerodynamic disturbances. The geometric configuration and stage separation sequence of the missile are illustrated in Figure 1.

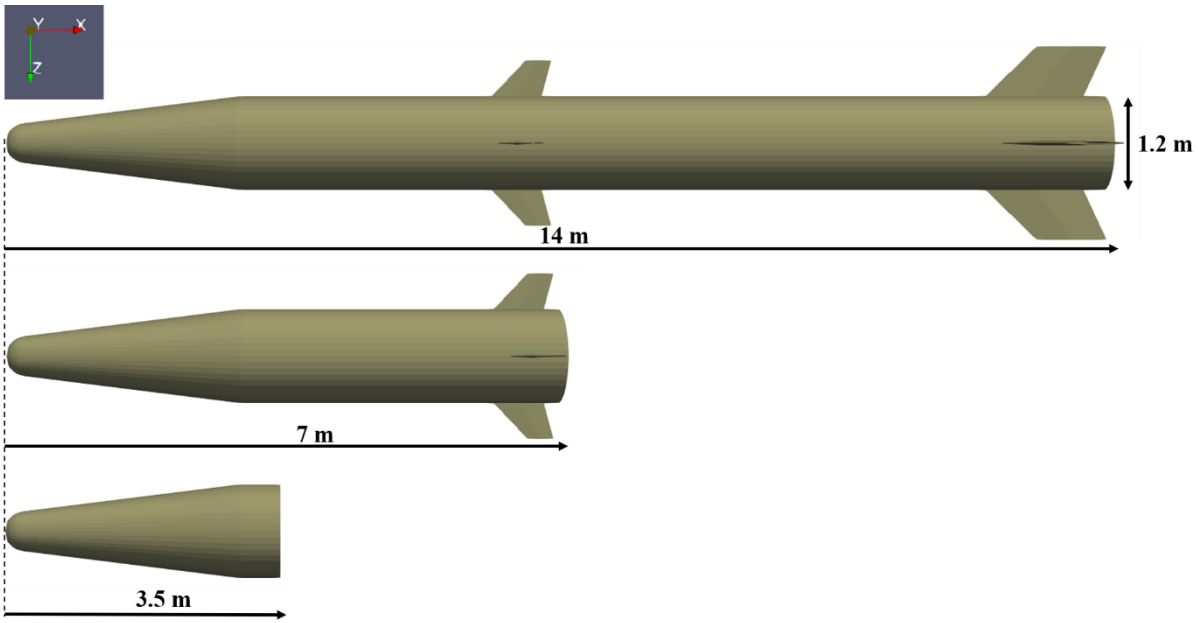

Figure 1. Representation of the three-stage ballistic missile model.

The missile's trajectory is simulated using a six degrees of freedom (6-DOF) model implemented in the MATLAB/Simulink programming environment [3,1]. The aerodynamic coefficients required for the flight simulation are derived from DATCOM software, providing a linearized representation of aerodynamic forces and

moments as functions of Mach number, angle of attack, and sideslip angle. To effectively utilize the aerodynamic coefficients, atmospheric modeling is incorporated to account for variations in air density, temperature, speed of sound, and pressure, which directly impact aerodynamic effects. A standard atmospheric model is implemented to ensure realistic aerodynamic effect estimations as the missile traverses different altitude layers and experiences changing environmental conditions [2].

In addition to aerodynamic modeling, the study incorporates comprehensive force models that account for all significant forces influencing the missile's flight dynamics. The forces considered in this study encompass:

- **Thrust Acceleration:** The missile undergoes a staged solid-propellant propulsion system where thrust is applied during the first and second stages [4]. The initial thrust stage is designed for rapid altitude gain, while the sustained thrust stage extends the missile's range before transitioning into the coasting phase. This ensures optimal fuel efficiency while maximizing range.
- **Gravitational Acceleration:** The simulation includes Earth's gravitational effects, modeled based on the WGS-84 gravitational model to ensure precise force representation throughout the flight envelope [3]. The gravitational pull remains a dominant force, particularly influencing the trajectory during the later stages as the missile ascends to higher altitudes and begins its descent phase.
- **Coriolis Acceleration:** Due to the rotation of the Earth, the missile experiences Coriolis acceleration, which introduces a slight deviation in its trajectory, particularly in the lateral direction at extended ranges [2]. This force becomes more pronounced as the missile reaches higher altitudes and velocities.

Trajectory outputs are expressed in Earth-Centered Earth-Fixed (ECEF) and Latitude-Longitude-Altitude (LLA) coordinate systems, allowing precise analysis and validation of missile behavior. The acceleration effects are extracted for each flight phase to assess their impact on trajectory characteristics and overall missile performance, providing crucial insights into the missile's motion in various operational scenarios.

Findings

The simulation results provide detailed insights into the acceleration effects across different missile stages, as depicted in Figure 2. The findings demonstrate significant variations in acceleration, highlighting the dominant physical forces at each stage of the missile's trajectory.

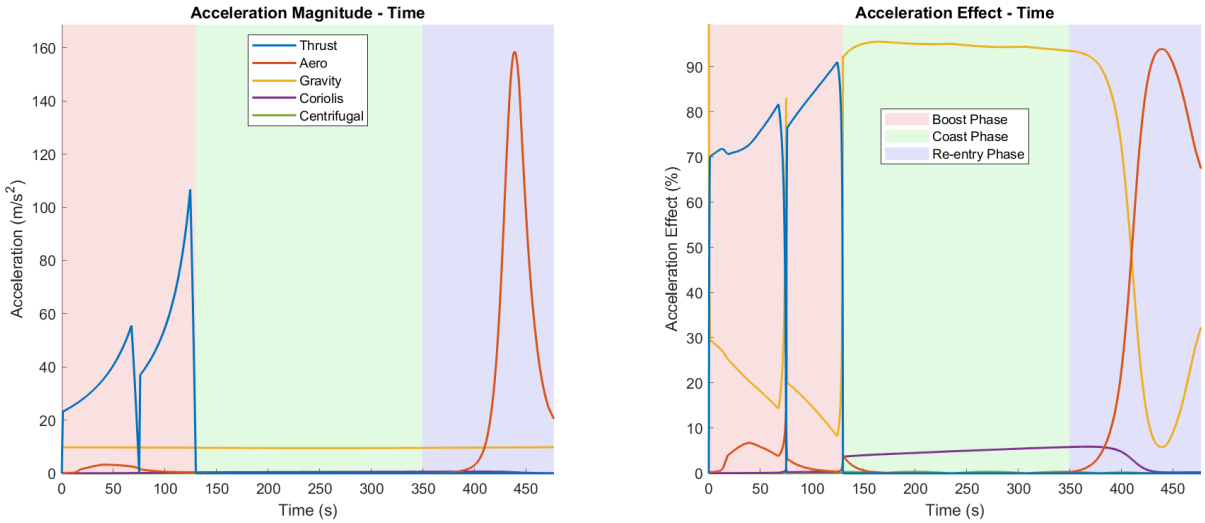

Figure 2. Acceleration effects on the missile at different flight phases.

1. **Initial Thrust Stage:** The first-stage propulsion system generates a rapid increase in acceleration, reaching peak values within the first few seconds after launch. This high acceleration phase is critical for clearing the launch area and overcoming the denser atmospheric layers. The thrust force results in a sharp

increase in net acceleration as the missile consumes fuel. Atmospheric drag is also significant in this phase due to the denser lower atmosphere, contributing to initial velocity fluctuations.

2. **Sustained Thrust Stage:** The second stage is optimized for maintaining energy efficiency while counteracting gravitational deceleration. This stage exhibits a lower thrust force than the initial stage, but as fuel consumption continues, the acceleration effect increases rapidly due to the decreasing total mass of the missile. Atmospheric drag effects diminish at higher altitudes, resulting in improved energy retention.
3. **Coasting (Free-Flight) Phase:** Once the propulsion phases are completed, the missile enters its coasting phase, where no additional thrust is applied. During this stage, gravitational pull predominantly influences acceleration, leading to a gradual reduction in velocity and altitude. Coriolis acceleration exerts a minor influence, particularly on the lateral deviation of the trajectory, affecting the final impact location. This phase is crucial for trajectory estimation, as the missile's motion follows a near-ballistic path. After the start of this phase, the simulations can be conducted primarily by considering gravitational and Coriolis forces until the reentry phase, simplifying computational efforts while maintaining accuracy.
4. **Reentry Phase:** As the missile reenters the denser atmospheric layers, it decelerates significantly due to aerodynamic drag. The acceleration values sharply decrease, highlighting the decline in missile speed and kinetic energy dissipation. During this phase, drag effects dominate, significantly influencing the missile's final descent trajectory and impact parameters. For accurate simulation of this phase, ballistic coefficient estimation or a priori information is crucial to model drag effects accurately. The rapid deceleration observed in this phase is critical in determining impact characteristics and final velocity prior to ground impact. Understanding the drag variations allows for more accurate impact prediction models and enhances the development of defensive countermeasures.

The detailed acceleration data provides a comprehensive understanding of the missile's dynamic behavior, forming a crucial foundation for developing tracking algorithms and trajectory estimation models. The findings reinforce the importance of detailed force modeling and accurate aerodynamic representation in missile trajectory simulations.

Conclusion

This study successfully develops a detailed simulation model of a medium-range ballistic missile, focusing on acceleration effects throughout the flight. The findings highlight the varying contributions of thrust, gravity, Coriolis acceleration, and aerodynamic drag across different flight stages, offering valuable insights into the missile's dynamic response. This study's trajectory and acceleration data are instrumental in refining ballistic missile tracking methodologies, improving impact point prediction accuracy, and enhancing defensive strategies.

Future research can build upon these results to enhance advanced filtering techniques, such as adaptive Kalman filtering and interacting multiple model (IMM) approaches, for real-time trajectory estimation. Additionally, integrating machine learning-based parameter estimation techniques could improve prediction accuracy in missile defense applications. Exploring additional high-fidelity computational fluid dynamics (CFD) simulations could refine drag estimates, improving overall system performance and strategic analysis.

WaveDrive: A Pipeline for Gesture Recognition Using Hands Coordinates

Abdülkerim Sipahi[a], Erdinç Altuğ[a]

[a] Istanbul Technical University, Mechatronics Engineering, Autonomous Vehicles, Türkiye
sipahi22@itu.edu.tr

Keywords: Autonomous Vehicles, Gesture Height, Gesture Recognition, Operator Detection, Pipeline.

Aim

The main aim of this paper is to develop an AI-based medium (WaveDrive) which evaluates the visual feed from a camera to enhance human communication and interaction with autonomous vehicles. The introduced pipeline addresses the problems of specific human operators' detection and precise interpretation of their hand gestures into actionable commands, such as Stop, Go Straight, Go Left, or Go Right. The main motivation behind this work was to improve safety and efficiency during short-term (but continuous) interactions between humans and self-driving vehicles / robots. Dynamic environments which include busy construction sites, smart warehouses, and industrial areas are all scenarios which could be considered when developing solutions in this field of study.
This study addresses a branch of explicit communication between operators and autonomous vehicles. Due to the challenges of getting hold of voice commands in high ambient noise environments, the paper focuses on providing a solution which interprets direct waved gesture messages. This bridges different gaps by providing well-defined communication channels and makes the system more reliable and certain in command generation under complex situations and diverse environmental conditions.

Material and Method

The WaveDrive pipeline is structured into four distinct yet interconnected sequential components: (1) Operator detection, (2) Gesture orientation recognition, (3) Gesture position prediction, and (4) Command generation.
The first 3 AI components required a time-extensive data collection and labelling process which was carefully conducted at Istanbul Technical University's Gümüşsuyu campus parking lot under specific conditions to ensure consistent and controlled lighting conditions. The place selection also focused on introducing different environmental factors to the gathered images in order to add variation and avoid any overfitting while testing the vision models. The photo gathering setup involved positioning volunteers at distances of 3.3 and 4.4 meters from the camera ensuring the inclusion of both fully and partially visible human subjects to simulate realistic operational cases. Volunteers performed a predefined set of gestures wearing reflective vests in two distinct colors (orange and yellow), and images were additionally diversified by including scenarios where participants wore gloves, thereby enhancing the generalizability of the data.
The Faster-RCNN [1] algorithm was implemented on WaveDrive for the operator detection stage training across various dataset combinations to identify operators under various conditions. Faster R-CNN is particularly noted for its two-stage detection process, involving region proposal and refinement, enabling robust operator detection even against complex or cluttered backgrounds.
Later in the pipeline, the large-size YOLOv10 [2] model was installed to recognize robustly the orientation (palm or dorsal sides) of the waived gestures. The selection of this model was particularly due to its well-known capability in detecting small and detailed objects efficiently. It was optimized through training on multiple dataset configurations accounting for variations such as vest colors and glove usage. Both the operator detection and gesture orientation recognition models were trained on visual data which was separated with an 80 percent portion for training versus 20 percent for testing.
The gesture position prediction component employed two duplicate Adaptive Neuro-Fuzzy Inference System [3] (ANFIS) acting in parallel (using threading in Python). ANFIS combines the learning capabilities of neural networks with fuzzy logic's interpretive strength. It decreases the uncertainty making the communication medium more reliable in the interpretation phase. Basically, the pipeline here preprocesses the hand coordinates predicted by the YOLO model to calculate the **magnitude** (Equation 1) and **orientation** (Equation 2) of the vector generated

from the origin of the operator bounding box. Both of those values are fed into ANFIS to predict the positioning of the gestures regarding their sides (left or right hands) and height (high, medium, or low) - 6 combinations. Unlike the earlier models, this component was trained on CSV data which was divided in 70 percent for training and 30 percent for testing.

$$|V| = \sqrt{(x_c^2 + y_c^2)} \quad \text{(Equation 1)}$$

$$\theta = (\frac{y_c}{x_c}) \quad \text{(Equation 2)}$$

Command generation was performed by combining the results from the gesture orientation recognition and position prediction stages. Detected gesture orientations (palm or dorsal) and positions (side and height) were translated into predefined commands (Stop, Go Straight, Go Left, Go Right) using a lookup table that matches specific gesture combinations to their corresponding actions. The predefined lookup table was designed to be flexible with different cultures that might interpret the same gestures with different meanings or need to extend the defined commands.

Findings

The study showed significant improvements in all parts of the WaveDrive pipeline. The Faster R-CNN model had excellent accuracy (mean Average Precision of 0.9091) as in Table 1, reliably detecting operators even in tough environments. The YOLOv10 model also performed very well, achieving a mean Average Precision of 0.99454, clearly distinguishing between back and front (palm and dorsal) hand orientations. Training leveraging dataset collections that included all image variations (different vest colors and gloves usage) generated models with better performance.

mAP@50 is the mean Average Precision at Intersection of Union greater than or equal to 50%.

The ANFIS model achieved an accuracy of 92.43% for gesture position prediction, demonstrating strong performance overall. However, it faced challenges in accurately distinguishing between left and right hands at medium-height elevations, highlighting areas needing further improvement. Figure 1 clearly demonstrates the performance of the model on the test data. (Equation 3 – Equation 8) clearly show the tuned membership functions.

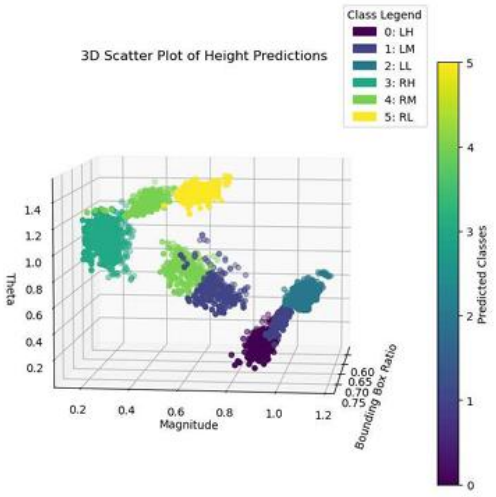

Figure 1. ANFIS Performance Visualization.

$$\mu_{Medium}(|V|) = \frac{1}{1 + \left|\frac{|V| - 0.7595}{0.0960}\right|^{2(1.8740)}} \quad \text{(Equation 4)}$$

$$\mu_{High}(|V|) = \frac{1}{1 + \left|\frac{|V| - 1.0543}{0.0436}\right|^{2(2.2869)}} \quad \text{(Equation 5)}$$

$$\mu_{Low}(\theta) = \frac{1}{1 + \left|\frac{\theta - 0.0352}{0.1362}\right|^{2(1.7634)}} \quad \text{(Equation 6)}$$

$$\mu_{Medium}(\theta) = \frac{1}{1 + \left|\frac{\theta - 0.6949}{0.0732}\right|^{2(1.5228)}} \quad \text{(Equation 7)}$$

$$\mu_{High}(\theta) = \frac{1}{1 + \left|\frac{\theta - 1.4723}{0.0633}\right|^{2(2.1177)}} \qquad \text{(Equation 8)}$$

Testing the integration (Figure 2) both outdoors (Figure 3) and indoors (Figure 4.) under different lighting conditions confirmed the effectiveness of WaveDrive pipeline, with outdoor tests showing better overall performance due to more favorable lighting conditions and to specifically collecting the images before at external environments. Gestures were better recognized at closer distances, while there was slight variability at longer distances due to less stable bounding box predictions. Additionally, wearing gloves improved recognition performance, providing clearer visual distinctions and better accuracy overall.

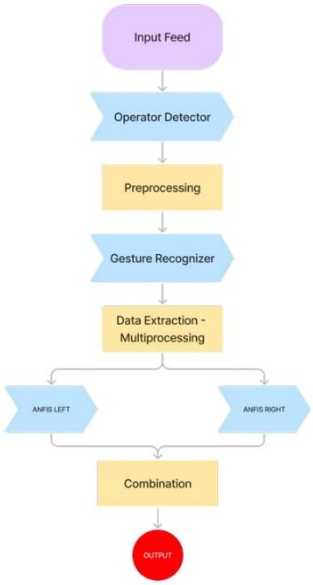

Figure 2. WaveDrive Flowchart .

Figure 3. Outdoor Standalone Testing.

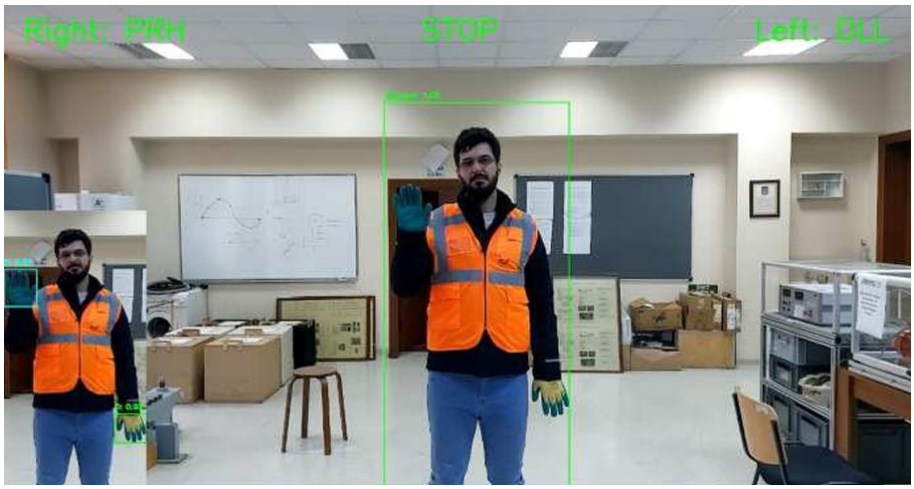

Figure 4. Indoor Standalone Testing.

Conclusion

The WaveDrive pipeline constitutes a significant advancement in autonomous vehicle communication through gesture-based systems. The pipeline is able to deal with real-world nuances in gesture recognition by integrating robust computer vision and deep learning technologies. This paper conclusively demonstrates the pipeline's capability to accurately recognize operators consistently, identify gesture orientation correctly, and predict gesture location accurately.

The robustness of WaveDrive in various test conditions is indicative of its usability and reliability in real-world application and is a giant leap towards universal application of gesture-based communication systems. However, the system's small deficiencies at longer ranges suggest future scope for improvement. Future research can focus on improving the flexibility of the system for more complex, dynamic, and uncontrolled environments, enhancing real-time computation performance, and further improving optimized hardware solutions to increase the usability of WaveDrive in a broad spectrum of industrial and safety-critical applications. It can also focus on studying dynamic gestures instead of static postures of operators.

Lastly, this study provides a tangible foundation for propelling explicit gesture-based interactions towards safer and more effective human-vehicle interaction, potentially transforming operational practice across different industry sectors.

A Study on the Performance of GNN, PDA, and JPDA in a ROS-Based Tracking Framework

Nurettin Özçelik[a], Volkan Sezer[b]

[a] Istanbul Technical University, Graduate School, Mechatronics Engineering Program, Smart and Autonomous System Laboratory (SASlab), Türkiye
[b] Istanbul Technical University, Faculty of Electrical and Electronics Engineering, Department of Robotics and Autonomous Systems Engineering, Smart and Autonomous System Laboratory (SASlab), Türkiye
ozcelikn22@itu.edu.tr

Keywords: Data Association, Kalman Filter, Mobile Robot, Multi-Target Tracking.

Aim

Robots in dynamic areas must detect and track moving and static objects like people, enabling tasks like guidance or patrol. Multi-target tracking involves estimating number of objects and maintaining a distinct track for each, typically including an ID and state such as position and velocity. A multi-target tracking system follows a repeated cycle (Blackman & Popoli, 1999) that processes sensor measurements and updates object tracks over time, as illustrated in Figure 1. It starts by converting raw data from sensors into usable observations such as bounding boxes. After that, data association module matches these observations to existing tracks, with gating used to remove unlikely matches. Track creation and deletion are handled by a track management component, while a prediction step estimates future positions for next round of associations.

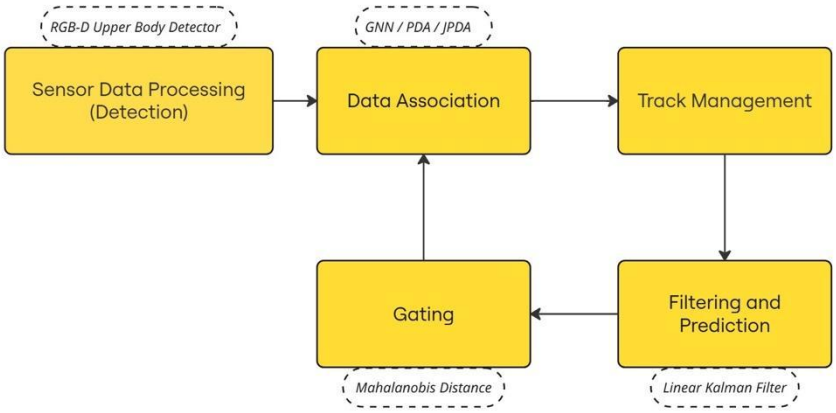

Figure 1. Block diagram illustrating the general structure of a conventional multi-target tracking system, along with its specific implementation details in this study.

During data association, various ambiguities may occur. As shown in Figure 2, measurements Z_4 and Z_5 fall within the gating regions of both targets T_1 and T_2, leading to assignment uncertainty. Target T_1 contains multiple measurements within its gate, creating ambiguity in selection. T_3 has an empty gate, raising possibility of occlusion or leaving scene. Meanwhile, Z_1 falls outside all gates and may indicate clutter or a new target. To address these challenges, a variety of data association strategies can be employed—from simple approaches like Global Nearest Neighbor (GNN) (Konstantinova et al., 2003) which selects the closest matching observation, to more advanced probabilistic methods such as Probabilistic Data Association (PDA) (Bar-Shalom et al., 2009) and Joint Probabilistic Data Association (JPDA) (Bar-Shalom et al., 1991), which perform soft assignment by distributing the influence of each measurement across multiple potential tracks based on their likelihood.

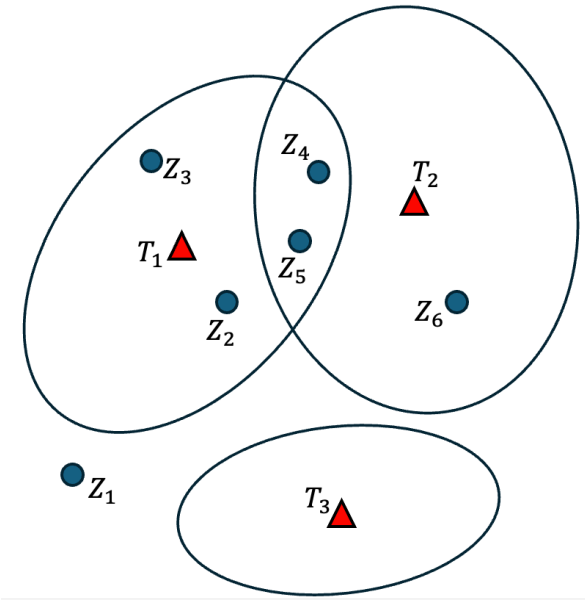

Figure 2. Illustration of typical data association ambiguities in multi-target tracking.

The relevance of comparing GNN, PDA, and JPDA has also been emphasized in prior work on multi-vehicle tracking (Buluttekin et al., 2017), where the authors evaluate these algorithms using a two-vehicle scenario and demonstrate the robustness of JPDA in cluttered environments. Our study aims to implement and compare these three algorithms in a simulation environment built with ROS and Gazebo, where sensor inputs, robot motion, and human movement can be modeled. By evaluating their performance under controlled yet practical scenarios, the goal is to better understand the characteristics and limitations of each approach in the context of mobile robots performing tasks such as person following.

Material and Method

The decision of which measurement should be used in the correction step in Kalman filter is handled by the data association algorithm. The first method considered in this study is GNN, which constructs a cost matrix where each entry represents Mahalanobis distance between a predicted track state and a measurement within its gating region. In the implementation, a large constant value (e.g., 999) is assigned as the cost for the measurement that falls outside the gate. A globally optimal assignment between tracks and measurements is computed using linear assignment algorithms such as Hungarian, Auction, or JVC (Crouse, 2016), which is used in this implementation. The global optimality of the result is ensured by the constraint that each measurement can be assigned to at most one track, and each track to at most one measurement.

PDA algorithm, originally developed for single-target tracking, computes the posterior probability that each measurement within the gate is the true measurement of the target, along with the probability that none of them is correct. These probabilities are then used as weights for the corresponding innovations in the Kalman filter update. As a result, all gated measurements contribute to the correction step, proportionally to their likelihood. PDA operates under a key assumption: there exists only one true target in the cluttered scene, and all other measurements are considered to be false alarms.

JPDA is designed to handle multiple targets simultaneously. It constructs a validation matrix, where each element is set to 1 if the corresponding measurement falls within the gating region of a given track. Based on this matrix, all valid joint association hypotheses are generated. Feasible associations are those that satisfy the one-to-one assignment constraint used in GNN. The probability of each joint hypothesis is then computed based on the likelihoods of individual associations. Finally, marginal association probabilities—such as the probability of assigning measurement Z_1 to track T_2—are obtained by summing the probabilities of all joint hypotheses that include that specific assignment. The innovation weighting step follows the same procedure as in PDA. As a consequence, JPDA accounts for the possibility that a shared measurement may originate from another target,

rather than treating it as clutter. For both PDA and JPDA implementations, the probability of detection $P_D = 0.8$, the probability that the true measurement lies within the gating region $P_G = 0.95$, and the spatial clutter density $\lambda = 0.05$ were used to compute association probabilities.

For comparison purposes, all data association algorithms were implemented as Python scripts in ROS, sharing a common structure for track initialization, deletion logic, and filtering. The SPENCER framework (Linder et al., 2016) serves as the baseline, providing message definitions, detection module (upper-body detector), RViz visualization plugins, and an OSPA metric (Ristic et al., 2011) calculator for performance evaluation. The experiments are conducted in the Gazebo simulation environment using an Ackermann-type mobile robot similar to the MIT Racecar. The robot model, described in URDF and derived from a SolidWorks design based on real-world dimensions, is equipped with a 2D LiDAR and a stereo camera. For human models, Gazebo actor plugin, which allows for scripted movement, is used. Ground truth positions of them is available through Gazebo. The simulation environment is based on the "Hospital World" provided by AWS RoboMaker, as shown in Figure 3.

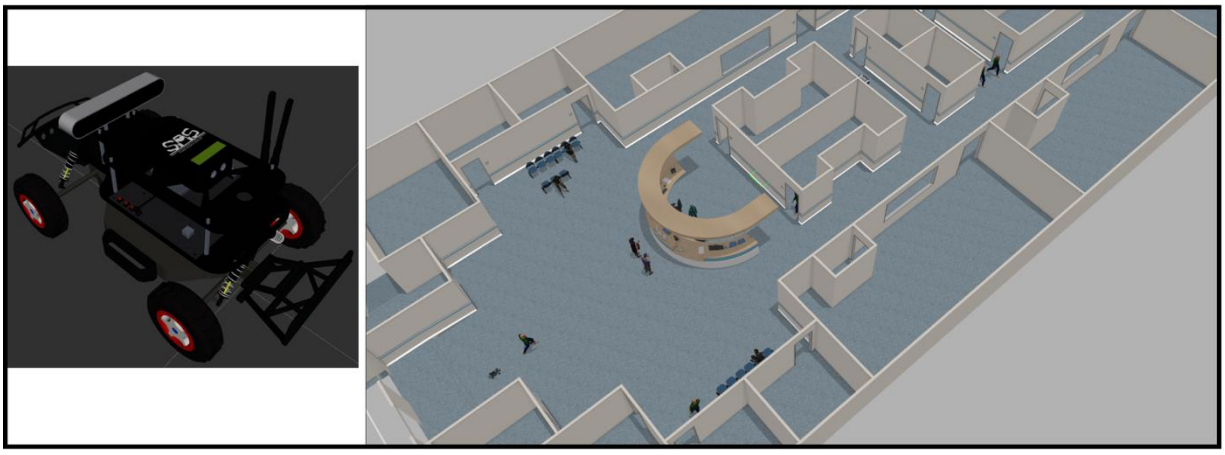

Figure 3. Left: Mobile robot used in the study. Right: Gazebo world for scenario.

A nearly constant velocity motion model was used to predict the state of each track. The state vector is defined as $x = [x, y, v_x, v_y]^T$ representing the 2D position and velocity of a tracked object. The state transition matrix F used in this model is defined in Equation (1) while the process noise is modeled as zero-mean Gaussian noise with covariance Q, given in Equation (2). Δt denotes the time interval between two consecutive tracking cycles. The measurement model observes only the 2D position, and the measurement noise covariance R is a diagonal matrix with all entries set to 0.05. For all three data association algorithms, the process noise level was set to $q_L = 0.1$.

$$F = [1\ 0\ \Delta t\ 0\ 0\ 1\ 0\ \Delta t\ 0\ 0\ 1\ 0\ 0\ 0\ 0\ 1\ ] \quad (1)$$

$$Q = \left[\frac{\Delta t^3}{3}\ 0\ \frac{\Delta t^2}{2}\ 0\ 0\ \frac{\Delta t^3}{3}\ 0\ \frac{\Delta t^2}{2}\ \frac{\Delta t^2}{2}\ 0\ \Delta t\ 0\ 0\ \frac{\Delta t^2}{2}\ 0\ \Delta t\right] q_L \quad (2)$$

After each data association step, every unmatched measurement is used to initiate a tentative track. If a tentative track is updated with a measurement in 10 separate steps, it is promoted to a confirmed track. Conversely, if it remains unmatched for 20 consecutive steps, it is deleted. A similar timeout rule is applied to confirmed tracks, but with a longer threshold of 40 steps. When probability that none of the measurements are correct is greater than %95 for a track, the track is flagged as missed in JPDA implementation.

Findings

The test scenario, as illustrated in Figure 4, was designed to evaluate the performance of data association algorithms under realistic and challenging tracking conditions. In this setup, the robot is manually driven to follow a single target person. Other people occasionally enter the scene, causing temporary occlusions of the tracked person. In some cases, two people walk side by side in close proximity, increasing the likelihood of measurement

ambiguity. Furthermore, new individuals enter and exit the environment over time, resulting in dynamic variations in the number of targets.

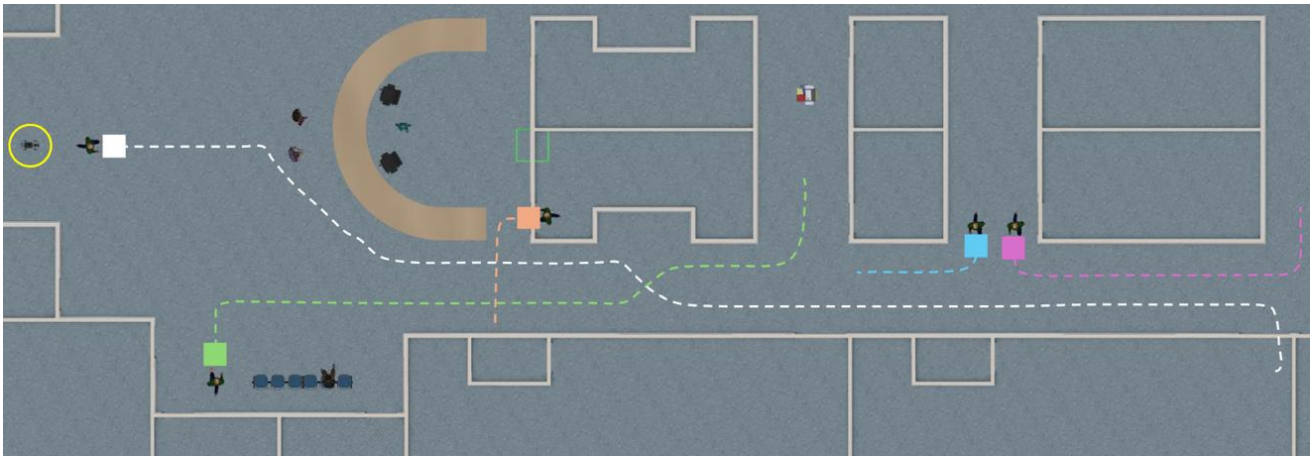

Figure 4. Path of each moving person in the scenario. Squares are starting points and yellow circle contains mobile robot.

The human actors in the simulation mostly moved at a constant speed of approximately 0.75 m/s. To ensure a fair comparison across different data association algorithms, the scenario was executed once and recorded as a ROS bag file. During evaluation, this bag file was replayed for each algorithm, allowing all methods to operate under identical sensor inputs and environmental conditions and the tracking output displayed in Rviz, as demonstrated in Figure 5. The system operated at 10 Hz.

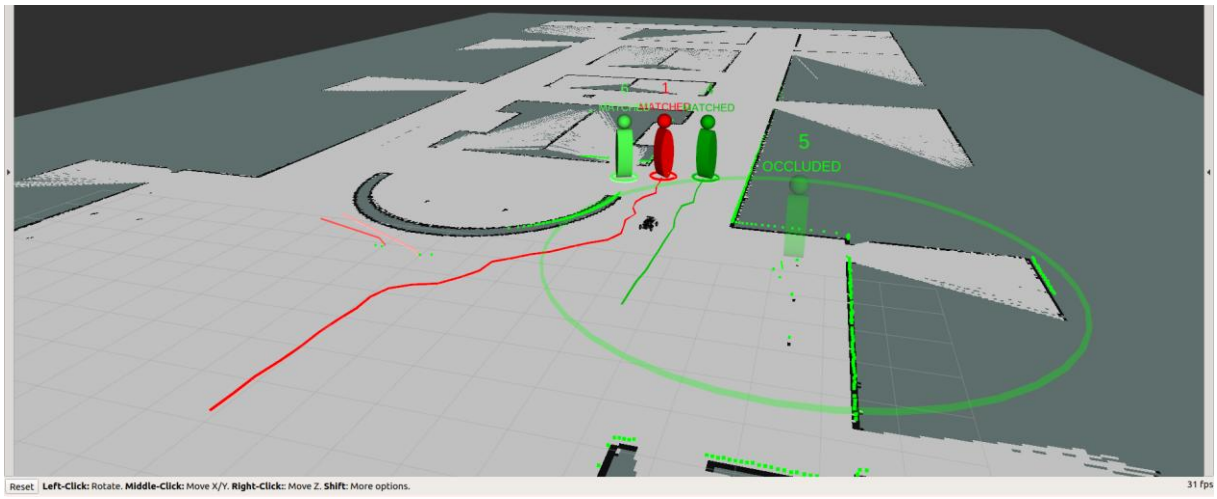

Figure 5. Visualization of tracking results in Rviz.

For performance evaluation, the Optimal Sub-Pattern Assignment (OSPA) metric was used. OSPA is well-suited for multi-target tracking tasks, as it jointly captures three types of errors: localization error, cardinality error, and labeling error. Localization error measures the spatial distance between correctly matched estimated and ground-truth targets. Cardinality error penalizes the mismatch in the number of estimated versus true targets, reflecting missed or false tracks. Labeling error, on the other hand, accounts for identity switches—cases where the associations between tracks and targets are inconsistent over time. For each time step, OSPA is calculated for each method with parameters $p = 1$ (order), $c = 0.5$ (cut-off distance), and $a = 10$ (cardinality penalty). All results represent the mean of OSPA scores computed over the full tracking sequence. Lower values indicate better performance in terms of tracking accuracy and identity consistency.

As summarized in Table 1, GNN and JPDA yielded similarly low OSPA distances, while PDA performed significantly worse with an OSPA of 0.907. The high cardinality and localization errors observed in PDA stem from its inherent assumption of single-target tracking as outlined in Material and Method section. PDA also exhibited wrong measurement-track association during the last part of the scenario. When two individuals walked in close proximity, the track's estimated position shifted to the middle of them, and once they separated, the tracker began updating its state using measurements from the wrong person—once again, a direct consequence of the single-target assumption. In contrast, both GNN and JPDA maintained multiple tracks and consistently achieved reliable measurement-to-track associations throughout the scenario. Although JPDA is theoretically better equipped to handle ambiguous cases—such as the persistent interference caused by closely spaced targets—no substantial advantage was observed over GNN in this scenario. This can be attributed to the relatively clean nature of the scenario: even when targets approached each other, they rarely shared a common measurement within their validation gates. One contributing factor may be due to the absence of externally added clutter and the fact that human actors moved at nearly constant velocities, closely aligning with the assumptions of the motion model. The similarity in performance suggests that under controlled conditions with limited measurement ambiguity, even simple methods like GNN can perform comparably to more complex probabilistic approaches such as JPDA.

Table 1. OSPA metric results for three data association algorithms.

Algorithm/Metric	GNN	PDA	JPDA
OSPA Distance	0.284	0.907	0.291
Localization Error	0.153	0.450	0.159
Cardinalization Error	0.131	0.499	0.132
Labeling Error	0.0	0.008	0.0

Conclusion

This study presents the implementation and evaluation of three data association algorithms—GNN, PDA, and JPDA—within a ROS-based tracking system, tested in a Gazebo simulation environment. The complete tracking pipeline was developed in Python, including track initialization, deletion logic, Kalman filtering, and association strategies. A realistic test scenario was designed where the robot followed a human while interacting with other moving individuals. The results highlight the importance of algorithm selection based on scenario complexity, showing that even simple methods like GNN can perform comparably to more complex approaches under structured conditions.

Future work may involve testing the system under more challenging conditions by introducing manually generated clutter without significantly increasing false positives. Additionally, defining an association confidence metric could enable dynamic switching between algorithms like GNN, JPDA, or suboptimal nearest neighbor within a hybrid framework.

Keywords: Genetic Algorithm, PID Controller, Steer-by-Wire.

Aim

Steer-by-wire (SbW) systems is an important change in vehicle steering technology by replacing the mechanical linkage between the steering wheel and the wheels with a fully electronic system including sensors, actuators, and control units. This transformation not only allows for advanced vehicle design flexibility, weight reduction and lower center of gravity, but also allows new possibilities in vehicle safety, automation, and adaptive control. The first objective of this study is to model a steer-by-wire system using MATLAB/Simulink and to design an optimal PID controller to regulate steering performance based on a time-domain performance metric. With this, the mechanical link between the steering wheel and wheel response is entirely removed, and control is performed electronically.

A secondary objective of the research is to assess the robustness of the proposed control system under varying levels of steering torque and vehicle speed. By investigating these operating conditions, the study provides insights into the resilience and adaptability of the SbW system and find areas where additional improvements might be needed.

Material and Method

The modeling process starts with a detailed breakdown of the main components of a steer-by-wire system, all of them were identified and showed in a Simulink-based environment. The key hardware elements include the steering actuator, torque and angle sensors, an electronic control unit (ECU), and a force feedback motor that simulates the road feel to the driver . These components are interconnected via high-speed communication protocols such as CAN or FlexRay and function together to transform driver input into appropriate wheel movements.

The developed steer-by-wire model, which is given in Figure 1, simulates the transformation of the driver's torque input into actual wheel movement through a sequence of physical and control-based components. The input torque signal is first converted into angular acceleration using the system's moment of inertia and damping coefficient. This acceleration is then integrated to obtain angular velocity, and subsequently integrated again to yield the steering wheel angle. This calculated angle is fed into MATLAB's built-in steering block, which models the vehicle's dynamic response and outputs the corresponding target wheel angle. This target angle is then used as a reference input for the controller. The output of the controller determines the required rotation of the motor in order to achieve the desired wheel deflection. This motor command passes through a coefficient that represents the rack-and-pinion conversion ratio, indicating how many degrees the motor must rotate. The resulting command is fed into the DC motor model, and after passing through the same mechanical coefficient again, the resulting actual wheel angle is obtained and compared against the reference for feedback control.

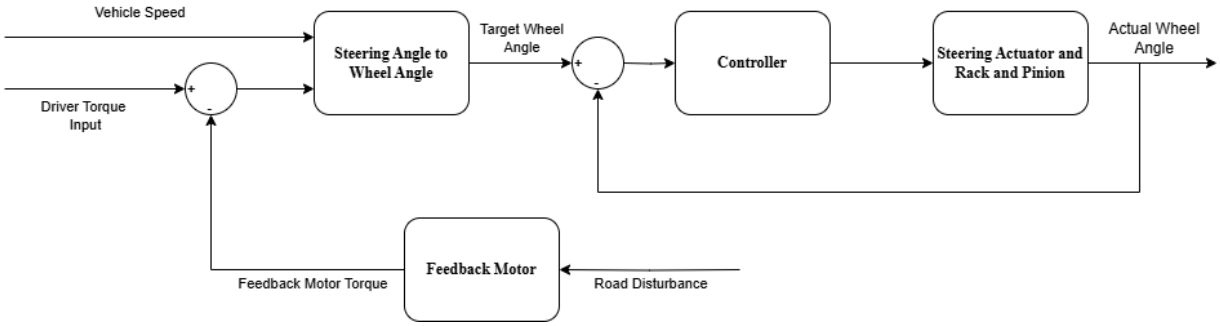

Figure 1. Block Diagram of the Designed Steer-by-Wire System Architecture.

A disturbance signal is used to simulate external effects such as road irregularity, potholes and cracks. Then the disturbance signal is fed to the feedback motor, where the wheel angle error is converted into the amount of torque required to simulate the same degree to the steering wheel. After that, the torque value is summed with the driver's torque input, the final net torque is fed to the system.

The force feedback motor is modeled using parameters such as motor inertia, damping coefficient, torque constant, and gear ratio, adapted from literature (Marouf et al., 2012). The system dynamics for the motor are captured using a second-order differential equation that represents its electromechanical behavior. The steering actuator is modeled similarly, converting electrical control signals into mechanical angular displacement (Mohamed et al., 2014).

For the control system design, PID controller was designed due to its well-known effectiveness in time-domain tracking and ease of implementation. The transfer function is given in Equation 1:

$$C(s) = K_p + \frac{K_i}{s} + K_d s \quad (1)$$

where Kp, Ki and Kd denote the proportional, integral and derivative gains, respectively. To prevent high-frequency noise amplification from the derivative term, a first-order low-pass filter is applied after differentiation. This filtering is implemented in Simulink using a transfer function block. The PID controller parameters is tuned using a Genetic Algorithm (GA) to optimize control system performance.

The cost function for optimization is based on the Integral of Time-weighted Absolute Error (ITAE), which penalizes prolonged errors more severely and improves system response smoothness by reducing oscillations. This is given in Equation 2,

$$ITAE = \int \quad t|e(t)|dt \quad (2)$$

where e(t) is the error signal and t is the simulation duration. ITAE increases the penalty for errors that persist over time.

One of the key advantages of using a GA for PID tuning is its ability to avoid local minima and effectively explore a wide solution space, which is particularly beneficial when optimizing nonlinear or complex systems (Xu et al., 2019; Załeski & Szczepanik, 2024).

The GA-based optimization is implemented within Simulink using MATLAB's Global Optimization Toolbox. The population size, mutation rate, crossover fraction, and generation limits are selected based on a trade-off between optimization time and solution accuracy, flow chart is given in Figure 2. This GA setup follows a real-coded, elitist configuration with stochastic uniform selection and intermediate crossover, in accordance with standard practices in control optimization (Dastanpour et al., 2014).

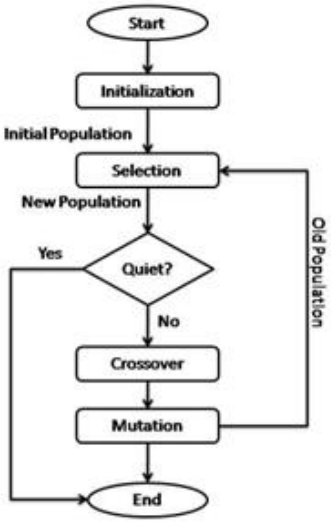

Figure 2. Genetic Algorithm Flow Chart (Dastanpour et al., 2014).

After the optimal PID gains for 50 kph vehicle speed and maximum of 10 Nm driver torque input are obtained, they are tested under a variety of input scenarios, including step and ramp steering inputs, varying speed profiles, and torque disturbances.

Findings

The complete SbW model in Simulink was successfully implemented with actuator behavior and vehicle steering response. Initial results from the PID controller tuned with GA showed acceptable performance under nominal conditions. Figure 3 shows the control system response using the GA-tuned PID controller. The GA-tuned PID controller achieved fast settling times, minimized overshoot, and minimal ITAE metric. Specifically, under constant-speed conditions, the controller maintained accurate tracking of the desired steering angle, even in the presence of moderate external torque disturbances. However, the optimal PID controller struggled to maintain stability when high external torque disturbances or rapid input changes were introduced. Overshoot and oscillations were particularly noticeable during abrupt steering maneuvers or low-speed parking conditions where steering sensitivity is higher.

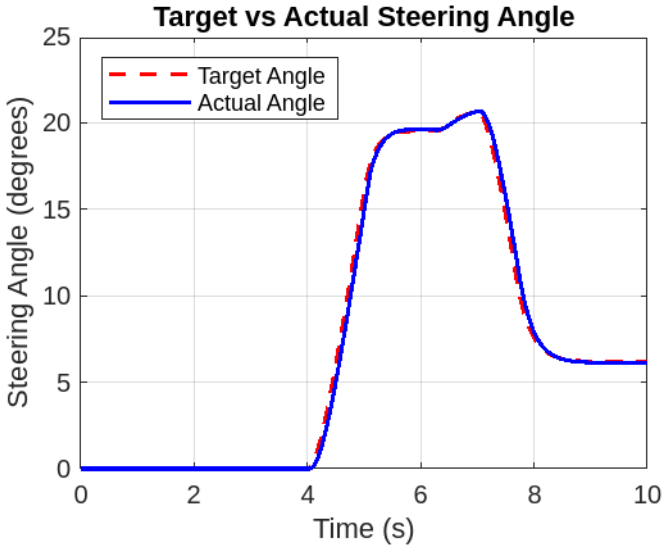

Figure 3. The responses of target and actual wheel angles using GA Tuned PID.

A series of robustness tests were conducted to evaluate how the control system performs when subjected to varying vehicle speeds and applied torques. The simulations demonstrated that speed changes had minimal impact on the system's performance, indicating a very effective way of robustness with respect to vehicle velocity. However, when the applied steering torque was significantly altered (such as during emergency maneuvers or aggressive cornering) the system's response began to degrade. This was realised through increased settling times and higher overshoot in the steering angle output. This control system response is illustrated in Figure 4.

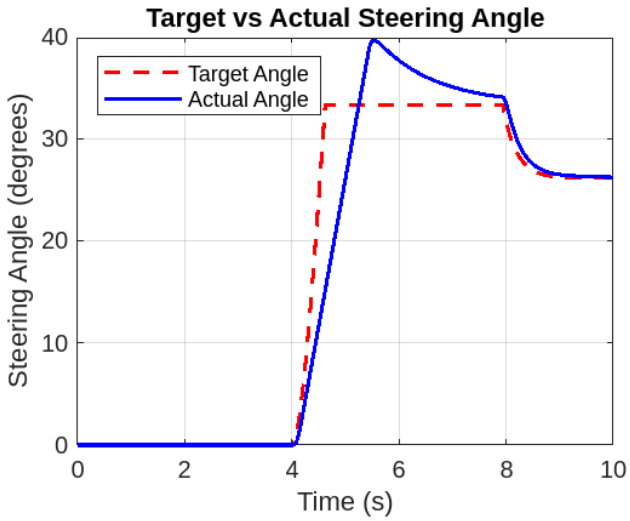

Figure 4. System Response Under High Torque Input.

Conclusion

This study successfully shows the development and control of a steer-by-wire system in a MATLAB/Simulink environment using a GA-tuned PID controller. The simulation results confirm that GA-based tuning offers good performance under nominal torque input, particularly in terms of minimizing error metrics and improving time-domain response.

The results also show an important limitation: while speed variations have negligible effect on control performance, torque inputs are still a problem for fixed-gain PID controllers. This finding suggests that implementing adaptive control strategies (such as gain scheduling based on torque magnitude or adaptive models) could significantly enhance system robustness.

These observations align with previous findings in the literature, which suggest that PID controllers, while effective in linear and nominal cases, may require adaptive or nonlinear control enhancements to perform well under highly dynamic or uncertain operating conditions (Tumari et al., 2017; Sun et al., 2016). The limitations of fixed-gain PID control in the presence of rapidly changing torque inputs highlight the need for future work in the area of adaptive gain scheduling or model-predictive control techniques.

Future work will explore the integration of vehicle-speed-dependent steering ratios to enhance low-speed maneuverability and high-speed stability.

Keywords: Polymer Composites, Polypropylyne, Reduced Graphene Oxide, Talc.

Aim

Due to their low density, low cost, ease of processing, and good chemical resistance, polymers are widely used in engineering applications (Kovacs & Suplicz, 2013). The demand for synthetic polymers in the automotive and aviation sectors has increased in recent years. Polyethylene, polypropylyne (PP), polycarbonat and polyamide are commonly used for inner, exterior and other functional parts for these areas (Lapcik et al., 2008). Among these polymers, polypropylene (PP) stands out due to its excellent moldability, mechanical properties, low cost and high recyclability making it widely used . Talc is generally used as reinforcement filler for PP because of its low cost and suitable flaky particle morphology (Kinoshita et al., 2023). Its content has magnesium silicat and its general chemical formula is $Mg_3Si_4O_{10}(OH)_2$ (Castillo et al., 2013). In recent years researchers focus on reinforced polymers with nano materials instead of commonly used fillers like talc. These materials are generally carbon-based materials. Carbon nanotups, carbon nanofibers, graphene and graphene-based materials such as graphene oxide (GO) and reduced GO (rGO) can be given as examples of carbon-based nano fillers. Graphene and graphene-based materials are gaining attention due to superior mechanical, thermal and electrical properties (Ghasemi et al., 2016). This study aims to investigate the effect of using talc and graphene-based additives in a hybrid form on the properties of PP.

Material and Method

In this study, PP (SABIC PP 595A, SABIC, Saudi Arabia) has chosen for main matrix, talc (RoseTalc RT-G 15, Gülmer, Turkey) and rGO (Aerofen, Turkey) have chosen for filler. Firstly, the material containing 10 wt. % rGO was prepared by Aerofen using a twin-screw extruder with stage temperatures of 50-140-145-150-160-180 °C. Then, the material containing 20 wt. % Talc was prepared by Farplas using a twin-screw extruder with stage temperatures of 50-185-190-200-205-210-220-225-225-230 °C. The prepared mixtures were then blended at 200 °C and 100 rpm using a 35 g capacity melt mixer to produce the PP/Talc18/rGO1 and PP/Talc16/rGO2 materials. The weight percentages of the components in the PP composites are provided in Table 1.

Table 1. The weight percentage composition of the materials.

Material	PP (%)	rGO (%)	Talc (%)
PP	100	0	0
PP/Talc20	80	0	20
PP/rGO10	90	10	0
PP/Talc18/rGO1	81	1	18
PP/Talc16/rGO2	82	2	16

To characterize the prepared composites and investigate their properties differential scanning calorimetry (DSC), thermal gravimetric analysis (TGA), Fourier transform infrared spectroscopy (FTIR), tensile and impact tests were performed. DSC test was carried out with Perkin Elmer DSC 4000 in a nitrogen atmosphere at a heating rate of 10°C/min, in the temperature range of 25-200 °C. TGA was conducted with Perkin Elmer TGA 4000 at a heating rate of 10°C/min from ambient temperature up to 550 °C in a nitrogen atmosphere to examine the thermal stability and degradation. FTIR was used to analyze the functional groups of the materials with Perkin Elmer Spectrum Two in the wavelength range of 650-4000 cm^{-1}. Tensile strength and elongation values were determined by the tensile test according to ISO 527. Impact testing was performed with a notched Charpy analysis according to ISO 178. Mechanical test specimens, including dog-bone (for tensile analysis) and flat bars (for impact analysis), were prepared using hot pressing at 200°C.

Findings

As a result of the DSC analysis, the melting points for PP, PP/Talc20, PP/rGO10, PP/Talc18/rGO1 and PP/Talc16/rGO2 were found to be 167.4, 167, 166.24, 165.3 and 165.61°C, respectively. It has been observed that no significant change in the melting temperature (T_m) occurred, as the crystal form of PP remained unchanged and Tm is solely dependent on its crystal structure (Patra et al., 2022). According to the TGA results shown, PP shows degradation in a single step (Bajsić et al., 2012). It can be said that the addition of talc and rGO separately increases the degradation onset temperature. In the mixtures containing both fillers, this value shows an increase compared to the neat PP. When examining the FTIR analysis, unlike the groups present in the neat PP matrix, the PP/Talc20, PP/Talc18/rGO1 and PP/Talc16/rGO2 mixtures show a Si-O-Si bond at ~1014 cm^{-1} and an OH deformation at ~670 cm^{-1} (Linares et al., 2019). The mechanical properties of the composites were investigated using the prepared dog-bone and flat bar specimens. Looking at these analyses the results showed that, following the tensile analysis, the tensile strength of the PP/Talc16/rGO2 mixture was found to be higher than the others. The tensile strength of PP/Talc16/rGO2 showed a 10.96% increase compared to neat PP. This higher value can be attributed to the synergistic effect of talc and rGO in the mixture (Mehrjerdi et al., 2013). Looking at the Charpy Notched Impact test results, it is observed that the impact resistance decreases with the addition of talc. The platelet-like structure of talc and its ability to increase crystallinity contribute to an increase in rigidity, which consequently leads to a reduction in impact resistance (Ammar et al., 2017). In addition rGO exhibits an increase in impact resistance due to its interfacial compatibility and hierarchical structural formation capability but its impact may vary depending on the content percentage (Xie et al., 2021).

Conclusion

This study investigate the effects of hybrid additives (talc and rGO) on the properties of PP. According to the DSC analysis, no significant change in the melting points was observed. The TGA analysis showed that the addition of these hybrid additives resulted in an increase in the initial degradation temperatures of the composites, suggesting

improved thermal stability. Based on the tensile test results, the PP/Talc16/rGO2 mixture exhibited the highest tensile strength, showing a 10.96% increase compared to neat PP. It was also observed that the impact resistance decreased with the addition of fillers.

Keywords: Mechanical Properties , Nanocomposites , Polypropylene , Reduced Graphene Oxide , Thermal Stability.

Aim

Polymer composites are widely used in various industries such as aerospace, automotive, and defense due to their high specific modulus and specific strength properties. These materials offer advantages such as reduced fuel consumption owing to their low density and can be easily processed into complex geometries using conventional manufacturing methods (Du & Cheng, 2012; Hsissou et al., 2021). Graphene oxide (GO) plays a crucial role as a filler material in nanocomposites due to its high surface-to-volume ratio, excellent dispersibility in both aqueous and organic solvents, and extensive reactive surface functional groups, which facilitate strong interactions with polymer matrices. These properties prevent aggregation, improve processability, and strengthen interactions between fillers and polymers (Compton & Nguyen, 2010). Furthermore, the superior mechanical properties of GO, such as its high Young's modulus and tensile strength, contribute to the enhancement of mechanical performance in polymer composites (Abdullah & Ansari, 2015). GO contains oxygen functional groups such as hydroxyl, epoxy, and carboxyl, which readily interact with polymer matrices (Phiri et al., 2017). These functional groups enhance the compatibility of GO and reduced graphene oxide (rGO) with polymer matrices, broadening their application in nanocomposite production. rGO has a structure similar to GO and can be produced via chemical or thermal reduction processes. Despite the reduction process, some functional groups remain on the surface (Phiri et al., 2018). When used as a reinforcement in polymer matrices, rGO improves mechanical properties such as Young's modulus, tensile strength, and toughness compared to pure polymers (Jang et al., 2014). This study aims to investigate the mechanical and thermal properties of polypropylene (PP) composites containing different concentrations of rGO.

Material and Method

Masterbatch containing 10 wt.% rGO was diluted with pure PP to prepare composites with 1, 3, and 5 wt.% rGO using a twin-screw extruder. Since polymer nanocomposites are widely used in high-temperature environments, investigating their thermal stability is crucial (Zhang et al., 2021). The thermal stability of polymer composites depends on two main factors; the composition of the constituent polymers and the interphase bonding and morphology within the polymer composites (Mat-Shayuti et al., n.d.). Graphene based nanomaterials have been shown to neutralize macroradicals formed during thermal degradation (George et al., 2018). Therefore, these nanomaterials are frequently used as reinforcements in polymers requiring high thermal and flame resistance. In this study for thermogravimetric analysis (TGA), each sample was heated from room temperature to 550°C under a pure nitrogen atmosphere at a heating rate of 10°C/min to prevent oxidation and other reactions. Differential scanning calorimetry (DSC) analyses were conducted for each sample under a nitrogen atmosphere with a heating/cooling rate of 10°C/min. The samples were first heated from 25°C to 200°C, then cooled back to 25°C, followed by heating from 25°C to 300°C. The melting temperatures (T), crystallization temperatures (T), and melting enthalpies (ΔH) were determined from the thermograms. Dog-bone-shaped specimens were prepared

using an injection molding machine, and tensile tests were conducted under ambient conditions at a crosshead speed of 5 mm/min. Five samples were tested, and the average results were recorded. For the flexural test, specimens with dimensions of 80 mm × 10 mm × 4 mm were prepared via injection molding. The three-point bending test was conducted using a Zwick Roell testing machine (1 N load cell) with a support span of 64 mm, in accordance with DIN ISO 178. Five samples were tested, and the average results were recorded.

Findings

The total weight loss was measured as 99.6% for the 1 wt.% composite, 97.8% for the 3 wt.% composite, and 95.8% for the 5 wt.% composite. The temperature corresponding to 50% weight loss (T) was defined, and the thermal stability of neat PP significantly improved with the inclusion of rGO. The T values increased with higher rGO content, recorded as 459.3°C for 1 wt.% PP/rGO, 460.7°C for 3 wt.% PP/rGO, and 463.3°C for 5 wt.% PP/rGO. The incorporation of rGO into the PP matrix increased the crystallization and melting temperatures of neat PP. This suggests that rGO exhibits a strong heterogeneous nucleation effect and promotes PP crystallization during cooling (Chen et al., 2018). The analysis confirmed an increase in melting and crystallization temperatures with increasing rGO content. The modulus and strength of composites generally increase with filler content, whereas elongation at break decreases. This is primarily because rigid filler materials reinforce the polymer matrix by restricting polymer chain mobility and enhancing load-bearing capacity (Ren et al., 2018). The results demonstrated that increasing the rGO content led to improvements in tensile strength and yield strength. Specifically, increasing the rGO content from 1 to 5 wt.% resulted in a 6.9% increase in tensile strength and a substantial 403.9% increase in yield strength, while elongation at break decreased by approximately 82.85%. The findings indicated that increasing the rGO content enhanced the flexural modulus. Increasing the rGO content from 1 to 5 wt.% resulted in a 20.8% increase in flexural modulus, a 7.5% increase in flexural strength, and a 6.91% decrease in f lexural elongation.

Conclusion

This study highlights the significant enhancement of both thermal and mechanical properties in PP composites reinforced with rGO. TGA results showed that the addition of rGO improved the thermal stability of the PP matrix, as evidenced by the higher T values and reduced overall weight loss with increasing rGO content. This indicates that rGO effectively strengthens the polymer's resistance to thermal degradation, making the composites more suitable for high-temperature applications. DSC further confirmed the positive impact of rGO on the crystallization and melting temperatures of PP, suggesting that rGO promotes heterogeneous nucleation, enhancing the crystallization process during cooling. This property is particularly beneficial for applications requiring precise control of the material's thermal properties. Mechanical testing revealed substantial improvements in both tensile and flexural properties with increasing rGO content. Specifically, a significant increase in tensile strength, yield strength, and flexural modulus was observed, making the composites more robust under load. Although elongation at break and flexural elongation decreased with higher rGO concentrations, these trade-offs are acceptable for applications where higher strength and rigidity are prioritized, such as in automotive and aerospace components. Overall, PP/rGO composites exhibit exceptional potential for use in industries requiring materials with both high thermal stability and superior mechanical performance. The incorporation of rGO not only enhances the performance of PP in these critical areas but also opens the door to further innovations in the development of advanced materials for high-demand applications.

Keywords: AZ31, Lightweight, Cold Spray, Wear Resistance.

Aim

Magnesium alloys are widely used in the automotive and aerospace industries due to their superior strength-to-weight ratio. Among the magnesium alloys, the Mg-Al-Zn alloy system (AZ series) offers increased mechanical properties by the precipitation hardening mechanism. AZ series alloys are used in automotive as wheels, seat rests, oil pans, cylinder head covers, and various frames in the chassis, and they are used in aerospace as brackets. [1] The alloy can be anodised to increase the corrosion and wear resistance; however, the resulting oxide is porous. Hence, the increase in the number of mentioned properties is limited.

Among the various surface modification methods, cold spray is a cost-efficient thermal spraying method where the particles do not reach their melting temperature. The method allows pure metal, alloy, and metal matrix composite (MMC) to be deposited on the substrate without disrupting the microstructure, which is achieved by conventional heat treatment or precipitation hardening treatments. Cold spray is also an attractive method in additive manufacturing and cost-efficient dimensional restoration of parts. Parts can also be cold sprayed and machined to their final dimension as a restoration procedure.[2] The cold spray method offers fast, cost-efficient and effective solutions to the maintenance of operating parts.

Among the studied cold spraying MMC coating blends, the aluminium matrix offers the optimum properties for embedding hard, wear-resistant particles. When compared with ceramic-based MMC coatings, intermetallic compound (IMC) based MMC coatings offer better interfacial bonding and less susceptibility for brittle phase formation. Al_2Zr is a hard, corrosion-resisting IMC found in the Al-Zr binary phase diagram. The compound has a density of 4.42 g/cm^3, a hardness of approximately 900 HV, a melting point of 1660 °C and is the compound with the highest melting point in the binary system. Owing to these properties, the Al_2Zr IMC provide higher hardness and operating temperature to the cold spray MMC coatings, along with increased metallurgical bonding and stable phase structure. [3] To the knowledge of the authors, Al/Al_2Zr composite coatings via the cold spray method are the first of their kind in the literature. This study aims to fabricate a cheap, wear-resistant and lightweight coating on the AZ31 alloy.

Materials and Methods

In this study, the AZ31 plates were obtained and cut to 15 mm specimen sizes. The specimens are grit blasted to ensure the adhesion of the coating layer to the substrate. The Al_2Zr IMC is obtained as cast buttons, produced via the vacuum arc melting method at 610 mbar pressure Argon atmosphere and 500 A. The obtained IMC buttons were crushed manually and ground in a high-energy ball mill at 300 RPM with zirconia spheres for 4 hours. The coating powders were mixed in a %40 Al_2Zr - %60 Al ratio. The blending and further grounding were performed in a mechanical alloying device at 10 Hz for 3 min with zirconia spheres to ensure complete and thorough blending. The grit-blasted specimens were mounted on the cold spray chuck, and particles were deposited at the surface with air pressurized to 6 bars with a 10 mm specimen standoff distance. The deposition process consisted of 4 passes.
Structural characterisation is achieved via X-ray diffraction (XRD) and scanning electron microscope (SEM) imaging. Both methods were conducted on unprocessed and cold spray processed AZ31 specimens. The XRD analysis is performed with $Cu_{K\alpha}$ radiation between the angles of 20º - 80º. Reciprocating ball on flat wear test was

performed for mechanical testing. The wear tests were performed at 3N load, 50 m sliding distance, 10 mm/s sliding speed and 5 mm wear track length. In order to evaluate the wear loss, surface profilometry is performed on both of the worn samples. The study aims to evaluate and compare the wear resistance of the unprocessed and cold spray processed specimens.

Findings

The XRD spectrum of the cold spray-processed AZ31 alloy is presented in Figure 1. The characteristic peaks belonging to aluminium are detected in the spectrum and are compared with the peaks in the literature.[4] Peaks of Al_2Zr are compared with the literature and found to be consistent with the works.[5, 6]

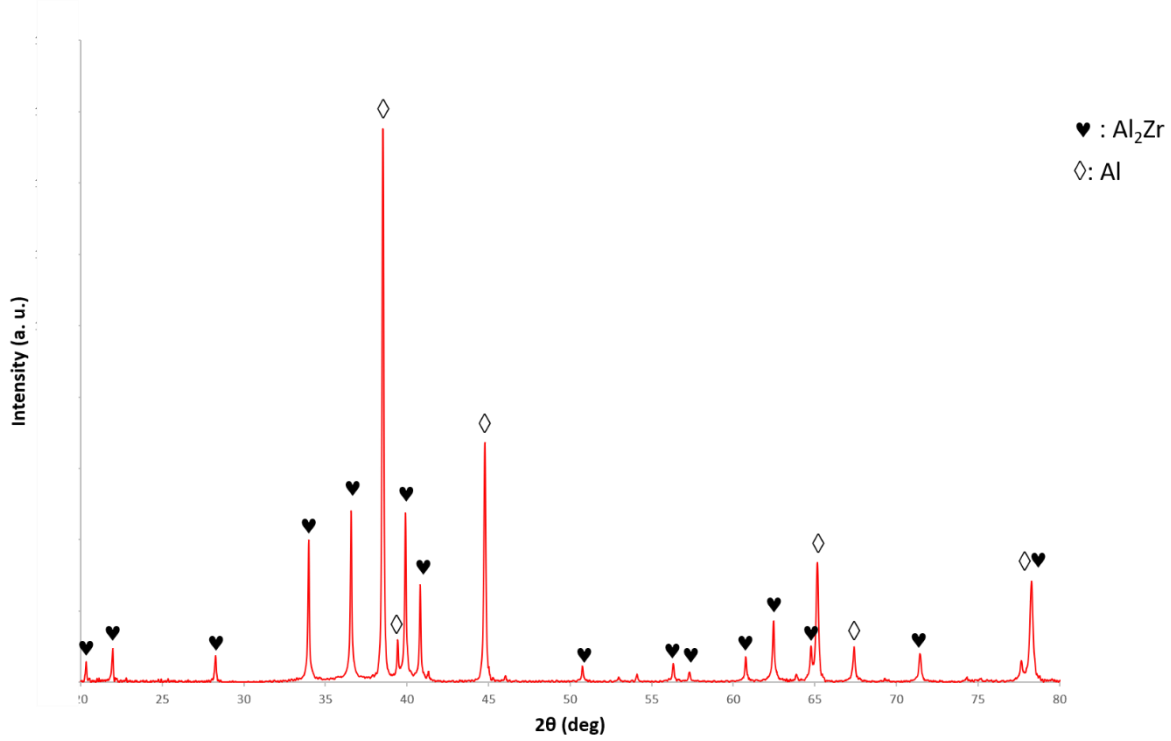

Figure 1. XRD spectrum of Al/Al_2Zr coated specimen.

The cross-sectional backscattered electron SEM images of the cold spray-processed AZ31 alloy are presented in Figure 2. The white particles indicate IMC, whereas the grey background indicates the aluminium matrix. The cold spray coating thickness is measured to be 438 µm on average. Roughly 100 µm thickness could be achieved per pass. The particles of Al_2Zr are found to be distributed evenly in the aluminium matrix. However, the particle dimensions indicate the grounding process to be inadequate due to the high hardness of the IMC, resulting in an uneven size distribution throughout the matrix. The aluminium matrix supports the Al_2Zr IMC without extreme strain hardening, and no cracking in the matrix is detected. The bonding of cold spray coating to the substrate AZ31 is achieved successfully, and no porosity or interfacial cracks between the substrate are detected.

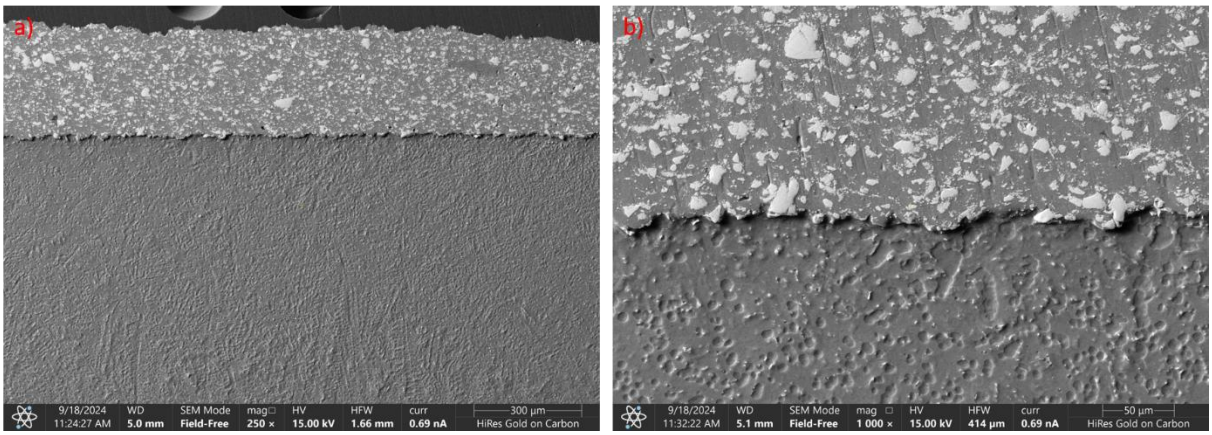

Figure 2. SEM images of the Al/Al_2Zr coated AZ31 specimen, a) cross section and b) interface.

The results of the wear tests performed are presented in Figure 3. The wear track depth and width of the unprocessed AZ31 alloy were found to be greater than that of the cold spray processed AZ31 (denoted CS%40), resulting in higher wear resistance. The volume loss of unprocessed AZ31 is calculated as 3.3 x 10^{-3} mm^3 N^{-1} m^{-1}, whereas the volume loss of cold spray processed AZ31 is 0.9 x 10^{-3} mm^3 N^{-1} m^{-1} supporting the higher wear resistance result observed in the wear track profiles. The wear track of cold spray processed AZ31 showed no delamination of coating or dislocation of the IMC particles, further supporting the strong bonding between the aluminium matrix and the IMC. The unprocessed AZ31 wear track showed plastic deformation-dominated wear mode. The counterface of both cold spray processed and unprocessed AZ31 revealed material transfer, indicating the wear mode is adhesive.

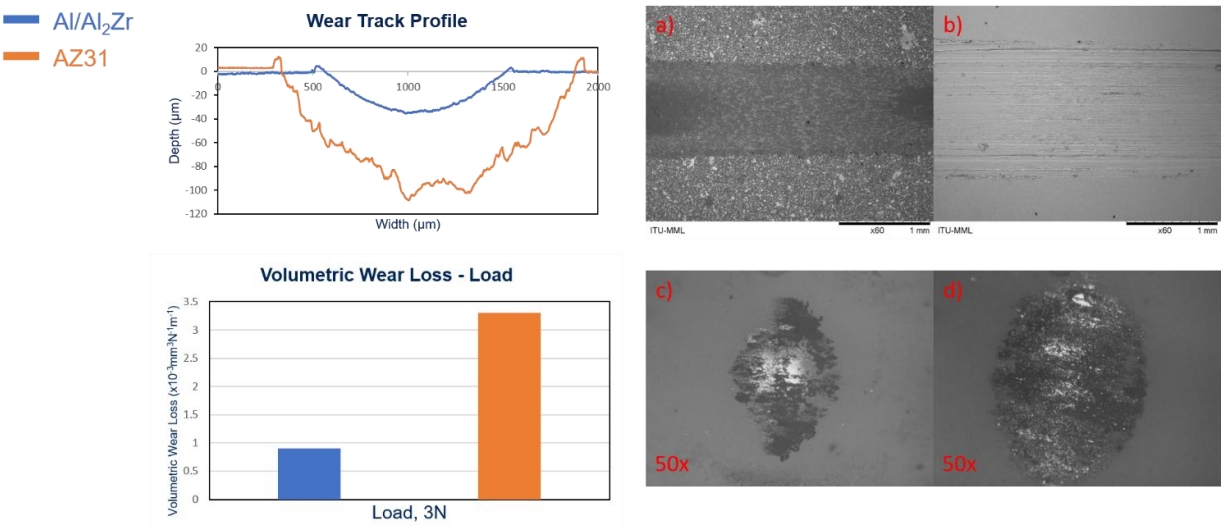

Figure 3. Wear track profile and the volumetric wear loss graphs for cold spray processed and unprocessed AZ31. a) Wear track of cold spray processed AZ31, b) wear track of the unprocessed AZ31, c) optical microscope image of counterface in image a, at x50 magnification and d) optical microscope image of counterface in image b, at x50 magnification.

Conclusion

The wear resistance of the AZ31 alloy is increased by approximately 4 times with the cold spray process. The resulting coating is found to be dense and defect-free within itself and at the coating/substrate interface. The IMC and the matrix are found to be firmly bonded. The coating showed no delamination or dislocation of hard particles. The study aims to further increase the wear resistance by subsequent micro-arc oxidation of the Al/Al_2Zr cold

spray coating after deposition and improve the size distribution by further milling and optimising the grounding operations.

Keywords: Ferrochrome, Chromite Reduction, Hydrogen, Carbon Emissions..

Aim

Ferrochrome (FeCr) is an essential material in metallurgical industries, particularly in the production of stainless steel, which ensures corrosion resistance and durability. Approximately 80% of global FeCr production supports the stainless-steel sector, with high-carbon ferrochrome (HC FeCr) being the dominant form (International Chromium Development Association, n.d.). However, the traditional carbothermic reduction method used for FeCr production, reliant on coke and operating at temperatures exceeding 1600°C in submerged arc furnaces (SAFs), results in substantial energy consumption and carbon emissions (Basson & Daavittila, 2013). On average, producing one ton of HC FeCr emits 4.7–6.1 tons of CO_2-equivalent greenhouse gases, presenting a critical environmental challenge (Wei et al., 2023). The energy required to produce HC FeCr varies between 40 and 59 GJ per metric ton, contingent upon the mode of supply. Of all the steps, smelting uses the greatest energy, making up between 64% and 98% of the total. Smelting arc furnaces depend on electricity, which has a major influence on the FeCr alloy's impact on the environment (Wei et al., 2023).

This study investigates the reduction behavior of chromite ore using hydrogen (H_2) as an alternative reductant to achieve a more environmentally friendly and sustainable FeCr production process than carbothermic methods. The primary objective is to reduce carbon emissions by minimizing the reliance on traditional carbon (C)-based reductants and optimizing gas-based reduction processes. Studies have shown that reduction temperature, duration, and gas composition are decisive factors in the metallurgical conversion rate and mechanical strength of chromite pellets. For example, Wu et al. (2024) showed that lowering the temperature by 3 hours at 1100 °C in an atmosphere with 10% methane (CH_4) and 90% H_2 resulted in a total metallization rate of 36.3%, with rates of 69.3% for iron (Fe) and 10.3% for Chrome (Cr).

The study aims to identify the optimal reduction conditions by analyzing the development of metallic phases and chromium carbide compounds, while also examining the influence of H_2 and CH_4 on process sustainability. This study seeks to advance low-emission metallurgical methods aligned with future decarbonization objectives by the systematic analysis of temperature, gas composition, and reaction time.

Materials and Methods

Chromite ore samples (42-44 Al_{min} grade – Turkish Ore) were conducted for reduction experiments in a horizontal tube furnace (Lenton, T_{max}=1800°C) under certain atmospheres. Chemical composition of the chromite ore is given in Table 1.

Table 1. Chemical composition of Chromite Ore (wt. %).

Material	Cr_2O_3	Al_2O_3	CaO	SiO_2	MgO	Fe_2O_3	TiO_2	S	P_4O_{10}	C	NiO
Turkish Ore	44.58	7.93	0.32	10.92	21.77	13.29	0.08	0.00272	0.001	0.112	0.18

The reduction of chromite ore using H_2 and CH_4 gases was investigated. The experimental setup includes an alumina-based ceramic combustion boat containing 10 g of chromite ore positioned in the middle region of a Lenton tube furnace. Reducing gas (H_2) was fed into the system via stainless steel tubes with controlled flow rates. Gas flow rates were maintained at 0.21 l/min, dependent upon the individual experiment.

The furnace was not evacuated before the experiment. Instead, a continuous flow of high-purity argon (Ar) gas was used to create and maintain an inert atmosphere during the heating and cooling phases. During heating and cooling processes, the system is fed inert gas to prevent any oxidative interaction in the reaction environment. The reduction parameters, such as temperature (between 1300°C and 1500°C) and dwell time (up to 4 hours), were investigated. Table 2 gives detailed data on the experiments on the reduction of chromite ore with H_2 gases.

Table 2. Experiments on the reduction of chromite ore with H_2.

Experiment No	Temperature (ºC)	Reduction Gas (L/min)	Dwell time (min)	Mass Change (g)	Experimental Mass Loss (%)
1	1300	0.21 l/min H_2	120	-0.67	6.67
2	1400	0.21 l/min H_2	120	-0.81	7.90
3	1500	0.21 l/min H_2	120	-1.00	9.48
4	1500	0.21 l/min H_2	180	-1.25	12.02
5	1500	0.21 l/min H_2	240	-1.83	17.35

5 experiments were conducted to investigate the H_2 reduction of chromite ore. The mass loss presented in the Table 2 represents the percentage change in mass observed as a result of the reduction experiment. The samples used in the experiment are approximately 10.56 grams (g). The theoretical mass loss during the reduction of a chromite ore sample using H_2 is approximately 1.91 g for 10.56 g of sample. The total theoretical mass loss due to the reduction of chromium oxide (Cr_2O_3) and iron oxide (Fe_2O_3) phases in the sample was found to be 18.07% based on stoichiometric calculations.

At the end of the experiment, products were weighed to calculate mass loss and then analyzed by Panalytical X'Pert Pro X-ray diffraction (XRD), utilizing Cu-Kα radiation with a scanning rate of 10°/min to find patterns within the 10-90° range, employing a step size of 0.02 at ITU to identify the phases generated during reduction.

Findings

XRD graphs were analyzed to examine which phases of the products were formed in the first place. The results of the experiments were compared with Low-Carbon Ferro Chrome (LC FeCr), as C is not expected in the content of the sample. LC FeCr contains 0.05% C and a minimum of 65% Cr.

To investigate the influence of temperature, experiments 1, 2, and 3 were carried out with identical dwell times and gas flow rates. The XRD results of the reduction of chromite ore at 1300, 1400, and 1500 ℃ with a gas flow rate of 0.21 L/min for 2 hours are shown in Figure 1.

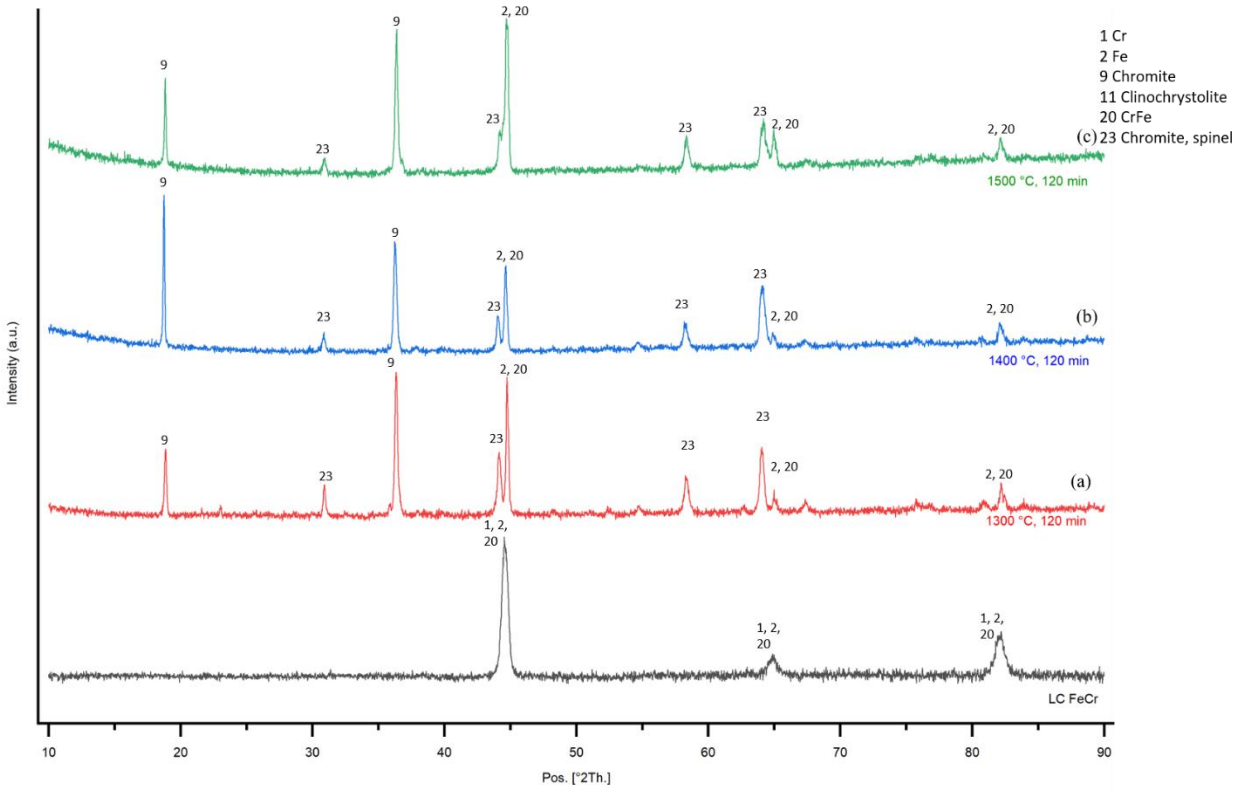

Figure 1. The XRD results of the reduction of chromite ore at 1300, 1400, and 1500 °C with a gas flow rate of 0.21 l/min for 2 hours.

When the XRD results were examined (Figure 1), metal peaks were found at the same degrees as LC FeCr. α-Fe (BCC) peak was detected in the XRD graphs of all 3 experiments. The phase identification of α-Fe (BCC) was confirmed by comparison with the ICDD PDF card No. 01-089-7194. The diffraction peaks corresponding to the spinel chromite phase (particularly those labeled as 9 and 23) are still observable in all samples, but a gradual decrease in their intensity is observed as temperature increases. This may indicate partial decomposition of the spinel structure; however, the extent of the transformation cannot be definitively determined based solely on peak intensity. Additionally, the presence and marked intensification of peaks assigned to Cr, Fe, and CrFe phases (peaks 1, 2, and 20) at high temperatures may indicate an increase in metallic phase formation; however, this interpretation remains qualitative without further phase quantification. Although reflections associated with metallic phases become more pronounced at 1400 °C and 1500 °C, the persistence of chromite peaks suggests that complete reduction may not have occurred under the conditions studied. Additionally, the experimental patterns do not fully align with that of the LC FeCr reference, which could point to an incomplete transformation, or possibly the presence of other residual phases not fully resolved by XRD alone.

The Fe phase observed in XRD analysis indicates that Fe_2O_3 is reduced by H_2 to metallic Fe. This finding coincides with the studies in the literature that Fe_2O_3 can be reduced in a H_2 atmosphere (Rukini et al., 2022).

At 1500 °C, experiments 3, 4, and 5 were analyzed together to investigate the effect of dwell time. In the experimental study, an experimental mass loss of approximately 9.48%, 12.02%, and 17.35% was observed during the reduction of the ore, respectively. Of these values, only experiment 5 is close to the theoretical mass loss (18.09%) and can be explained by the removal from the system as H_2O formed during reduction.

Conclusion

When the studies are examined, it is thought that the increase in temperature and time will lead to an increase in metal formation. More analyses are needed to analyze the results in detail, to determine the amount of metal and to identify the phases formed, and more experiments are needed for hydrogen reduction of chromite ore.

The reduction of chromite ore with H_2 revealed that Fe_2O_3 was effectively reduced to metallic Fe, whereas Cr_2O_3 reduction was limited due to thermodynamic constraints. Higher temperatures and prolonged durations enhanced mass loss and phase transformation, indicating the role of thermal energy in breaking down spinel structures. Mixed gas or stepwise reduction approaches may further improve efficiency and support sustainable metallurgical practices.

Production and Characterization of Lanthanum Hexaboride Powder

Deniz Nalci[a], Mehtap Arslan-Kaba[a], Guldem Kartal Sireli[a], M. Kursat Kazmanli[a]

[a]Istanbul Technical University, Faculty of Chemical and Metallurgical Engineering, Department of Metallurgical and Materials Engineering, Türkiye
nalcid@itu.edu.tr

Keywords: Lanthanum Hexaboride, Molten Salt Electrolysis, Thermionic Emitter.

Aim

Rare-earth hexaborides exhibit exceptional thermal, electrical, magnetic and physical properties. Among them, lanthanum hexaboride (LaB_6) is a critical material for advanced technological applications due to its remarkable characteristics, including a high melting point and low work function (2.6 eV) [1]. Thanks to their unique properties, hexaborides are used in important applications, including electron emission and thermoelectric devices, thin film coatings, photon detectors, and superconducting materials [2]. The production of LaB_6 has traditionally been conducted using metallothermic reduction, chemical vapor deposition (CVD) and molten salt electrolysis methods. In the metallothermic method, boron compounds are reduced with metals that have a high affinity for oxygen, typically magnesium [2]. However, this process leads to the formation of unwanted by-products and results in low purity, making it unsuitable for especially semiconductor applications. The CVD method, on the other hand, involves the reduction of boron halides with hydrogen gas, producing high-purity LaB_6 [3]. Despite this advantage, it has several drawbacks, including the use of toxic and corrosive gases, the requirement for expensive equipment, and low production efficiency. With traditional molten salt electrolysis, high purity production is possible in ultra short times. Since the environment is very corrosive in fluoride and chloride electrolyte production, the system must be adjusted very well [4]. In addition, halides pose a serious threat to health and the environment.

In this study, high-purity LaB_6 powder was synthesized using a novel and environmentally friendly molten salt electrolysis method incorporating oxide-based salts. Additionally, the structural characterization of the produced LaB_6 powder was conducted. The use of borax as an electrolyte in molten salt electrolysis enables green production by achieving high purity and high capacities in a remarkably short time.

Materials and Methods

Grade 2 titanium (Ti) was chosen as a cathode material with dimensions of 2.5 cm × 6 cm × 1 mm. The chemical composition of the cathode material is presented in Table 1. To remove contaminants such as oil and dirt, the surface was first ground with 800 and 1000-grit sandpaper, followed by ultrasonic cleaning in an acetone bath.

Table 1. Chemical composition of the grade 2 titanium used.

Element	C	N	O	H	Fe	Ti
wt%	≤ 0.080	≤ 0.030	≤ 0.25	≤ 0.015	≤ 0.30	≥ 98.9

The parameters examined in the production of LaB_6 powder were determined based on previous studies of the research group [5]. Accordingly, the process was conducted at 900°C with a current density of 200 mA/cm^2 for 1 hour. The electrolyte composition used in the experiment was 93 wt% $Na_2B_4O_7$, 5% La_2O_3, and 2% CaF_2. These experimental parameters are shown in Table 2.

Table 2. Experimental parameters examined in LaB_6 production.

	Cathode Material	Temperature	Current Density	Electrolyte Composition wt%	Time
Experiment	Ti	900 ºC	200 mA/cm2	93% Na2B4O7+ 5% La2O3+ 2% CaF2	60 min

The electrolysis was conducted within a medium-frequency induction furnace. The titanium substrate was used as a cathode, a graphite crucible containing electrolyte was utilized as an anode. The electrolyte composition included lanthanum oxide (La_2O_3) and borax ($Na_2B_4O_7$), with a small addition of calcium fluoride (CaF_2) at 2 wt% as an activator [6]. After the electrolysis completed, the cathode was withdrawn, and the remnant electrolyte was eliminated by rinsing them in boiling water. The deposited powder was then scraped off and thoroughly washed with hot water. To remove impurities, an HCl washing process was carried out. The powder was then filtered and dried. The produced powder was structurally characterized by X-ray diffractometry (XRD), scanning electron microscopy (SEM) and raman spectroscopy.

Findings

The XRD results of the powder collected on the cathode surface in the experiment are presented in Figure 1. According to the XRD analysis, LaB_6 structure was obtained under these experimental parameters. In addition to the LaB_6 main phase, $LaBO_3$ formation was observed before HCl cleaning. All of the $LaBO_3$ phases were removed after the cleaning process with HCl.

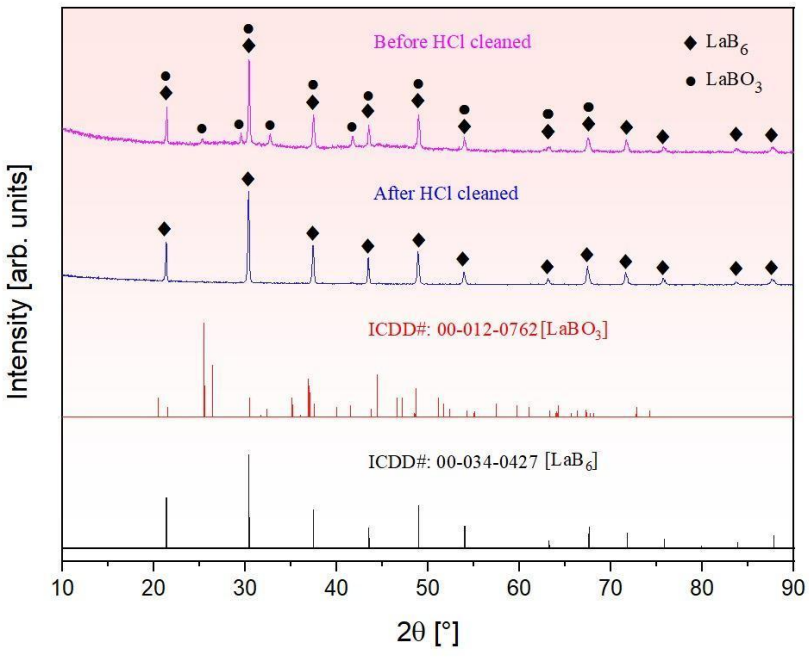

Figure 1. XRD pattern of LaB_6 powder synthesized from a composition of 93 wt% $Na_2B_4O_7$, 5% La_2O_3, and 2% CaF_2, before and after HCl cleaning [Ti cathode, 900 °C, 200 mA/cm²].

The SEM analysis conducted to investigate the morphology of the synthesized powder is shown in Figure 2. The SEM results revealed that the characteristic cubic morphology was observed. The crystals exhibit homogeneous and uniform distribution. When the SEM results are evaluated together with the XRD analysis, no phases other than LaB_6 were detected.

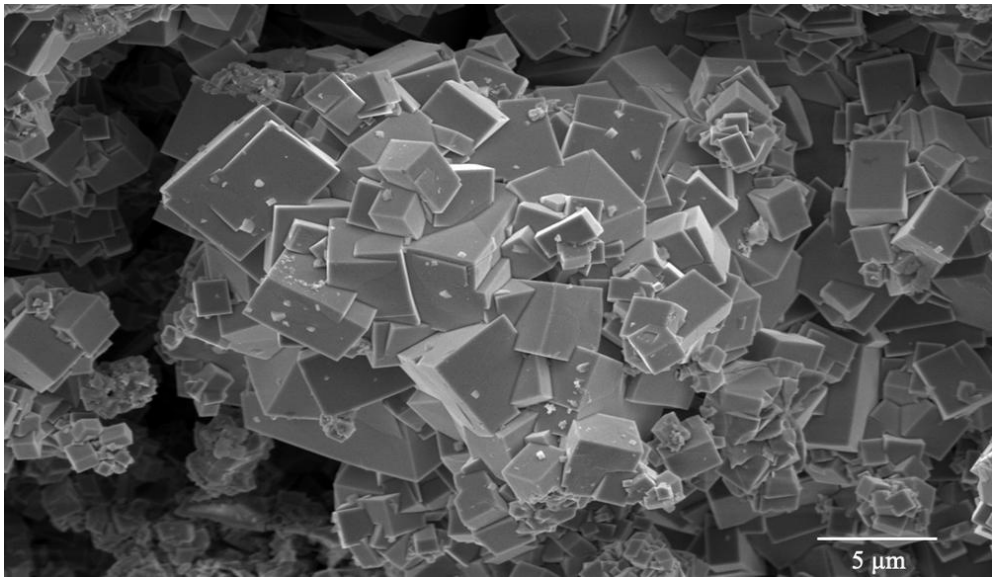

Figure 2. SEM image of LaB_6 powder obtained from a compositon of 93 wt% $Na_2B_4O_7$, 5% La_2O_3, and 2% CaF_2, after HCl cleaning [Ti cathode, 900 °C, 200 mA/cm²].

LaB_6 shares a structural similarity with CsCl in terms of its unit cell, which is a simple cubic crystal structure [7]. In this configuration, lanthanum ions are positioned at the center, while boron octahedra are located at the corners of the crystal [8]. Raman-active modes are mainly influenced by octahedral boron cluster [9]. Three Raman-active modes of this octahedral structure are the A_{1g} and E_g stretching modes, as well as the T_{2g} bending mode [10]. According to the literature, these three vibrational modes are observed within the frequency range of 600–1400 cm^{-1} [11]. Raman spectroscopy was conducted on the LaB_6 powder. In Figure 3, the Raman spectroscopy results before and after HCl cleaning are presented. The Raman peaks of the powder cleaned with HCl are observed at 770 cm^{-1}, 1118 cm^{-1}, and 1263 cm^{-1}, corresponding to the T_{2g}, E_g, and A_{1g} active raman modes, respectively [12]. The acid cleaning process did not have a significant effect on the raman peaks.

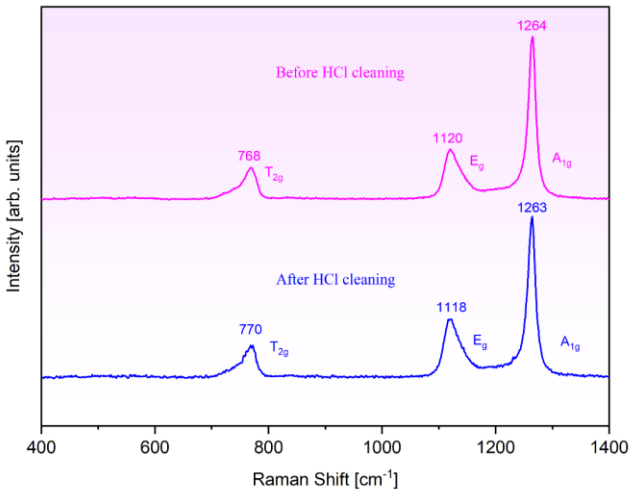

Figure 3: Raman spectra of LaB_6 powder synthesized from a composition of 93 wt% $Na_2B_4O_7$, 5 wt% La_2O_3, and 2 wt% CaF_2, before and after HCl cleaning [Ti cathode, 900 °C, 200 mA/cm^2]

Conclusion

In this research, it has been shown that it is possible to produce high purity LaB_6 powder using borax electrolyte by molten salt electrolysis method. XRD and SEM analysis results showed that these experimental parameters

were effective in the production of high purity LaB_6 powder. The characteristic T_{2g}, E_g and A_{1g} modes of LaB_6 powder produced in raman spectroscopy were obtained. In addition, considering the advantages of the low cost of the production system and raw material source, the use of environmentally friendly electrolyte and the ability to obtain high amounts of product in short periods of time have been demonstrated. This study aims to utilise the boron resources of our country to produce high value-added advanced technology products.

Keywords: Lamellar Graphite Cast Iron, Stress Relief Annealing, Mechanical Properties, Residual Stress, Engine Block.

Aim

The aim of this study is to investigate the effects of increasing the stress-relief heat treatment time on the mechanical properties and operational costs of motor blocks produced from lamellar graphite gray cast iron EN GJL-250 material. The lamellar graphite gray cast iron material used in the production of motor blocks offers advantages such as lower production costs, durability, and thermal conductivity, making it suitable for a wide range of applications, from automotive engines to truck, boat, tractor, and other industrial vehicle engine blocks [Arran A.,Elliott R.]. Motor blocks must meet mechanical durability, fatigue resistance, and high thermal conductivity requirements, especially under harsh operating conditions.Therefore, the design and material properties of the motor block play a crucial role in ensuring efficient engine operation. During the casting process, cooling variations that occur after the production of the engines induce stresses on the motor block, and it is not possible to prevent this situation under mass production conditions.[Baş B., Şen N.B]. The optimal solution for businesses in this regard is post-production stress-relief heat treatment processes. This study aims to demonstrate how increasing the stress-relief heat treatment time affects the mechanical properties and residual stresses of the motor block.[Yenici B.S.,Çoşar B.] Additionally, this study aims to evaluate the cost-effectiveness of stress-relief heat treatments from the perspective of businesses and determine the optimal (graph) stress-relief heat treatment time.

Material and Method

The motor blocks used in this study are made of lamellar graphite gray cast iron EN GJL-250 material. The motor block production took place at the Döktaş Orhangazi factory. The raw materials used in the production include gray cast iron, automotive scrap, and recycled runners. The chemical composition of the engine block is shown in table 1.

Table 1. Chemical composition of the engine block (EN GJL 250).

Chemical Composition											
C	Si	S	Mo	Cr	Cu	Sn	Mn	Ti	Mg	P	Ni
3.100	2.137	0.77	0.022	0.268	0.663	0.073	0.857	0.020	0.001	0.026	0.024

The cleaning and grinding processes of the produced motor blocks were carried out in the fettling department of Döktaş. Figure 1 shows the pattern and filter placement in the molding line during the production of the motor blocks. After casting, the blocks are left in the cooling tunnel for 3 hours and then allowed to cool in the atmospheric environment. During this process, internal stresses caused by uneven cooling are generated in the blocks. Therefore, after grinding and cleaning, the blocks underwent stress-relief heat treatment.

Figure 1. Core and filter placement before molding of engine blocks.

For the heat treatment, the motor blocks were subjected to stress-relief annealing in a System Teknik branded natural gas heated 6-burner trolley-type furnace. During the heat treatment, the stress-relief times and cooling rates of the blocks were considered as variable parameters. These variables were adjusted on the stress-relief heat treatment curve by setting holding times and cooling durations. The 10-hour and 15-hour stress-relief heat treatment curves are shown in Figures 2 and 3. In the 10-hour heat treatment curve, the temperature reaches 600°C within 2 hours and is held at 600°C for 2 hours. Then, the blocks are cooled in the furnace at 75°C per hour until they reach 150°C, after which the furnace doors are opened. In the 15-hour heat treatment curve, the temperature also reaches 600°C within 2 hours, and the blocks are held at 600°C for 3 hours. Then, the cooling continues at a rate of 40°C per hour until the blocks reach 300°C. After 150°C, the cooling rate is 75°C per hour, and the furnace doors are opened.

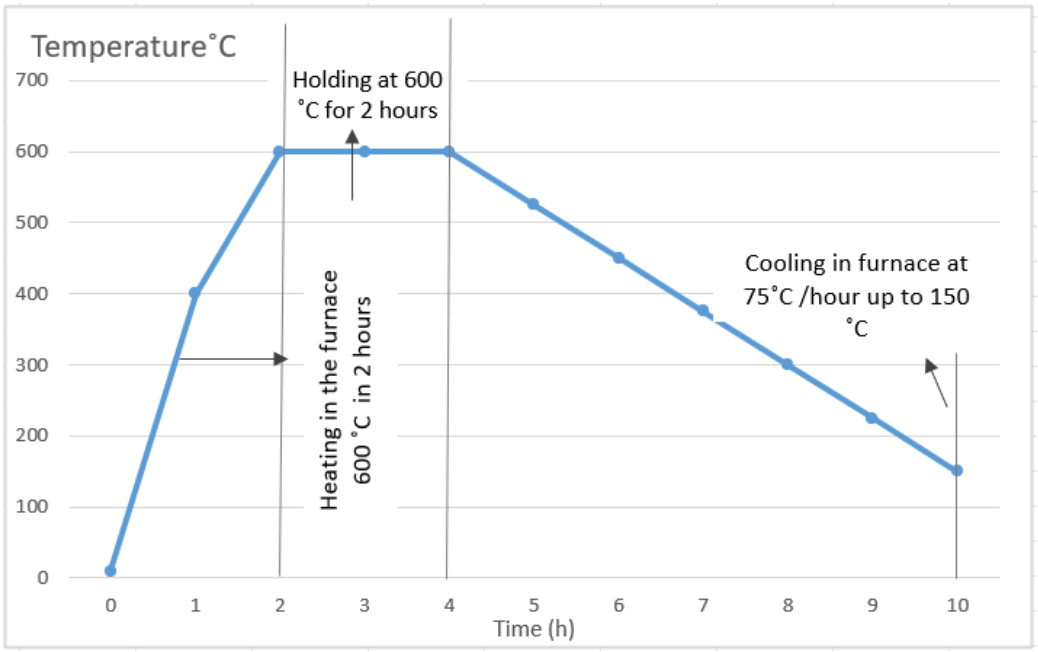

Figure 2. 10 hours stress relief chart.

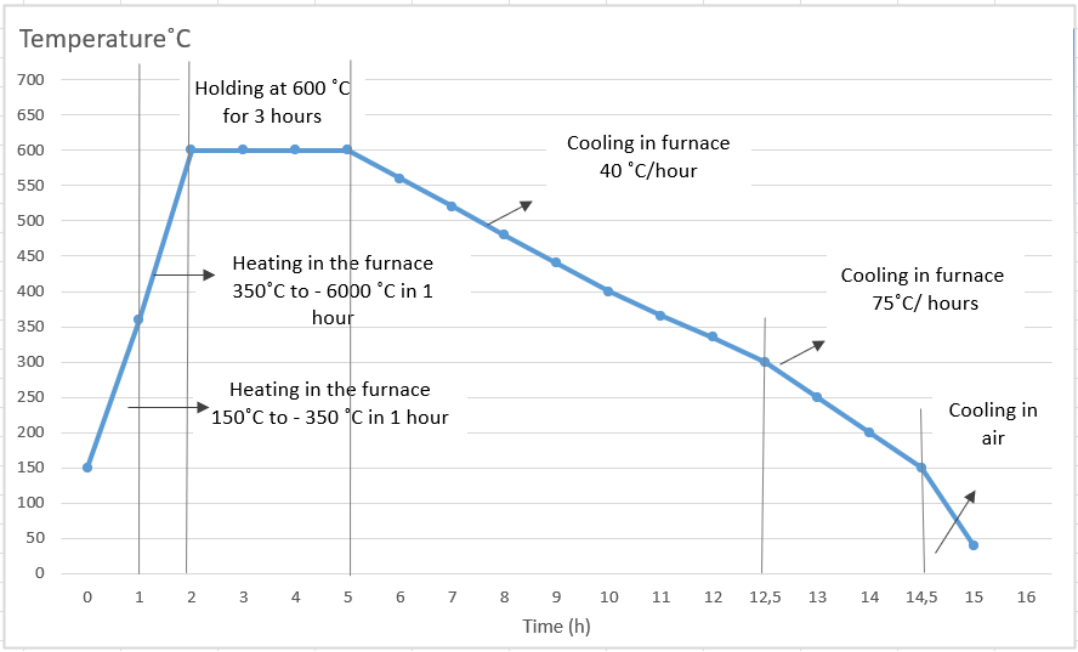

Figure 3. 15 hours stress relief chart.

Equipment Used

- **Dimensional Measurement:** Dimensional measurements of the motor blocks were performed using a Coord 3 CMM device.
- **Tensile Test:** Tensile tests were carried out using a Shimadzu brand device with a 250 kN capacity and an extensometer. The tests were conducted according to customer technical specifications.
- **Hardness Measurement:** Hardness measurements were taken using a Reicherter brand device with a 10 mm diameter probe and a 3-ton capacity. The hardness measurements were conducted on the head and crankcase surfaces in accordance with ASTM E10-96 standards.

- **Chemical Analysis:** Chemical analyses were performed using an ARL 4460 optical emission spectrometer. Sampling was done using a ladle sampling tool from the molten metal before casting.
- **Microstructure Analysis:** Microstructure analysis was carried out using a Nikon optical microscope. The analyses were conducted according to the instructions specified in the customer's technical specifications.
- **Residual Stress Measurement:** Residual stress measurements were performed using an IMC Chronosflex data collection system and 19 analog channels.The stress measurements were carried out with devices capable of data collection at a speed of 100 Hz.

Sample Preparation and Testing

Samples from the motor blocks were taken from areas suitable for tensile testing according to customer technical specifications and then machined to conform to DIN 50125 standards using a lathe. A visual of the sample is shown in Figure 4. Hardness measurements were made on samples taken from the head and crankcase surfaces according to ASTM E10-96 standards. For microstructure analysis, the samples were prepared according to the instructions specified in the customer's technical specifications. The chemical composition of the motor block was determined using the ARL 4460 optical emission spectrometer.

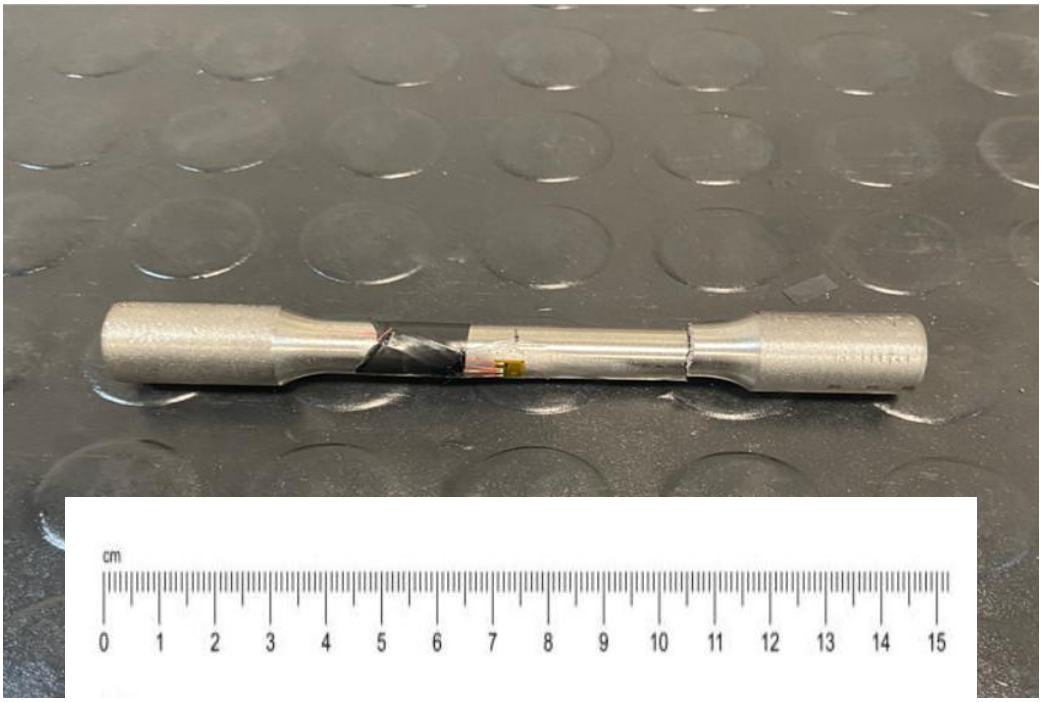

Figure 4. Tensile test sample prepared according to DIN 50125 Standarts.

Experimental Parameters

In this study, the variable parameters included the holding time and cooling durations in the stress-relief heat treatment curve. Two different stress-relief heat treatment recipes of 10 hours and 15 hours were applied to the motor blocks, and mechanical properties were tested and analyzed after these heat treatments.

Findings

This study examined the effects of stress-relief heat treatment times on the mechanical properties of EN GJL-250 lamellar graphite gray cast iron motor blocks. The results obtained after the 10-hour and 15-hour stress-relief heat treatments are presented in detail in Table 2.

Table 2.Results of mechanical tests after 10-hour and 15-hour stress relief heat treatment.

Heat Treatment Duration	After 10-Hour Stress-Relief Heat Treatment	After 15-Hour Stress-Relief Heat Treatment
Residual Stress [MPa] SG 5.2	-75.97	-40.47
Residual Stress [MPa] SG 5.3	-65.10	-25.00
Residual Stress [MPa] SG 5.5	-108.14	-20.38
Residual Stress [MPa] SG 10.	-4.97	-2.98
Tensile Strength [N/mm²]	248	246
Average Hardness [Brinell]	210	208
Dimensional Measurement [mm]	480	480.1

Residual Stresses: According to the results shown in Table 2, the residual stresses measured after the 10-hour stress-relief process were -75.97 MPa, -65.10 MPa, -108.14 MPa, and -4.97 MPa in the SG 5.2, SG 5.3, SG 5.5, and SG 10 regions, respectively. However, after the 15-hour stress-relief process, a significant reduction was observed in these values. The residual stresses measured after the 15-hour process were -40.47 MPa, -25.00 MPa, -20.38 MPa, and -2.98 MPa, indicating a reduction of 50% to 80% in the residual stresses.The cutting depth and residual strain measurement visual is shown in Figure 5.

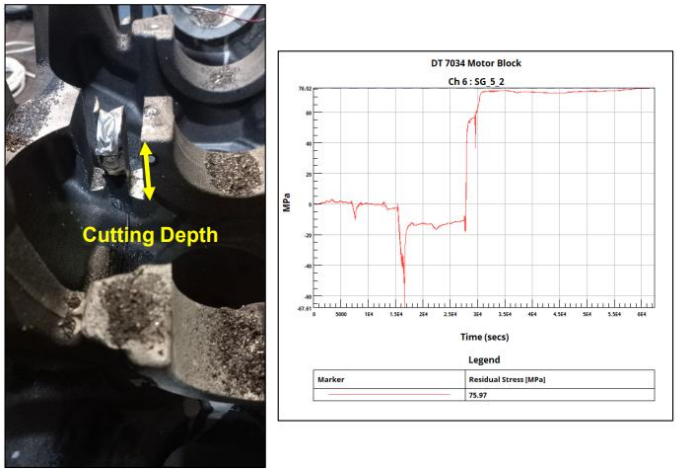

Figure 5. Residual strain measurement and depth of cut image.

Tensile Strength and Hardness: No significant change was observed between the tensile tests and hardness measurements after both heat treatment durations. After the 10-hour stress-relief process, the tensile strength was 248 N/mm², and the average hardness was 210 Brinell. After the 15-hour process, the tensile strength was 246 N/mm², and the average hardness was 208 Brinell. The difference between these values is quite small and negligible. This suggests that the hardness values did not decrease significantly, which is crucial for maintaining the motor block's high performance under harsh working conditions.

Dimensional Measurements: The effect of heat treatment time on dimensional measurements was also examined. After the 10-hour stress-relief process, the dimensional measurement was 480 mm, while after the 15-hour process, the measurement was 480.1 mm. This result indicates that no significant dimensional change occurred in the motor block after either heat treatment duration, and the motor block remained within the desired tolerance limits.

Microstructure Analysis: Microstructure analysis was performed after both heat treatment durations. Microscopic examination revealed the presence of similar A-type graphite structures in both cases. Additionally,

the matrix structure was found to be 99% pearlitic in both samples. This indicates that no significant change occurred in the microstructure of the motor blocks after both the 10-hour and 15-hour stress-relief processes.10 hours and 15 hours annealed unetched microstructure images are shown in Figure 6 and 7.

Figure 6. 10 hours annealed unetched microstructure image 100 X Magnification.

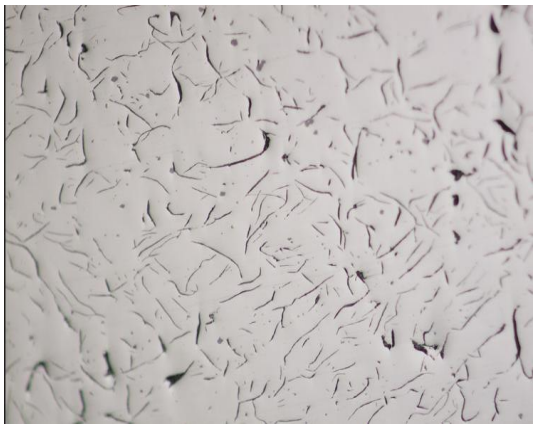

Figure 7. 15 hours annealed unetched microstructure image 100 X Magnification.

Cost Analysis: The additional costs of extending the heat treatment time for businesses are calculated and presented in Table 3. The analysis highlights that extending the stress-relief heat treatment time will increase costs for natural gas, electricity consumption, and labor. If one annealing cycle is performed daily, with 280 cycles annually, the use of the 15-hour recipe would result in an additional annual cost of 26.273 €. The impact on the unit part cost is 0.4%. This increase is considered insignificant when considering the high performance and durability required for the motor blocks over their service life.

Table 3. Effect of 15 hours stress relieving heat treatment on difference cost calculation and unit part cost calculation compared to 10 hours stress relieving treatment.(The calculation is based on 28 000 pieces per year.)

Cost Item	Annual Cost (€)
Annual Natural Gas Cost Difference	€ 16 949
Annual Labor Cost Difference	€ 8 400
Annual Electricity Cost Difference	€ 924
Total Annual Cost Difference	€ 26 273
Impact on Unit Part Cost	0.4 %

Conclusion

In this study, motor blocks produced by sand casting using EN GJL-250 material were annealed with two different stress-relief heat treatment recipes, and their mechanical properties were examined. No significant change was observed in hardness, tensile strength, and dimensional measurements. The microstructures of both cases showed similar A-type graphites, and the matrix was found to be 99% pearlitic. The most significant variability was observed in the residual stress measurements. By increasing the stress-relief annealing time and lowering the cooling temperature, the residual stresses in the motor blocks were reduced by 50% to 80%, remaining within the tolerance limits specified in the customer's technical specifications. These results are important for ensuring high performance when the motor is subjected to dynamic and static stresses during its service life. This study confirmed the optimal stress-relief heat treatment graph required to minimize internal stresses in lamellar graphite gray cast iron motor blocks produced by sand casting. The additional cost associated with increased heat treatment time is considered negligible when considering the motor's lifetime, performance, and potential quality issues.

Keywords: Biomass, Adsorption, Metal-Alloy, Precious Metal Removal.

Aim

The recovery of precious metals using biomass is of great environmental and economic importance. While traditional mining methods cause environmental pollution due to high energy consumption and toxic chemicals, the use of biomass enables the recovery of heavy metals and valuable elements through biological processes without harming nature.[1] Precious metals such as gold, platinum and palladium found in electronic waste (e-waste), mining waste and industrial waste can be recovered using biomass.

While traditional methods require large amounts of energy and chemicals, biomass-based methods are inexpensive and more energy efficient. Metal ion recovery can be achieved by utilising the metal adsorption capacity of natural organisms. Therefore, the recovery of precious metals from biomass has great potential in terms of both environmental sustainability and economic value creation.(Wang, S., & Chen, C. (2006)

In this study, the recovery behaviour of precious metals from refinery solutions using different biomasses was investigated.

The recovery of precious metals from industrial and electronic waste streams has gained increasing attention due to the scarcity and high economic value of these elements. Biomass-derived sorbents offer a sustainable and cost-effective alternative for the selective adsorption of precious metals from aqueous solutions. (Veglio, F., & Beolchini, F. (1997).)

This study aims to explore the potential of torrefied biomass materials in the recovery of gold (Au), platinum (Pt), palladium (Pd), and rhodium (Rh) from solution, with a focus on optimizing torrefaction conditions and adsorption parameters..

Material and Method

Biomass has started to be used not only as a fuel and energy source, but also as an alternative material in various fields of use, due to its features such as having great potential, being renewable and sustainable, and being carbon-neutral. The torrefaction process applied in this context is carried out by heating the biomass to a temperature range of 200-300°C in an airless environment. As a result of this process, some changes occur in the biomass structure. While hemicellulosics are degraded, other macromolecules such as cellulose and lignin are hardly affected. In addition, the biomass changes from hydrophilic to hydrophobic due to the removal of oxygen-containing functional groups. The surface area of the biomass expands somewhat and its sorptive capacity improves. In this study, the recovery of precious metals (gold, platinum, palladium, rhodium) from solution was tested by using various biomass materials including forest biomass, marine biomass and agricultural wastes that had undergone torrefaction. Namely, corn waste as agricultural biomass, rhododendron as forest biomass, algae samples were used as marine biomass. In this context, some of the parameters that need to be controlled during both biomass sample preparation and metal retention were examined. Of which, the torrefaction temperature and the exposure time at the final torrefaction temperature accounted for the parameters relevant during the preparation stage of

biomass samples. Besides, the parameters that investigated during the metal retention included temperature, stirring speed. In this way, adsorption capacities of torrefied biomass samples toward Au, Pt, Pd, Rh were determined. Effects of the mentioned parameters on the metal recovery from solution were discussed and the optimum conditions were specified. Statistical analysis was also employed to understand the effectiveness of the individual parameters on sorption capacities. Concentration of these metals were examined by ICP technique. To enhance the sorption capacity of biomass, torrefaction was applied to different biomass sources, including forest biomass (rhododendron), marine biomass (algae), and agricultural waste (corn waste). The torrefaction process involved heating biomass in an oxygen-free tube furnace at temperatures between 200 and 300°C. This treatment altered the physicochemical properties of the biomass by increasing its hydrophobicity and modifying its surface structure, making it more suitable for metal adsorption.

For instance, Sharma et al. (2013) demonstrated that up to 85% of gold (Au) ions could be recovered using Spirulina platensis microalgae Likewise, modified corn stalks have been reported to selectively adsorb palladium (Pd) ions with high efficiency (Zhang, L., Wang, Y., & Zhao, J. (2019). In another study, torrefied biomass derived from forest residues showed promising results for the recovery of rhodium (Rh) ions, attributed to its increased surface porosity and carbon content(Lee, K., Oh, M., & Park, J. (2021).)

Key experimental parameters were assessed at two stages: biomass preparation and metal adsorption. During biomass preparation, torrefaction temperature and exposure time were varied to determine their influence on sorption efficiency. In the metal adsorption stage, factors such as temperature and stirring speed were optimized to enhance the recovery rates of the target metals.

The adsorption efficiencies of the torrefied biomass samples were evaluated using Inductively Coupled Plasma (ICP) spectroscopy, which measured the concentration of metals before and after adsorption. Additionally, statistical analyses were conducted to identify the significance of each parameter on metal recovery.

Biomass samples used in this study; Rhododendron, maize stalks as agricultural waste biomass sample and seaweed sample as marine biomass sample were selected.

The selected samples were kept under laboratory conditions for one week and then kept in an oven at 60 °C . After these processes, the samples were ground in a ring mill and the entire ground sample was sieved so that the grain size was less than 250 microns. To determine the thermal behaviour of the samples, thermal analyses were carried out in a nitrogen atmosphere and the torrefaction temperatures were determined from the DTG curves obtained.

The torrefaction of each sample was carried out in a horizontal tube reactor under N_2 atmosphere at specified temperatures. Solutions containing 10 ppm Au, Pt, Pd and Rh were prepared. 0.1 gram of torrefied sample was mixed with the solution by stirring in the mixer for 18 hours and then filtered. The obtained liquid portion was subjected to ICP analysis to determine the adsorption efficiency of Au, Pt, Pd and Rh on the torrefied biomasses (Figure 1). The ICP experiments were repeated twice to ensure the repeatability of the results.

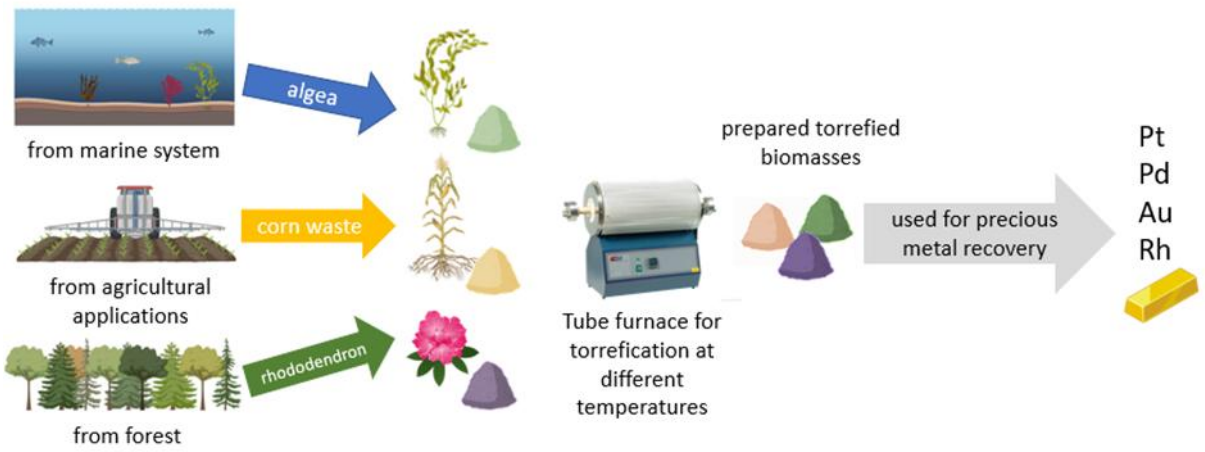

Figure 1. Graphical summary for this work.

Findings

From the samples with high yields, ICP experiments were carried out by producing semi-coke again under the specified conditions for control purposes.

The findings provide valuable insights into optimizing biomass-based sorbents for precious metal recovery and contribute to the development of environmentally friendly and economically viable methods for extracting valuable metals from solution. Future research should focus on scaling up the process and assessing the recyclability of torrefied biomass sorbents for long-term industrial applications.

The results demonstrated that torrefied biomass materials exhibited strong sorption capabilities for precious metal recovery. Nearly 99% of Au was recovered by all torrefied biomass samples, with corn waste torrefied at 200°C performing similarly to those torrefied at higher temperatures. For Pt recovery, approximately 90% was successfully removed using corn waste-based sorbents torrefied at 200°C. In the case of Pd, algae-based sorbents torrefied at 550°C showed the highest efficiency, achieving 100% adsorption. Similarly, the highest Rh recovery was observed with algae-based sorbents torrefied at 550°C. These findings suggest that torrefaction conditions and biomass type play a crucial role in optimizing metal adsorption efficiency.

Conclusion

This study highlights the significant potential of torrefied biomass as an efficient and sustainable sorbent for precious metal recovery. Torrefaction enhances the sorption properties of biomass by modifying its surface structure and hydrophobicity. Among the tested biomass sources, algae torrefied at 550°C demonstrated the highest recovery rates for Pd and Rh, while corn waste torrefied at 200°C effectively recovered Au and Pt, offering a low-energy alternative for metal recovery applications

Effect of Heat Treatment on Inconel 718 Superalloy Produced by Cold Spray Additive Manufacturing

Serra Bayram[a], Erdem Balcı[a], Aptullah Karakaş[b], Murat Baydoğan[a]

[a]Istanbul Technical University, Faculty of Chemical and Metallurgical Engineering, Department of Metallurgy and Materials Engineering, Türkiye
[b]Repkon Makine ve Kalıp Sanayi ve Ticaret Anonim Şirketi, Türkiye
bayrams17@itu.edu.tr

Keywords: Inconel 718, Cold Spray Additive Manufacturing, Heat Treatment.

Aim

Inconel 718 is an nickel-based superalloy with a wide range of applications in the gas turbine engines and aerospace industry, due to its ability to withstand temperatures up to 650 °C (Thomas et al., 2006). Conventionally, the production of the alloy has been accomplished through casting, forging and rolling. However, alternative methods have also been employed in recent years. The most current of these alternative methods is the cold spray method (Garfias et al., 2025). Initially employed in surface coating technology, the cold spray method has evolved to play a pivotal role in additive manufacturing, facilitating the production of Inconel 718 alloy. The method involves the successive application of layers through spray deposition, resulting in the formation of new layers as the process progresses. This process is conducted at supersonic speeds and low temperatures, ensuring preservation of the initial microstructure of the base material. The deposition process is thus repeated until desired form of the final part is achieved. It should be noted that no melting or sintering stage is incorporated. In alternative additive manufacturing methods, the material is melted and deposited in layers, and is exposed to elevated temperatures. This results in residual stresses being induced in the material. Furthermore, these alternative additive manufacturing methods are not compatible with heat-sensitive materials (Yin et al., 2018). Inconel 718 alloy, produced by conventional casting and forging methods, exhibits superior mechanical properties in comparison to material produced exclusively by cold spray additive manufacturing. The application of secondary processes, such as hot isostatic pressing and heat treatment, serves to enhance these lower mechanical properties. The cold spray process is applied layer by layer without melting, thus enabling the creation of a microstructure with high porosity due to its inherent nature. It has been demonstrated that the reduction of porosity in base materials characterized by high porosity values can be achieved through the application of specific heat treatments (Assadi et al., 2011). These heat treatments are also implemented with the objective of enhancing corrosion resistance. The precipitation hardening mechanism is responsible for the formation of phases such as γ' ($Ni_3(Al,Ti)$) and γ'' (Ni_3Nb), resulting in enhanced strength.

Material and Method

Inconel 718 sample, utilized as the substrate in the study, was produced by cold spray additive manufacturing method. The sample produced by the cold spray process was subsequently subjected to a heat treatment process at 1200 °C for 2 h. Hardness and Archimedes density measurements were conducted prior to and following the heat treatment process. Samples were prepared from the cross sections prior to and following the application of heat treatment. Porosity measurements were performed on the polished microstructure by using point counting method. Subsequently, the samples were subjected to etching with a waterless Kalling solution comprising 2 grams of $CuCl_2$, 40 ml of HCl, and 60 ml of ethanol. Subsequent analyses were performed on the etched samples, employing both an optical microscope and a scanning electron microscope (SEM). Electron microscopy analyses were performed using energy dispersive x-ray spectroscopy (EDS) and mapping methods.

Findings

When the microstructure of Inconel 718 sample was examined, a layer-by-layer formation was observed in the microstructure. This observation is attributed to the nature of the cold spray additive manufacturing production method. Porosity measurements made on the microstructure after the heat treatment showed a decrease in porosity fractions compared to before the heat treatment. The porosity fraction in the sample produced only with cold spray additive manufacturing is 1.25%, and in the sample with the heat treatment process is 0.07%. This indicates the effectiveness of the heat treatment at 1200 °C in minimizing the porosity level. As illustrated in Figure 1, the cross-sectional optical microscope images of etched samples are presented, both prior to and following the application of the heat treatment.

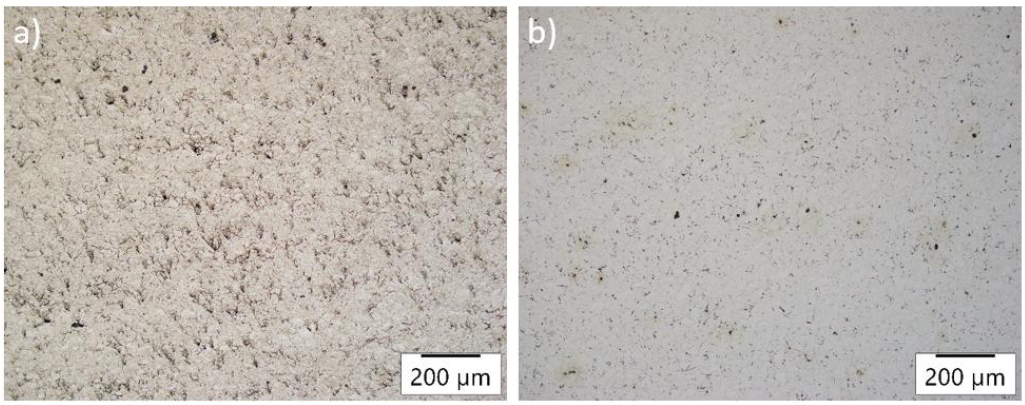

Figure 1. Cross-sectional optical microscope images of the etched samples a) before and b) after the heat treatment.

As illustrated in Figure 2, the images obtained from the SEM analyses prior to and following the heat treatment process are displayed. The microstructure of the samples revealed the presence of both grain formation and the formation of annealing twins. The presence of titanium nitride (TiN) phases was determined both prior to and following the process of the heat treatment.

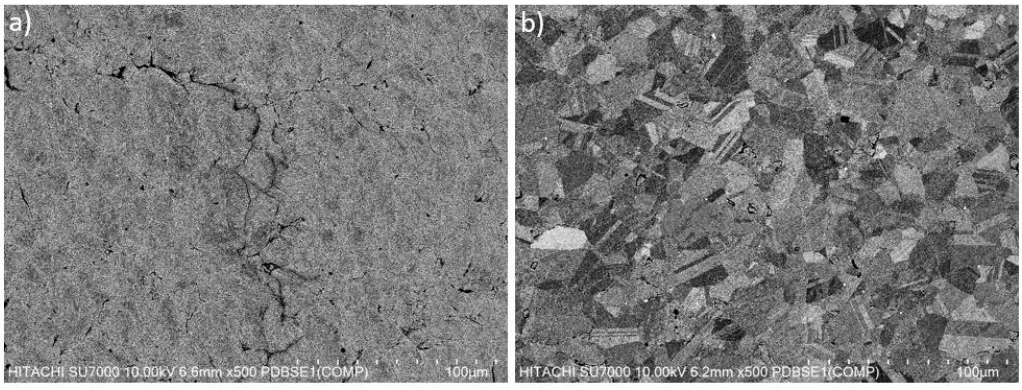

Figure 2. a) Before b) after the heat treatment SEM analysis images of Inconel 718 alloy produced by cold spray additive manufacturing.

Furthermore, the SEM mapping analysis of the region of the grain boundaries in Figure 3 determined the presence of Nb and Mo-rich phases precipitated along the grain boundaries.

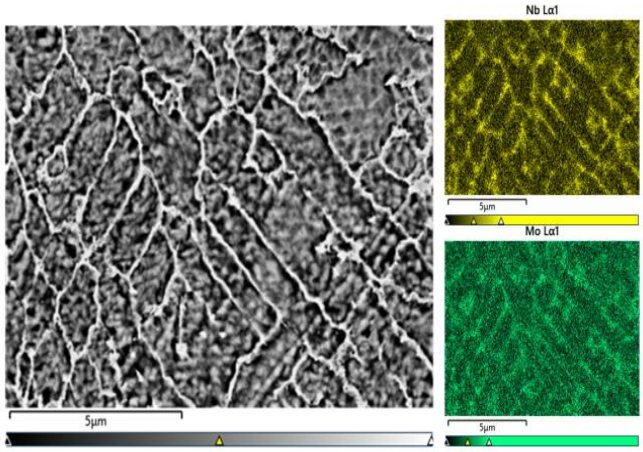

Figure 3. SEM Mapping analysis of Inconel 718 alloy produced by cold spray additive manufacturing after the heat treatment process.

Conclusion

A SEM examination was conducted prior to the application of heat treatment, which revealed a highly porous and hollow microstructure. Intergranular segregation was observed between layers. The heat treatment process led to a decrease in the porosity, thereby enhancing the microstructural properties of the base material. In comparison to the material that underwent no heat treatment and possessed higher porosity values, the material could demonstrate enhanced oxidation resistance. Annealing twins, as observed in the microstructure subsequent to the heat treatment, have a potential to enhance strength and improve creep strength. This can be attributed to the partial prevention of dislocation movement. The presence of Nb and Mo-rich phases at the grain boundaries was observed to be more prevalent than the Laves phases detected in the Inconel 718 microstructure. The precipitation of Laves phases in a controlled manner has been shown to impede grain boundary sliding and augment the high-temperature strength to a certain extent. However, these phases are known as hard and brittle intermetallic compounds, which have a detrimental effect on ductility and toughness of the material when their percentage in the microstructure and grain boundaries is excessive. Laves phases can be minimized by an ageing processes following a homogenization heat treatment. The ageing processes ensure that the Nb element precipitates as γ" (Ni_3Nb) and mechanically increases the strength of the material.

Effect of Niobium Addition on the Microstructural Features of Titanium Alloys for Dental Implants

Sena Burcu Hayirci[a], Faiz Muhaffel[a], Hüseyin Cimenoglu[a]

[a]Istanbul Technical University, Department of Metallurgical and Materials Engineering, Türkiye
hayirci16@itu.edu.tr

Keywords: Powder Metallurgy, Titanium, Titanium-Niobium Alloy.

Aim

Recent progress in the field of dental implants has significantly enhanced their feasibility for longer lifespan, through the development of materials that offer improved corrosion and wear resistance, biocompatibility and reduced toxicity. Metals and their alloys are particularly favored in biomedical applications due to their relatively low modulus, good fatigue strength, corrosion resistant and good biocompatibility. Despite their many advantages, titanium and its alloys cannot meet all the requirements. One of the primary limitations is their inherently low surface hardness and high friction coefficient, which leads to severe adhesive wear (Li et al., 2014; Korneva et al., 2022).

Titanium, which has allotropic transformation like Fe, Co, Zr, is in the α-Ti phase with hexagonal closed packed (HCP) structure at room temperature, while it transforms into the β-Ti phase with body centered cubic (BCC) structure above 883°C. According to the lattice structure at room temperature, Ti alloys can be classified as α, α+β and β type when alloying element are added. The alloying elements of titanium are classified as neutral, α-stabilizers and β-stabilizers according to their effects on the transus temperature. Neutral elements (Sn, Zr) have little effect on the transus temperature, while α-stabilizers (Al, O, N, C) shift the α phase field to higher temperatures and β-stabilizers (Mo, V, Ta, Nb) shift the β phase field to lower temperatures (Kaur and Singh, 2019; Peters et al., 2003).

Ti-6Al-4V, one of the most commonly used titanium alloys has prompted the search for alternative compositions due to concerns over the potential toxicity of aluminum and vanadium, as well as its relatively high elastic modulus. Compared to other β-phase stabilizers such as Ta, Zr, Nb offers superior biocompatibility (Ibrahim et al., 2022; Han et al., 2015).

Titanium and its alloys have a protective, inert oxide layer on the surface at room temperature. Increasing the thickness of this oxide layer, which contributes to the surface properties of the material, results in an increase in chemical, physical and mechanical properties. Methods such as anodization, micro-arc oxidation and thermal oxidation can be used for controlled oxide layer applications. The increase in corrosion and wear resistance and hardness in the coating obtained as a result of micro arc oxidation and the low cost and equally effective method of thermal oxidation bring these two methods to the forefront in thick oxide layer formation methods (Velten et al.,2002; Wilks et al., 2009).

This study aims to investigate the effect of varying Nb content (x = 0, 23, 45 wt.%) on the microstructure of the sintered Ti-xNb. The objective is to developed materials with improved hardness and wear resistance while ralso evaluating the role of Nb in modifying the alloy's microstructural characteristics and mechanical performance.

Material and Method

In this study, the spherical Ti and Nb powders (Alfa Aesar, 99% purity, ≤45μm) were weighted for different ratios Ti-xNb (x = 0, 23, 45 Nb wt.%), and samples were produced by powder metallurgy. The mixtures were mixed in a turbula mixer for 1 hour for a homogeneous distribution. The powder mixtures were pressed in a 13 mm mould under a pressure of 370 MPa with a uniaxial press (MSETMMP 0710). The green bodies were sintered in a tube furnace (ProthermPTF17/75/300) under argon gas for about 1 hour at 1400°C.

Archimedes' densities were measured. The phase composition of sintered samples was investigated by X-ray diffractometer (XRD, X'Pert PRO PANalytical). The analysis conditions were Cu-Kα radiation at 35 kV and 40 mA with the range of 20°- 80° at 0.02° step size. Sample surfaces and cross-sections were examined with light optical microscopy (OM, Nikon Eclipse L150) and Scanning electron microscopy (SEM, Hitachi TM-1000) for higher magnifications. Mechanical characteristics of the specimens were evaluated with Vickers hardness (TUKON 1102) and wear test (Tribotech Oscillating Tribotester). For Vickers hardness assessment, 100 g load was applied. The reciprocating wear test were carried out x1.5 simulated body fluid (SBF) environment at 37°C. The counter face was chosen as 6 mm diameter alumina ball and ball's amplitude and sliding speed were 2mm, 6mm/s under 1N for a total sliding distance of 50m. After the wear tests, wear tracks formed on the samples were examined by using EDS equipped SEM (SEM, Hitachi TM-1000) and 2-D surface profilometer (Veeco Dectac 6 M). Also, the contact surface of the counter face balls was examined by OM.

Findings

Archimedes' densities are measured for Ti, Ti-23Nb and Ti-45Nb. Archimedes' and theoretical densities and % porosity can be seen in Table 1. Because niobium has a higher density than titanium, theoretical and Archimedes' densities are increased by Nb addition, as shown in Table 1. Porosity calculation based on theoretical and Archimedes' density measurements indicates porosity increasing with Nb addition due to the slow diffusion rate of niobium compare to titanium.

Table 1. Archimedes' density, relative density and porosity values of the sintered samples.

	Ti	Ti-23Nb	Ti-45Nb
Theoretical density (g/cm^3)	4.51	5.32	6.08
Archimedes' Density (g/cm^3)	4.24 ± 0.05	4.72 ± 0.11	4.85 ± 0.20
Porosity (%)	5.98	11.23	20.23

XRD phase analysis shows only α-Ti peaks for Ti. XRD pattern of Ti-23Nb indicates both α-Ti and β-Ti peaks. After %45 weight Nb addition β-Ti phase stabilized in the microstructure. The phase ratios calculated by the Rietveld method for Ti 23Nb were 41.2 wt% α-Ti and 58.8 wt% β-Ti. This value corresponds to 59.3 vol% β-Ti.

SEM images of Ti-xNb (x= 0, 23, 45 Nb wt%) were given in Figure 1. SEM images confirmed porosity increase as the result of Nb addition. By using ImageJ software based on different SEM images of Ti-23Nb β-Ti calculated 59.18 ± 1.3 % vol. Moreover, while α-Ti seen in Ti, β-Ti was seen in Ti-45Nb and β-Ti coexisted with α-Ti in Ti-23Nb.

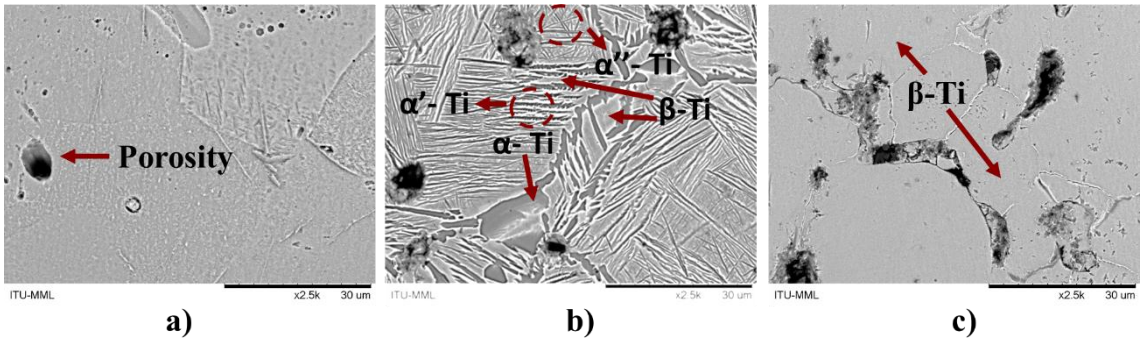

Figure 1. SEM micrographs of a) Ti, b) Ti-23Nb and c) Ti-45Nb samples.

Vickers' Hardness of the samples are measured as 315, 357 and 205 HV0.1 for Ti, Ti-23Nb and Ti-45Nb, respectively. It is suggested that the α"-Ti increased the hardness for Ti-23Nb. Because of β -Ti is more ductile compare to Ti, the lowest hardness was measured in Ti-45Nb, as 205 HV0.1.

The tribological performance of Ti, Ti-23Nb and Ti-45Nb alloys has been conducted in 1.5× SBF solution. The results showed a clear correlation between increasing Nb content and deteriorating wear resistance in Ti. In particular, the volumetric wear loss values increased from about 2.1×10^{-3} mm³ for Ti to 9.4×10^{-2} mm³ for Ti-45Nb, indicating a more than 40-times increase in material loss with 45 wt% Nb. The average coefficient of friction increased from ~0.3 (Ti) to ~0.4 (Ti-23Nb) and reached ~0.65 (Ti-45Nb); Ti-45Nb also exhibited more irregular and unstable friction behavior.

Optical and SEM analyses revealed a progression in wear mechanisms from mild adhesive wear in Ti to severe adhesive and abrasive wear in Nb-containing alloys, with Ti-45Nb showing the largest and most damaging wear scars, wide grooves and material delamination.

Conclusion

In this study, Ti-xNb (x = 0, 23, 45 Nb wt%) sintered at 1400°C was characterized from the view of the Nb addition effects on the microstructure, and the main findings are as follows:

• An increase in porosity was observed with the addition of Nb, and this increment was confirmed by SEM images. The higher porosity leads to a reduction in the modulus of elasticity. Nb addition reduces the elastic modulus in Ti (~110 GPa), and the elastic modulus approaches the elastic modulus of bone tissue (10-30 GPa).
• XRD results confirm that the β phase is stabilized by the addition of Nb, which is a β stabilizer.
• Nb addition slightly increase the hardness of Ti-23Nb and further addition of Nb led to a higher fraction of β-Ti in the microstructure and a reduction in hardness. While the hardness of the Ti was ~315 HV 0.1, the hardnesses of Ti-23Nb and Ti-45Nb alloys measured as ~357 HV0.1 and ~ 221 HV0.1, respectively.
• Ti-xNb alloys exhibited adhesive wear as the dominant mechanism, with the intensity of this wear increasing proportionally to the niobium content in the alloy.

Consequently, while increased Nb content adversely affects the wear resistance and frictional behavior of Ti alloys in their untreated state, surface modifications such as thermal oxidation and micro-arc oxidation can effectively overcome these limitations and enable the use of β-Ti alloys in applications where both mechanical compatibility and wear resistance are critical.

Acknowledgement

The authors would like to express their acknowledgements to Batuhan Sorusbay and H. Ozkan Gulsoy for the production of Ti-Nb alloys. Also, authors would like to thank Res. Ass. Mertcan Kaba for support.

Keywords: 6xxx Alloy, Aluminium, Mechanical Properties, Recycling, Welding.

Aim

Aluminium alloys especially 6xxx series, are widely preferred in structural parts of electric vehicles (EV) due to their high specific strength, corrosion resistance and recyclability. The European Commission (EC) has determined Critical Raw Materials (CRM) which means Europe is depended to other continents for their supply and yet CRMs have emerged to be recycled. Bauxite which is the primary ore of aluminium, magnesium (Mg) and silicon (Si) which are the main alloying elements of 6xxx aluminium alloys are stated in the CRM list of EC. To balance CRMs usage in EVs, 2 solutions can be adapted. The first one is to limit usage of CRMs (6111 alloy development), and the second one is to recycle what has already existed. In this work, both approaches have been studied and compared with the performances of the alloys produced without recycling.

Material and Method

In this study, 6063 and 6082 alloys are selected for EV structural part production. They have been produced using both primary feedstock and post-consumer scraps. Post consumer scraps in this study have been separated from waste first by eddy-current separator and then with Multi Pick system which enables separation of aluminium alloys with respect to their main alloying elements using Laser Induced Beam Spectrometer (LIBS) technology. As an alternative for these alloys, 6111 alloys have been developed. Figure 1 shows industrial production steps of the extrusion profiles of EVs structural parts.

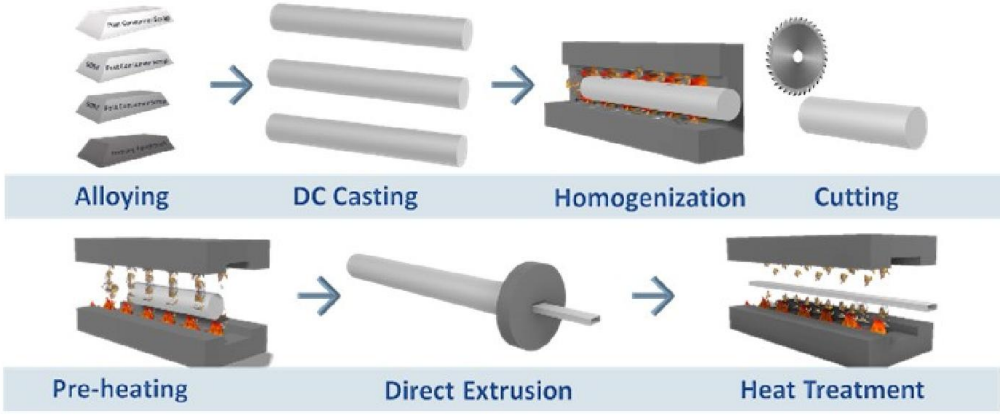

Figure 1. Process flow-chart for 6xxx aluminium alloy production.

Production route started using post-consumer scraps, primary aluminium and alloying elements. Table 1 demonstrates used feedstock for each alloy production.

Table 1. Feedstock Content.

	6063-C	6082-C	6063-R	6082-R	6111
Post-Consumer Scrap	0	0	16%	34%	0
6063 PC Scrap	0	0	54%	12%	0
6082 PC Scrap	0	0	0	44%	0
Primary Feedstock	100%	100%	30%	10%	100%

Determined feedstocks have been melted in a prototype casting furnace with 500 kg capacity and then direct chill (DC) cast into billets. Billets have been homogenised in Hertwich Batch Type Furnace. 6111 billets have been heated up to 540 °C in 7 hours and kept in this temperature for another 7 hours. 6082 billets are heated up to 555 °C in 6 hours and kept for another 6 hours. 6063 billets are heated to 570 °C in 6 hours and kept for another 6 hours. Homogenised billets are cut into length (850-1050 mm) that can be fed into 29 MN extrusion press. Pre-heating is applied to cut billets. 6111 extrusion is applied in 490°C induction heat with 4,5 mm/s speed having 538°C exit temperature 6082alloys extrusion is applied in 490°C induction heat with 5,1 mm/s speed having 533°C exit temperature. 6063 alloys Extrusion is applied in500°C induction heat with 7,5 mm/s speed having 556°C exit temperature. After the Extrusion procedure, T5 heat treatment has been applied. Profile samples are prepared for investigation using Struers Secotom-15 cutting equipment. After that they have mounted to the bakelite. Struers Tegramin-30 grinding equipment is used to complete sample preparation. Samples are chemically analyzed using Thermo fischer Optical Emission Spectrometer. ZwickRoell Z050 Tensile Testing Equipment is used for anisotropy, bake paint and plate bending tests. Anisotropy tests are carried out with respect to EN ISO 6892-1:2020 in room temperature. Bake paint tests are applied to the specimens with respect to EN ISO 6892-1:2020 standard after exposing 180°C for 20 minutes. Plate bending tests were conducted according to the VDA 238-100 standard. Following this standard, bending test specimens were prepared with dimensions of 30x60mm. Roller spacings used in the test were adjusted to be twice the sample thickness, and bending tests were performed using the specified punch as outlined in the standard. In the test procedure, a preload of 30N was applied, with a test speed set at 20 mm/min. The drop-in force was defined as 60N, meaning that the test was halted when there was a deviation of this magnitude in the applied force. Finally, Tungsten Inert Gas (TIG) welding is applied to profiles joining. Welding speeds of 8 – 8,5 and 9 m/min have been applied to the samples. Welding zones are investigated via Optical microscope of Zeiss Axio Imager and hardness test is applied. Figure 2 demonstrates the used equipments and the experimental loop of the study.

Figure 2. Schematic representation of the experimental setup, including the equipment used and the experimental loop.

Findings

The Table 2 demonstrates the results of the OES analysis where "C" stands for conventional production using no scrap and "R" stands for alloys produced with recycling content. All alloys are validated with respect to EN 573-3 standard.

Table 2. Chemical Compositions of the Alloys measured by OES.

	Si	Fe	Cu	Mn	Mg	Cr	Ni	Zn	Pb	Ti
6063-C	0,559	0,219	0,03	0,041	0,561	0,012	0,01	0,031	0,004	0,02
6082-C	0,849	0,235	0,075	0,545	0,861	0,02	N/A	0,04	N/A	0,02
6063-R	0,648	0,265	0,075	0,103	0,502	0,015	0,01	0,063	0,0047	0,021
6082-R	0,869	0,227	0,071	0,535	0,879	0,05	N/A	0,045	N/A	0,038
6111	0,672	0,156	0,872	0,246	0,681	0,002	N/A	0,008	N/A	0,041

Anisotropy analysis results have been shown in Table 3. According to the results, the yield strengths of 6063 alloys decrease from parallel to perpendicular direction. While the yield strength of the 6082 alloys increases from the direction of 0° to 90° while it shows lowest value at 45°.

Table 3. Anisotropy results obtained from tensile test.

	Angle	Rp0,2 [MPa]	Rm[MPa]	A (%)
6063-C	0	218	247	12,2
6082-C	0	264	296	13,7
6063-R	0	244	270	13,16
6082-R	0	267	293	15,3
6111	0	306	326	10
6063-C	45	210	239	5,2
6082-C	45	261	288	8,2
6063-R	45	238	257	5,95
6082-R	45	264	287	9,1
6111	45	302	325	5,3
6063-C	90	238	271	6,1
6082-C	90	268	302	8,5
6063-R	90	281	321	8,9
6082-R	90	276	300	9,2
6111	90	303	324	7,6

Tensile strength of the alloys showed similar behavior with yield strengths. When the testing direction is diagonal and perpendicular to the extrusion direction, tensile strengths of the 6063 alloys are 4-5% lower than the 0°. This behavior is primarily due to the alignment of grains and precipitates along the direction of extrusion. Highest tensile strength values are achieved with testing in 0° angle for 6063 alloys. 6082alloys highest strength seen at 90° angle. The tensile strength of these alloys has decreased from 0° to 45°. The unexpected result of 6082 alloy can be explained by its high alloying rates and Cu elements have created Al_2Cu precipitates which caused directional strengthening. Comparison of the yield strengths, tensile strengths and elongation behaviors of the recycled and conventional alloys carried out. Less CRM used alloy shower highest strength properties while recycled alloys have higher than the conventional ones. The reason behind this may be explained by the chemical composition. Higher Si content yields in more Al-Si particles formation and precipitation of them increases the strength.

Table 4 demonstrates the bake paint test results. According to bake paint results it can be noticed that yield and tensile strength of both 6063 and 6082 alloys have been increased. However, the elongations of both alloys have slightly decreased.

Table 4. Bake Paint Test Results.

	Rp0,2 [MPa]	Rm[MPa]	A (%)
6063-C	258	274	12,2
6063-R	233	278	11,7
6082-R	279	306	15
6111	306	330	11

This process promotes the formation of fine, coherent precipitates (e.g., Mg_2Si in 6063 and Al_2Cu in 6082), which impede dislocation motion and enhance strength. The more significant increase in 6082 alloy can be attributed to its higher alloying content, which provides a greater potential for precipitation strengthening. The decrease in elongation after the bake-paint test is a typical consequence of increased precipitation density. While the precipitates improve strength, they also reduce the material's ability to deform plastically, leading to lower elongation. According to these results it can be discussed that the thermal treatment applied before tensile test section of bake paint test has increased the strength of the alloys. As characteristics of aluminium alloys, one can notice that these alloys have converged to the peak age aging condition. Recycling content has caused increased strength but decreased elongation because of increased precipitation hardening mechanisms in the microstructure. Table 5 shows the plate bending results. It can be noticed that all the alloys have passed the target value. Comparisons were made by considering a minimum bending angle of 90° for the 6082 and 6111 alloys, and a minimum of 120°C for the 6063 alloy. The obtained results exhibit satisfactory performance compared with mechanical properties.

Table 5. Plate Bending Test Results.

	α	Target	Thickness	Result
6063-C	88°	120°	4,3	124°
6063-R	124°	120°	3,8	124°
6082-R	65°	90°	3,7	92°
6111	67°	90°	4,3	95°

Figure 3 demonstrates microstructures of the welding zones. It can be seen that penetration of the welding area is more qualified in recycling content alloys. The micrographic analyses showed a good quality of the weld, in terms of throat and depth of penetration, and comply with the required standards. The presence of porosity appears to be marked but still does not affect the weld's resistant section. The hardness measured showed consistent values throughout all the welding samples. The Heat Affected Zone (HAZ) showed values in the range of 73-75 HB, while the weld itself is 63-65 HB.

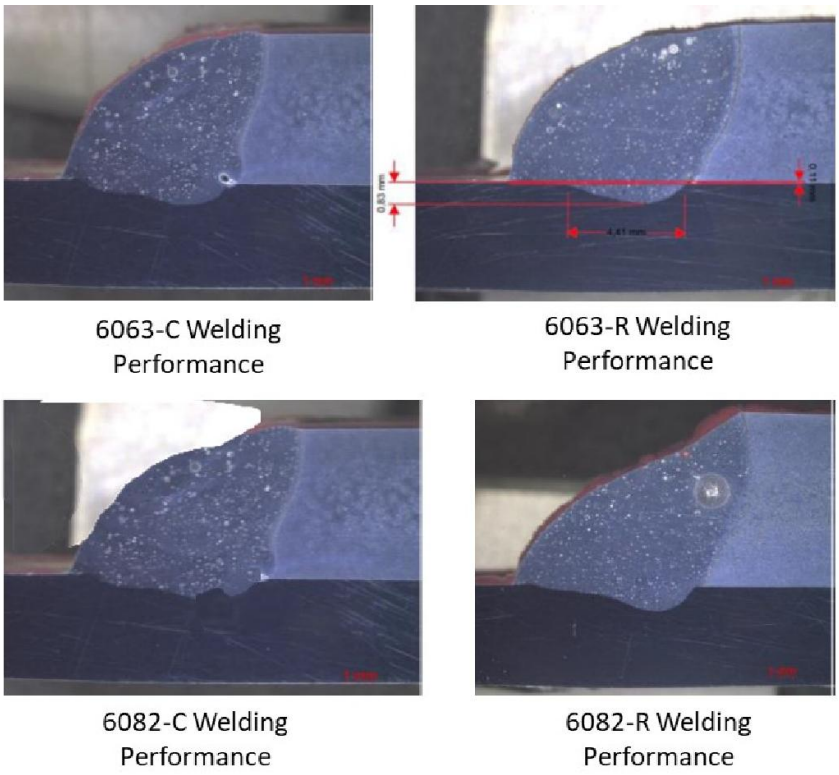

Figure 3. Weld Zone Investigation via Optical Microscope.

Conclusion

The In this study, comprehensive mechanical characterization of three distinct alloys (6063, 6082, and 6111) produced via DC casting method was conducted. Their chemical compositions were determined through the OES method. Subsequently, the billets were extruded and transformed into final shapes. After extrusion, profiles were subjected to quenching and subsequent artificial aging to attain the T5 temper condition. Tensile and bending tests were conducted in accordance with EN standards to assess the performance of the profiles. Additionally, bake paint test was conducted to comprehend the thermal stability of the profiles. Considering the directional alignment of grains during the extrusion process, investigations into their anisotropic behavior were also conducted. Evaluation of all results reveals that the mechanical performance of the material is in good accordance with European standards. To sum up, the mechanical properties, elongation percentage, bending values, thermal stability, and microstructure performance obtained after productions using recycled materials within the study are comparable and similar to standard productions.

Effect of Pack Aluminizing on Hydrogen Charging Behavior of Ti6Al4V Alloy Fabricated by Selective Laser Melting

Belgin Ataman[a], Burak Bayram[a], Erdem Balcı[a], Murat Baydoğan[a]

[a] Istanbul Technical University, Faculty of Chemical and Metallurgical Engineering, Department of Metallurgy and Materials Engineering, Türkiye
ataman17@itu.edu.tr

Keywords: Additive Manufacturing, Pack Aluminizing, Ti6Al4V Alloy, Hydrogen Charging.

Aim

The primary objective of this study is to comprehensively investigate the surface properties of Ti6Al4V alloy fabricated through Selective Laser Melting (SLM) after exposure to hydrogen charging and applying aluminizing. The study aims to analyze the microstructural changes and potential embrittlement effects induced by hydrogen absorption in the SLM-manufactured Ti6Al4V alloy, which is widely used in aerospace, biomedical, and industrial applications due to its superior mechanical strength and corrosion resistance. Furthermore, this research explores the impact of pack aluminization on the hydrogen charging behavior of the alloy. By combining optical microscope and hardness testing, this research provides a characterization of the microstructural modifications induced by hydrogen exposure and pack aluminization treatment.

Material and Method

Ti6Al4V alloy is the most commonly used commercial titanium alloy. Due to the addition of elements such as aluminium and vanadium, it possesses high strength and ductility, good corrosion resistance, and low modulus of elasticity, making it suitable for a wide range of industrial applications, especially in the biomedical, aerospace, and automotive sectors. In recent years, additive manufacturing (3D printing) has gained prominence for producing complex titanium alloy parts with minimal material waste. Additive manufacturing is a manufacturing technology where parts are produced by layering materials based on a 3D model using computer-aided CAD software and then joining these layers. Currently, three different additive manufacturing methods are in use: selective laser melting (SLM), laser metal deposition, and electron beam melting (EBM). SLM uses a high-powered laser to melt and fuse metallic powders, layer by layer, to form a 3D object. This process is particularly well-suited for titanium alloys as it offers controlling the microstructure, which directly affects the mechanical properties of the part.

Aluminizing is a process in which aluminum is deposited onto the surface of the titanium alloy in a high-temperature vacuum or gaseous environment. As a result of this process, intermetallic phases form between titanium and aluminum, significantly increasing the surface hardness and oxidation resistance of the alloy. Additionally, the aluminizing process can improve the performance of titanium alloys in high-temperature applications by enhancing their oxidation and wear resistance.

A serious problem that compromises the structural integrity of many alloys used in engineering applications is hydrogen embrittlement (HE). It refers to the deterioration of mechanical properties such as ductility, toughness, and load-bearing capacity due to the ingress and interaction of hydrogen with the metal's microstructure. Titanium alloys are extensively utilized in aerospace, biomedical, and marine applications due to their excellent strength-to-weight ratio and corrosion resistance. However, the presence of hydrogen, either during manufacturing or in service, poses significant challenges, making an in-depth understanding of HE mechanisms essential. Hydrogen charge is a process used to study issues such as hydrogen embrittlement in titanium alloys. When hydrogen diffuses into the Ti6Al4V alloy, it can induce microstructural changes that negatively affect the mechanical properties. The hydrogen charging process is essential for investigating these effects and understanding the interactions between hydrogen and the alloy.

In this study, the surface properties of Ti6Al4V alloy fabricated by the SLM method after aluminizing and hydrogen charge were investigated. For this purpose, the pack aluminizing method was employed. In this method, $AlCl_3$ powder was used as the activator, Al_2O_3 powder as the filler material, and aluminium powder as the aluminium source. After mixing these powder components, they were placed into a steel crucible, and then the Ti6Al4V alloy to be coated was immersed into the powder mixture. The pack aluminizing process was performed at 700 °C for 4 h. After the coating process was completed, the samples were cooled in the furnace to the room temperature. For comparison, as built with aluminizing and as built without aluminizing samples were subjected to the hydrogen charge process. Hydrogen charging was conducted in an electrochemical cell, where the electrolyte consists of glycerin and H_3PO_4 with a ratio of 2:1. In the cell, the cathode is a platinum sheet, and the anode is the material to be charged. Cross sectional microstructures of the samples were made by using optical microscopy. Microhardness of the samples was measured by Vickers microhardness method.

Findings

Figure 1 shows average surface and cross-section hardness values for the as built, as built charged, and as built aluminizing charged samples. The average hardness values for cross section of the as built sample was measured as 395 HV0.3. As built charged sample was measured 433 HV0.3, as built aluminized charged sample was measured 401 HV0.3. Based on these results, the cross-sectional hardness of the sample did not change significantly after the coating process. However, in the absence of coating, the cross-sectional hardness increased. The hardness of the hydride layer in as built charged sample was measured 366 HV0.3.

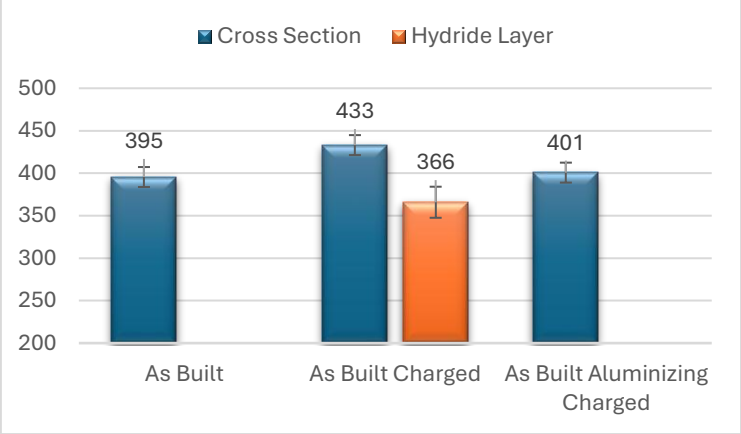

Figure 1. Vickers hardness measurements.

Figure 2 shows etched cross sectional images for as built, as built charged and as built aluminizing charged samples. According to these images, a dark layer was observed on the charged surface. It is an indication of hydrides formation in the surface region after the hydrogen charging process. On the other hand, the surface of the aluminized sample does not have a color change, possible due to enhanced resistance to hydrogen charging.

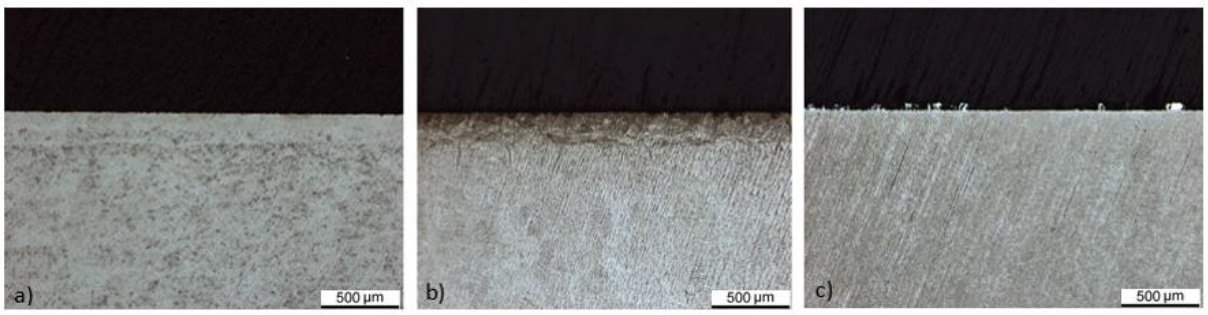

Figure 2. Cross sectional optical microscope images a) as built b) as built charged, c) as built aluminizing charged.

Conclusion

The aluminizing process involves the formation of aluminides on the surface, which enhances oxidation and wear resistance. This process also modifies the microstructure and composition of the surface. The presence of aluminium has been demonstrated to influence the diffusion and accumulation of hydrogen within the material (Zhao et al., 2007). The aluminium based coating may act as a barrier, limiting hydrogen penetration into the alloy, thereby reducing its hardening effect (Zeng et al., 2023).

The lower hardness values observed in the aluminized samples can be attributed to the aluminized layer restricting hydrogen absorption, thereby mitigating the hardening effect typically induced by hydrogen charging (Christ et al., 2000). Furthermore, phase transformations or microstructural changes occurring during the aluminizing process may contribute to the reduction in hardness. In conclusion, these results indicate that the aluminizing process, followed by hydrogen charging, leads to a noticeable reduction in hardness (Gao et al., 2024). The as built charged sample has higher hardness values than as built and aluminizing charged samples.

In summary, the aluminized coating was degraded after the charging process; however, it prevented the formation of a hydride layer. While there was no significant change in the hardness of the coated sample, an increase was observed in the cross-sectional hardness of the uncoated sample.

Keywords: Al-Si Casting Alloy, Micro-Arc Oxidation, Ni-SiC Composite Coating.

Aim

Aluminium and its alloys are widely used in automotive and aerospace industries thanks to their superior properties, such as high specific strength, excellent formability, and corrosion resistance. Moreover, they have attracted many industries owing to electrical conductivity, low thermal expansion coefficient and high thermal conductivity, which are other important properties. Among the aluminium alloys, Al-Si casting alloys are one of the most favoured alloys owing to good castability, suitability of many casting methods and having a wide strength range in addition to outstanding properties of aluminium alloys. However, application areas of Al-Si castings are limited due to their low wear resistance and low hardness. The surface properties of Al-Si casting are insufficient, especially in rotating and reciprocating sliding conditions. In order to overcome these disadvantages, various types of surface modification methods have been improved, such as conventional anodizing, hard anodizing, thermal spray coating, physical vapour deposition (PVD), chemical vapour deposition (CVD), cold spraying, nickel ceramic composite coating and micro-arc oxidation (MAO).

Ni-SiC composite coating is one of the most common electroplating coatings that enhance the tribological behaviour of Al-Si casting. The size of the coating may vary depending on applications but is commonly between 70-200 µm, and the hardness of the coating is usually between 500-600 HV. In Ni-SiC coating, Ni holds and supports SiC particles as a matrix by plating to bore surfaces. SiC particles are the reinforcement phase and provide the desired tribological properties of coating with approximately 2500 HV hardness. The size of the particles is 1-10 µm, and it forms 20% of the coating. Nikasil, the commercial name of Ni/SiC coating, has been used for several years by many automotive firms. In addition to the standard application of this coating, the presence of sulphur in the fuels can react with the nickel coating, causing corrosion and premature failure. Nikasil coating can be used when the sulphur level is low and the quality of fuel is high, as in sports car applications, but alternative coating needs have arisen.

Micro arc oxidation coating (MAO), also known as plasma electrolytic oxidation (PEO), is another electrochemical process to obtain the desired surface properties of aluminium alloys. MAO coating offers remarkable wear and corrosion resistance by forming a complex ceramic layer on the substrate. The complex layer mainly consists of aluminium oxides (α-Al2O3, γ-Al_2O_3) and mullite ($3Al_2O_3{\cdot}2SiO_2$) phases, and this layer acts as a protective layer between the base metal and corrosion environment. The oxide layer has a porous structure, which is favourable for retaining lubricant. Moreover, its oxidized layer provides superior adhesion properties compared to deposition coatings. In addition, micro arc oxidation is a enviromental friendly coating due to using non-toxic electroltyres during the process. Besides all these advantages, MAO coating is not as common as Nikasil coating on Al-Si casting on an industrial scale.

The purpose of this study is to develop an MAO process as an alternative to the Nikasil coating, which is widely used industrially on Al-Si casting alloys. There are some studies to investigate both coating separately. However there are no specific comprehensive work to compare both coatings directly. In this way, SEM and XRD analyses were conducted on MAO coatings fabricated from Al-Si casting. Further, it aims to develop an alternative coating for commercial application and examine the application of MAO to Al-Si castings.

Material and Method

Samples with the dimension of 10 mm x 10 mm x 4 mm (L x W x T) cut from the Al-Si casting alloy tensile test bar were used as the substrate for MAO coating. Prior to the MAO process, the samples were grounded by using SiC abrasive papers up to a size of P2500. Then, it was washed with ethanol and distilled water and dried at room temperature.

In this study, the MAO equipment used included a 30 kW bipolar pulsed DC power supply unit, a stainless steel electrolyte container, an air pump for mixing the electrolyte and an external cooling system. The stainless steel container served as a cathode, and samples were connected to the electrochemical cell as an anode. The electrolyte consisted of sodium aluminate, sodium hydroxide and sodium phosphate. The positive and negative voltages were selected as 450 and 100 V, respectively. The process duration was 4 min.

The samples were cut to a size of 10 mm x 10 mm x 10 mm (L x W x T) dimensions from Al-Si casting alloy, which has commercial Nikasil coating. Then, it was washed with ethanol and distilled water and dried at room temperature. The structures of both samples were characterized by using a scanning electron microscope (SEM, Hitachi TM-1000). In order to identify phases, energy dispersive X-ray spectrometer (EDX) analysis was performed on the coatings. A qualitative phase analysis of the coatings was conducted by using X-ray diffraction (XRD, X'Pert PRO PANalytical).

Findings

Surface SEM micrographs of MAO coatings fabricated on an Al-Si casting substrate are shown in Figure 1 at 500x, 1000x, 2500x and 5000x magnification. The surface of the coated samples is composed of typical morphology, including micro-pores and micro-cracks. The different sizes of pores are uniformly distributed along the surface, arising from the discharge channels which are formed during the coating process. Moreover, micro-cracks are observed on the surface. These cracks are common in MAO coatings and result from a high thermal gradient between molten oxide and cold electrolytes during the process.

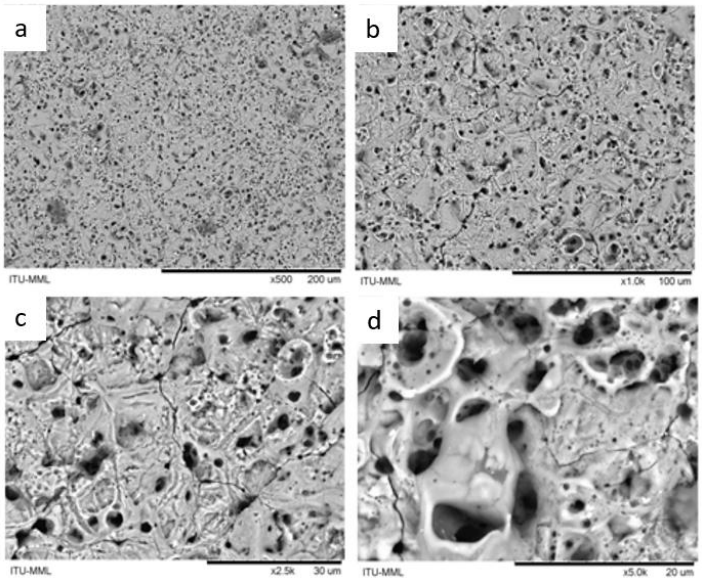

Figure 1. Surface SEM micrographs at (a) 500x, (b) 1000x, (c) 2500x, (d) 5000x magnifications.

The XRD spectra of MAO coating are shown in Figure 2. The coating was mainly composed of Al_2O_3. Aluminium and silicon peaks, which came from underlying substrates, were also observed, caused by the penetration of X-rays with the substrate material.

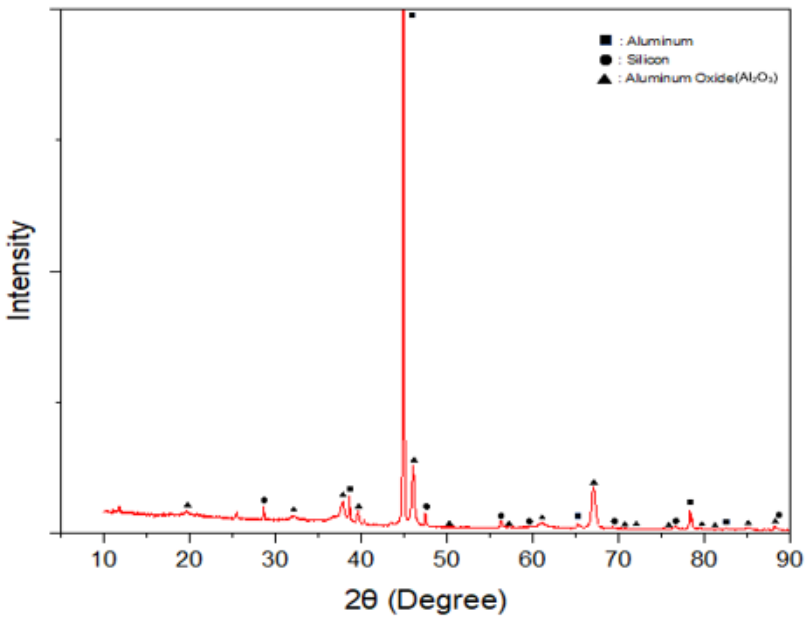

Figure 2. XRD spectrum of the MAO sample.

Conclusion

In the present study, MAO coating was successfully formed on an Al-Si casting substrate in an alkaline electrolyte. SEM analysis was conducted on the coating. It revealed that the surface of the coating had a conventional morphology, including micro-pores and micro-cracks throughout the surface, causing discharge channels during the process. Furthermore, XRD analysis was performed, and the phase of the coating was characterized. The coating layer was composed of aluminium oxide (Al_2O_3) as a main phase, and aluminium and silicon were detected from the base metal.

Keywords: CMAS, Cold Spray, Corrosion, Gas Turbine, Thermal Barrier Coating.

In this study, an aluminium coating was applied using the cold spray method to enhance the CMAS and hot corrosion properties of YSZ (yttria-stabilized zirconia) thermal barrier coating (TBC) systems on a stainless steel substrate. Following the aluminium deposition, the coated aluminium will undergo thermal oxidation to form a new oxide layer. This newly formed layer is expected to play a crucial role in mitigating the detrimental effects of CMAS and hot corrosion. The investigation will focus on analysing the CMAS and hot corrosion behaviour of the system with the aluminium oxide layer in order to understand its impact on the durability and performance of the coating under high-temperature conditions. Ultimately, the goal is to improve the resistance of the material to these damage mechanisms, thereby extending the lifespan and reliability of thermal barrier coatings in industrial applications.

Aim

Thermal barrier coatings (TBC) have been widely used in the gas turbine industry for over 30 years. TBCs consist of at least three component layers. The first layer is the bond coat applied to the base material. During operation, an intermediate layer called thermally grown oxide (TGO) forms. The final layer is the ceramic top coat, which enables an increase in the operating temperature. The selected ceramic material has very low thermal conductivity, allowing for a temperature drop of up to 200 K throughout the coating [1]. Two commonly used methods for the production of thermal barrier coatings are thermal spray and EB-PVD methods. While many other methods exist, they have not yet become accepted industrial methods. Each process produces very different and distinct microstructures, each with its specific advantages and disadvantages [2]. When examining various industries, one of the most commonly used thermal barrier coatings is the yttria-stabilized zirconia (YSZ) structure. Pure zirconia (ZrO_2) has distinct characteristics, such as a high melting point (2680 ºC) and low thermal conductivity (1.6 W/mK). However, the phase transformation of zirconia between room temperature and higher operating temperatures presents a significant challenge. At room temperature, zirconia exists in a monoclinic phase, but at temperatures above 1170 ºC, it transitions to a tetragonal phase. This transformation exhibits martensitic characteristics and results in a volume increase of approximately 3-5%. This volume expansion can lead to internal stresses within the material, causing crack formation.

To prevent volume expansion, zirconia must be stabilized with the appropriate elements, most commonly using yttria (Y_2O_3). The Y_2O_3 ratio varies depending on the application and operating conditions. For example, stabilized zirconia containing 6-8% Y_2O_3 is used in high-temperature applications, such as turbine engines [3, 4]. Thermal barrier coatings (TBCs) may be subjected to three primary damage mechanisms: CMAS, hot corrosion, and thermal shock [5, 6, 7]. Protection against these damage mechanisms can provide significant benefits in terms of lifespan and efficiency. Research on aluminium coatings is ongoing. For example, Rami and colleagues observed that coatings containing aluminium oxide provide better insulation [8]. In this study, the goal is to improve the hot corrosion and CMAS behaviour of the coating using an industrial method like aluminium cold spray.

Material and Method

Initially, samples with YSZ coatings were applied to stainless steel substrates in the form of disks using thermal spray. Then, aluminium spraying was carried out using cold spray with various parameters. These parameters were determined as the spray nozzle traverse speed, powder feed rate, and spray nozzle distance. For one sample, spraying was performed at a 10 mm distance with a feed rate of 1 unit at speeds of 30 cm/min and 40 cm/min. The coating formation was then examined using optical microscopy. Afterwards, another sample was sprayed at a 10 mm distance with the same speeds (30 cm/min and 40 cm/min) but with a powder feed rate of 2 units. All process parameters used in the present study are listed in Table 1. The optical microscopy images of the coatings are present in the study. SEM and EDS analyses, along with X-ray diffraction (XRD) tests, are planned for the characterisation of the coatings. SEM and optical microscopy are planned to analyze the microstructures and alumina transformations. Subsequently, a formal investigation into CMAS and hot corrosion behaviour will be conducted.

Table 1. Experimental parameters of the cold spray process used in the present study.

Experiment No.	Powder Feed (level)	Pacing (cm/min)	Powder Size (mesh)	Spraying Distance (mm)	Pressure(bar)	Result
1	1	30	325	10	6	Discontinuous and inadequate formation
2	1	40	325	10	6	Discontinuous and inadequate formation
3	2	40	325	10	6	Discontinuous formation
4	2	30	325	10	6	Successful formation

Findings

Upon examining the surface morphologies through SEM and optical microscopy, it was observed that more distinct coating formations occurred with the parameters involving a traverse speed of 30 cm/min. Furthermore, when the powder feed rate was increased from 1 unit to 2 units, a more continuous coating was also observed. Cross-sectional analysis of the samples revealed that a traverse speed of 30 cm/min, combined with a 2-unit powder feed rate, resulted in the formation of a more continuous and thicker coating, as can be seen in Figure 1. In the process of alumina formation, thermal oxidation is planned to be applied to the coating exhibiting optimal characteristics. It is anticipated that the most continuous and homogeneous coating, after thermal oxidation, will yield the best results in terms of CMAS and hot corrosion behaviour.

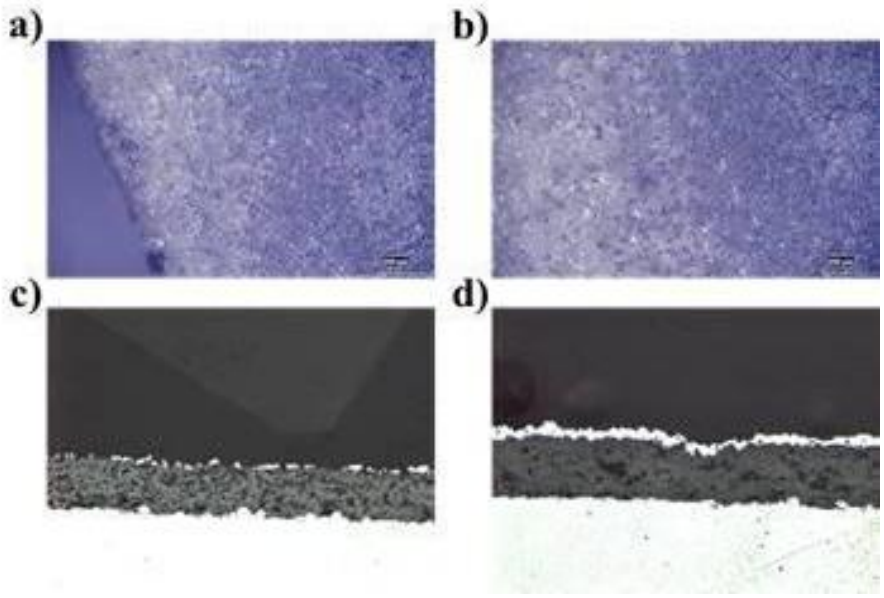

Figure 1. Optical microscopy images of a) Experiment no. 1, b) Experiment no. 2, c) Experiment no. 3, d) Experiment no. 4.

Conclusions

According to the results of this study, several conclusions can be drawn:

- Cold spray aluminium coatings on ceramic systems are improved by lowering traverse speeds and increasing powder feed rates.
- The use of homogenous and continuous coatings facilitates the achievement of impermeability and helps to preserve the structure.
- Sacrificial aluminium provides a more effective means of protecting the structure from corrosion.

Aim

Aluminum alloys are the most widely used materials that provide weight advantage, especially in the automotive, aviation, military, marine and railway industries, thanks to their very ambitious mechanical properties such as high strength/weight ratio, flexibility in static and dynamic loading working environment and good formability [1]. Aluminum is often combined with other elements to produce various commercial alloys. An example of this is Al-Si alloys. This alloy constitutes more than 80% of the cast aluminum alloys in the world [2]. Al-Si-Cu alloys are the dominant casting alloys preferred in high pressure die casting due to their excellent castability. In order to fully meet the needs of the sector, the Al-Si-Cu alloy must also provide electrical insulation and advanced surface mechanical properties such as hardness, wear and corrosion resistance [3]. EN AB 46000, the most common die casting alloy in Europe, is one of the most important representatives of the Al-Si-Cu alloy group [4].

When comparing all casting techniques for aluminum alloys, the high-pressure die casting method carries the flag as a forming technology that is very close to the final shape commonly used for light metals such as Al, Mg and Zn alloys. It is one of the most well-known and efficient methods for mass-produced aluminum parts. HPDC has the ability to produce aluminum parts with intricate and thin-walled parts, high measurement accuracy and low surface roughness.[5]

The insufficiently high surface hardness and low wear resistance of aluminum alloys are enhanced by different surface modification methods, including conventional anodization, conversion coatings, physical vapor deposition (PVD),chemical vapor deposition (CVD),thermal spraying and micro arc oxidation (MAO). When these methods are considered, the MAO process, also known as plasma electrolytic oxidation (PEO), is an innovative and environmentally friendly method, which is electrochemical surface oxidation in an alkaline electrolyte and under higher voltage or current density conditions compared to conventional anodic oxidation. Immediately after this process, a thin, hard wear and corrosion resistant oxide layer can be formed on the surface of various metals such as Al, Ti, Mg, Zr and their alloys. [6]

In this context, there are countless studies in the literature reporting significant increases in wear and corrosion resistance as a result of coating the surfaces of aluminum and its alloys with an alumina layer using the MAO process. [7]

Plasma electrolytic oxidation (PEO), also known as microarc oxidation (MAO), is an electrochemical plasma-assisted technology preferred for the development of ceramic coatings that improve multiple properties on the surface of different valve metals. PEO combines electrochemical oxidation processes with plasma discharges to sinter the treated metal surface. The properties of PEO coatings are closely related to the type of alloy being treated, the chemical composition of the electrolyte used and the electrical parameters implemented during the process. The prominent properties of PEO coatings include high wear resistance strong corrosion protection high hardness and excellent adhesion to metallic substrates.The surface condition of PEO coatings also provides a suitable ground for the adhesion of other overcoatings such as sol-gel layers and can act as a reservoir for liquid or solid lubricants, creating self-lubricating properties. [1] Despite all its advantages, MAO coating is not currently as common as anodizing coating on Al-Si alloys.

The aim of this study is to apply an MAO process as an alternative to the anodizing coating used industrially on Al-Si casting alloys and to compare its mechanical, corrosion and tribological properties.

Materials and Method

Samples with dimensions of 15x15x4 mm were cut from en ac 46000 aluminum ingot and then drilled with a tip with a diameter of 1.9 mm from one edge for micro arc oxidation. Then, the samples were grinded with 180-320 400-600 800 1200 2500 sandpapers respectively. It was applied to both surfaces. Right after, Samples were washed with ethanol and distilled water and dried at room temperature. Then the samples were subjected to MAO test. Afterwards, SEM and XRD were performed on the samples resulting from the MAO test.

As experimental equipment: 30 kW bipolar pulsed DC power supply unit, stainless steel electrolyte container, an air pump for mixing the electrolyte and an external cooling system were used. The stainless-steel container acted as cathode and the samples were connected to the electrochemical cell as anode.

Findings

Figure 1 shows the surface SEM photographs of MAO coatings produced on Al-Si casting substrate at 500x, 1000x, 2500x and 5000x scale magnifications. Micropores and microcracks are seen on the surface of the samples and this shows that we encounter a typical morphology. Different pore sizes are evenly distributed throughout the surface resulting from discharge channels formed during the coating process. In addition, microcracks are observed on the surface. These cracks are a common occurrence in MAO coatings and the reason is the high thermal gradient between the molten oxide and cold electrolytes

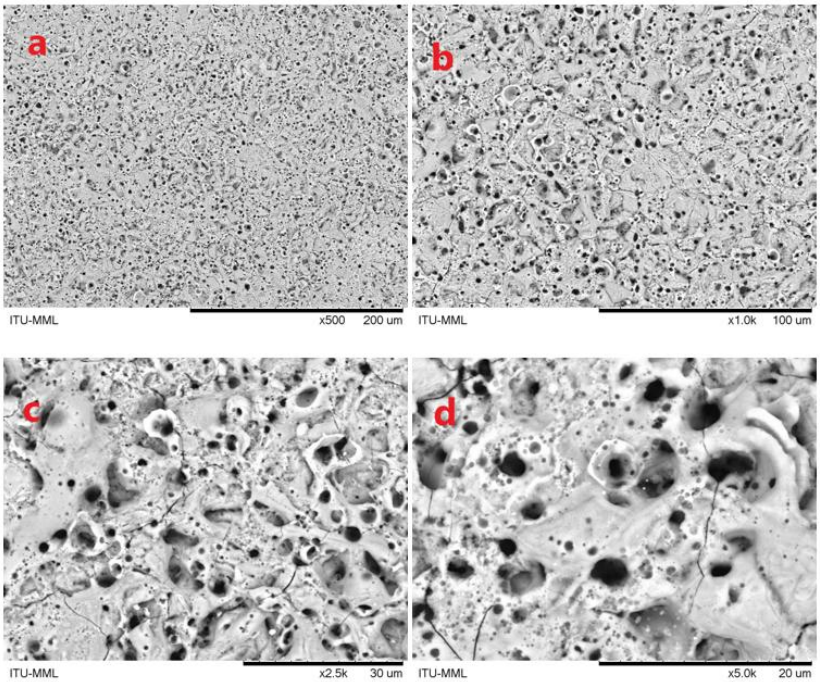

Figure 1. Surface SEM micrographs at (a) 500x, (b) 1000x, (c) 2500x and (d) 5000x magnifications.

Conclusion

In this study, MAO coating was successfully implemented on Al-Si casting substrate in an alkaline electrolyte. SEM analysis was performed on the coating. It realised that the surface of the coating had a conventional morphology with micropores and microcracks along the surface, causing discharge channels during implemention of the MAO. In addition, XRD analysis was done. Aluminum and silicon were detected from the base metal. Anodized coating will be performed and the study will be continued.

Heatwave Analysis Approach

Anıl Eken[a], Sevinç Asilhan[a]

[a] Istanbul Technical University/Department of Climate Science and Meteorological Engineering, Faculty of Aeronautics and Astronautics, Türkiye

Keywords : Heatwave Analysis, Heatwave Characterization, Heatwave Coefficient, Heatwave Unit.

Aim

This paper aims to offer a new perspective on the analysis of heatwaves. The heatwave is one of the most natural weather hazards. According to the UN, a study found that from 2000 to 2019, approximately 489,000 heat-related deaths occurred each year, including more than 70,000 who died during the 2003 heatwave in Europe (Zhao, 2021). Heatwave analysis, risk identification, and measurements against heatwaves are weak and unsuccessful; therefore, new perspectives are required in the analysis because human losses are highly due to heatwave, especially in urban area or city centres. For example, a study from South Korea found that a total of 590,639 deaths was observed during the study period; of these, 493,911 were in urban areas, and the remaining deaths were in rural areas (Kang & Park, 2020). Because of all those reasons, the cities in a country must be considered in the heatwave analysis, so the climatological city-specific heatwave coefficient identification were aimed to form as a new perspective, leading to the heatwave prediction and heatwave risk identification in the cities of the countries; it must be identified in each city for public health associated with heatwaves, which can be achieved by using only the longest climatological temperature data for the city. Those climatological temperatures of the cities are aimed to integrated into a coefficient to show the heatwave coefficient (HWC) of the cities, which represents the climatological-city specific coefficient and climatological heatwave risks of those cities.

Developing a city-specific heatwave analysis approach were aimed in this research, which were significant to forecast, mitigate, and eliminate the hazards and risks of heatwaves. Cities on the Mediterranean, Aegean, and Adriatic coasts suffer from forest fires associated with heatwaves, and people lost their lives and forests every summer. Also, EU states blame people for attempts to commit arson in forests, especially the people from non-EU countries, including immigrant or refugees, even meteorologists and environmentalists (France24, 2023). A research express that wildfires are political events (Karyotakis, 2024). If wildfires are politic events and the politics do not bring a solution to the problems of wildfires and heatwaves through a science and systematic mathematical methodology developed depending on objective data, those events cannot be described as politics, which can be defined as unacceptable behaviours such as blame and slander. Heatwave management policies serve nature, the environment, and people to save lives (BBC, 2018), ecology, life for humanity, eliminate diseases and forest fires before, during, and after heatwaves, and to increase the quality of life, humans, and the environment; not such as politics. Because of all those reasons, heatwave. Unit (HWU) and HWC have been aimed and developed to predict the onset, development, and severity of the heatwave. Heatwaves, along with climate change, have an increasing impact on human health, which is important to diagnose and take precautions before the passage of heatwave. For this reason, suggestions were aimed at about indices such as humidex and heat index. Through this heatwave methodology, it was proposed to determine the presence and absence of heatwave during a forest fire, which may contribute to the identification of burning attempts or other reasons behind events. At least the heatwave was aimed to distinguished, which measures the power of the heatwave via HWU, depending on HWC.

Below 25 ^{0}C, forest fires are not expected, so the months that have a climatological temperature above 25 ^{0}C were expected to be forest fire and heatwave risk months; therefore, climatological temperatures above 25 ^{0}C of the months were aimed to group for the determination of HWC in Figure 1. However, each month's heatwave analysis below 25 ^{0}C temperatures can also be implemented; the result can be associated with the warming or heatwave; so, heatwave can also be determined in cold months. Drought and heatwaves are extreme events that are closely related to climate with heatwave conditions, which can intensify drought conditions and vice versa (Mishra &

Mukherjee, 2020). Therefore, the high HWC not only shows heatwave risk or heat-related illness risky cities, but also potential drought risky via HWU and dry heatwave types and climate risky places because HWC as a climatological heatwave coefficient reflects the climatological risks or problems on cities due to warming. Especially summer months were categorized in this research, which are associated with heatwaves and forest fires, although heatwaves can occur in every climatic month.

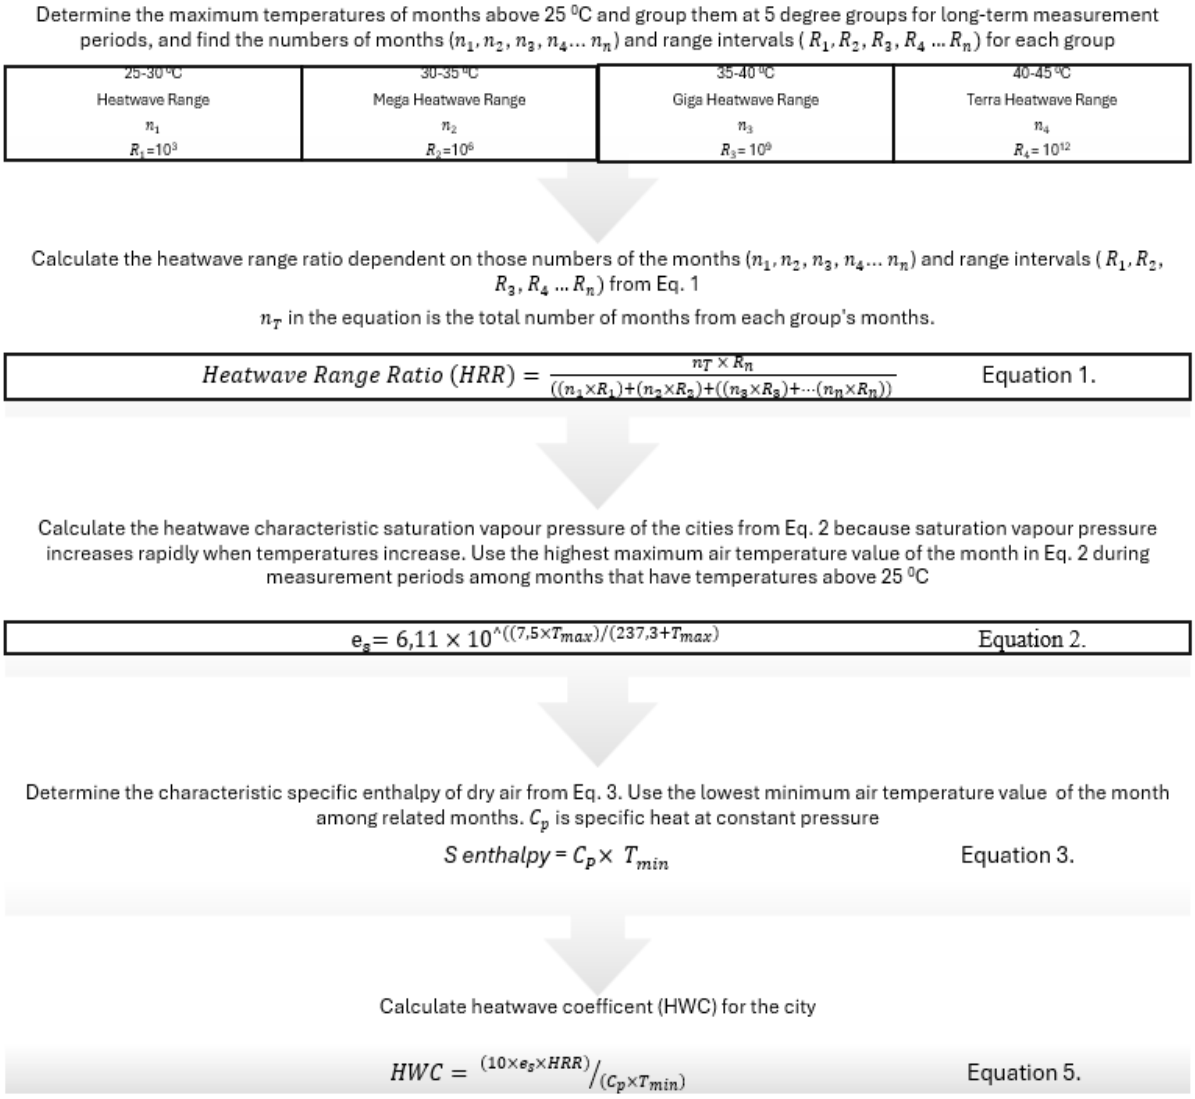

Figure 1. Climatological city-specific heatwave coefficient (HWC) determination process.

Climate change is increasing the frequency and intensity of heatwaves, raising concerns about their detrimental effects on air quality; however, a role for heatwave-human-environment interaction in air pollution exacerbation has not been established (Wang, 2024). The impacts of heatwaves on air quality can substantially very depending on the characteristics of heatwaves (Jin, 2023). Heatwaves are also related to air pollution; therefore, measurement of heatwaves via HWU and the characterization of heatwave types become significant, especially the comparison of heatwave types or fluctuations of pollutant concentrations during high HWU values. The exact mechanisms connecting heatwave to extreme rainfall process is not well understood yet, a there could be found on convective development due to heat over the surface, the identification of the heatwave or convection via HWU and heatwave types, especially the moist heatwave types that lead to convective precipitation and can also be significant to forecast the summer extreme precipitation after heatwave, and were aimed to be used in the future warming or

cooling of climate for cities. Briefly, new heatwave analysis and heatwave type identification methodologies were developed to achieve those aims.

Material and Method

The saturation vapor pressure, which is a function of air temperature, provides a basis for determining other thermodynamic properties of moist air (Huang, 2018). Specific enthalpy is a thermodynamic property that is the sum of specific enthalpy and the product of pressure and specific volume (Jamil, 2023). In the calculation of HWC, the heatwave range ratio (HRR), characteristic saturation vapor pressure, and characteristic specific enthalpy were used, which are a result of the longest climatological temperature data of the cities and defined as climatological city-specific heatwave coefficient. In characteristic saturation pressure calculation, the city's climatological minimum temperature was used because characteristic saturation vapor pressure and enthalpy are climatological temperature limits of heat in cities for the longest available measurement periods. HRR was obtained through grouping the months climatologically in the city for a 5 0C temperature interval and a 103-fold range ratio for each 5 0C interval. The calculation of HWC can be seen in Figure 1.

The HWU unit calculation can be seen in Figure 2, while the characterization of heatwave type can be seen in Figure 3. HWU depends on the hourly temperature and hourly relative humidity of the day, which was evaluated in 12-hour averages as nighttime (18-06) between 6 pm and 6 am and daytime (06-18) between 6 am and 6 pm hours in a day for both variables (temperature and relative humidity), which was compared with HWC to determine

The warming or heatwave in the city. RH18-06/RH06-18 in Figure 2 also becomes an important identification of moist heatwaves from dry heatwaves, which can be seen in Figure 4.

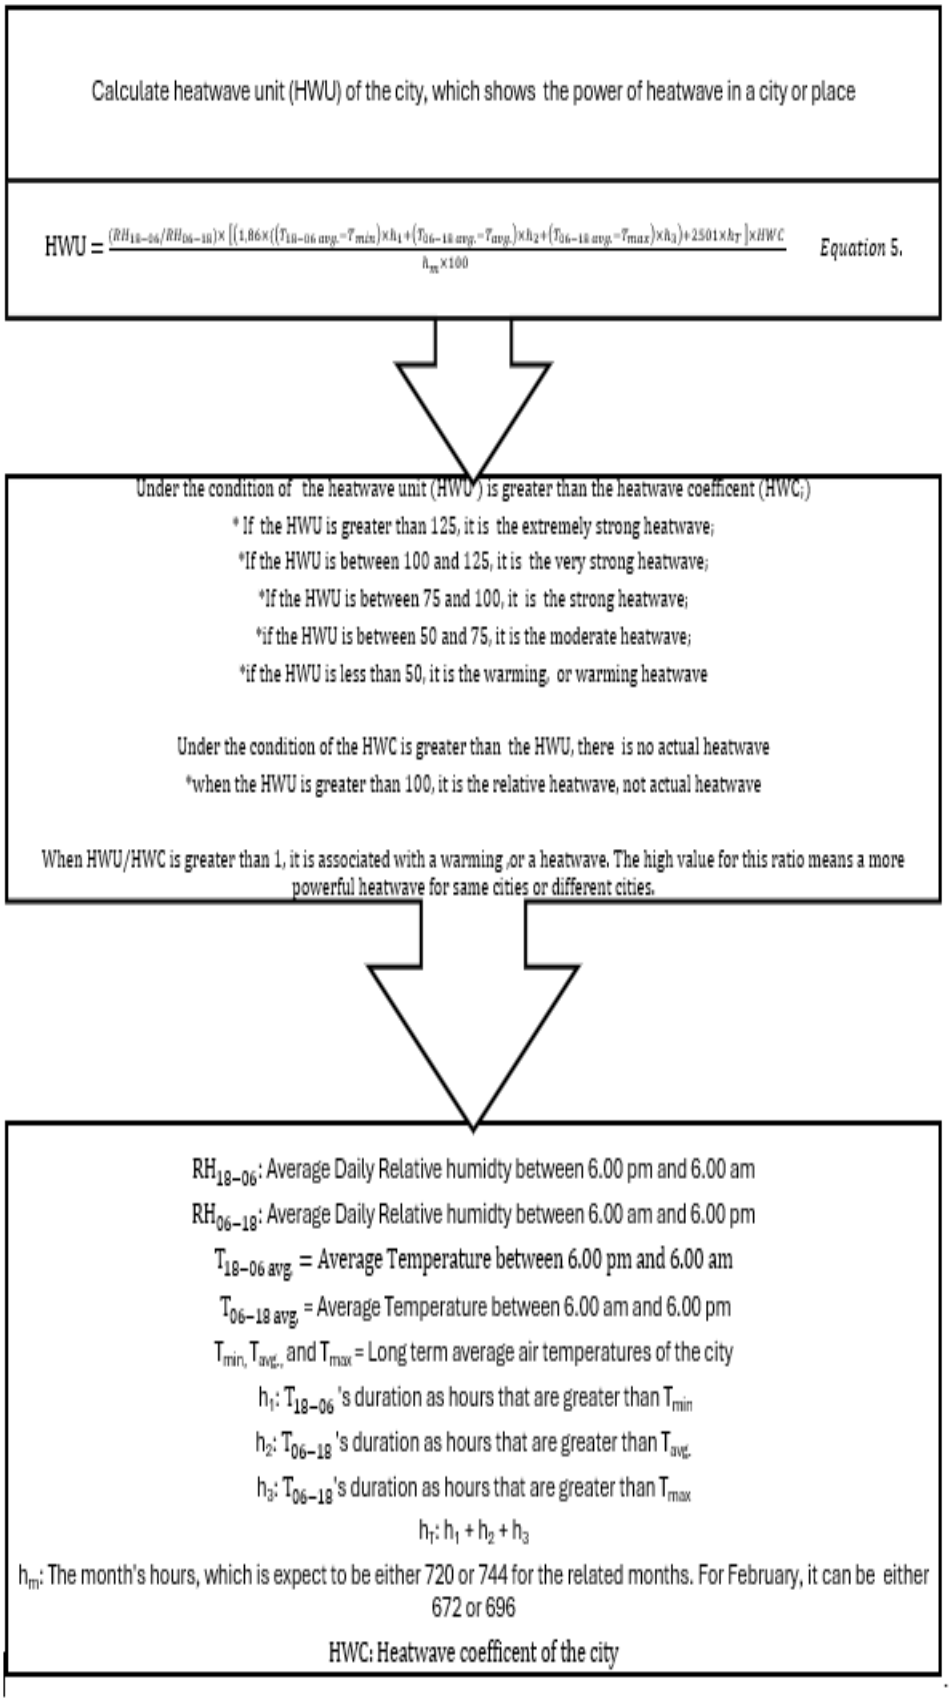

Figure 2. HWU determination process.

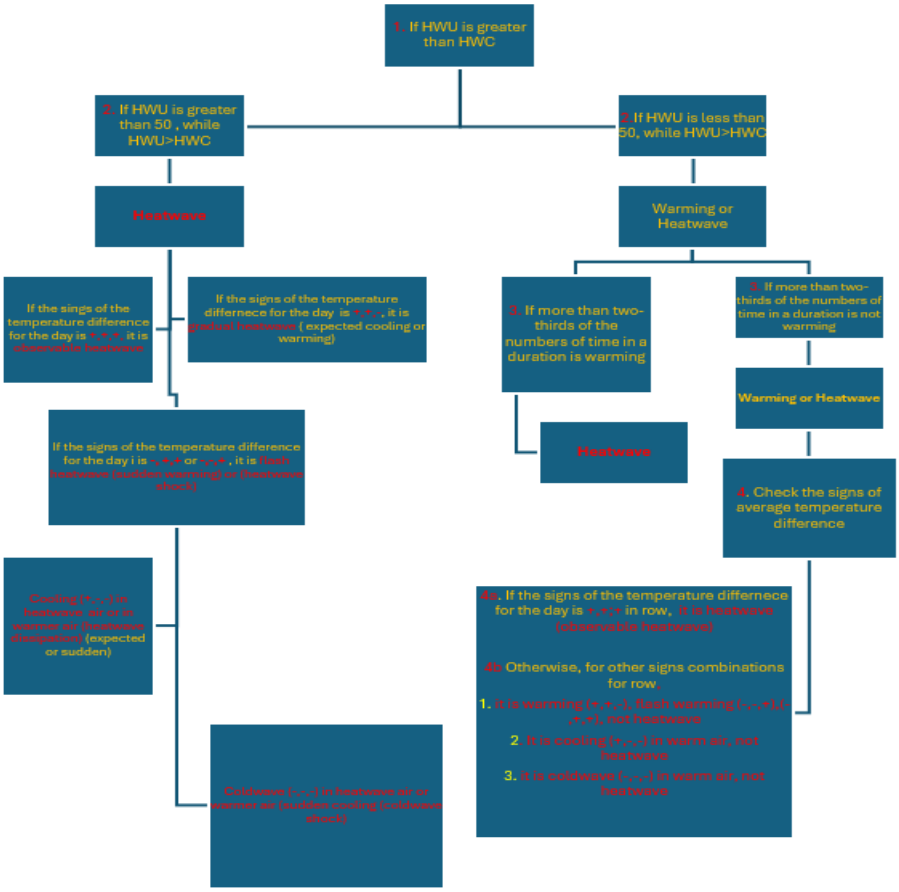

Figure 3. Characterization of heatwave types depending on HWU and average temperature.

R_N: Nighttime RH values between 6 pm and 6 am (RH_{18-06}), R_D: Daytime RH values between 6am and 6 pm (RH_{06-18}), and R_{HR}: Heatwave ratio ($R_{HR}=R_N/R_D = RH_{18-06}/RH_{06-18}$)

Figure 4. Characterization of heatwave types depending on RH.

Environment Canada uses humidex ratings to inform the public when conditions of heat and humidity are potentially uncomfortable (CCOHS, 2025). The humidex was introduced into Canada in 1965, which is calculated with a series of complex formulae using a combination of temperature and humidity level (The Canadian Encyclopedia, 2025). Rothfusz (1990) showed an equation for estimating heat index (HI), which consists of a series of multiple regression analysis of air temperature and relative humidity, based on the assumption described in the very first version developed by (STEADMAN, 1979). The heatwave analysis approach was also compared to Canada Humidex and Rothfusz's heat index (HI) close to the Kula district (38.25 N and 28.25 E) of Manisa city in Türkiye, vertically for June 2024 for each day to compare those three methods.

Findings

The climatological city-specific HWC determination process was implemented in each Turkish city in this study and HWCs were determined for each one. High HWC cities were observed in Southeastern Anatolian cities, which are prone to deaths due to extreme heat, heatwave, drought, and warming compared to other regions, relatively.

HWU and HWC were vertically implemented in Manisa city for June 2024. All days of the month for 1000 mb and 950 mb levels were heatwaves, which were observable and moist heatwave types. 28 days for 900 mb were heatwaves, while 2 days' HWU values were below HWC that were not heatwave. For 850 mb level, only 4 days' HWU values were above HWC, and at the 800 mb level, all days' HWU values in the month were less than HWC, which was associated with complete cooling; so, heatwave was active from the surface down to 900 mb in the location.

The HWU/HWC method and humidex of Canada were consistent and reasonable for vertical analysis, but HI were inconsistent and contradictory. The convective development and its precipitation were not observed in the location, although chronic heatwave was determined.

Conclusion

Heatwave and heatwave type analysis were introduced and implemented, which measures the heatwave in cities and determine the presence or absence of heatwave during forest fires. Chronic heatwave was determined in the location. Under the low HWU, arson attempts can be behind the forest fires, not heatwave. Low HWC cities and moist heatwave types can lead to convective precipitation after heatwaves, compared to high HWC cities and moist heatwave types, because exceeding the high HWC cities' value is not easy for convective development. The method measures and identifies heatwave during forest fires, convective precipitation development, and air pollution, which may also be used in industrial facilities' smokestacks to observe heat contribution of the facilities to the atmosphere via measuring hourly RH and temperature value in the inside of chimney to calculate HWU and compare it with HWC. The facilities may be taxed dependent on this extreme HWU value contribution into atmosphere.

Repowering at Türkiye's Leading Power Plant: An Analysis of Energy Production Increase

İpeknur Hazar[a,b], Mehmet Özkan Başar[b], Elçin Tan[a]

[a] Istanbul Technical University, Faculty of Aeronautics and Astronautics, Department of Climate Science and Meteorological Engineering, Türkiye
[b] Entek Elektrik Üretim A.Ş., Head Office, Strategy and Business Development Directore, Türkiye
hazar18@itu.edu.tr

Keywords : Wind Energy, Repowering, Wind Turbine.

Aim

Renewable energy is indispensable in combating climate change due to its unlimited nature, eco-friendly characteristics, and technological efficiency gains. Solar, hydroelectric, geothermal, and especially wind energy offer effective alternatives to fossil fuels, with wind energy providing notable advantages through low operating costs and high capacity.

In response to rising energy demand and environmental concerns, Türkiye has prioritized renewable energy investments (Ministry of Environment, Urbanization, and Climate Change & Presidency of Strategy and Budget of the Republic of Türkiye, 2023). The country's long-term climate strategy should maximize wind energy efficiency while modernizing existing plants and strengthening technological infrastructure. This strategy aims to optimize production capacity through enhanced plant potential and innovative technologies, contributing to sustainable development both locally and internationally.

Repowering refers to modernizing outdated wind farms by replacing old turbines with modern technology to boost performance. It offers benefits such as increased capacity factor, reduced operating costs, and lower environmental impacts. Key advantages include higher specific energy production from increased hub heights, superior performance of new multi-megawatt turbines, improved wind resource assessment, better utilization of prime windy sites, fewer turbines leading to reduced visual impact and avian mortality, minimized use of undeveloped land, improved grid integration, lower capital and maintenance costs, and job creation (Serri, Lembo, Airoldi, Gelli, & Beccarello, 2018).

The primary objective of this study is to quantitatively determine the change in the production capacity factor when a repowering application is implemented in one of Türkiye's oldest wind farms. In this study, the performance of the existing plant will be analyzed in detail, and a model will be developed to assess the expected increase in efficiency and the effects on the capacity factor following repowering. In doing so, the study systematically examines both the advantages and potential challenges associated with the repowering process, thereby demonstrating the contribution of plant modernization to the broader renewable energy strategy.

Material and Method

Various data sources and computational approaches were integrated in the materials and methods section to evaluate the plant's production performance. Initially, production data for the 2018–2024 period were obtained from the Transparency Portal of Energy Exchange Istanbul (EXIST), known in Turkish as Enerji Piyasaları İşletme A.Ş. (EPİAŞ), and used as a reference during the simulation process (Url-1, accessed February 5, 2025). Information on the plant's land area and turbine locations was sourced from the Turkish Energy Market Regulatory Authority (EPDK) and transferred to the WindPRO software, while turbine-type data were obtained from the Turkish Wind Energy Association (TÜREB) Statistical Report (Türkiye Rüzgar Enerjisi Birliği, n.d.; Url-2, accessed March 4, 2025; Url-3, accessed February 12, 2025). The existing installation comprises three E40 turbines (0.5 MW, 65 m hub height) and four E82 turbines (2.3 MW, 78.3 m hub height). Additionally, the EMD-WRF Europe+ MesoScale (EMD-WRF) dataset was downloaded (Url-4, accessed February 3, 2025). A 0.03°×0.03°

resolution version of the EMD-WRF data for 2018–2024 was calibrated against the EPİAŞ data and then extended to cover the period from 2005 to 2024 for production calculations.

The PARK module of WindPRO was applied to the production calculations. Initially, a 10% technical and suitability loss was imposed on the EMD-WRF data to reflect realistic operational conditions. A scaling factor was then applied to accurately reproduce the production values for the 2018–2024 period, ensuring that the simulation results aligned with the EPİAŞ data. A graphical comparison of the production curves from EPİAŞ and WindPRO for 2018–2024 revealed very similar oscillations, confirming the validity of the methodology.

To further assess the plant's performance, the analysis was extended to a 20-year period (2005–2024). This long-term simulation provided a solid basis for evaluating both the historical performance of the plant and the potential production increase following repowering. In addition to assessing the existing plant, the production performance of new turbine models was analyzed under similar computational conditions. This evaluation ensured that the integration of new turbines did not exceed the plant's production license limits, as grid capacity restrictions were maintained. Consequently, this approach allowed for a comprehensive comparative assessment of the advantages and disadvantages of the repowering application.

Findings

Before presenting the results, it is important to note that the EMD-WRF dataset was scaled by 89.4% to match actual generation data from EXIST. This calibration ensured that the simulation results accurately represented real operational performance. The applied scaling factor is site-specific and depends on both the model setup and the local meteorological conditions.

Initial simulations for the 2018–2024 period indicated that the existing plant's annual production was 32.1 GWh. Within the scope of the repowering evaluation, eight different turbine models were examined. Among these, the best result was achieved by integrating the new Goldwind182 turbine, with a capacity of 7.5 MW and a hub height of 110 meters. With this turbine, the annual production increased to 47.5 GWh, representing an approximate 48% increase.

In addition, the Vestas V162 turbine model with a capacity of 6.2 MW and a hub height of 119 meters yielded an annual production of 44.6 GWh, corresponding to a 39% increase compared to the current setup. These results demonstrate the potential of repowering to significantly boost energy output, depending on turbine specifications and site compatibility.

Conclusion

In conclusion, the repowering application demonstrates significant potential for enhancing the production performance of the existing plant. Considering the constraints imposed by the production license capacity and grid capacity limits, the integration of the Goldwind182 turbine—which resulted in a 48% increase in production—demonstrates the effectiveness of the repowering strategy. Similarly, the Vestas V162 turbine also provided considerable improvement, with a 39% increase in energy output. These results confirm that even under existing licensing and grid constraints, upgrading turbines can yield notable gains in production and efficiency. Moreover, the long-term analysis covering 2005–2024 supports the contribution of this strategy to sustainable energy production. It is also critical to note that the regulatory framework for repowering is essential; legal regulations substantially increase the feasibility of such modernization projects and provide vital support in accelerating the transformation process within the energy sector.

MINING ENGINEERING

Excavation Mechanics

Machine Learning-Based Prediction of Thrust Force in Tunnel Boring Machines

Hadi Alizadeh[a], Ömür Acaroğlu Ergün[a]

[a] Istanbul Technical University, Mining Engineering Department, Mining Engineering, Türkiye
alizadeh23@itu.edu.tr

Keywords: Tunnel Boring Machine, Machine Learning, Thrust Force Prediction, Rock Mechanics, Performance Estimation.

Aim

Accurate prediction of thrust (normal force) in Tunnel Boring Machines (TBMs) is critical for optimizing excavation efficiency, cutterhead design, and operational cost management. O. Acaroglu et al (2008) developed a fuzzy logic model to predict the specific energy (SE) requirements for Tunnel Boring Machines (TBMs), with a focus on Constant Cross-Section (CCS) disc cutters.Satar Mahdevari et al (2014) developed a support vector regression (SVR) model to predict the penetration rate (PR) of Tunnel Boring Machines (TBMs) in hard rock tunneling, using the Queens Water Tunnel project in New York as a case study. A. Salimi, J. Rostami, C. Moormann, and A. Delisio (2016) explore the application of nonlinear regression and artificial intelligence (AI) algorithms to predict the performance of Tunnel Boring Machines (TBMs) in hard rock conditions. Ebrahim Ghorbani and Saffet Yagiz (2024) developed a machine learning approach using gradient boosting algorithms to predict the penetration rate (PR) of Tunnel Boring Machines (TBMs) in varied rock conditions. Arsalan Mahmoodzadeh et al. (2021) applied machine learning models to forecast the lifespan of Tunnel Boring Machine (TBM) disc cutters. Yin Bo, Quansheng Liu, Xing Huang, and Yucong Pan (2022) developed a real-time rock mass classification model for hard-rock tunneling, using CatBoost integrated with Sequential Model-Based Optimization (SMBO). Andreas Benardos (2008) from the National Technical University of Athens explores the use of artificial intelligence (AI) methods, particularly artificial neural networks (ANNs), for predicting Tunnel Boring Machine (TBM) performance in underground development. Yang Liu, Shuaiwen Huang, Di Wang, Guoli Zhu, and Dailin Zhang (2022) developed a kernel support vector machine (KSVM) model to predict the need for disc cutter replacements in Tunnel Boring Machines (TBMs). Saffet Yagiz and Halil Karahan (2015) used various optimization techniques including Differential Evolution (DE), Hybrid Harmony Search (HS-BFGS) and Grey Wolf Optimizer (GWO) for estimating TBM penetration rate. Ling, J., Sun, C., Wang, Q., & Zhang, H. (2024). Analysis of Rock Breaking Load Characteristics and Efficiency Optimization of Roller Cutters under Multi-Factor Coupling.

While traditional methods like fuzzy logic (Acaroglu et al., 2008) have been applied to predict specific energy (SE), this study focuses on advancing thrust prediction using machine learning (ML). Leveraging the same dataset from the Colorado School of Mines' Earth Mechanics Institute, this work employs a Random Forest Regressor to model thrust (NF) based on rock properties, cutter geometry, and cutting parameters. The primary objective is to demonstrate the superiority of ML over conventional methods in capturing complex, non-linear relationships to achieve high predictive accuracy.

The objective of this study is to develop a machine learning model, specifically a Random Forest Regressor, to accurately predict thrust force (normal force) in TBM operations based on rock and cutter parameters.

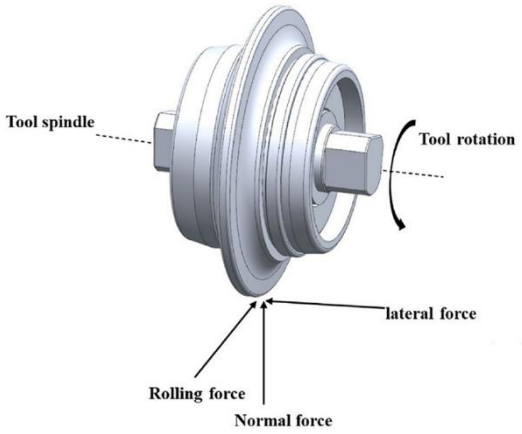

Figure 1. Cutting forces acting on a disc (Ling, J., Sun, C., Wang, Q., & Zhang, H. (2024)).

Material and Method

The dataset used in this study originates from a previously published research article and comprises six input parameters: uniaxial compressive strength (UCS), Brazilian tensile strength (BTS), disc diameter (DD), tip width (DTW), cutter spacing (S), and penetration (p). These inputs are used to predict thrust (NF), a key mechanical output critical for TBM performance. The dataset, originally utilized for fuzzy logic-based SE prediction, was preprocessed to address outliers and normalized to ensure balanced model training.

The Random Forest Regressor, an ensemble learning algorithm, was selected for its ability to handle high-dimensional, non-linear data through bootstrap aggregation and feature randomness. The model was trained on 80% of the data, with 20% reserved for testing. Hyperparameter tuning (e.g., tree depth, number of estimators) was conducted via grid search to optimize performance. Model efficacy was evaluated using R-squared (R^2) and mean squared error (MSE).

Figure 2, The residual plot shows the difference between actual and predicted values for both the training and test sets. In the training set, most residuals are clustered around zero, indicating a good fit, though some dispersion increases with higher predicted values, suggesting possible heteroscedasticity. A few outliers exist, such as residuals below -10,000, but they don't significantly impact the model. In the test set, residuals are also centered around zero, showing that the model generalizes reasonably well; however, there is greater variance at higher predicted values, including some extreme errors below -15,000, which may point to slight overfitting. Despite this, the residuals display no clear trend or pattern, supporting that the Random Forest model's assumptions hold. Overall, the model performs well, with mostly random residuals close to zero. Enhancing performance further may involve hyperparameter tuning, feature transformation, or analyzing outliers.

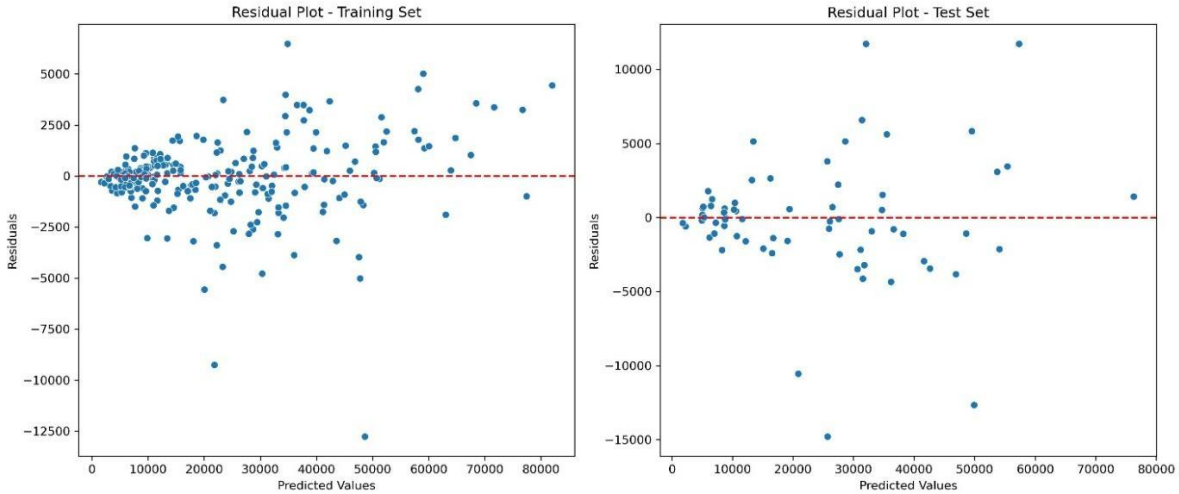

Figure 2. Residual Plot for the Random Forest Regressor model predicting Normal Force (NF).

Figure 3, the lift chart, The model curve rising above the baseline indicates that the model is effective at prioritizing high actual values, such as high Normal Force. The red dashed 45° line represents random guessing, serving as a benchmark. A steeper lift in the early percentiles of the curve suggests that the model is particularly good at identifying and capturing the highest values early on, which reflects strong predictive performance.

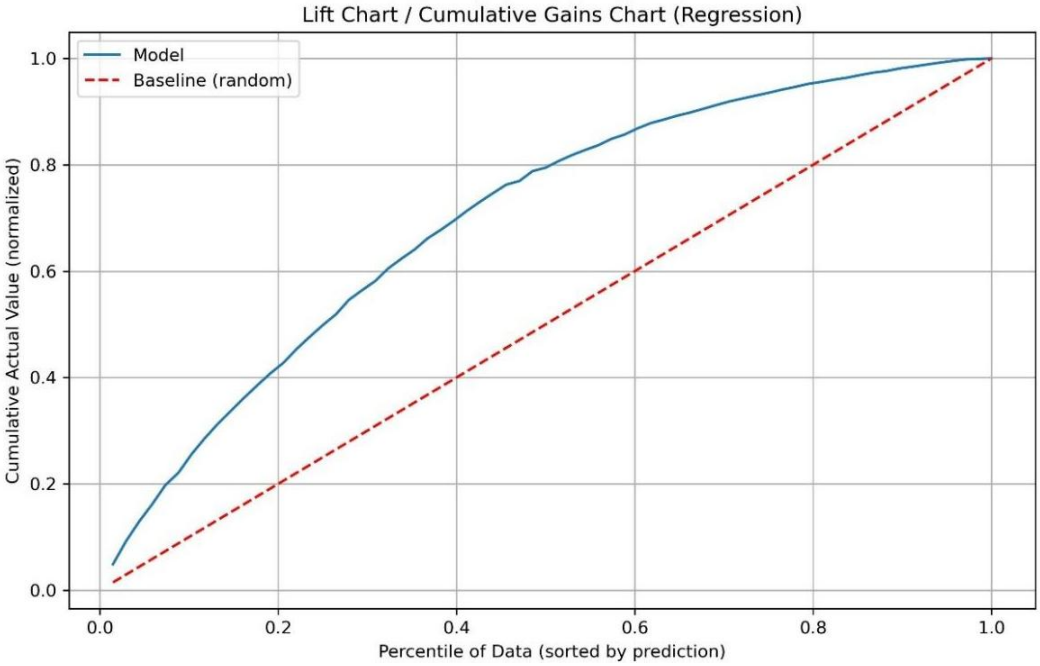

Figure 3. Lift chart.

Findings

The machine learning model was evaluated based on performance metrics such as R^2 (coefficient of determination), Mean Squared Error (MSE), and Mean Absolute Error (MAE). Among the models tested, the Random Forest Regressor achieved the highest accuracy with an R^2 value of 0.94 on the test dataset, indicating excellent predictive capability.

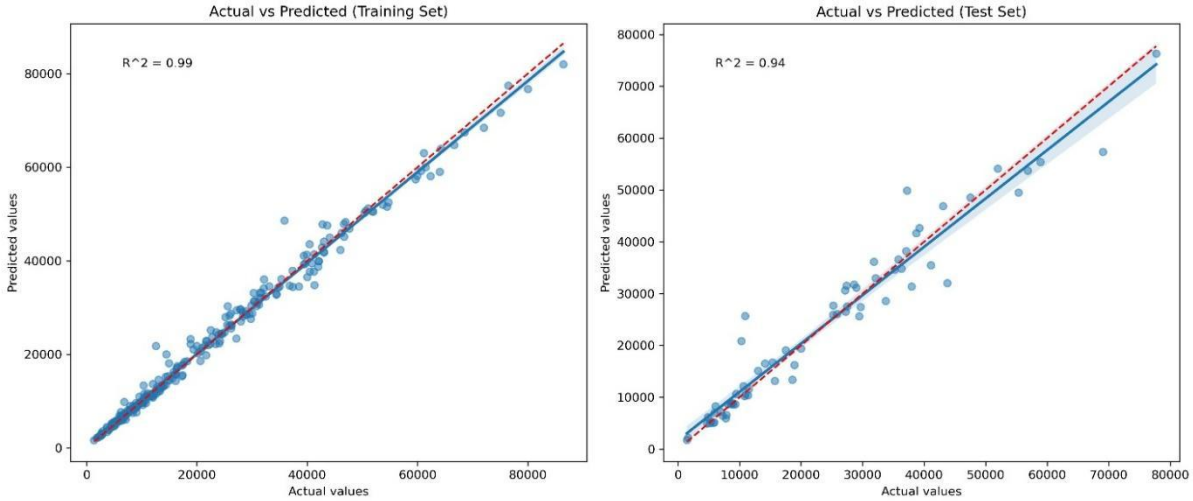

Figure 4. Random Forest regression model.

The results confirm that the machine learning-based approach significantly improves the accuracy of thrust force prediction compared to traditional methods. Figure 4 presents the predicted vs. actual thrust force values, demonstrating a strong correlation between the model's predictions and the experimental results.

Additionally, feature importance analysis revealed that penetration depth (p) and UCS are the most influential parameters in determining the thrust force, aligning with theoretical expectations in rock cutting mechanics.

Conclusion

This study demonstrates the effectiveness of machine learning models, particularly the Random Forest Regressor, in accurately predicting the Thrust Force (Normal Force) in TBM operations. The high R^2 values obtained indicate that ML models outperform traditional empirical approaches, offering improved precision and reliability.
The application of ML-based predictions in TBM operations can assist engineers in making data-driven decisions, optimizing machine performance, reducing wear on cutting tools, and ultimately enhancing the efficiency of tunnel excavation projects. Future research may explore deep learning techniques and hybrid modeling approaches to further refine the predictive capability of TBM performance estimation models.

dizer24@itu.edu.tr

Keywords: Ferredoxin-NADP$^+$ Reductase, Oxidoreductases, Recombinant Protein Production, Expression Optimization.

Aim

Ferredoxin-NADP$^+$ reductases (FNR, EC 1.18.1.2) are a family of monomeric enzymes containing noncovalently bound flavin adenine dinucleotide (FAD) cofactor as their prosthetic group. The first case of isolated FNR was reported in 1956 using pea chloroplasts (Avron and Jagendorf, 1956). Thereafter, it was shown that the catalytic function of the chloroplast reductase was to facilitate the electron transfer between the reduced iron-sulfur protein ferredoxin (Fd) and NADP$^+$ (Equation 1.), generating NADPH required for CO_2 assimilation in cyanobacteria and plants (Shin and Arnon, 1965).

$$2Fd_{red} + NADP^+ + H^+ \leftrightarrow 2Fd_{ox} + NADPH \qquad (1)$$

This reaction requires the transfer of electrons from the one-electron donor Fd to the two-electron acceptor NADP$^+$. FNR facilitates this process by linking one-electron and two-electron carriers, a function determined by the biochemical characteristics of its FAD prosthetic group. Flavins (Fl), including FAD, can exist in three redox states: oxidized, semiquinone (one-electron reduced radical), and hydroquinone (fully reduced form) (Dudley et al., 1964). The FNR catalytic cycle (Figure 1.) begins with the sequential reduction of FAD to its semiquinone form ($FADH^{\cdot}$), followed by its further reduction to hydroquinone form ($FADH^-$) (Corrado et al., 1996). The final reaction steps likely involve hydride transfer from $FADH^-$ to NADP$^+$, leading to the release of NADPH (Carrillo and Ceccarelli, 2003; Karplus and Faber, 2004; Medina and Gomez-Moreno, 2004). Additionally, this reaction can also occur in the reverse direction with FNR using NADPH to reduce Fd, which is particularly relevant in nonphotosynthetic plant tissues (Onda et al., 2000; Aliverti et al., 2001) and cyanobacterial heterocysts (Weber-Main et al., 1998) where specific isoforms possess redox potentials favoring this reverse electron flow.

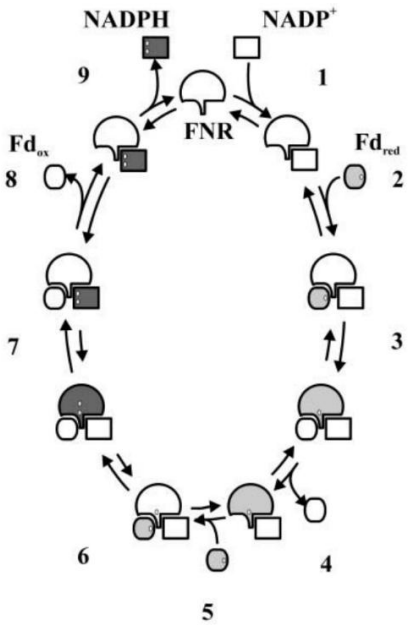

Figure 1. The catalytic cycle of ferredoxin-$NADP^+$ reductase (Carrillo and Ceccarelli, 2003).

After the chloroplast reductase was isolated, novel FNRs were discovered in various organisms, including phototrophic and heterotrophic bacteria, mitochondria of animals and yeast, and the apicoplasts of intracellular parasites (Jungermann et al., 1974; Chen and Yoch, 1989; Hanukoglu and Gutfinger, 1989; Bianchi et al., 1995; Razquin et al., 1996; Lacour and Dumas, 1996; Vollmer et al., 2001). Research on several species has shown that FNR functions as an electronic switch at the key branching points of different electron transfer pathways. In heterotrophic organisms and tissues, the reaction primarily drives Fd reduction, providing mobile low-potential electrons for various metabolic processes, including nitrogen and hydrogen fixation, steroid hydroxylation, anaerobic pyruvate assimilation, fatty acid desaturation, and the synthesis of amino acids and dNTPs (Carrillo, 1998).

FNR exhibits strong NADP(H) oxidoreductase activity and low affinity for NAD(H). The site where the reduced FAD donates its electrons can accommodate a wide range of oxidants in an irreversible manner. This led the original discoverers of FNR to describe the enzyme as a "thylakoid-bound NADPH diaphorase" (Avron and Jagendorf, 1956). Some of the oxidants of FNR include NAD^+, ferricyanide, substituted phenols, nitro derivatives, viologens, quinones, and cytochromes (Carrillo and Vallejos, 1987). While the diaphorase activity is generally not physiologically significant, it has greatly contributed to the understanding of the function and catalytic mechanism of FNRs and can adopt practical applications in the pharmaceutical industry and bioremediation in the near future (Shah and Spain, 1996; Kranendonk et al., 1997).

In this study, cloning, heterologous expression, and purification of two novel ferredoxin-$NADP^+$ reductases, namely Fpr1 and Fpr2, from previously characterized Pseudomonas mandelii KGI_MA19 and the optimization of conditions affecting recombinant protein production were aimed. In further studies, these FNRs will be compared with often-used ferredoxin reductases in terms of their electron transfer capabilities and coupled with different ferredoxins to reconstitute the catalytic activities of cytochrome P450s, a protein family of high industrial significance.

Material and Method

The genomic DNA of Pseudomonas mandelii KGI_MA19 was isolated and used as a template for PCR reactions to amplify the fpr1 and fpr2 genes with attached restriction sites. The PCR products were digested using NdeI and HindIII restriction enzymes. The digested products were ligated into the pET-28a(+) expression vector, which had been cut with the same enzymes, using T4 DNA ligase. Chemically competent E. coli BL21 (DE3) cells were transformed with the constructed plasmids and incubated overnight at 37°C on lysogeny broth (LB) agar plates

containing 40 µg/mL kanamycin. The next day, a few single colonies were picked from each plate, and the presence of fpr genes was analyzed by colony PCR. LB liquid cultures were prepared for each selected positive colony and incubated overnight at 37°C with shaking at 200 rpm. The cells were harvested by centrifugation, and the constructed plasmids were isolated. To further confirm the presence of the fpr1 and fpr2 genes in the isolated plasmids, a diagnostic digest was performed using HindIII on both the isolated plasmids and the empty pET-28a(+) vector.

The expression of FNR proteins was performed using E. coli C43 (DE3) cells as expression hosts. The chemically competent E. coli C43 (DE3) cells were transformed with the constructed expression plasmids and cultured overnight in LB at 37°C and 200 rpm. These precultures were then used to inoculate the main cultures of terrific broth (TB). The main cultures were grown at 37°C with gentle shaking until OD_{600} reached 0.8. When OD_{600} reached 0.8, the cultures were induced by adding isopropyl β-D-1-thiogalactopyranoside (IPTG), and incubation continued at 25°C for 16 hours. The E. coli cells were harvested by centrifugation, and the cell pellets were stored at −20°C until further use. The cell pellets were resuspended in 20 mM sodium phosphate buffer (pH 8.0) containing 0.5 M NaCl and disrupted by sonication. After centrifugation, the His-tagged proteins in the cell lysates were purified by immobilized metal ion affinity chromatography (IMAC) using Ni^{2+}-charged HisTrap affinity columns according to the manufacturer's instructions. Fractions containing the purified proteins were collected, concentrated using Amicon Ultra centrifugal filters, and stored at −20°C.

Findings

After the PCR reactions of the fpr1 and fpr2 genes, products with respective sizes of 793 bp and 791 bp were obtained (Figure 1.). Many single colonies were observed on LB agar plates after transformation (Figure 2.).

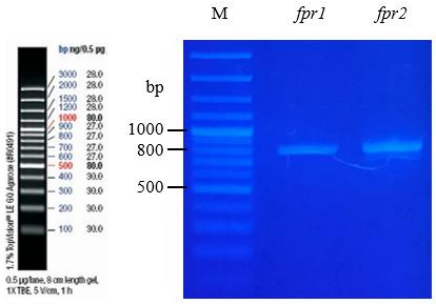

Figure 2. PCR products of fpr1 and fpr2 genes.

All three selected colonies tested positive for the fpr1 gene, and two out of four colonies were confirmed to have the fpr2 gene by colony PCR (Figure 3.). Two positive colonies from each plate were selected for plasmid isolation. After the diagnostic digest, all constructed plasmids were confirmed to contain the genes of interest since there was a significant size difference between the constructed plasmids (≈6200 bp) and the empty pET-28a(+) vector (5369 bp) (Figure 4.).

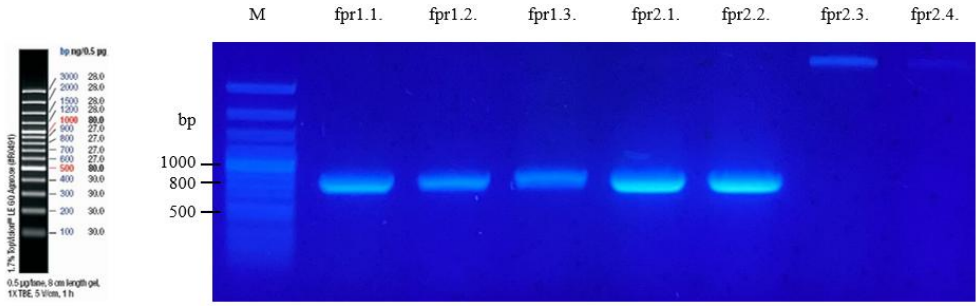

Figure 3. Colony PCR results.

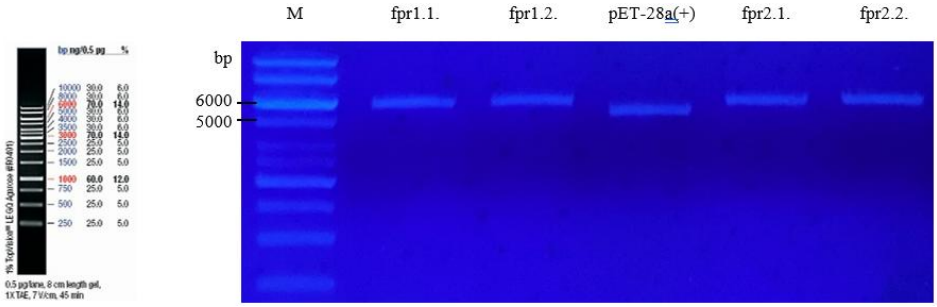

Figure 4. Diagnostic digestion results of constructed plasmids.

Following the purification of Fpr1, the purified protein showed a band at approximately 25 kDa, significantly lower than the expected size of 31.9 kDa (Figure 5.). The E1, E2, and E3 fractions were selected for buffer exchange and concentration. However, under the same conditions, the purification of the Fpr2 protein resulted in significant impurity. Therefore, optimization of the Fpr2 purification process is still ongoing. In future experiments, the induction time will be reduced to obtain the protein with relatively higher purity.

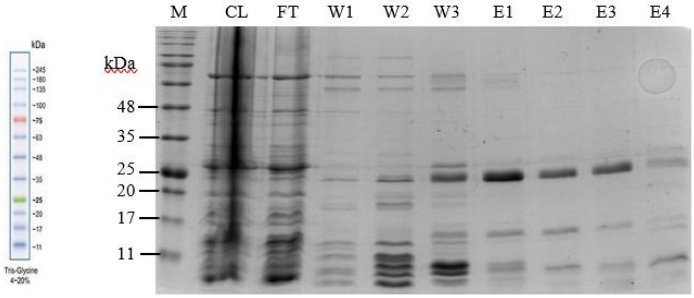

Figure 5. SDS-PAGE analysis of purified Fpr1. Abbreviations: M, marker; CL, clear lysate; FT, flow-through; W, wash; E, elution.

Both purified proteins exhibited a yellowish appearance, a direct consequence of the FAD prosthetic group, which displays a yellow color when fully oxidized.

Conclusion

In this study, Fpr1 and Fpr2 ferredoxin-$NADP^+$ reductases from the previously characterized Pseudomonas mandelii KGI_MA19 were heterologously expressed in the E. coli expression system and purified to a level sufficient for further studies in which the catalytic activities of these FNRs will be required. As a continuation of this study, the electron transfer capabilities of these FNRs will be tested and compared to commonly used ferredoxin reductases, such as adrenodoxin reductase (AdR) and putidaredoxin reductase (PdR). Additionally, Fpr1 and Fpr2 will be coupled with ferredoxins from Pseudomonas mandelii KGI_MA19, as well as several other Fds, for a cytochrome c reduction assay to determine the most efficient redox pair that can be used for in vitro activity reconstitution of cytochrome P450s.

Keywords: Hydrothermal Hot Spring, Self-sufficient P450, Site-Directed Mutagenesis.

Aim

Cytochrome P450s that use heme as a prosthetic group are monooxygenase enzyme systems that play essential roles in xenobiotic and drug metabolism, steroid and natural bioproduct synthesis (McDonnell, A. M., and Dang, C. H., (2013)). The active site of the enzyme contains cysteine residues that are bound to heme, which has a highly conserved motif among organisms. Even though some P450s require external redox partners, some cytochromes found as natural fusion proteins, called self-sufficient P450s, have their redox partners on the same polypeptide chain (Li, Z., et. al., (2020). CYP102A178 is a self-sufficient P450 that was recently obtained from the Hisaralan hydrothermal region of Balıkesir in Türkiye, and it has been defined with metagenomic approaches and bioinformatic applications by the Protein Engineering and Metagenomics group at Istanbul Technical University. The fact that CYP102A178 is obtained from Hisaralan, a thermophilic region, makes the enzyme's characterization more vital since it is an extremozyme and potentially can be active in high temperatures. The sequencing and multiple-sequence alignment results have shown that CYP102A178 has a tyrosine residue at the 440th position. This residue, which has a highly conserved heme-bound cysteine among other species, could potentially be responsible for inactive P450. This project aims to change the tyrosine residue with PCR-based site-directed mutagenesis to cysteine. Since the mutation is found at the active site, particularly at the heme-bound conserved location, it is thought to be playing an important role in the activity and functionality of the protein.
Within the scope of this project, the Y440C mutation of CYP102A178 were constructed. The biochemical characterizations will be carried out following the purification of the reverse mutated "potentially active" CYP102A178 (Y440C), and inactive CYP102A178 collected from Hisaralan. The findings of this project will provide evidence of the role and importance of heme-bound cysteine in the functionality and activity of the protein by reverse mutation.

Material and Method

1. Recombinant Expression and Purification

The plasmid of inactive CYP102A178 collected from Hisaralan was transformed to E. coli C43 chemically competent cells. The cells were centrifuged at 13000xg for 5 mins, and the supernatant was removed. Then, the resuspended cells were spread to kanamycin positive LB agar and incubated at 37 °C for 18 hours.
After 18-hour incubation, a selected positive colony was inoculated to 10 ml LB containing 10 µl (1:1000) kanamycin and incubated at 37 °C, 200 rpm for 18 hours.
10 ml of incubated pre-culture was transferred to 1-liter of TB and autoinducing media, which contains 0.6% glycerol, 0.05% glucose and 0.2% lactose, and the appropriate amount of kanamycin (1:1000), 5-ALA (5-Aminolevulinic acid), thiamine, riboflavin and trace element supplements was added further separately for finding the optimal medium for the expression condition. The culture was incubated at 20 °C and 25 °C for 12 to 24 hours

at 200 rpm, for selecting the appropriate induction conditions as well. The cells were harvested at 4000 rpm, at 4 ºC. The cells were sonicated (20 s on/20 s off for 3 mins) then, centrifuged. The supernatant was collected as clear lysate, which contains the protein of interest. For finding the optimal conditions for induction, expression studies are still being performed.

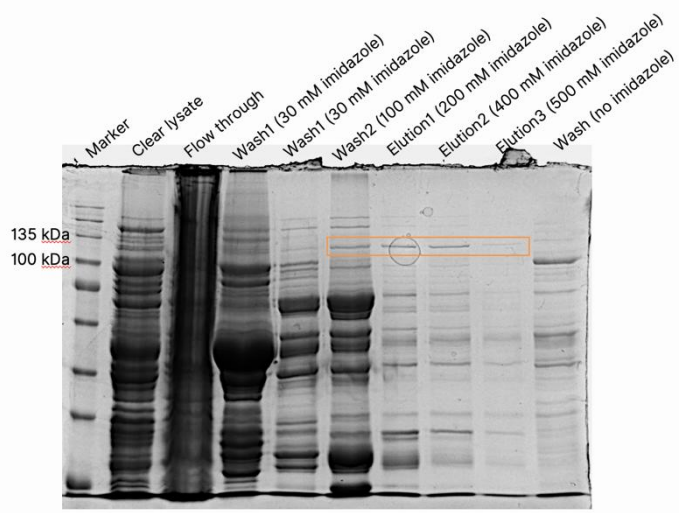

Figure 1. SDS-PAGE image for purified inactive CYP102A178 is shown. Molecular weight of CYP102A178 is 119 kDa and the protein is marked with orange square.

Immobilized Metal Affinity Chromatography (IMAC) purification of inactive CYP102A178 was carried out by cytiva HisTrap column. Purified protein was verified with SDS-PAGE, as can be seen in Figure 1, above. For the removal of residual imidazole and concentration of protein, 50 kDa cut-off Amicons was used.

2. PCR-based site-directed mutagenesis

A single substitution mutation was introduced into the CYP102A178 gene at position 440 with site-directed mutagenesis by usage of overlap extension PCR. The following gene-specific mutagenic primers was used for changing the tyrosine into cysteine amino acid residue.

Forward mutagenic primer: TGAGCGCGCCTGTATCGGCAT (5'->3')

Reverse mutagenic primer: ATGCCGATACAGGCGCGCTCA (5'->3')

For overlap extension PCR, another set of primers, which are plasmid-specific, were used and their sequences are shown below.

BamR (plasmid-specific) reverse primer: GCTAGTTATTGCTCAGCGG (5'->3')

T7 (plasmid-specific) forward primer: TAATACGACTCACTATAGGG (5'->3')

For overlap extension PCR, 2 fragments were obtained by independent PCRs. Forward mutagenic and BamR reverse primers were used to amplify the first fragment, while reverse mutagenic and T7 forward primers were used to amplify the second fragment. Both fragments are shown in Figure 2 below. PCR conditions for the nested PCRs are given in Tables 1 and 2.

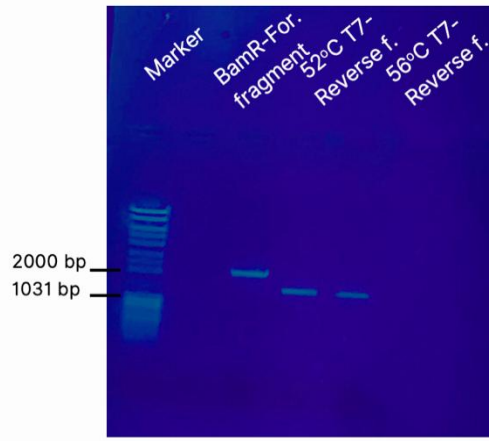

Figure 2. 0.7% Agarose gel image showing the BamR-forward mutagenic primer-fragment in the third lane, having 2.1 kb molecular weight, gradient PCR results for T7-reverse mutagenic primer fragment is shown at 4 and 5th lanes, having 1.4 kb molecular weight.

Table 1. PCR conditions for BamR-forward mutagenic primer fragment.

	Temperature (°C)	Time
In. Denaturation (x1 cycle)	98	30 sec
Denaturation (x30 cycle)	98	10 sec
Annealing (x30 cycle)	61	30 sec
Extension (x30 cycle)	72	1 min 3 sec
Final Extension (x1 cycle)	72	10 min

Table 2. PCR conditions for T7-Reverse mutagenic primer fragment.

	Temperature (°C)	Time
In. Denaturation (x1 cycle)	98	30 sec
Denaturation (x30 cycle)	98	10 sec
Annealing (x30 cycle)	56	30 sec
Extension (x30 cycle)	72	42 sec
Final Extension (x1 cycle)	72	10 min

After obtaining 2 fragments separately, an overlap PCR without any primers were set for annealing 2 fragments. Agarose gel result for the overlap PCR can be seen in Figure 3; gel extraction was performed for purifying the overlapped product from other non-annealed fragments.

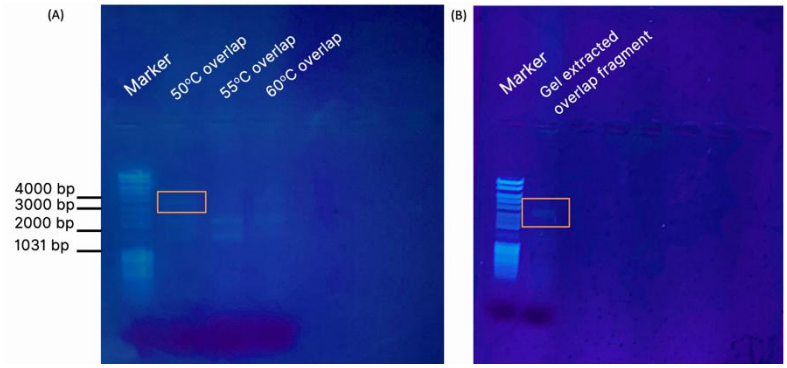

Figure 3. Gradient and primer-less overlap PCR was used for annealing 2 fragments (A), Overlapped fragments are marked with orange square, having 3.4 kb molecular weight. Overlapped fragment was gel extracted (B).

However, PCR amplification of overlapped product wasn't achieved yet, PCR optimization studies for amplification of the overlapped product is still being made. After successful amplification, the PCR product will be cloned to TOPO plasmid and will be blunt-end cloned to E. coli TOP10 cells. Expression, purification and characterization studies for potentially active CYP102A178 will be made further.

3. Spectral scanning and CO-binding assay

2 types of spectral scanning of purified active and inactive CYP102A178 will be performed. Purified enzymes will be reduced by 15 mg/ml Na-dithionate by a few minutes of incubation, their spectral scanning will be performed at 350-700 nm UV-VIS. The reduced samples will be saturated by CO to >90% level, and the same spectral scanning will be performed. Before and after saturation values will be used for drawing CO spectral graphic. As an alternative, characteristic Soret maxima of CYP102A178 will be determined for the water-bound state. Spectral scanning will be performed between 350-700 nm and the values obtained from the scanning will be used for low spin state characteristic Soret. With spectral scanning, characteristic Soret band of inactive CYP102A178 was determined as 408 nm, the characteristic Soret peak due to heme group of the enzyme can be seen in Figure 4, below.

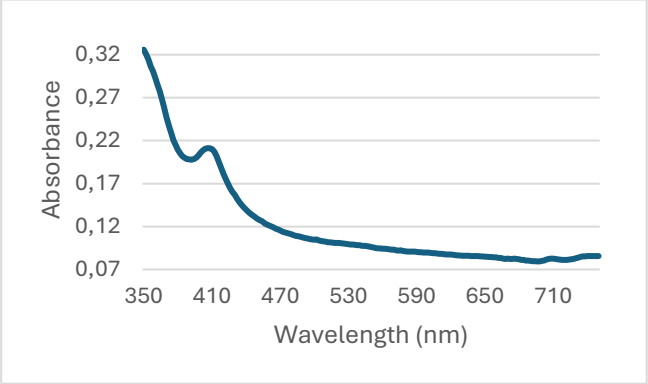

Figure 4. Spectral scanning of inactive CYP102A178 is shown for 350-700 nm, Soret maxima peak can be seen at 408 nm.

CO-binding assay will be performed both for active and inactive enzymes to determine their activity, a shift from 450 to 420 nm will be indicating the inactive or misfolded protein.

Findings

Recombinant expression, purification and biochemical characterization studies for inactive CYP102A178 was performed. Even though expression optimization studies were conducted for the inactive enzyme, only limited expression was achieved, there was no overexpression. The tyrosine residue, which could be responsible for inactive form of the enzyme could be a potential explanation for limited recombinant expression. Characteristic Soret maxima was determined with spectral scanning at 408 nm for the inactive enzyme. Overlap extension PCR with 2 sets of primers was used for Y440C mutation, but amplification of the final overlapped product couldn't achieve yet, PCR optimization studies are still being held. After successful PCR, cloning and Sanger sequencing, following expression, purification and characterization with CO-binding assay will be performed further for comparing inactive and potentially active CYP102A178.

Conclusion

Gene specific forward and reverse mutagenic primers with plasmid specific primers (BamR and T7) and PCR conditions for desired (Y440C) mutation at pET28(a)+CYP102A178 construct were designed and determined. Autoinducing medium containing necessary supplements, with induction at 25 °C were selected as the optimal conditions for recombinant expression of inactive CYP102A178 collected from Hisaralan but optimization studies are still being made. Spectral scanning, which will be held at later stages of the project, will compare the mutated and inactive CYP102A178. With the characterization step that is performed with CO-binding assay, functionality of the inactive and active CYP102A178 will be determined.

Introduction

What is that event we feel as an earthquake, or try to make sense of by checking with one another: "Was that an earthquake?" or "Did you feel it?" I usually check the stillness of the water in a jug or look for swinging ceiling lamps. Besides the usual minor earthquakes, I have only experienced one major earthquake in my life—a destructive one where houses collapsed and people lost their lives. Even in the middle of such a strong tremor, I could still ask myself, "Is this an earthquake?" because I didn't fully understand what was happening. It was only when my uncle rushed in that the situation crystallized—the place transformed into the earthquake itself. That's when we transitioned into "drop, cover, and hold on." Looking back, I realize that, aside from the drills we practiced in elementary school, that was the first time I ever truly performed "drop, cover, and hold on." I believe that paralysis seems entirely plausible in such an unexpected event. But if we fully recognized what was happening, would that also be the moment when we understood what needed to be done?

According to Kandilli Observatory and Earthquake Research Institute Press Release (2020), on October 30, 2020, a very strong earthquake with an instrumental magnitude of 6.9 occurred in the Aegean Sea, between the north of Samos Island and off the coast of Doğanbey-Izmir, at 14:51 local time (Figure 1). It was felt over a wide area, particularly in İzmir and its districts, as well as throughout the Aegean and Marmara regions. Unfortunately, 119 people lost their lives and 1053 people got injured in Izmir, and Samos. I experienced the event at home with my mom, aunt, uncle, and two young cousins. It was the biggest seismic tremor I have ever felt in my life. The following week was quite traumatic for me. I could do nothing but follow the news, waiting to hear whether more people would be pulled from the wreckage of collapsed buildings. Although I was mostly traumatized by it, I was also fascinated by that powerful seismic vibration I experienced at home. I thought about how I can reflect on that rare physical sensation. That experience, together with the sad memory of the 2023 Kahramanmaraş Earthquakes led me to research tectonic experiences through sound, vibration, and body. With Sonified Memory of the 2020 Aegean Sea Earthquake, I explore what I recognized in the moment of the earthquake and what I realized afterward, through my engagement with scientific data and the artistic production process.

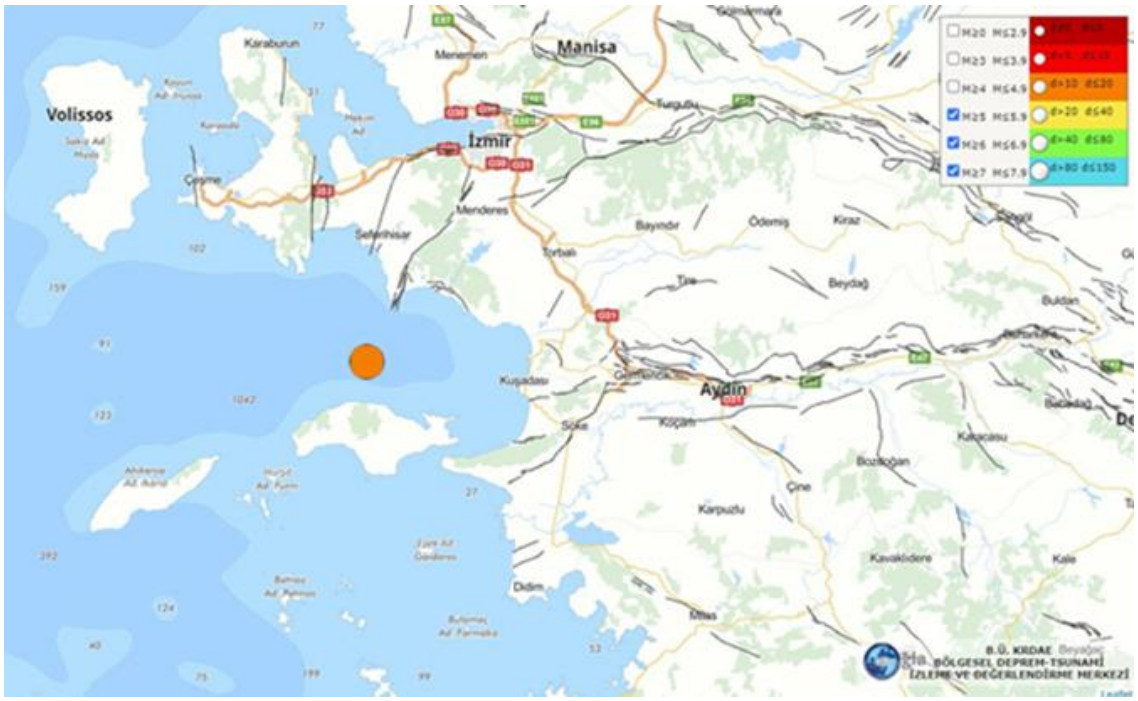

Figure 1. 2020 Aegean Sea Earthquake map (Kandilli Observatory and Earthquake Research Institute, 2020).

Seismic Data Sonification

Earthquake sonification has been a common method since the 1960s for processing earthquake data (Michael, 2019). The sonification process involves speeding up seismic waveform data and shifting the pitch, as seismic waves must be accelerated to reach the human hearing range, since earthquakes produce vibrations mostly below 10 Hz, which humans are not capable of hearing (Hirai et al., 2012). However, in case the more the data is sped up, the more once can grasp the vibratory texture of the event as whole, meaning the contribution of lower frequencies to the whole group of vibrations. On the contrary, the more the data is sped up, the shorter the sonification occurs. Reducing the duration in the event may somehow make it harder for us to process it by hearing, by making the earthquake sound for just a very little moment in space-time.

Aim

This study explores the ways in which tectonic vibrations are felt, remembered, and sensed by human bodies, examining the intersection of seismic phenomena, memory, affect and sensations. It seeks to create an artistic form of seismic waveform data sonification to recreate my memory of the earthquake, reflecting not only the temporal aspect of the event but also its emotional and physical impact. The aim is to understand how the tectonic vibrations manifested in the shaking I felt at home five years ago, how much earlier my cat in İzmir could have sensed the earthquake—particularly the earlier arrival of vertically propagating primary waves from the epicenter—and how the sonification and my artistic choices to reproduce the earthquake via Virtual ANS software correlate politically and ethically with the shaking I experienced. By bridging the gap between scientific data and personal narrative, this work seeks to develop an alternative way of understanding the spatio-temporal, sensory, and emotional dimensions of the earthquake experience, connecting objective seismic data with subjective human perception.

Material and Method

Located 5 kilometers away from where I physically vibrated with the earthquake, the Balçova (BLCB) seismology station recorded seismic vibrations originating from the northeast of Samos Island, 58 kilometers away from the epicenter. The seismogram recording of the BLCB seismology station was collected from the Kandilli Observatory Regional Earthquake and Tsunami Research Institute database. Using the ObsPy seismology software and the Virtual ANS spectral synthesizer, the frequency spectrogram of the seismic waveform data (Figure 2) from this

earthquake was sonified. While moving back and forth between image and sound, I carefully adjusted the settings on the Virtual ANS software, observing the sonic outcomes and their alignment with my memory of the event. The reproduction tempo is set as 60 beats per minute for every beat to take 1 second. The playback rate is changed to 5 pixels per beat. Since the horizontal axis of the seismic spectrogram image contains 616 pixels, it takes 123 seconds to reproduce the whole image, as the original duration of the event recorded by BLCB seismology station between 11.51 to 11.53, 2 minutes. The multimedia interface of Virtual ANS, while sounding the earthquake's frequency spectrogram, was combined with the chronological order of events in my recalled experience. By inscribing my episodic memory of the temporal order of events that occurred at home during the earthquake, a 2-minute-long audiovisual material (Figure 3) was created to reproduce the shaking with the 2020 Aegean Sea Earthquake at home.

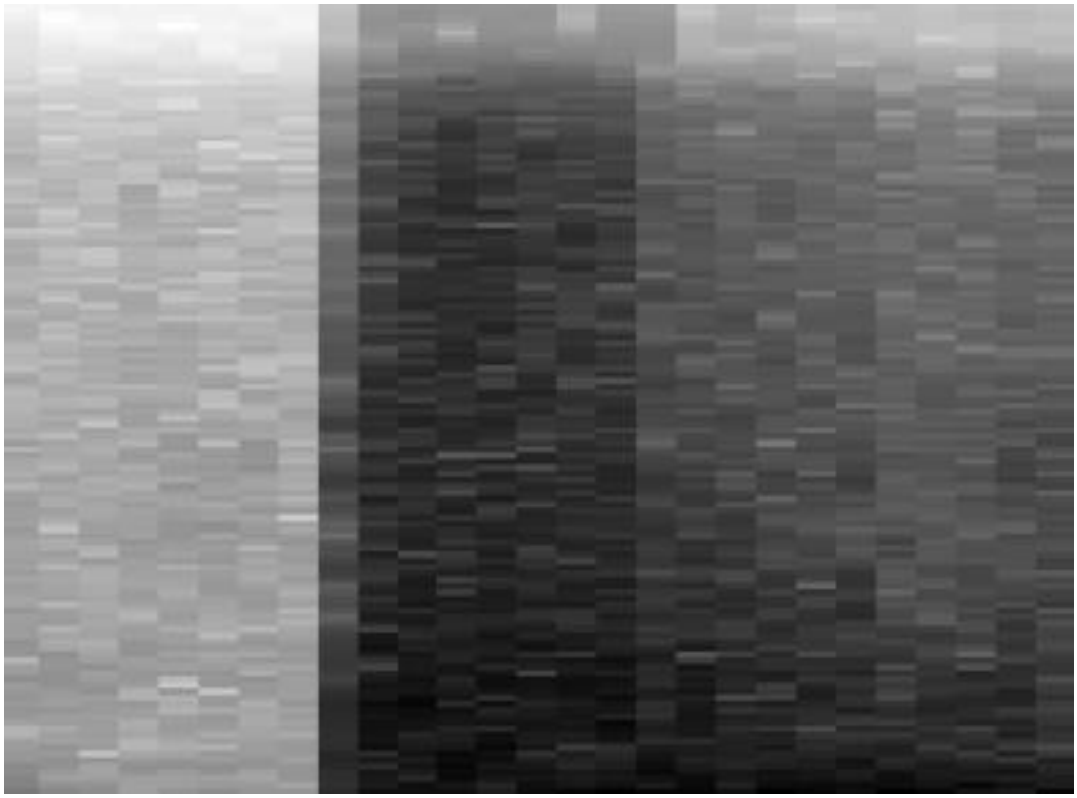

Figure 2. BLCB seismogram recording's frequency spectogram image, October 30 2020, from 11.51 to 11.53.

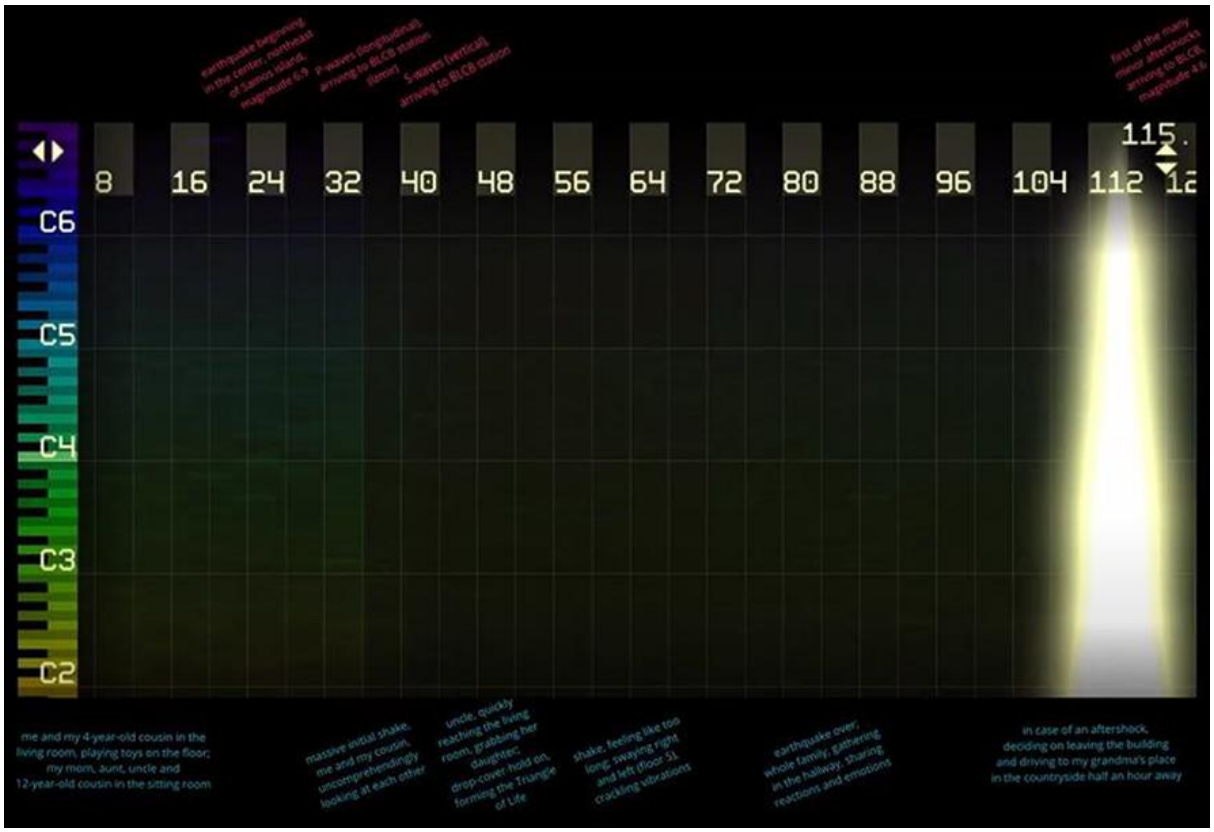

Figure 3. Seismic frequency spectrogram image sonification on Virtual ANS playback interface, along with my earthquake experience depicted over the timeline. "me and my 4-year-old cousin in the living room, playing toys on the floor; my mom, aunt, uncle and 12-year-old cousin in the sitting room - massive initial shake, me and my cousin uncomprehendingly looking at each other - uncle, quickly reaching to the living room, grabbing her daughter; drop-cover-hold on, forming the Triangle of life - shake, feeling like too long; swaying right and left at floor 5, crackling vibrations - earthquake over; whole family, gathering in the hallway, sharing reactions and emotions - in case of an aftershock, deciding on leaving the building and driving to my grandma's place in the countryside half an hour away".

Findings

The ultimate sound is like a broadband noise that is not particularly creepy and, if its source is not specified, could resemble the base-level sound of any constant process. When the earthquake event takes place, what is heard as changing is not much beyond the overall intensity; no particular group of sounds stands out to indicate that something specific happened. Instead, it sounds like an intensification of the existing noise. However, on the spectrogram and from the sonification, we can still see and hear that the earthquake emerges with a sudden saturation at the bottom of the spectrum. While the time-compressed earthquake data sonifications do not fully capture the dynamic range of the phenomena, Virtual ANS allows one to perceive the shifts in frequency and loudness of the seismic vibrations from an auditory perspective. While listening to the temporal and timbral qualities of the Sonified Memory of the 2020 Aegean Sea Earthquake, I was able to reconstruct the sequence of events in the house—how one act followed another, and another act followed that. This approach not only embodied the intensity of the orderly events from my memory but also allowed me to explore the intersection of scientific data and personal narrative. Such an artistic auto-ethnography helped me revisit the earthquake experience, and placed me into a personal transformation process. I was able to narrate my densely lived experience in an alternative way, creating new meaning and understanding from the chaos I had endured.

Conclusion

The sonification of the 2020 Aegean Sea Earthquake's frequency spectrogram evolved into a process of both remembering and reconstructing, as I narrated my experience by inscribing my voice and text onto the sonification interface during the audiovisual playback created by Virtual ANS software. Moreover, shifting between the data from different seismographs, including those beyond the BLCB seismology station, that recorded the earthquake, as well as navigating between sound, image, and coding, enriched my conceptualization of earthquakes beyond a human-centered perception range. This multidimensional exploration not only deepened my understanding of the intricate relationship between body, sound, vibration, movement, and time but also revealed how seismic phenomena can be experienced and interpreted through multiple sensory and artistic lenses. By engaging with the earthquake data in this way, I was able to uncover new layers of meaning, connecting the scientific and the personal, the objective and the subjective. What one could learn from such a process of remembering, at best, would be a kind of mental preparedness for a similar experience in the future—which, I guess, I eventually realized during the 2025 Istanbul Earthquake. I recognized that we were experiencing real tectonic seismicity. I quickly reached out to the washing machine—just as I had previously decided—and dropped, covered, and held on without losing any time. Like my uncle did for me five years ago, I shouted to my flatmate to recognize the shaking, take his position, and wait. The attack and decay of the vibration, as well as the building's oscillatory profile, felt familiar to me; I observed the vibrational time of the quake in relation to my previous tectonic experience. When I realized that I didn't feel the same shock during the 2025 Istanbul earthquake, I understood how reassuring body memory can be in the moment of a disaster. In conclusion, this process of reinterpreting the earthquake through sound and memory has opened up a space for healing and reflection, allowing me to reframe my relationship with the event as a form of future preparedness.

Lastly, the relationship of sound with other forms of graphic or digital representations is fascinating in terms of their indexicality to each other. Though neither intended to be heard nor graphically viewed, seismic waveform data constantly document the frequency of the ground's wiggle under the lands, oceans, volcanoes, mines… Prior to this sonification process, I had no idea how my physical experience of tectonic vibrations through the solid would sound to my auditory organs, as sound waves. I never knew that one day I could seismically play that tactile sensation underneath my feet, inside the building, in the Triangle of Life five years ago. I also didn't know that I could listen to the physical movement, speed and texture of this solid earth matter, captured by a transduction instrument in Izmir, built by Kandilli seismologists 20 years ago. In conclusion, this artistic and auto-ethnographic approach to seismic data highlighted the potential of sonification as a transformative tool for bridging scientific data, personal memory, and emotional resonance.

Music Memes and the Relationship Between Music Marketing and Humor in Turkey: The Past, Present, and Future

Alp Timuçin Bulut [a], Can Karadoğan [b]

Keywords: Music, Humor, Meme Culture, Digital Activism.

Aim

The significant role of music and humor in creating and enhancing experiences, as well as fostering connections and building enduring memories, cannot be overstated. In recent times, digital platforms have transformed the ways in which we discover and disseminate music, with memes and viral trends becoming increasingly popular. Historically, Turkey has employed satire and folklore in its marketing strategies, but the current landscape is dominated by digital culture, as social media and memes have taken over from traditional approaches. Currently, music memes function as not only a source of amusement but also serve as a tool for making social commentary, thereby shaping individuals' perceptions of music and cultural identity. This study aims to examine the historical and contemporary impact of humorous music content on Turkish audiences, with a focus on determining whether music memes create a lasting cultural and emotional impact or merely generate transient impressions. For example, research on digital culture reveals that memes have created a new language of communication among individuals while diminishing the influence of traditional media tools (Shifman, 2014). The communicative power of memes has been observed throughout history, not only in the field of music but also in politics and economics, where they have created significant impacts. As an example, The GameStop incident, when examined within the framework of subculture and social identity, demonstrates the impact of digital platforms on financial markets (Tanrıverdi & Pehlivan, 2023). In another resarch about politics shows It has been noted that caps are sometimes used as ideological and political tools, while at other times they function as a means of communication with both supporters and opposing views (Kahya, 2018).

Material and Method

This study employs a qualitative methodology, incorporating content analysis and case studies of digital music marketing campaigns and music memes in Turkey. Archival research examines how humor and music have historically been used to evoke emotions and foster cultural bonds. Additionally, digital ethnography will be used to analyze viral music memes, digitally marketed music videos, and audience reactions on social media platforms to assess levels of engagement and perception. This study will also examine historical music-related cartoons used in Turkish media, analyzing their role in shaping public opinion and cultural discourse. Furthermore, articles published in music magazines will be reviewed to understand how humor and music have been discussed over time. Interviews with musicians, cultural experts, and digital content producers will provide further insights into the psychological and social effects of humorous music content. Turkish case studies will be evaluated alongside international examples to provide a comparative perspective on the role of humor in music marketing and audience interaction.

Findings

The emerging findings reveal that both music and humor exert a significant influence over cultural narratives and personal opinions. Turkish music marketing has successfully merged past and present elements to generate a sense of nostalgia and community, an approach that has been further enhanced by digital platforms like memes and viral campaigns. Memes offer easily accessible and engaging content, which can provoke emotional responses rapidly. However, there is also a risk that they might trivialize rich cultural traditions, which could lead to superficial and transient impressions. Music is a strong way to people impress their ideas.Furthermore, In a study examining the impact of music on social identities, it was emphasized that music serves as an important social tool for individuals to express themselves and as a domain where social identities are reflected (Sağır & Öztürk, 2015). Music memes have been successful in driving digital activism, enabling individuals to engage in serious social and political discussions using humor and satire. Research suggests that when integrated effectively, music and humor can strengthen social bonds, bolster collective memory, and encourage deeper cultural engagement. Humor and music coming together online show how people engage with content in various ways based on culture. Personal taste and understanding of digital tools also play a role. A key finding is the change in audience engagement from just consuming music to actively participating in it. Online platforms let people remix and share music memes. This creates a culture where humor is a vital communication tool.

Unlike traditional music marketing controlled solely by industry experts, digital meme culture enables users to craft narratives and influence trends. They can form online communities based on shared jokes and music tastes. Challenges remain regarding the sustainability of music memes in maintaining audience engagement. Humor can make content go viral but may not maintain long-term interest in an artist or music trend. Music companies and musicians using memes for promotion need to balance authenticity with marketing. Audiences often reject humor that feels too commercial or fake. Music memes can break through language and cultural barriers. Humor is often tied to culture, but themes like satire and irony resonate universally. This allows music memes to reach a wide audience globally, expanding the influence of Turkish music beyond national borders. The rapid spread of memes enables musicians to quickly adapt to trends, keeping their content relevant in the ever-changing digital landscape. The monopolistic structure of traditional music marketing is being replaced by a dynamic structure where users can create trends and shape content. Music memes are at the center of this structure and have become an important tool in marketing strategies. However, humor that feels overly commercialized and artificial is generally perceived negatively by the audience.

The authenticity of humor stands out as a determining factor in the acceptance of content. Therefore, music producers and marketing experts should turn to strategies that include sincere and culturally meaningful humorous elements.The marketing dimension of the study shows how music memes are positioned as strategic communication tools rather than cultural narratives. The power of viral content to trigger emotional interaction is particularly valuable in terms of creating brand equity, strengthening the artist's image and connecting with the target audience.Through music memes, artists are remembered and talked about not only for their songs but also for the meme culture of which those songs are a part. This creates a kind of cultural "co-branding" effect and becomes an element that supports permanence in music marketing.Moreover, humor's ability to incorporate both universal and local elements makes it easier for Turkish music to cross borders and reach international audiences. The cross-cultural transitivity of forms of expression such as satire, irony, and parody makes it possible for memes to function in the global digital market.

Conclusion

The impact of humor on music should not be underestimated, as it has the potential to significantly enhance our enjoyment and appreciation of songs. Studies have demonstrated that humor can facilitate memory retention, thereby suggesting that amusing elements in music could contribute to an increased likelihood of recalling specific songs and the artists associated with them. Humor plays a critical role in engaging people and informing their musical tastes, all while reinforcing cultural values and beliefs. With this in mind, future academic inquiries would be well-served to explore the lasting cultural ramifications of music memes and their potential to exert influence beyond their initial surge in popularity. The impact of these memes on the transformation of music-listening habits and their utilization in online activism remain largely unexplored. Additionally, research that delves into the

influence of music memes on humor trends across various generations is both timely and essential. By comparing Turkish music meme trends with those observed on a global scale, a more comprehensive understanding of the interplay between humor and music-related content can be achieved. As Turkish music continues to mature and adapt within the digital realm, it is of the utmost importance to investigate the role of humor in shaping audience receptions and behaviors. This line of inquiry significantly enriches our understanding of the intricate relationship between humor, music, and digital culture and emphasizes the continually evolving nature of music engagement in the modern era. On the other hand, internet memes have been noted to play an active role in internet-based communication as a digital cultural object.(Yılmaz,2017)

Furthermore, humor and music play a crucial role in the formation of collective identity and community building. Through shared jokes, nostalgic references, and viral trends, online audiences develop a sense of belonging that transcends geographical boundaries. Whether through satire, irony, or parody, humorous music content fosters a dynamic space where individuals engage with one another, reinforcing cultural ties and collective memory. Music memes act as a digital storytelling mechanism, allowing communities to express themselves, critique societal norms, and celebrate musical heritage. This interplay between humor and music not only enhances entertainment but also serves as a powerful social tool that strengthens community bonds and collective experiences. Which is another form of humor memes, as a digital cultural object, play an active role in internet-mediated communication.(Yılmaz, 2017).

From a marketing perspective, music memes offer a lower-cost, more intimate and faster response strategy than traditional advertising methods. However, the viability of such content depends not only on its viral potential, but also on its authenticity and social sensitivity. Commercially motivated, fake or forced humor is easily detected by the audience and is often met with a negative reaction. It is therefore important for artists and music marketing teams to develop creative strategies to ensure that content 'naturally goes viral'.

The international impact of music memes is also noteworthy. Despite cultural differences, some forms of humor (e.g. visual jokes, gestures, absurd expressions) can find universal appeal. In this respect, music memes can be considered as a tool with the potential to bring Turkish music to international audiences. Especially for diaspora communities and digital migrants, this content functions as both a reminder of identity and a means of social bonding.

Challenging Conventions: Clara Wieck's Op. 20 and the Gendered Landscape of 19th-Century Music

İrem Hayrioğlu[a]

[a] Istanbul Technical University/Social Sciences Institute, Music, Music Performance, Turkiye
iremhayrioglu@gmail.com

Keywords: Clara Wieck, Gender and Composition, Romanticism, Variations Op. 20, Women in Music.

Aim

In spite of the fact that Clara Wieck is the most widely recognized female composer of the present day, her compositional capabilities have not been sufficiently investigated. Academic studies predominantly focus on her role as a pianist or teacher, often neglecting her identity as a composer. This analysis aims to examine how Schumann developed her artistic individuality despite societal constraints, how her style evolved over time, and how Op. 20 serves as both a deeply personal confession and a declaration of artistic independence. By addressing these questions, this study highlights Clara Wieck's contributions beyond her roles as a pianist and Robert Schumann's spouse, emphasizing her rightful place as a composer who demanded recognition.

In 1853, Clara composed Variations on a Theme by Robert Schumann, Op. 20 in honor of Robert's 43rd birthday, using a theme from Bunte Blätter, Op. 99. This work represents one of Clara's last piano compositions and serves as a critical point in her stylistic development. To understand her compositional identity, her career can be divided into three distinct periods: the early years (1830s–1840s), the mature period (1850s), and the late period (1860s and beyond). This study will provide an in-depth examination of these periods with a particular focus on Op. 20.

Material and Method

This study focuses on Clara Wieck's Variations on a Theme by Robert Schumann, Op. 20, because it represents a critical turning point in her stylistic development, bridging her earlier virtuosic writing with a more introspective, harmonically complex language. While previous studies (e.g., Buer, 2000; Reich, 2001) have analyzed the autobiographical and technical aspects of this work, they often treat it within broader surveys of her life rather than as a site of artistic declaration. Through a detailed musicological analysis of Op. 20—focusing on its harmonic, rhythmic, motivic, and formal innovations—this study aims to highlight aspects of her compositional voice that have been underexplored.

A feminist theoretical lens is also applied to reevaluate how gendered expectations influenced both the reception of her work and her self-perception as a composer. Primary sources such as concert programs, personal correspondence, and historical critiques are used to situate Op. 20 within the broader cultural and personal context of mid-19th-century Europe. In doing so, this analysis offers new insights into how Wieck's compositional language matured independently of her better-documented roles as a pianist and muse, challenging earlier narratives that inadvertently subordinate her identity as a composer.

Findings

Clara Wieck's formative years (1830s–1840s) were profoundly affected by her father, Friedrich Wieck, who significantly influenced her pianistic and creative growth. During this period, she created compositions that conformed to the virtuoso standards of the era, highlighting dexterity and technical excellence. Soirées Musicales, Op. 6 (1836) is a quintessential composition from this era, characterized by swift figurations and ornamental embellishments akin to those of Chopin and Liszt. Likewise, her Piano Concerto in A Minor, Op. 7 (1833–1835) exemplifies her initial emphasis on magnificence and virtuosity over substantial theme evolution.

In the mature period (1850s), Clara's composing approach progressed towards enhanced harmonic depth, structural intricacy, and emotional closeness. Op. 20 exemplifies this transition by elaborating on Robert Schumann's theme with harmonic sophistication and emotional profundity. Despite societal limitations that frequently obscured her

individuality as a composer, Op. 20 underscores her artistic independence within the Romantic tradition. Moreover, numerous historical documents indicate Robert Schumann's intrigue with the interplay of tone, color, and character, especially his preference for the key of F-sharp minor, which he linked to a nebulous and sad essence. This key, widely featured in Bunte Blätter, also plays a crucial role in Clara's Op. 20, enhancing their musical conversation.

Insights acquired during the performance preparation indicate that the structure of the variations is intentionally designed to oscillate between instability and resolve, both harmonically and emotionally. Specifically, Variation III's rhythmic fluidity and tonal ambiguity, along with Variation VI's progressively introspective and fractured texture, underscore Clara's ability to subvert the listener's expectations in favor of reflection. These selections indicate a deliberate manipulation of musical time and narrative—a characteristic frequently overlooked in current analytical work.

Moreover, it is significant because prior research has seldom recognized Op. 20 as Clara Schumann's ultimate completed solo piano work. This study, grounded in analytical inquiry and performative involvement, posits that the variations collectively function as a retrospective self-portrait, with each representing a distinct phase in her artistic and emotional evolution. The practice and memorization of the work revealed that the cycle not only elaborates on a certain theme but also defines a profoundly personal narrative loop.

An in-depth analysis of each variant, both analytically and in terms of performance practice, uncovers a comprehensive framework that reflects Clara's developing identity. The initial variation presents a Romanticized interpretation of Robert's subject, characterized by intricate elaboration and harmonic richness. The expressive intimacy indicates the influence of Mendelssohn and a hint of salon-style elegance—an emblem of Clara's nascent musical identity. Variation II, more delicate and uncertain, expresses emotional weakness, potentially reflecting the sensation of youthful doubt. The third version intensifies the emotional complexity: harmonically rich and rhythmically constricted, it suggests psychological turmoil—possibly illness, depression, or grief. Breath and phrasing emerge as essential instruments for the artist in expressing its intrinsic significance.

Variation IV exhibits a notable disparity through its virtuoso brightness and swift articulation. Clara demonstrates her pianistic prowess through rapid staccato passages and dynamic energy. Variation V, characterized by its intense octave writing and vigorous dynamics, conveys a profound sense of turmoil—nearly a musical dissent. This may reference Clara's unhappiness with societal constraints or possibly Robert's Florestan persona. The abrupt transition in Variation VI to a rigid canon structure signifies a reversion to discipline and contemplation, potentially evoking her formative studies with her father. This variation's sense of control and internal tension might be seen as a sound metaphor for obedience and initial creative training.

The seventh variation cohesively unites the expressive elements of the cycle, culminating in a serene yet potent finish. It is abundant in thematic references and structural unity, offering both formal resolution and emotional validation. It appears to be Clara's ultimate artistic declaration—simultaneously a farewell and a subtle affirmation of identity. Consequently, Op. 20 can be interpreted as more than only a birthday present for Robert Schumann; it serves as a comprehensive and introspective work, cognizant of its own conclusion.

In the late period (1860s and thereafter), subsequent to Robert Schumann's demise in 1856, Clara's compositional productivity diminished markedly. She predominantly forsook writing to prioritize her career as a performer and instructor, shaped by personal sorrow and societal constraints that dissuaded women from engaging in composition as a permanent vocation.

During the 19th century, female composers were anticipated to create salon music—enjoyable, small-scale compositions that adhered to gendered norms of musical artistry. Although variation form was esteemed by male composers such as Brahms, Beethoven, and Mendelssohn, Clara Wieck's involvement in the genre contests the notion that women's compositions were merely decorative. Her employment of contrapuntal textures, harmonic intricacy, and motivic evolution positions her with prominent composers of her era, challenging the marginalization of female composers in the annals of music history.

Furthermore, Op. 20 holds considerable importance for Clara's career as a performer. During a period when she was financially sustaining her family through concert appearances, this work was produced not for monetary profit but for sheer artistic gratification. Unlike Soirées Musicales, which satisfied audience demand for spectacular virtuosity, Op. 20 is a contemplative composition that emphasizes musical profundity over technical exhibition.

This distinction highlights the desire for female artists to exhibit technical excellence to attain reputation. In contrast to male composers, who were not obligated to demonstrate their virtuosity in their works, female composers were compelled to validate their merit as performers. Clara Wieck's capacity to reconcile these expectations while maintaining a dedication to musical profundity is apparent in Op. 20.

Conclusion

Though history often portrays Clara Wieck as being overshadowed by Robert Schumann, the reality is that she was the one financially supporting their family, raising their children, and premiering her husband's works—all while maintaining her own artistic career. While the men around her admired her resilience, her personal writings reveal persistent self-doubt. In her letters, she repeatedly expressed the belief that, as a woman, her artistic potential was inherently limited, thereby underestimating her own accomplishments. Variations on a Theme by Robert Schumann, Op. 20 exemplifies her fully developed compositional voice, yet her self-imposed doubts reflect the broader gendered constraints of her era. Despite these challenges, she sought the recognition that had been denied to her in life. It remains compelling to consider how her compositional voice might have evolved had she been afforded the same artistic freedoms as her male contemporaries.

Messiaen as Liturgist: A Contextual Reading of the Vingt Regards sur l'Enfant-Jésus

Robert McDonald[a]

[a] Istanbul Technical University, Center for Advanced Studies in Music (MIAM), Türkiye
robbiemacplayspiano@gmail.com

Keywords: Catholicism, Liturgy, Messiaen, Vingt Regards sur l'Enfant-Jésus.

Aim

Olivier Messiaen's paraliturgical religious music has benefited from thorough scholarship on its theological, ornithological, theoretical, and prismatic properties. His compositional output and the above inspiring forces have been strangely divorced by many academicians from his longest lifetime appointment, the organist at Église de la Sainte-Trinité in Paris. That he played countless Masses and other liturgical services for Catholic worship for more than 60 years may indicate a coded yet necessary index through which to hear and "practice" large-scale works like Vingt Regards sur l'Enfant-Jésus, which at two hours is itself a ritual beyond mere cognitive engagement, and still renders an opacity to modern audiences due to its layers of religious symbolism. Without the context of liturgy, the work fails to merely conform to the usual desirable models, be they a highly programmatic concert piece, an academic monument rife with subtext for analysis, or a historical testament of a piece written under Nazi occupation and just a few years following Messiaen's own imprisonment at Stalag VIII-A during the height of the Second World War. Certainly these each contain a part of the story, but a liturgical framework suggests a holistic viewing of Messiaen and his work from the compositional chair and the organ bench, and necessarily points to a connection between the two stations of a lengthy career. Central to my research was an attempt to experience a performance of the Vingt Regards in a new manner, with the worshipful posture that the composer maintained throughout his accomplished life.

Material and Method

My first task was to study liturgy in its ecclesiastical contexts, and compare Catholic models with my own Protestant heritage. As I surveyed the literature on Messiaen, a noticeable trend toward his liturgical inspirations emerged, and the relationship of his concert music and the liturgy, without having been formally explored by published scholars. My research therefore extended through a significant portion of what has been written on Messiaen over the past several decades, and also into the liturgy itself, so as to provide a clear definition of its use inside the Church and into other parts of life. Since Vingt Regards and other comparable works are not written for the liturgy itself, but rather further liturgical praxis into concert and secular settings, the theological discussions of liturgical and anthropological scholars like James K.A. Smith and others yielded immense benefit toward a more cross-disciplinary study. I created a simple matrix of the movements of the Vingt Regards and several elements from a liturgical service, including sermons, hymns, prayers, blessings, sacraments, and processions, and considered how this enhanced an understanding of Messiaen's religious music. Following this research, interviews with Catholic musicians fluent in liturgical patterns was highly valuable; in May 2025 I was fortunate to meet Thomas Lacôte, the current organist at la Trinité, observe a Sunday Mass from the organ loft, and share a brief discussion following the service. Finally, as a performer of most of the movements of Vingt Regards, I am keenly interested in the ongoing task of finding performance settings that bring this music and an audience into closer proximity, and drawing out liturgical actions that normalize the music rather than create further alienation and misunderstanding.

Findings

"Liturgy" itself is not outside of Messiaen's lexicon when considering the titles or movement titles to his compositions: the opening movement of Quatuor pour la fin du temps is marked "Liturgie de cristal", and the

suggestive Trois Petites Liturgies de la Présence Divine for mixed ensemble are concert works described by Robert Scholl as "paraliturgical" in their liminal stations (Scholl, 2024). These have value in being inclusive to those outside of the faith, while retaining liturgical properties. From the discussions of Smith and others, I considered five critical components inherent in the liturgy: the use of sacrament, repetition, narrative, embodiment, and pedagogy. All components conform to a viewing of Messiaen's music. Sacraments like the Eucharist are a mystical centerpoint to liturgical services, and similarly Messiaen reserves a hallowedness when penning movements XI. Première communion de la Vierge or XV. Le baiser de l'Enfant-Jésus, both about communion with the Christ Child. The liturgy is highly recurrent so as to guide the heart to a healthier modus operandi; Messiaen often gets lost in his own writing through lengthy restatements of entire passages, potentially in an effort to shut out the horrors of a ravaged Europe in 1944. Narrative is a driving force in liturgical services, communicating the gospel through a series of planned elements, as Messiaen skillfully sets the stage (movements I–III.), introduces central characters (IV., VIII.), foreshadows what is to come (VI. and VII.), builds the suspense (XIII. and XIV.), creates a climactic event (XV.), and promises an end to the story (XIX. and XX.). Catholic services go beyond theoretical engagement to somatic corporate actions, through kneeling, singing, eating and drinking, and receiving blessings with outstretched hands. A corollary embodiment is more coded in Vingt Regards, but potential can be found in experimenting with mixed media, extra sensorial prompts, and other somatic exercises like those found in Pauline Oliveros's Sonic Meditations. Finally, the liturgy is inherently didactic as parishioners gradually grow in their catecheses, learning the heart of God through the practices of the Church. Messiaen similarly exhibited the care of a teacher throughout his career, giving no shortage of programmatic materials in order to instruct musicians and listeners. The performer of Vingt Regards then serves as a kind of priest tasked with handling the source material and contextualizing it for the enrichment, education, and enjoyment of their audience.

Conclusion

Considering the liturgical components of Messiaen's religious music generally, and Vingt Regards in particular, distinguishes it from surrounding music with alternative aims. The intent of Messiaen's paraliturgical offerings go beyond historic or academic models, they further aid the faithful in search of beauty and truth. The role of the Church is to shepherd parishioners through the regular use of the liturgy, or the sum of the aesthetic, moralistic, and teleological parts; similarly Messiaen aims to woo his church into an upward gaze of wonder through music that is sacramental, repetitive, storied, somatic, and pedagogical. By synthesizing Messiaen's roles as liturgist and composer, the music of the Vingt Regards comes into sharper focus as music of worship.

The Relentless Clash of Dissonant Harmonies and Lyric Melodic Lines… An Extensive Look into the Sound of Sergei Prokofiev

Selçuk Ener[a]

[a] Istanbul Technical University, Music, Music Performance, Türkiye
ener22@itu.edu.tr

Keywords: Industrial Revolution, Machine Music, Prokofiev.

Aim

This paper will be focusing on the sound of one of the most prolific composers of the early 20th century, Sergei Prokofiev. Prokofiev's music, while consisting of sharp dissonances and motor driven, tight rhythmic patterns, also involves subtle sarcastic or humorous motives and lyric themes. These components of his music, constantly clashing and battling each other, are creating a striking, dazzling sound which is extremely unique. I believe that the changing paradigms of day to day life that came with the Industrial Revolution in the 19th century as well as the political turmoil that led to October Revolution in 1917 and the two world wars that followed have huge effects and contributions to Prokofiev's sound. The main objective of this paper is to analyze the contributions of industrial revolution and the political, social environment in Russia on Prokofiev's sound through looking into his music and having a chronological look into his life starting from his childhood and education, his abroad years in Paris and his later years in Soviet Russia.

Material and Method

To understand the effects of new industrialized lifestyle and the political environment of the composer's early years on the development of his unique sound, I will be using two approaches. The first approach will be a historical one, focusing first on the effects of industrialization on classical music in general (examples from 1920s which are called machine music) and then on Prokofiev's childhood, his musical education, influences and how he was effected by the trending compositional practices of his early years. The second approach will be analyzing the composer's music through case studies such as his 3rd piano sonata and his second symphony. These compositions, both written through 1910s and 1920s, contains evident links to Prokofiev's influences from industrialization, politics and war. I will be identifying and showing the sections of his music that are influenced by the industrializing world through highlighting sections in score.

The first step to understand the elements creating the sound of Prokofiev is to do extensive readings on the life and the compositions of the composer. Many musicologists and musicians have written articles and books on various topics, some examples including but not limited to Stephen Press's book on Prokofiev's operas, pianist Boris Berman's book on his piano sonatas or Harlow Robinson's extensive biography, throughout the years, and these resources are the first step to the research on the composer. As the research continues, the music, which is the main element of our research will be studied. The 1917 3rd piano sonata and the 1925 2nd symphony are excellent case studies and are selected to be examined, analyzed and studied in detail in order to understand the harmonies, rhythms, melodies and motifs, their roots or in general the main components that are creating the unique sound of the composer. Especially the moderato section gives us a great example of the lyric melodic lines supported with chromatic figures on the left hand which creates many dissonant harmonies clashing with the lyric nature of this section. Another very good source to understand the output of Prokofiev is his letters, journals and interviews as well as the comments of his close circle on the composer such as his wife, sons, teachers, students or contemporary musicians. Some very good research material are, Simon Morrison's book on Lina Prokofiev, or Anthony Phillips's anthology on the composer's diaries. These material are our primary resources in order to understand his struggles, ambitions, influences all contributing to our understanding of the elements creating his style of composition and sound.

Findings

After the research was completed, it is evident that Sergei Prokofiev, among many other composers of the early 20th century, was deeply influenced by the new sounds that were brought into life by the industrial revolution (the factories, railroads, steam engines and machines). His compositional techniques were also influenced by his upbringing in the politically chaotic Russian Empire in his early years as well as the dark and somber atmosphere that the two world wars created. These influences are quite apparent in our case studies that are his 3rd piano sonata (filled with mechanic rhythmic patterns influenced by engines and machines) and his 2nd symphony which was described as "a piece of iron and steel" by the composer himself referring to the changing day to day sounds of the early 20th century. His later sonatas number 7, 8 and 9 (which are also known as war sonatas) are also great examples of how much the composer's sound was effected and influenced by the second world war.

Conclusion

In conclusion, this paper is focusing on the unique sound of one of the most prolific composer of the early 20th century, Sergei Prokofiev. My main objective is to show and prove that the composer's rhythmically mechanical, relentless, and extremely dissonant but at the same time also quite lyrical sound was hugely influenced by the industrialized world and the political events of the early 20th century.

Effects of Performance Space on Free Improvisation Practices

Aslıhan Adlin[a]

[a]Istanbul Technical University, Graduate School, Musicology and Music Theory Program, Türkiye
adlina@itu.edu.tr

Keywords: Space, Free Improvisation, Performance Space, Place, Experience.

Aim

Music-space interaction is most apparently related to acoustics, however, the experience of space as atmosphere, especially in free improvisation practices, does not seem to have gained enough prominence to be the focus of a research topic. The experimental and unpredictable nature of free improvisation makes the space in which it is experienced versatile and variable. Rather than approaching space solely as an acoustic phenomenon, considering it as an element socially constructed by musicians and listeners and actively involved in the music is important to grasp the role of space in free improvisation. In addition, space and music create an atmosphere for those present at that moment, namely the musician and the listener. Examining this dynamic and changing space, which is constructed socially by its performers and audience, might have methodological challenges. Thus, this study aims to review the methodologies used in the relevant literature, providing examples for future studies that examine the relationship between space and free improvisation practices in the context of musicians' experience of space as an atmosphere. It demonstrates three case studies and discusses different approaches to performance space involved in free improvisation practices.

Material and Method

The methodology of this study is a field research conducted in a studio recording as a pilot study to find out what aspects of space can be approached and examined, as well as a literature review. The research has been conducted on the axis of space, free improvisation, and the music-space relationship. To understand the meaning of the space concept from a phenomenological perspective, approaches from different disciplines in social sciences were examined. Additionally, studies were reviewed on music-space interaction to apprehend the contexts in which the concepts of music and space come together. Later, the research was focused on free improvisation, and studies that addressed this genre concerning the notion of space were investigated. Three studies were found on this approach, and the methodologies of these three case studies have been discussed. After examining the methods used in these studies, a studio recording was made as a participant observer, and interviews were conducted with other musicians about the spatial experience in the studio.

Findings

Most studies on free improvisation have focused on creativity and the interaction between performer and audience (Ford, 1995; Andean, 2023; Wilson & MacDonald, 2016; Canonne, 2018; Hatipoğlu, 2022). Few studies taking spatial interaction in its center have been found in the written literature of this genre. Here, three cases relating space and free improvisation from different perspectives will be examined through their methodologies.

The first case is a study by Pauline Oliveros (2007) in which she explains three different performances by the Deep Listening Band and compares acoustic features of three different places through the listening experience of musicians and the audience. These places are a cistern with 45 seconds of reverberation time, Biblioteca National in Buenos Aires, Argentina, and the chapel of Pomfret School in Connecticut. This study shows that changing acoustical characteristics in different places has an impact on musicians' listening perception, and Oliveros states that these characteristics for musicians are musical parameters like as melody, rhythm, harmony, or timbre. Additionally, Oliveros, here, points out that listening practices in different acoustical environments change accordingly, and changing places provide changing experiences for listening (Oliveros, 2007, pp. 68-69).

Chris Atton's mention to performance space in free improvisation is the second case of this study. Atton investigates (2012) free improvisation genre culture and the transformation of the performance space by analyzing

live performances in Leeds, England, from a micro-sociological perspective on cultural interactions between performers and audience, and socioeconomics. He provides analyses of four free improvisation performances placed in Termite Club between 1985-1999 and demonstrates performers' approach to space with their claiming it as a musical territory. In these examples, musicians choose to play the performance space either playfully or in a physically threatening way, giving that, Atton discusses the unpredictability of live experiences that create an unstable music culture (Atton, 2012, p. 439).

The third case is David Leahy's study (2021) regarding his "Musicians in Space (MiS)" project. Leahy here uses a phenomenology-based heuristic methodology and conducts two-staged research including a series of performances in several British cities and participant interviews following these performances. With this study, Leahy aims to give insight into developing a comprehensive and non-hierarchical method for music-making by providing the opportunity for free improvisers to shape their spatial location during the performances (Leahy, 2021, pp. 335-336). The study shows that the flexibility in moving in the space fosters immersive listening and provides a deep connection for both musicians and the audience.

The three case studies show that space might be involved and discussed in free improvisation studies from different perspectives. Except for acoustical measurements, socially constructed space and its phenomenological experience are evaluated by mostly qualitative methods such as listening practices, theoretical discussions, and interviews.

Following this literature review, a pilot study was conducted in PERA Studio at the Bahçeşehir University, Conservatory, and musicians were asked to evaluate their experience of space. These evaluations have raised new questions about how to approach the recording studio spatially. The psychology of recording in the studio has a distinctive aspect from the performance experience in other spaces. In this context, discussions are ongoing to compare the experience in the studio with the spatial experience in different areas.

Conclusion

Focusing on studies related to performance space and its impact on free improvisation practices, this study aimed to provide a perspective of the methodologies used in the pertinent literature to gain insight into space investigations. The three case studies by Oliveros, Atton, and Leahy examined in this study show that there is no commonly accepted methodology to conduct such research on the impacts of space on free improvisation yet, they commonly rely on the phenomenological perspective. So, this study drew attention to the limitations of methodologies used in the field and opened qualitative and quantitative approaches for discussion. In addition, the pilot study conducted in this research shows that each spatial experience raises new questions but also provides an in-depth understanding of the space itself. The hope is that this study will shed light on the creation of new methods in future studies. By finding a peculiar methodology, a further study might involve a set of experiments in different places through a versatile analysis and exploration of performance space.

Cyclic Unity and Romantic Expression in Robert Schumann's Fantasiestücke, Op. 12: A Schenkerian Perspective

Doğucan Temizel[a]

[a] Istanbul Technical University, Department of Music, Music Programme, Türkiye
temizeld@itu.edu.tr

Keywords: Cyclic, Robert Schumann, Schenkerian Analysis, Tonality.

Aim

From the Renaissance through the early Romantic periods, the cyclic principle evolved as a compositional tool in Western classical music. In this tradition, Robert Schumann's Fantasiestücke, Op. 12 (1837), represents how cyclic organization can create a musical narrative in a multi-movement work. The research aims to examine the underlying melodic and harmonic relationships of Schumann's Fantasiestücke. Using the Schenkerian perspective I will demonstrate how it reveals the fundamental structural coherence of the cycle despite the diversity of the character pieces within the overarching formal design. Some music scholars, such as Arthur Komar (1971), Patrick Mccreless (1986), David Neumeyer (1982), and Peter Kaminsky (1989), debate whether Schenkerian analysis applies to the music of the Romantic era. This study suggests that Schenker's concept of Ursatz (Fundamental structure) and Composing-out (Auskomponierung) is still valid for the Romantic repertoire since it can illustrate fundamental structures even in fragmented music with tonal ambiguity.

Material and Method

The stylistic aspects of Fantasiestücke, Op. 12 balance resonant sonorities with dynamic piano texture while utilizing a blurred harmonic language that undermines conventional tonal hierarchies. Moreover, Schumann's original title, 'Phantasien,' in which Brown (2001) indicates that there is an allusion made to E.T.A. Hoffmann's 'Fantasiestücke in Callots Manier' (1814–15), positions the piece in a broader nineteenth-century fantasia tradition. This literary association, therefore, shows his intent in relating individual movements in an organized whole, following on in a process evident in earlier cycles such as Papillons, Op. 2 (1829–31), Carnaval, Op. 9 (1834–35), and Davidsbündlertänze, Op. 6 (1837).
For the methodology, I used the analytical perspective based on Schenker's Free Composition (1935). I created the representations of structural relationships through the reductive Schenkerian graphs, which are Schenker's core theories being used as a basis for teaching purposes, on which Forte and Gilbert (1982), Beach (2012), and Cadwallader, Gagné, and Samarotto (2020) expanded. The first phase includes examining the foreground (Vordergrund) and middle-ground (Mittelgrund) structures of the work exhibiting how techniques of extension and recurring motifs sustain continuity within certain sections and how they contribute to the development of the narrative. It also shows how the detailed graphs can represent the implementation of fairly disguised harmonic progressions through sections, and of the prolongation of substituted tonic harmony across these eight character pieces. The second phase begins with a discussion of how these basic elements all work together to form a single organic unity within the overall structure.

Findings

The analytical results reveal that each piece's fundamental line consists mainly of descending Urlinie, 3^, 2^, 1^. In particular, in Warum?, the prolonged structural motion concludes at the 3^ on the final chord without resolution, whereas in Grillen, the introduction of the first Urlinie pattern 5^, 4^, 3^, 2^, 1', indicates a pivotal large-scale transition. The tonal axis extends in the substituted tonic D♭ (♭VII) between Des Abends and In der Nacht, then leads to C major (V) in Fabel, and arrives at F major (I) in Traumes Wirren. Ultimately, at the finale, Ende vom Lied accommodates the F major tonality by consolidating these elements, particularly at the coda, an abrupt modulation to the D♭major before the closure that reinforces the work's tonal coherence. The Schenkerian graphs

show how these harmonic progressions modify conventional formal structures on the local and large-scale levels. In addition, recurring intervallic gestures, such as descending and ascending stepwise motions and leaps of the 6th interval, further unify the cycle. This primary motive occurs either at the beginning or in the transitions between the character pieces.

Conclusion

In conclusion, my interpretive study shows that Schumann's Fantasiestücke Op. 12 encompasses a formal integrity through the revelation of 'F' as a pitch element and tonality that underpins the cycle's Ursatz as an organic structure. In addition, the musical dialogue between 'Eusebius and Florestan' represented in succession throughout the entire piece includes harmonically innovative techniques, such as remote-key relations, destabilizing modulations, and tonal ambiguity. For this regard, an adapted Schenkerian analysis explicitly connects narrative and theoretical perspectives so that these insights may help performers and music scholars. Besides, it contributes to a deeper comprehension of Schumann's compositional techniques in cyclic works, enriching the nineteenth-century music analysis.

Exploring Dance Floor Tactility: Sonic Ethnography and Artistic Inquiry through Audio Paper

Gazele Aydın[a]

[a] İstanbul Technical University, MIAM, Sonic Arts, Turkey
ayding22@itu.edu.tr

Keywords: Artistic Research, Dance Floor, Sonic Ethnography, Tactility.

Aim

This paper will introduce a section from my thesis that explores dancefloor tactility through sonic ethnography and artistic research. The focus will be on the methodologies and theoretical framework that guide my research, as well as the necessity of an audio paper as an outcome. While I will include excerpts from the audio paper, the presentation itself will follow a conventional format; it will outline how my research process and methodology leads to the creation of an audio paper and the creative audio is needed to comprehend dance floor tactility. By demonstrating how sound can function as both a research method and a form of knowledge production, I aim to highlight that the addition of an audio paper is an important method for sonic ethnography and artistic research practice. In this research sonic ethnography and artistic research methodology has been employed as methods to enhance the understanding of dance floor tactility. By editing a collection of field recordings and manipulating sounds according to context and meaning, and by using these field recording collages in feedback interviews in a cyclical form to deepen the analysis, this research aims at a reflective listening and creation process. This study allows participants in a reflective listening process; through feedback interviews, the research not only gathers interpretations of sonic tactility but also allows the sonic material to evolve based on feedback. This cyclical approach aligns with artistic research principles and also sonic ethnography, where the creation and contextual analysis of sound are integral.

Material and Method

Sonic ethnography, as outlined by Gershon (2019), emphasizes the relational and processual nature of sound, revealing the complex interactions between humans and their sonic environments. For many studies sound has been central to ethnographic practices, but the sonic often remained neglected to a second-class positionality in ethnographic research. But sound is an important, integral part of ethnographic processes; most forms of ethnography rely on rendering ideas, interactions, and images as texts; they often maintain Western visually oriented conceptualizations of sense-making. But when examining a field, such as the dance floor, which is inside a rich sonic environment, doing ethnography in sound is crucial. Peterson and Brennan (2021) further highlights this importance of sonic ethnography as a collaborative and immersive practice, prioritizing the acoustemological aspect of sound as a way of knowing. They mention that sonic ethnography understands sound as processual and relational; and it requires collaborative practices that bring together different perspectives towards listening. Furthermore Littlejohn (2021) underscores the importance of field recordings and editing in sonic ethnography, emphasizing how field recordings and their manipulation offer partial truths and insights into the lived experience of a site. Collecting field recordings and editing them according to a context offers new and different understandings of experiences, meanings and relations between experience and meanings, different from textual ethnography.

Sonic ethnography, as a methodology, allows immersive engagement with sound, collecting experiences through listening and field recording. However, rather than treating these recordings as fixed data, this research engages with them artistically with the audio paper; editing and manipulating them to reveal new layers of meaning. This artistic approach aligns with artistic research principles, where creative processes become a method of inquiry.In this context, the editing on sonic ethnography works also have an artistic tendency. As a musician and researcher I have both insider and outsider roles in my field. This duality gives me space to experiment on both my roles as

musician and researcher. Because artistic research is a practice based, open ended, self critical, context aware research that embodies participatory act, self reflective text and creation making I believe it is an important ally for sonic ethnography, doing ethnography in sound while creating sound, getting feedback and writing on it can bring inclusive outcomes.

In this research Garcia's concept of sonic tactility provides a theoretical foundation for understanding how sound can be felt beyond the auditory sense, engaging the body through beats, flesh and grain. According to Garcia, because the dance floor employs electronic dance music, it has tactile qualities. This research explores dance floor tactility through experimenting on features of sonic tactility presented by Garcia in terms of tactility through vibrations, tactility through association and tactility through sonic texture itself. To explore these sonic qualities, field recordings were gathered from actual dance floors, while additional materials were sourced from online spaces, including radios, albums and DJ sets that are actively followed by local dance floor participants. This combination of real-world and virtual soundscapes provided a different approach to understanding how sound manifests tactility in the context of electronic dance music.

Findings

This research demonstrates how sound can be experienced not just as an auditory phenomenon but as a bodily, tactile encounter. By analyzing field recordings from both real and virtual dancefloor environments, this study examines how sound acts upon the body through vibrations, associations, and textures. As a result, the final audio work reflects a layered exploration of dancefloor tactility. The manipulation of these field recordings, whether through editing or contextualization, has demonstrated how different sounds can evoke various associations, textures, and emotional responses. This process aligns with Littlejohn's (2021) view that field recordings, when edited, provide insights into the lived experience and can reveal partial truths about a sonic environment. The integration of participant feedback further deepens the analysis, making it possible to capture multiple perspectives and meanings attached to these sonic experiences. The use of an artistic approach in sonic ethnography, particularly through the creation of an audio paper, has also emphasized the performative nature of research, allowing sound to evolve as an integral part of the inquiry itself.

Conclusion

Several different audio works have been done and by reflecting on those audio works this research extends ethnographic representation beyond traditional written formats, embracing the sonic as a mode of knowing and knowledge production. The final audio paper, shaped through fieldwork, artistic intervention, and participant feedback, ultimately reflects a multi-layered exploration of dancefloor tactility, approaching sound not only as an object of study but as a methodological and epistemological framework in itself.

Spatial Auditory Masking in 3D Audio: Challenges, Experimentation and Implications for Immersive Sound

Emre Tenker[a], Taylan Özdemir[a]

[a] Istanbul Technical University, Centre for Advanced Studies in Music, Music, Türkiye
tenker@itu.edu.tr

Keywords: Spatial Auditory Masking Phenomenon, Aural Perception, Masking Threshold, Dolby Atmos, Audio Coding, 3D Audio.

Aim

Auditory perception is continuously evolving with advancements in 3D audio technologies, expanding traditional monaural and stereophonic formats into more immersive spatial sound environments that heighten the sense of realism. These innovations have been significantly impacting industries such as music production, gaming, virtual and augmented reality (VR/AR), cinema sound and assistive hearing technologies. Unlike conventional two-dimensional audio, 3D audio systems allow for precise spatial positioning of sound sources, resulting in a heightened sense of realism and listener immersion. However, as the auditory space is filled with more sound sources, the perception of individual auditory elements becomes more complex due to auditory masking effects, in which one sound obscures the perception of another. While spectral and temporal masking are well-documented in psychoacoustics, the role of spatial auditory masking in immersive sound environments remains an active area of research.

Spatial auditory masking refers to the phenomenon in which a sound becomes less audible due to the presence of another sound, depending on their relative spatial positions [4]. The human auditory system relies on binaural cues, such as interaural time differences (ITD), interaural level differences (ILD), and head-related transfer functions (HRTF), to localize and separate sounds in a three-dimensional environment. These mechanisms contribute to spatial release from masking (SRM), which occurs when sounds are easier to detect due to their spatial separation. Understanding spatial auditory masking is crucial for optimizing sound clarity and intelligibility in modern immersive audio formats. This study aims to investigate the impact of spatial positioning on auditory masking thresholds in a controlled Dolby Atmos environment, examining how different spatial arrangements of the masker and the maskee influence detection. The findings will provide insights into psychoacoustics and spatial audio applications, with implications for audio mixing and immersive sound design. The aim section should be written in Times New Roman font, justified-alignment and in 10-point size.

Material and Method

This study includes a literature review of how locations of auditory objects affect the auditory masking thresholds and subjective listening tests which are conducted in a calibrated Dolby Atmos studio, ensuring accurate spatial reproduction of sound sources. The foundation of the literature review is primarily based on Blauert's "Spatial Hearing: The Psychophysics of Human Sound Localization" [1], while the experimental design is inspired by the work of Nishiguchi and his collaborators [6][7], as presented in their articles published by the Audio Engineering Society.

The experiment includes a masker and a maskee presented from various spatial positions. The masker is a narrowband pink noise centered at 400 Hz, with a bandwidth limited to 350–450 Hz using a band-pass filter, while the maskee is a pure 400 Hz sine tone [2]. To ensure that the pink noise masker does not exceed the target frequency range, a band-pass filter is applied using REQ 2 Waves EQ, with the high-pass filter set at 350 Hz and the low-pass filter at 450 Hz. This ensures that the masker energy remains within the same frequency band as the maskee. During the experiment, participants are seated at the sweet spot and presented with masker and maskee signals from different spatial locations to determine how their relative positioning influences detectability. The masker

plays continuously, while the maskee is introduced in discrete 2 dB SPL steps until the participant perceives it. Upon detection, the participant presses a key and the masking threshold is recorded.

The experiment consists of five sessions that are divided into nine groups. Session 0 serves as an introductory phase and includes Group 0, which performs Test 0 to familiarize participants with the task. Session A follows, comprising Group 1 and Group 2, which collectively cover Tests 1 to 14. Group 1 observes conditions where the masker remains directly in front of the listener, while the maskee travels to various locations along the horizontal plane. Group 2 is similar to Group 1, but in this case, the maskee travels along the horizontal plane with maximum elevation, allowing the investigation of vertical localization effects on spatial masking.

Session B includes Group 3 and Group 4, covering Tests 15 to 28. These groups replicate the conditions of Group 1 and Group 2 respectively, but instead of the center speaker, the masker in front of the listener is a phantom signal produced by the left and right speakers, providing insight into masking effects created by phantom auditory sources.

Throughout Session C, Group 5 examines symmetrical median plane combinations, while Group 6 focuses on symmetrical frontal plane combinations. Both Group 5 and Group 6 investigate masking thresholds across minimum and maximum elevations for the same spatial configurations.

Session D includes Group 7 and Group 8, which were designed to examine spatial auditory masking across diagonal sound source placements across the frontal and median planes.

All sessions take place after different durations of silent breaks to mitigate auditory fatigue [5]. This structure allows for a systematic assessment of spatial masking thresholds while balancing the participant's cognitive load and minimizing the effects of fatigue over the course of 49 total tests.

The experiment involved a diverse group of voluntary participants with varying levels of expertise in sound and music-related fields. Participants were categorized into distinct groups based on their academic and professional backgrounds, including sound engineers with completed doctoral degrees (Experts), ongoing PhD candidates in sound engineering (Future Experts), master's students in related disciplines (Prospects), and individuals from adjacent fields such as ethnomusicology, performance, and music theory. Additional groups included participants with no formal background in music or sound studies to provide a comparative basis for perceptual thresholds. All participants confirmed having normal hearing and relevant demographic and experiential data—such as age, years of critical listening experience, and areas of musical engagement—were collected to support further analysis.

Findings

Previous studies on spatial auditory masking have revealed several key findings that provide a valuable framework for understanding the relationship between sound source positioning and masking thresholds. Research indicates that spatial separation between the masker and maskee generally lowers masking thresholds, with the least masking observed between left and right opposed sources, showing a reduction of up to 5 dB compared to coincident sources [3]. However, symmetrical positioning of the maskee relative to the frontal plane does not consistently reduce masking, challenging initial expectations. Additionally, phantom masker signals produced by virtual sources exhibit similar masking thresholds to those of real sound sources, suggesting that spatial auditory masking occurs consistently with both physical and virtually localized sound images. Masking thresholds reported across these studies typically range between -35 dB and -26 dB probe-to-masker ratios [3], with increased masking observed at certain elevations and cases of selective masking reduction linked to interaural phase difference phenomena. In addition to examining horizontal and frontal plane interactions, our study incorporates height channels to explore how vertical spatial positioning influences masking thresholds. This expanded spatial dimension allows for a more comprehensive investigation into the effects of sound source elevation on auditory masking, contributing to a broader understanding of spatial perception in immersive environments. As spatial audio technologies continue to evolve, these findings offer critical insights into optimizing sound clarity and reducing masking interference in immersive environments.

Our initial results indicate that spatial masking decreases as both azimuth and elevation between the masker and maskee increase. This suggests that greater spatial separation across multiple dimensions enhances the listener's ability to detect the target signal. The findings support the role of three-dimensional spatial unmasking in complex auditory scenes.

Conclusion

This study provides new insights into how spatial positioning affects auditory masking thresholds, contributing to a better understanding of sound perception in immersive environments. The findings have direct applications in Dolby Atmos mixing and sound design, as they demonstrate how strategic spatial placement of audio elements can reduce masking effects, ensuring better clarity and depth in 3D audio environments. Additionally, these results contribute to VR/AR audio development, where ensuring critical auditory cues remain perceptible is essential for creating a realistic and interactive user experience. The study also offers implications for hearing aid and cochlear implant development, where understanding spatial release from masking can improve speech intelligibility in noisy conditions.

As 3D audio technologies continue to evolve, understanding spatial auditory masking will be crucial in shaping the next generation of immersive sound experiences. Further research could expand on these findings by investigating how different frequency ranges, room acoustics and dynamic sound movements influence masking thresholds, ultimately leading to refinements in spatial audio engineering and psychoacoustic modeling.

Methodology on Participatory Media Analysis: Insights from the Audio Modding Scene on Nexus Mods

Başar Ünder[a], Taylan Özdemir[b]

[a] Istanbul Technical University Graduate School, Music PhD Program, Türkiye
[b] Istanbul Technical University, Turkish Music State Conservatory, Music Technology Department, Türkiye
under@itu.edu.tr

Keywords : Game Audio, Game Modding, Participatory Media, Sound Design, User-Generated Content.

Aim

This study explores participatory sound design in video game modding communities, focusing on The Elder Scrolls V: Skyrim Special Edition (Skyrim SE). In particular, it investigates how players modify game audio and how these practices reflect user expectations and preferences. Situating this inquiry within Henry Jenkins' (2006) concept of participatory culture—defined by low barriers to entry, community support, and meaningful contribution—the research highlights how modders and users co-create the auditory experience of a game.
The aim is twofold: (1) to identify which categories of sound are most frequently modified and endorsed, and (2) to develop a scalable methodology for analyzing participatory trends in game audio modding using real-world data from Nexus Mods.

Material and Method

This study adopts a platform-based content analysis methodology to investigate how the Skyrim SE audio modding community shapes game sound through participatory practices. Data was collected from Nexus Mods, focusing on the twenty most-endorsed audio mods, a sample that represents community-preferred and widely-used content. Each mod entry includes two key text fields:
- Tags (user-defined metadata)
- Text (free-text description by the mod author)

To analyze mod content, we developed a categorization system informed by domain knowledge and established taxonomies such as the Universal Category System (UCS). The categories used were:
- Enhancements – fidelity upgrades, remasters, overhauls
- Music – background music or soundtrack additions
- Combat Sounds – weapon, spell, or impact sound effects
- Ambient – environmental or spatialized sounds (e.g., wind, rain, dungeons)
- Voice (Shouts & Player Sounds) – vocalizations such as dragon shouts and grunts
- Utility for Modders – sound scripting tools or frameworks
- Mod Patches – compatibility layers between audio mods or updates

Classification was carried out in two stages:
1. Automated Tag Matching: Each mod's tags were matched against predefined keyword lists to infer categories.
2. Manual Review: Mods with ambiguous or missing tags were reviewed through close reading of their descriptions to ensure accurate classification.

Once each mod was assigned to a single audio category, we constructed two numeric vectors:
- A Creator Focus Vector (number of mods per category)
- A User Preference Vector (total endorsements per category)

We applied the cosine similarity formula to measure the alignment between creator focus and user approval:

$$\text{cosine similarity} = (A \cdot B) / (\|A\| \times \|B\|)$$

Where:

- A = mod count per category
- B = endorsements per category

This model was adapted from Dey et al. (2016), who used a similar framework to quantify alignment in broader modding ecosystems. While their focus spanned multiple games, our adaptation zeroes in on audio-specific modding to provide domain-level insight into participatory resonance.
Although the dataset includes only 20 mods, this sample represents a targeted examination of the most impactful audio contributions within the community. The methodology is scalable to larger datasets and adaptable across modding platforms.

Findings

The analysis yielded a cosine similarity score of ≈0.98, indicating a remarkably high degree of alignment between creator output and user appreciation. This suggests that in the Skyrim audio modding scene, modders are highly attuned to player expectations. The most common categories were 'Enhancements' and 'Ambient', which together comprised over half of the selected mods. For example, 'Audio Overhaul for Skyrim SE'—a comprehensive remaster of ambient and combat sounds—garnered tens of thousands of endorsements, signaling strong communal approval. Similarly, the 'Sounds of Skyrim' series focused on expanding environmental immersion and was frequently cited in user reviews as a must-have mod for new players. These examples reinforce the idea that community consensus prioritizes realism and environmental depth in sound design. On the other hand, less represented categories like 'Utility for Modders' and 'Mod Patches' had fewer mods and lower cumulative endorsements, suggesting more niche appeal or backstage usage. The methodology's ability to surface these distinctions offers a replicable framework for analyzing participatory design focus within modding ecosystems.

Conclusion

High alignment between modder output and user endorsement reflects a healthy participatory ecosystem. In this context, modders act not only as creative individuals but also as responsive contributors to a shared aesthetic vision. The results affirm the notion that participatory media is not only about access to creation tools but about active listening, cultural negotiation, and shared meaning-making. In the case of audio modding, modders appear to internalize user preferences and produce content that directly addresses community desires for immersion, realism, and sonic quality.

Moreover, the methodology presented here bridges computational and cultural analysis. By offering a means to quantify aesthetic alignment, it invites further applications across modding communities and media types. Future work may involve cross-game comparisons, longitudinal tracking of mod trends, or deeper ethnographic study of modder-player dialogue. Ultimately, this study contributes to growing scholarship that recognizes fan production not as peripheral, but as central to media experience.

Transformation of Digital Audio from Metaverse to Web3

Günsel Işık Gruson[a], Taylan Özdemir[a]

[a]Istanbul Technical University, Music Department, Music PhD Program, Turkey
gunyilmaz@itu.edu.tr

Keywords: Metaverse, Web3, NFT.

The digital audio transmission format was envisioned as part of the digital transformation in the 1990s with Dolby Digital's 5.1 capable AC3 codec. After the 2000s, stereo analog broadcasting was gradually abandoned and replaced by digital broadcasting. Today, digital audio streaming is part of new markets that includes VR concerts taking place at video game events in metaverses[11]: In fact, the concept of the metaverse (a virtual universe visited by VR glasses) was first introduced as an idea in Neal Stephenson's 1992 novel Snow Crash and was first implemented as a gathering event, such as live concerts, in 2003 with 'Second Life'. Research projects such as 'Empty Room', which has been ongoing since 2013 on composing in VR and sound spatialization, have demonstrated the potential of musical practices in digital universes and since 2017, millions of Play Station users have introduced to VR concerts utilizing Unreal Engine.[12] Sharing the features of the metaverse that offers an immersive, interactive, 3D experiences and togetherness of the social community in a game concept, new digital economy instrument 'Web3' (e.g., blockchain-based games, eSports) offers 'virtual trades' such as earning, buying and selling digital assets with 'decentralized' real-time payments through 'cryptocurrency wallet' which eliminates the commission that goes to the third parties. Meanwhile, a unique blockchain -achieved through code algorithms that create a string data protocol- is essential for 'non-fungible tokens' (NFTs) as digital legal proof of creator ownership, as well as for the security of cryptocurrencies (Bitcoin, Ethereum, Phantom, Polygon, etc.). Thus, in theory, the new digital economy model opens a window into the future of the distribution, reception and copyright for artists, composers, designers and content creators; it contains the possibility of transforming the digital music markets and related industries together.

Aim

While digital audio technology is evolving, how is the transition taking place between the metaverse and the digital economy instrument, Web3? How can Web3 and NFTs be applied to music? This brief research aims to introduce the connection and integration of music in the new digital economy order.

Material and Method

In the preliminary study, the inadequacy of secondary data in Web3, the existence of conceptual gaps and the uncertainty regarding the possible connection of digitized audio with NFTs in the context of musical practice were observed. Therefore, beside technopolitical publications and the latest standard instructions on sound distribution, primary data on related subjects such as international conferences, interviews with experts and online pages with technology content have been carefully evaluated.

Findings

1) Promising to support the rights of individual artists and internet entrepreneurs in the new digital economy order, Web3 and NFT still may seem like 'utopian futuristic ideas' however their potential and use for music has been already implemented as will be seen in the following examples: 1) Taylor Swift who promotes herself, owns her

[11] Whereas a headset is required in VR, where users can move in a virtual space, it is not required in the Metaverse, which consists of various universes in an interconnected network.

[12] Some of the early VR concerts that are given by using Epic Games' Unreal Engine (3D computer graphic game engine) are Sony's Chainsmokers' Paris concert in 2017; Marshmello's live, motion captured VR concert in Fortnite, in 2019; Travis Scott's VR concert with pre-recorded five songs from *Astroworld* album (2018) in 2020; VR concerts of Muse, Justin Bieber and Finland metal band Nightwish in 2021.

own copyrights and 'uses the fan-artist (fan-token) system' contributes to the small investor model in the context of decentralization. 2) Referring to the fact that 'artists' cannot earn income from YouTube video views, Snoop Dogg - who known as a property owner in Web3- acclaims that he can buy NFTs to remix (and 'control') their albums. 3) Kings of Leon who released their 2021 album as an NFT on the 'Yellowheart platform' and offered new delivery strategies -such as a new album or concert tickets to their listeners as promotions- have shown that new e-marketing strategies can be successful. 2) In return, to be one of the artists in Web3, it is important to be surrounded by a community that can invite one to e-marketing platforms, therefore, understanding these new concepts seems crucial: For instance, in the field of music marketing, some of the Web3 communities in NFT platforms can be listed as Friends With Benefits, SongCamp, Royal, Zora. In addition, some of the music NFT marketplaces are 'catalog' (songs can be streamed and marketed while adding to open music library), 'sound.xyz:' (artists can stream their tracks, a mixed album can be sold and listening parties can be organized) and 'Async Music' (recorded tracks can be sold separately). However, 'Mint Songs' is one of the rare platforms that does not require an invite for an artist to take part in the NFT world. 3) Hypothetically, it is predicted that with Web3, independent content producers will be freed from the dominance of large platforms, shared management will become indispensable and monopolization will decrease. Accordingly, it is promised that NFT owners will have control over digital creations and that intermediaries will be eliminated however when owning a NFT and becoming a member of a blockchain, high commission is charged from users and paradoxically, this 'hegemonial' and closed structure brings gatekeepers to mind.

Conclusion

1) In this research, valid examples of digital audio and music use in Web3 (which does not have a classical banking system but instead has a decentralized structure and offers a consistent digital economic system) have been briefly presented. While new e-markets are being developed for universes of the digital age where hyperreality will be shaped, it is seen that metaverse platforms will be used more actively for social events such as music festivals or artist-fan meetings of the future. 2) Since the access model offered by the music platforms to the artists is not a profitable mechanism, a promising system of NFT can replace or be an alternative to the traditional 'label' application where the music can be accepted and valued as digital asset. Furthermore, through NFT, digitized versions of artworks such as recorded takes from archives, can be valued, bought, sold or remixed in audiovisual industry; enhanced with Next Gen technologies (e.g., AR/VR, holograms, AI) for sonification purposes or incorporated into industrial design products. 3) The possibilities provided by VR technology are appreciated by the fact that the shared moment is remotely accessible to a large number of people; therefore, VR events (that can include all types of VR meetings and VR concerts) will be more developed with 3D real time technology and the new production methods. 4) Although the dominance of AI technology over the future is widely emphasized, economists, creators and designers of Metaverses may also gain more importance.

Ecomusicological Methods in Soundscape Research: Analyzing Sounds on the Water in Haliç

Semin Tunalı[a]

[a] Istanbul Technical University, Graduate School, Musicology and Music Theory, Turkey
sener16@itu.edu.tr

Keywords: Ecomusicology, Soundscape, Golden Horn, Rowing, Ethnomusicology.

Aim

This research aims to explore ecomusicological methods used to study soundscapes and apply them in the analysis of the specific acoustic environment of Haliç (Golden Horn). Haliç is a historically and geographically significant waterway in Istanbul and has an attractive biodiversity. These features make this area ecologically important and worth examining. The intention of this study is to determine the sounds of the environment in the field and to understand how these sounds contribute to spatial awareness. In that aspect, the study will try to explain the human and non-human interactions/intra-actions, particularly in the context of rowing, where auditory cues play a crucial role in navigation and synchronization.

Ecomusicology, as an interdisciplinary field combining ethnomusicology, sound studies, and ecological research, provides various methodological approaches to understanding the relationship between sound, environment, and human and non-human interactions. Established research methods in ecomusicology include methods such as field recordings, comparative analysis, soundwalks, sound mapping etc. This research will show us how these approaches can be adapted to this specific soundscape.

Ultimately, this study aims to assess the effectiveness of ecomusicological methods in studying urban aquatic soundscapes, providing insights into both the sonic environment of Haliç and the broader applicability of these methods to similar ecological and cultural contexts.

This research is the starting point of a study to be done for the author's PhD dissertation, and it is inspired from the author's personal experiences in rowing, where sound serves as a vital guide for synchronization, navigation, and engagement with the environment.

Material and Method

For this research the author has adopted a qualitative methodology, combining fieldwork, observation, sound recordings, and interviews to analyze the soundscape of Haliç. Since the research is based on real-life experience and evidence, the collected data is empirical. The details of the used methods are as below:

Field Recordings and data-collection: The author did several field recordings between October 2024 and January 2025. The recordings were not taken regularly. They consist of recordings taken at random days and random hours. The author used a Tascam DR40X recorder to record environmental sounds, capturing sounds within the reach of the device when it was located on the rowing boat, over the water. In addition, she used her mobile phone to capture videos and sounds.

Observation: The author documented her personal experience and auditory (as well as visual) observations during rowing sessions. She observed how sound affected her movement, her decisions on the water, and her environmental perception. The observation helped her to reveal the relationship of the human and non-human beings in the field.

Interviews: A short questionnaire was prepared, and the fellow rowers were asked about their experience during their own rowing sessions. She collected information regarding their perception of the sounds and their environments, their awareness and interaction with their environment. She tried to find out common points between her own perception and the perception of the participants.

Sound Analysis: Sounds were classified into three main categories:

- Anthropogenic (Human-made) Sounds – Boat engines, ferry announcements, road traffic, construction noise, human voices.

- Biophonic (animal) Sounds – Bird calls, aquatic life sounds.
- Geophonic Sounds – Water movement, wind, rain.

Literature Review and Approaches: While evaluating the data, the author mainly benefited from Schaffer's approach to the sound and noise pollution, and his concept of soundscape; Oliveros' deep listening concept; Ingold's view about sound and immersive experience. Other studies about soundscape were taken as example as well. Main foci of these studies were the soundscapes of certain neighborhoods and cultural meaning of the sounds; noises on the water, underwater noises and their impacts on the environment.

Findings

We infer from the analysis of field recordings, observations, interviews several key findings regarding the soundscape of Haliç:

1. Dominance of Anthropogenic Sounds:
   - The soundscape is largely influenced and formed by human activity, with the most dominant sounds originating from boat engines, road traffic, tram announcements, and people's voices on the shore.
   - These sounds create an auditory masking effect, reducing the ability to hear natural sounds or biophonic sounds clearly.
2. Role of Sonic Elements in Navigation and Awareness:
   - Rowers rely on natural sounds as well as other rowers' and engine noises to orient themselves.
   - Avian species, including cormorants, seagulls, ducks, and herons, are key contributors to the sonic environment apart from anthropogenic noises.
   - Some birds, such as ducks and geese, react to human presence and activities, particularly when anticipating food. Their vocalizations and movements change in response to environmental stimuli, including interactions with humans on the shoreline. Observations also suggest that waterfowl communicate with each other through sound, especially when responding to shared stimuli like food availability.
3. Sonic Synchronization in Rowing:
   - Sound plays a crucial role in rowing synchronization, as rowers depend on the rhythmic sounds of their oars and sliding seats to maintain coordinated movement.
   - When rowing in the dark or in conditions with limited visibility, rowers rely primarily on auditory cues to navigate.
4. Sound as an Immersive Experience:
   - Participants are aware of their environmental sounds although their perception depends on several factors. They described their rowing experience as deeply immersive, shaped by a continuous engagement with environmental sounds.
   - The presence or absence of specific sounds (such as bird calls, water ripples, or engine noise) influences rowers' emotional and physical states.
   - Certain sounds, particularly biophonic and geophonic sounds (e.g., water movement, birds), were reported to have a calming and meditative effect. Mechanical noise incite rowers to move away from noisy parts on the water because they cannot find the piece they are looking for and cannot get all the benefits they are supposed to obtain with their training.
5. Sound Pollution and Its Ecological Implications:

Human-induced noise pollution affects the natural soundscape, probably disrupts animal communication and alters the acoustic environment. Urban noise pollution affects Haliç and human-induced voices blend in with the biophonic voices in Haliç. Further investigation is necessary to measure the dimension of this disturbance and how the human and non-human elements react to this pollution.

Conclusion

The soundscape of Haliç is a rich and dynamic environment shaped by the interactions of human and non-human actors. This environment deserves a deeper analysis because of its value, its significance as location and its

biodiversity. This study reveals that we can conduct an ecomusicological analysis on this habitat following the methods used in similar ecomusicological studies.

So far, this study has revealed the complex interplay between human and non-human sound sources in that urban aquatic environment. The findings suggest that sound is a fundamental element in ecological relationships, and it shapes both human experiences and non-human behaviors. By listening to the voices of both humans and non-humans, we can develop a deeper appreciation for the sonic complexity of our environment and the ecological narratives embedded within them.

The research also underlines the importance of the environmental awareness. We can reach this awareness through active listening and participatory soundscape documentation.

Future research will consider expanding soundscape studies to include long-term sound monitoring projects by conducting a more serious field research with a specific program, including regular sound recordings taken on definite times. The content of interviews may be extended with more participants. The classification of existing sounds in the soundscape, the definition of human and non-human factors, of their interactions and intra-actions and determination of participants' experiences already brings out the state of environmental awareness. Henceforth, through interdisciplinary collaboration, expanded studies and immersive listening practices, we can work towards a more sustainable and sonically attuned urban environment. Raising awareness of sonic environments through ecomusicological research can contribute to broader ecological consciousness and sustainable urban planning strategies.

Analysis Of Some Makams From The Arabic Music Conference 1932

Mohamed Mostafa Ahmed Mohamed[a]

[a] Istanbul Technical University, Social Sciences Institute, Musicology and Music Theory Department, PhD Program, Türkiye

ahmed@itu.edu.tr

Keywords: 1932 Conference, Committee of Makams-Rhythm and Composition, Makams, Notations, 1932 Conference Book.

The 1932 conference featured seven committees, notably the Committee of Makams, Rhythm and Composition, which was vital in exploring scales and rhythms in Arabic and oriental music. This committee concentrated on the makams, examining notations, musical symbols, names, and forms presented in the research. Their decisions and findings were documented in the 1932 conference book, underlining the significance of thorough analysis in preserving the legacy of discussions that shaped the understanding of Arabic music during this pivotal time.

Introduction

The twentieth century marked a significant transformation in Arabic music, fostering remarkable advancements. A key contributor to this development was the 1932 Arabic Music Conference, which played an essential role in Egypt's scientific, artistic, and musical progress during this era. Despite its importance, the conference proceedings have gone mainly unexamined in Egyptian libraries for nearly a century, receiving limited scholarly attention.

The Cairo conference organized its research and findings into seven sections across various committees. Each member chose a committee that aligned with their expertise and interests. During their initial meetings, each committee elected a chairman and a secretary. The committees were categorized as: a) Committee of Recording, b) Committee of Music History, c) Committee of Makams, Rhythms and Compositions, d) Committee of Instruments, e) Committee of Scale, f) Committee of General Matters, g) Committee of Music Education.

Among the seven committees established during the conference, the Committee of Makams, Rhythm, and Composition played a vital role in developing a systematic approach to Arabic music. Its primary objective was to explore and codify the critical musical elements of makams and rhythms, creating a coherent framework for standardizing these components across various regions, including Egypt, Syria, and Iraq (Katz, 2015). Notable European scholars such as Baron d'Erlanger and Sachs significantly influenced the committee's efforts, often employing Western methodologies for analyzing and classifying Arabic music (Thomas, 2007). Consequently, the conference not only reflected the cultural ambitions of the Arab world but also underscored the geopolitical dynamics of the era as Arab nations endeavored to assert their cultural independence in the face of colonial pressures (Llano, 2023).

Aim

This study focuses on the makam analyses presented in the 1932 conference book and aims to compare selected makams with their counterparts in contemporary Arabic music. It will explore differences across various aspects, including tones, symbols, and methodologies for presenting the makams. A comparison will be drawn between the makams documented in the early twentieth-century conference book and those taught in the twenty-first century at the Higher Institute of Arabic Music.

The primary objective is to bridge the gap between the past and the present by analyzing the selected makams from the minutes recorded by the Committee of Makams, Rhythm, and Composition in the official conference book. By examining these primary sources, the analysis will assess how early twentieth-century formulations relate to makam theory and practice as taught today, particularly at the Higher Institute of Arabic Music. This exploration

aims to highlight the evolution and continuity of makam practice within the context of contemporary music education.

Materials And Methods

This study evaluates the theoretical models presented in the official 1932 conference publication to explore the historical development of Arabic makams. It involves a comparative analysis of Egyptian makams as documented in the 1932 source, alongside corresponding concepts in modern Arabic and Turkish music traditions.

The methodology includes a review of both primary and secondary sources in Arabic, English, and French. Key texts, articles, and books were consulted to provide historical and analytical context. Selected makams were further examined through musical analysis, focusing on structure and pedagogy.

Findings

The study of Turkish music provides insights that align with the methodologies employed during the 1932 conference for notating Egyptian makams. The Rast note corresponds to G within the Turkish music makam framework. Certain makam families, such as Ajem, which relates to the Beyati family in Turkish music, exhibit similar structures in the conference book; however, in contemporary Arabic music, Ajem makam often aligns with the Western major scale (Arabic, 1933; Hashad, 2015).

Conclusion

The 1932 conference aimed to unify Arabic music and firmly establish its identity, drawing inspiration from Egypt's cultural renaissance in the early nineteenth century. It successfully harmonized the terminology for makams and rhythms across Arab countries, ultimately standardizing both lyrical and instrumental forms of Arabic music. Remarkably, participants agreed on the unification of musical terminology, including note names, with minimal disagreements. The conference book has since become an essential reference, marking a pivotal shift from the scarcity of scientific resources on Arabic music in Egypt.

The analysis employs various methodologies, and the makam explanations presented at the 1932 conference encompass a range of octaves, providing a broader perspective on the makams. Moreover, the incorporation of makams in pedagogical contexts is evident in the scores included in the conference book, reflecting contemporary teaching methodologies found in Turkish music. Notably, some discrepancies exist in the symbols representing the makams between the 1932 conference and modern Arabic music, which do not entirely correspond with those used in Turkish music.

Upon reviewing the makams from the Institute of Oriental Music and those curated by Baron d'Erlanger, it becomes clear that Baron offers a more extensive selection that closely aligns with Turkish music traditions, organizing makams according to their respective degrees. In contrast, the 1932 Institute's approach to makams minimized redundancy by refraining from presenting them under different names (Arabic, 1933).

Music as Refuge From Reality: Schopenhauerian Aesthetics Revisited

Selim Güre[a]

[a] Istanbul Technical University, Turkish Music State Conservatory, Musicology, Türkiye
gurese17@itu.edu.tr

Keywords: German Idealism, Musical Aesthetics, Musical Perception, Philosophical Pessimism, Psychology of Aesthetics.

Aim

Taking my departure from the third section of The World as Will and Representation, Schopenhauer's magnum opus, I posit that the merit of aesthetic contemplation is not to be sought in its revelatory potential, but its capability to distract the audience from what is called in the pessimistic literature "the brotherhood of suffering between everything alive" (Zapffe & Tangenes, 2004). Within this framework, aesthetic contemplation serves as a momentary refuge from reality. I use the word 'refuge' instead of 'escape' precisely because 'refuge' implies 'a place to escape with the intention of returning to one's place of origin,' whereas a given act of escape need not necessarily carry an intention of return. To this end, I draw upon various empirical findings concerning 'flow states' and 'function of music' research (Harmat et al., 2021; Schäfer et al., 2013). I conclude by arguing that music, while not necessarily being a pathway to 'the kernel of being' as Schopenhauer postulated, may nonetheless serve as a momentary refuge from the bleak reality often depicted in his writings (Jacquette, 2007).

Material and Method

I employ a bidisciplinary approach incorporating the Schopenhauerian worldview, and a close reading thereof, with contemporary psychological research on aesthetic experience. The philosophical lens, rooted in Schopenhauer's understanding of human existence and suffering, offers a foundation for investigating the psychological benefits of engaging with art. The methodological focus is on combining these philosophical insights with modern empirical studies on human emotional responses to art and the cognitive processes underlying aesthetic appreciation.

The principal material for this investigation is the philosopher's seminal work, The World as Will and Representation, particularly the third section, in which he lays out the nature of aesthetic contemplation (Vandenabeele, 2008). Schopenhauer articulates that aesthetic engagement, through art, enables an individual to momentarily transcend the will — the fundamental driving force of all human striving — and achieve a state of pure, selfless perception (Shapshay, 2023). This moment of detachment from the relentless cycle of desire, suffering, and striving reveals to the individual an opportunity to experience the world not as a manifestation of will, but as an objective reality (Alperson, 1981). This critical concept forms the basis of the theoretical inquiry presented in this study.

Secondary materials consist of a plethora of articles published on Schopenhauer's aesthetic teleology and related subjects. These include interpretations of his theories on the nature of aesthetic experience, critiques of his pessimism, and recent debates regarding the significance of his views on music as a unique and elevated form of art (Leikert, 2021; Venetianer, 1873; Wicks, 2020). Moreover, I incorporate findings from psychological studies concerning 'flow states,' where individuals become fully immersed and engaged in an activity to the extent that they experience an altered state of consciousness, characterized by deep focus, joy, and a sense of timelessness (Tan & Sin, 2021). By juxtaposing Schopenhauer's arguably dated apprehension with contemporary approaches, I aim to illuminate how aesthetic contemplation, especially through music, can serve as a symbolic refuge.

Findings

The study provides several insights into the nature of aesthetic contemplation and its psychological benefits. First, Schopenhauer's notion of transcendence through art resonates with modern psychological findings on 'flow' and the cognitive immersion induced by activities pertaining to music (Johanis, 2024). Empirical studies show that

music, as one of the most powerful forms of aesthetic engagement, can elicit a flow state where listeners experience a temporary escape from the demands and stresses of daily life (Harmat et al., 2021). The phenomenon of 'flow' is often accompanied by a sense of timelessness, complete absorption in the experience, and a loss of self-consciousness — all features that align with Schopenhauer's idea of aesthetic contemplation.

The extent to which music, in particular, serves as an emotional and psychological refuge is notable (Leikert, 2021). Numerous research on the matter indicate that music has a profound ability to regulate emotions, reduce stress, and even mitigate symptoms of anxiety and depression (Dhippayom et al., 2022; Hartmann et al., 2023; Xu et al., 2024). These effects are particularly pronounced when the individual listens to music in a deeply engaged, contemplative manner, allowing the mind to detach from the anxieties of existence (Dalton, 2024). Schopenhauer's claim that art provides a refuge from the otherwise ceaseless suffering of life is supported by studies showing that aesthetic experiences can function as a psychological sanctuary, providing relief from emotional turmoil and offering temporary respite from not only existential but also day-to-day concerns (Cormack, 2022; Ridder & Jacobsen, 2024).

Moreover, the relationship between Schopenhauer's philosophical assertions and contemporary neuroscience provides valuable insights into the effects of music on the brain. Neuroimaging studies reveal that listening to music activates regions associated with focus and reward, thereby providing grounds for flow states and further suggesting that music can function as a mental 'refuge' (Vuust et al., 2022). These findings suggest that music offers not only emotional relief but also a means of cognitive disengagement, where listeners may momentarily disconnect from their immediate surroundings and inner conflicts. This aligns with Schopenhauer's understanding of aesthetic contemplation as an interruption of the will's grip on the individual.

The empirical data concerning 'musical imagery' — the ability to mentally hear music without actual sound — supports the idea that aesthetic engagement in music can create an internal space for reflection and transcendence (Floridou et al., 2022). As per Schopenhauer, the contemplation of music allows an individual to move beyond the confines of individual desires and experience the world as an objective and harmonious whole. This transcendence, while not necessarily revealing the deepest metaphysical truths, provides an opportunity for the listener to experience a sense of unity with the world, albeit only temporarily. However, there ought to be limitations in Schopenhauer's theory of music as a path to metaphysical insight. Schopenhauer believed that music, as the most direct expression of the will, could reveal the essential nature of existence. Contemporary research, while acknowledging music's emotional and cognitive benefits, suggests that the effect of music on the listener is more transient and subjective, rather than revelatory in the metaphysical sense that Schopenhauer envisioned. In essence, music serves more as a momentary refuge than as a profound means of accessing the "kernel of being."

Conclusion

In conclusion, this study affirms the relevance of Schopenhauer's ideas in contemporary discussions on aesthetic experience while also highlighting the ways in which modern psychological research has expanded and refined our understanding of the psychological effects of indulgence in art. Aesthetic contemplation, especially through music, indeed offers a metaphorical refuge from the suffering intrinsic to the human condition, providing listeners with temporary relief from the relentless cycle of desire and vicissitude. While music may not lead to the metaphysical revelations Schopenhauer posited, it may serve as an emotional sanctuary, a momentary respite from the life force (der Wille zum Leben). By incorporating Schopenhauer's philosophy with recent empirical findings, this study demonstrates that music can offer more than mere pleasure or entertainment: it provides a space for reflection, emotional regulation, and, perhaps most importantly, a brief seclusion from the harsh realities of day-to-day existence. Through this lens, music emerges not as a path to ultimate truth, as Schopenhauer would rather have us believe, but as a vital tool for inner reflection — a momentary refuge in an otherwise turbulent world.

Folk Music and Classical Composition: A New Framework in Scottish Music Based on Bartok's Three Folk Music Categorizations

Senay Yılmaz[a]

[a] Istanbul Technical University, Music, Music Theory, Türkiye

senayyilmaz1@gmail.com

Keywords: Scots Melodies, Bartok's Folk Categories, Folk-classical interaction, Arrangements, Modality.

Aim

Introduction

Scottish folk music, like all folk traditions, has played a crucial role in shaping national identity, serving as both a cultural artefact and an artistic influence. In classical music, folk traditions have often been preserved through arrangements and adaptations, yet the interaction between folk and classical idioms is more complex than mere quotation. This research seeks to investigate how Scottish folk music has influenced classical composition, focusing on the implicit transmission of folk elements rather than dşrect melodic quotation.

The primary framework for this study is Bela Bartok's tripartite classification of folk music's influence on classical composition, as explained in The Influence of Peasant Music on Modern Music. While Bartok's theory has been widely applied in the context of Eastern European music, it has not yet been systematically used to examine Scottish music before. By employing this model, this research has categorised Scottish-influenced classical compositions into three distinct types and, more importantly, established a refined third category that challenges conventional understandings of folk-inspired music.

The key contribution of this research was to demonstrate that folk music could permeate classical compositions without direct quotation - a process often overlooked in previous studies. Rather than viewing folk influence as mere borrowing, this study explored how Scottish folk idioms including rhythmic patterns, modal structures, and textural features, subtly manifested within classical works and how these elements were embodied in classical compositions.

Literature Review

The relationship between folk and classical music has been extensively studied in various contexts. Early research on Scottish folk music's integration into classical works focused on arrangements and adaptations of traditional melodies. Prominent examples include Beethoven's and Haydn's Scottish Song Arrangements and Mendelssohn's Scottish Symphony, all of which incorporate direct references to folk tunes. However, these works fall into Bartók's first two categories and do not fully account for more nuanced forms of folk music integration.

Existing studies have examined composers influenced by Scottish folk music and identified explicit quotations of folk melodies, yet there has been little systematic analysis of works that embody folk characteristics without quoting specific tunes. This gap in the literature is where this study intervenes.

Additionally, Bartók's theoretical framework has been applied primarily to Hungarian, Romanian, and Slovak folk music, leaving Scottish folk music largely unexamined. This research contributes a new perspective to folk-classical interactions by extending Bartók's model to a Scottish musical context and refining his third category as it applies to compositions that exhibit Scottish qualities without directly borrowing folk material. A significant number of examples were found during the analysis of selected pieces for the third category. By addressing this gap, the study broadens the application of Bartók's framework and offers a deeper understanding of how Scottish folk traditions subtly permeate classical compositions. This approach provides a foundation for future research on implicit folk influences and encourages a reevaluation of how cultural identity is expressed in classical music.

Material and Method

Bartok's Three Categories and Their Application to Scottish Music

This study applied Béla Bartók's categorization of folk music's influence on classical composition to Scottish music, dividing compositions into three distinct types.

The first category, "Directly Arranged Folk Melodies", consisted of compositions that incorporated unaltered folk tunes with minimal modification, often presented with harmonic accompaniment. Examples of this approach included Beethoven's 25 Scottish Songs and Haydn's arrangements for George Thomson's Scottish collections, both of which retained the original folk melodies while adapting them for a classical framework.

The second category, "Folk-Inspired Compositions", encompassed works that did not directly use traditional folk melodies but were clearly modeled after folk styles. These compositions captured the essence of folk music through melodic contour, rhythmic structure, and form. A key example was Bruch's Scottish Fantasy, which evoked Scottish musical characteristics despite employing newly composed themes rather than existing folk tunes.

The third category, "Subconscious Folk Influence", comprised compositions that contained no direct folk quotations yet retained defining elements of Scottish folk music. These works incorporated Scottish modal language, ornamentation, phrasing, rhythmic stress, and instrumentation, creating a distinctly Scottish sound world without referencing specific melodies. Hamish MacCunn's The Land of the Mountain and the Flood served as an example of this category, as it conveyed a strong Scottish character without explicitly borrowing folk material.

This study primarily focused on Category 3, analyzing compositions that fell outside the conventional definitions of folk-inspired music but still exhibited the unmistakable sonic fingerprint of Scottish folk traditions.

Analytical Approach

The approach is designed to capture the essence of Scottish folk influence by analyzing key musical parameters such as modal and harmonic structures, rhythmic and melodic patterns, orchestration, and form. By focusing on these components, the study seeks to determine how composers internalized and transformed folk idioms within a classical framework. The goal is to identify the distinct sonic fingerprints that mark a composition as rooted in Scottish folk tradition, even if these connections are not overtly stated.

The following analytical criteria were applied to examine the selected compositions in Category 3:

Modal and Harmonic Analysis

This research identified the frequent use of Dorian, Mixolydian, and pentatonic scales, characteristic of Scottish folk music. These modes shape the distinct tonal color of Scottish melodies, often evoking simplicity and timelessness. The Dorian mode, with its minor quality and raised sixth, and the Mixolydian mode, marked by its lowered seventh, were particularly prominent in the analyzed compositions.

The study also explored drone effects and pedal points, reminiscent of the sustained harmonies typical of bagpipe music. These elements contribute to harmonic stability and often anchor melodies, reinforcing the traditional Scottish soundscape.

Attention was also given to intervallic relationships within melodies. Open intervals, such as fourths and fifths—common in Scottish folk traditions and emphasized in bagpipe music—were frequently observed. These intervals enhance the distinctive melodic contour and tonal texture across various instruments. Their subtle presence suggests a deeper, subconscious influence of Scottish folk traditions, even when direct quotations of folk melodies are absent.

Rhythmic and Melodic Structure

The analysis focused on recognising rhythmic patterns characteristic of Scottish folk traditions, such as the distinctive "Scottish snap," which consists of a short, accented note followed by a longer one. This rhythm

contributes to the energetic and dynamic quality of Scottish dance music. Strathspey accents, known for their strong, syncopated stress patterns, and jig rhythms, characterised by lively, compound meter patterns, were also frequently observed.

In terms of melody, the study examined phrasing for contour patterns reflective of oral tradition transmission, including the use of repetitive motifs, stepwise motion, and ornamental figures. These features help maintain the folk character of the music, even when not directly quoting traditional tunes.

Orchestration and Form

The study examined instrumentation choices that reflected folk performance practices, particularly the emulation of fiddle techniques in string writing, such as ornamentation, double stops, and drone-like open strings.

In terms of form, it observed structures resembling folk dance forms like reels and jigs, characterised by repetitive rhythmic figures and symmetrical phrasing. These elements contributed to creating a subtle yet distinct folk character within the classical compositions. By applying these criteria, this research constructed a new framework for understanding implicit folk influence in classical composition.

Category 3 and Selected Composers

This study identified several composers and works as candidates for Category 3, focusing on compositions that embody Scottish folk characteristics without directly quoting traditional melodies. Examples include Hamish MacCunn's The Land of the Mountain and the Flood, which evokes a strong Scottish atmosphere through its use of modal harmonies and rhythmic patterns reminiscent of folk traditions. James MacMillan's Tryst incorporates rhythmic and textural elements inspired by Scottish folk music, particularly through its dynamic phrasing and ornamentation. James Oswald's Airs for the Seasons subtly integrates modal structures and phrasing that reflect folk practices, while Erik Chisholm's Sonatine Ecossaise demonstrates folk-inspired rhythms and melodic contours without direct quotation.

Selected works by David Johnson, Francis George Scott, and John McEwen also displayed characteristics aligned with Category 3. These compositions revealed folk influence through modal language, rhythmic motifs, and instrumentation choices that echoed traditional Scottish sounds.

A detailed analysis of these works confirmed that they embody Bartók's third category, demonstrating how Scottish folk idioms can subtly shape classical compositions in terms of form, texture, and style—without explicit references to traditional melodies. This highlights the depth of subconscious folk influence present in Scottish classical music.

Findings

Research Significance & Goals

This research offers a new theoretical perspective on the adaptation of Scottish music within classical composition. It challenges the conventional assumption that folk influence relies on direct melodic quotation, instead emphasizing how cultural idioms can subtly shape compositional style. It explores how Scottish musical characteristics—such as modal structures, rhythmic patterns, and textural elements—manifest within classical works without direct reference to folk melodies. It also examines the compositional techniques that facilitate the internalization and reinterpretation of folk elements, revealing how these influences become embedded within the musical language of classical composers. By applying and refining Bartók's model, this research expands the classification of folk-influenced classical works, particularly regarding compositions that reflect folk characteristics through subconscious or indirect means.

Ultimately, this study broadens the understanding of folk music's role in classical composition, offering new insights into how cross-genre interaction shapes musical identity and cultural expression.

Conclusion

By applying Bartók's framework in an innovative way, this study redefines the boundaries between folk and classical music within the Scottish context. Category 1 consists of direct arrangements of folk songs by classical composers, preserving the original melodies with minimal modification. Category 2 includes compositions that feature direct quotations or identifiable patterns from folk songs, incorporating them into classical forms while maintaining a recognizable folk character.

Category 3, however, represents a previously under-explored dimension of folk-classical synthesis. It focuses on compositions where folk influence is present through subtle, implicit elements—such as modal language, rhythmic structures, and textural choices—without the use of direct quotations. This category highlights how folk traditions can shape the stylistic and aesthetic aspects of classical music in less overt but equally significant ways.

This research establishes a foundational model for future studies on how folk traditions are assimilated into classical compositions beyond direct quotation. By demonstrating how folk music can influence classical language on a subconscious level, it bridges ethnomusicology and music analysis. Ultimately, this study contributes to a broader understanding of Scottish musical identity and encourages a more nuanced approach to examining cross-genre musical interactions.

Harmony in Brouwer's Late Period: Use of Extended Tonality in the First Movement of Del Pensador

Tamer Celik[a], Recep Gül[a]

[a]Istanbul Technical University/Graduate School, Conservatory, Music Theory and Composition, Turkey
celikt17@itu.edu.tr

Keywords: Leo Brouwer, Extended Tonality, Neo-Riemann Theory, Music Theory, Guitar Music.

Aim

Leo Brouwer is arguably one of the most influential guitar composers of the 20th century. His musical style is very diverse and encompasses different compositional aesthetics. His musical oeuvre is generally categorized into three distinct periods. Nevertheless, in his interview with Paul Reed Century (Century, 1985), Brouwer himself adds a fourth one, which indicates the period after 1984. Even though there are numerous studies regarding his first three periods, analysis for the fourth is scarce. This study aims to show the ways in which Brouwer utilizes techniques of extended tonality, thus gaining a better understanding of his last musical period. Extended tonality, developing from classical major-minor tonality, is a system with a set of rules that include relaxed functional constraints, the freedom to combine chords in sentences, and the ambiguity of the key (Rohrmeier & C. Moss, 2021). Combining modal scales with tonal ones and the use of non-functional progressions, this tonal palette draws the unique world Brouwer's music manifests itself.

Materials and Methods

Previous research on the harmonic syntax of Brouwer focused on his earlier three periods. A pedagogical perspective has been employed in order to analyze Brouwer's tonal (Pastilla, Penaranda, 2009), whereas set-theoretical approaches have been utilized for his non-tonal/avant-garde works (Century, 1991). A study on La Espiral Eterna (1971), a piece from Brouwer's avant-garde period, has revealed the existence of three note clusters predominantly used in the piece (Century, 1985). El Decameron Negro (1981) has been analyzed by Demir (2023) focusing on it rhythmic and formal structure. Brouwer's sarabandes have been studied in the thesis of Fülöp (2021), in which tonality and harmonic chord progressions were examined. An analysis of Canticum, a work written in 1968, from his second period revealed that the three-note cluster approach has been freemployed (Suzuki, 1981). La Espiral Eterna has been analyzed by Gülfırat in the thesis "Symmetrical and Cyclical Relationships in La Espiral Eterna." In this study, Gülfırat (2023) revealed that symmetric x, y, and z cells of Bela Bartok were utilized (Treitler, 1959). Although a set-theoretical approach could be the most of post-tonal works of Brouwer, observed that it poses several limitations in describing Recuperacion de La Memoria, such as analyzing chord progressions, cadential points, and resolutions. For example, a set-theoretical method can examine certain intersections of this piece, but may not precisely, whereas extended tonality reveals the hidden tonal structure of this piece. Moreover, Schenkerian approach determines whether a piece is constructed with tonal or not. Our analysis contributes to the study of twentieth-century music, not only in the use of functional tonality or set theory for atonality but also by employing the concept of extended tonality for the composition of neo-tonal music.

To our knowledge, no previous studies investigated Brouwer's fourth-period works. This study aims to assess the part of Del Pensador's first movement, utilizing extended tonality as a central concept, investigating Brouwer's style in his late period. Extended tonality can reveal hierarchical relationships in pieces that do not readily seem tonal in the foreground level. Nevertheless, it has the power to uncover hidden tonal relations as well as the use of neo-tonal constructions. Rohrmeier et al. (2021) proposed a formal model for extended tonality that stemmed from Neo-Riemannian and Tonfeld theories. Neo-Riemann theory analyses triadic chord progressions via parsimonious voice-leading transformation, utilizing a geometric map called Tonnetz. Tonfeld theory complements Neo-Riemannian theory's triadic approach and extends it to hexatonic, octatonic, and fifth-related collections. It is not based on voice leading; instead, individual tones are regarded as elements of a particular tone (pitch) field (Polth, 2018). We claim that the extended tonality concepts can reveal the usage of hidden tonality in the first movement of the Sonata del Pensador.

Findings

Our analysis showed that tonal and modal collections organize the first movement of Del Pensador. The interplay between multiple closely-related scales has been extensively used. It can further be observer that the organizations via collections and their related chords mostly entail diatonic and modal ones throughout the piece.

As a general overview, the first movement of Del Pensador, in particular, has been evaluated by indicating the specific characteristics of all formal sections. The form of the piece is as follows: A- B- C- A'- D- B'-E- A- B-Coda, the measures of A: 1-8, B: 9-25, C: 26-42, A': 43-50, D: 50-58, B': 59-71, E: 72-95, A: 96-103, B: 104-120, and Coda: 121-123. We observed that this segmentation delineates the differentiation of tonal and modal collections clearly. For instance, in measures 1-2 and 5-6 (A section), as seen in Figure 1, a stack of fifths is used, whereas in measures 9-16 (B section), as seen in Figure 2, D-9 chord sonority and octatonic 2-3 A collection are used.

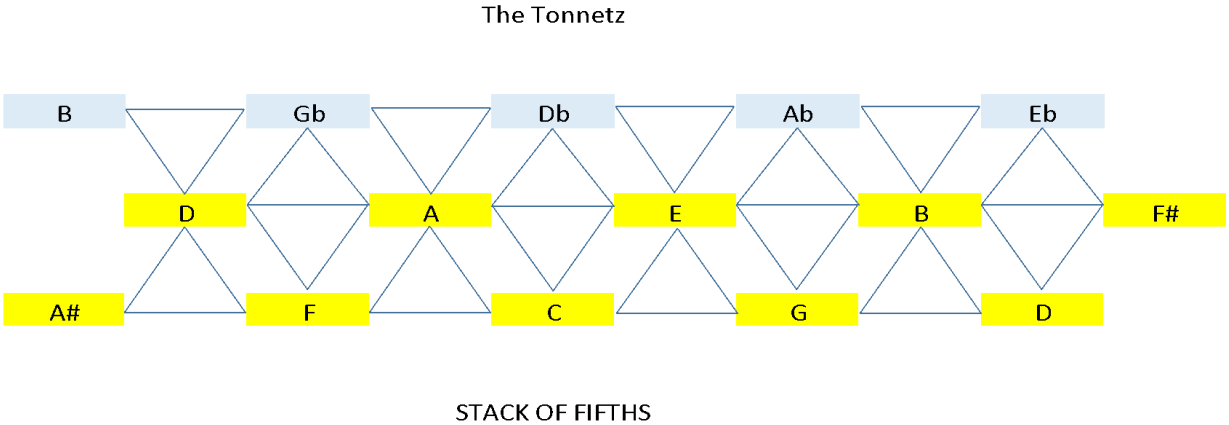

Figure 1: Notes shaded in yellow represent the chord sonorities in measures 1-2 and 5-6 within the axis of D.

As shown in Figure 2, Brouwer expands the musical narrative by employing both diatonic and octatonic collections. D-9 sonority, in measures 9-16 (B section), establishes a theme and subsequently extends the tonality through the octatonic 2-3 A collection.[13] While D-9 sonority comprises a fifth-related collection, represented as a rightward fifth-step progression on the Tonnetz[14], the octatonic collection, consisting of D, Eb, F, F#, G#, A, B, and C, appears diagonally upward to the left on the Tonnetz, as demonstrated in Figure 3. D functions as the tonic.

[13] The naming convention of the octatonic is the same as in Francoli (2008).

[14] Tonnetz is a conceptual lattice diagram representing tonal space, first described by Leonard Euler in 1739.

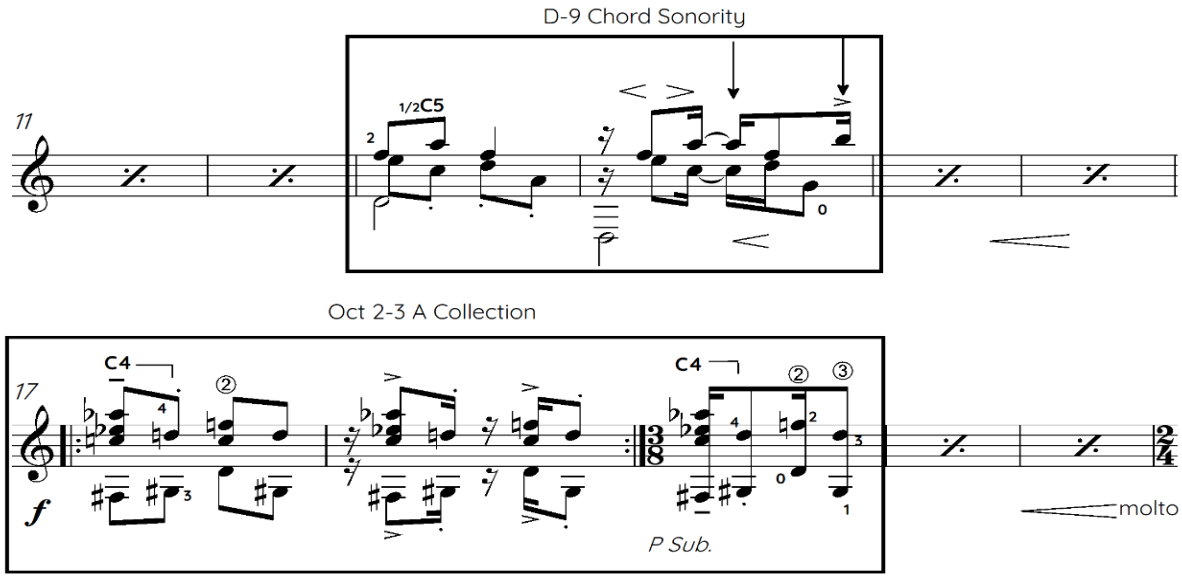

Figure 2: Two collections are merged to form the B section.

The Tonnetz

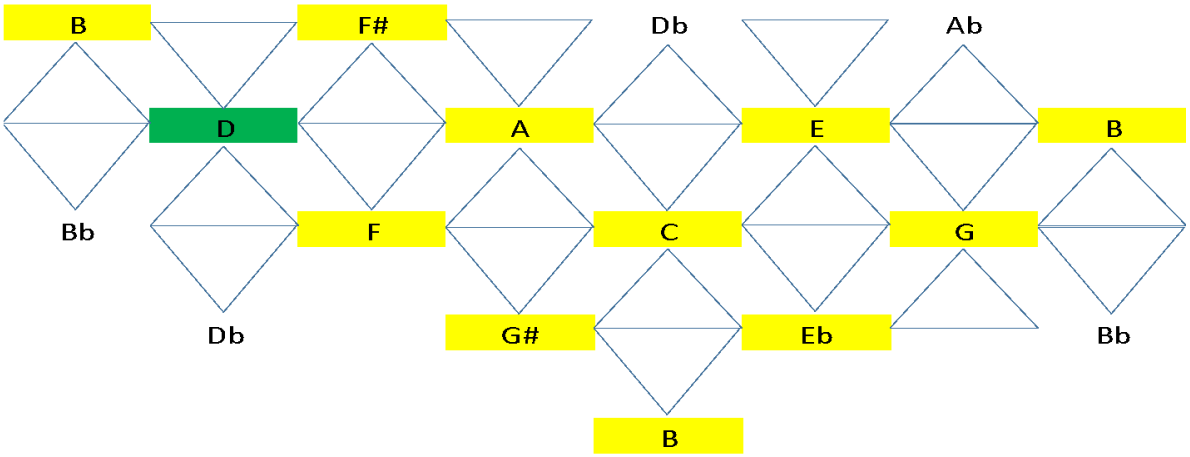

Figure 3: Fifth-related and Octatonic collections' Map.

In the E section, Brouwer employs E Lydian scale to establish a theme, which is enriched with B harmonic major, B major, E major, E major Phrygian (Figure 4a), and ultimately E acoustic collections (Figure 4b). These collections serve to guide the passage back to the beginning, as illustrated in Figure 4a-b.

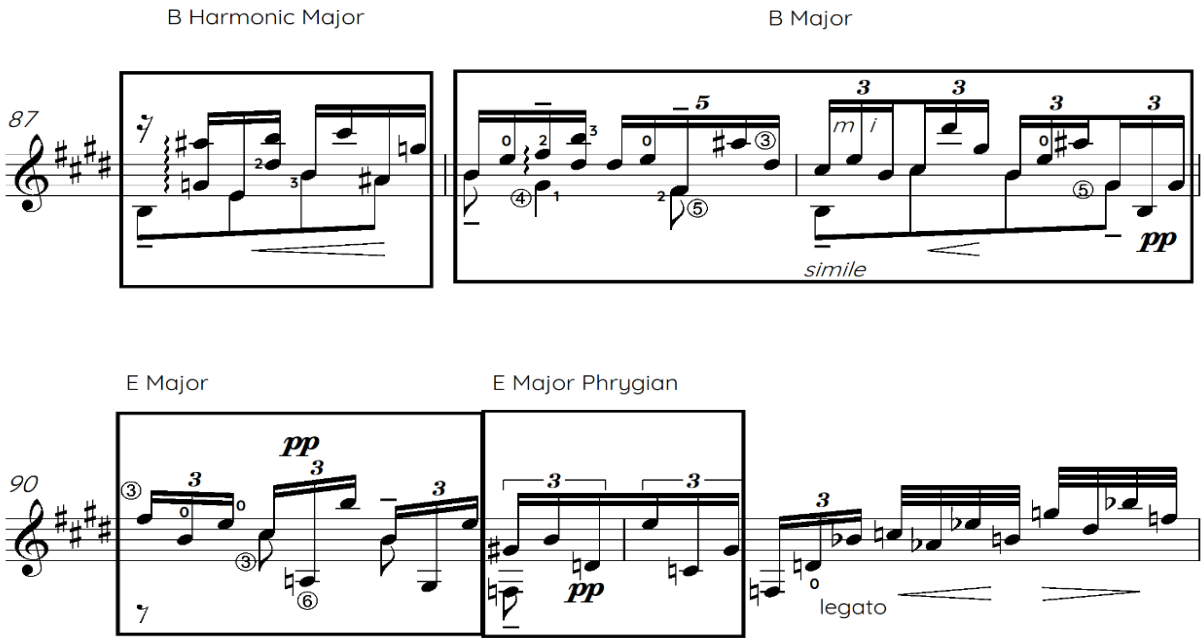

Figure 4a: Diatonic collections.

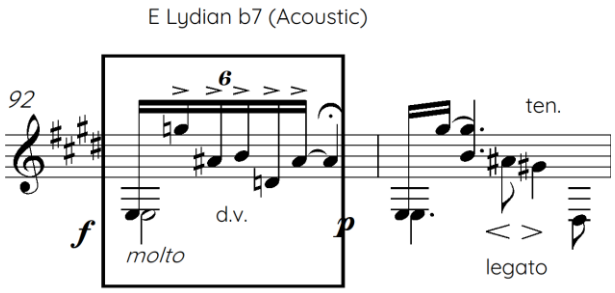

Figure 4b: Diatonic collection, E Acoustic Scale.

We also explored this passage (E) within the framework of Schenkerian approach, in order to explore hidden layers of tonality, as illustrated in Figure 5. At first glance, B leaps into its octave in measure 77, with A# functioning as a neighbor note. The melodic line begins on B in measure 78 and descends into G. Although A# is absent, an imaginary continuum can be presumed. Bass line prolongs the overall harmonic structure using only two degrees: II and iii. In measures 78-79, the passage exhibits increased motion, including arpeggiation, fifth leaps, and neighbor tones.

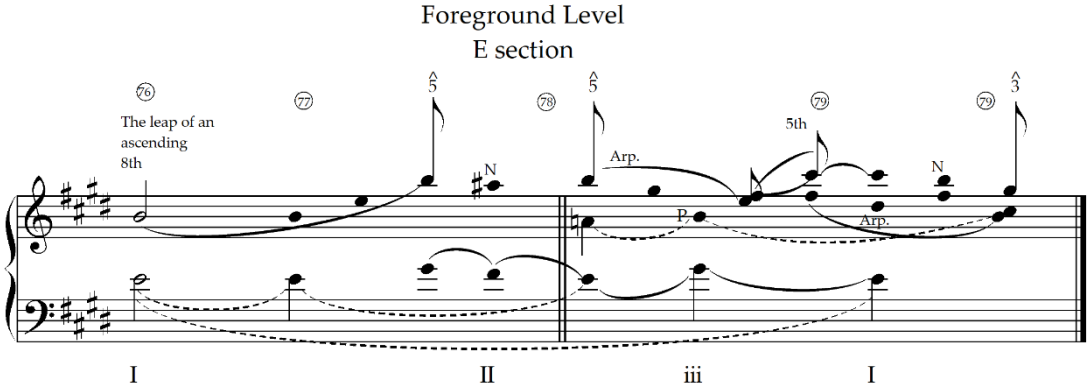

Figure 5: Schenkerian approach to E section, harmonic progression is I-II-iii-I while the melodic line degree is 5ˆ-4ˆ-3ˆ.

An incomplete neighbor motion from A# to B emerges in the upper octave before returning, in measures 86-88, creating a sense of superposition. A# serves as a leading tone in the E Lydian Mode. The composer consistently employs this tone, incorporating fifth and fourth leaps to frame the section, as shown in Figure 6.

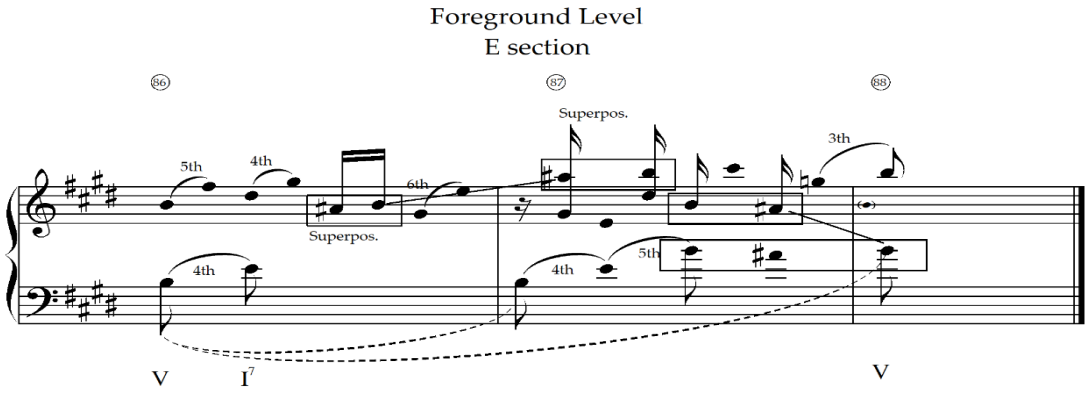

Figure 6: Superposition of the A#-B motive represented at Foreground Level.

In Figure 7, the entire E section is analyzed at the middleground level. G# prolongs the melodic line towards B in measure 88, and subsequently initiates the linear progression, sustaining the prolongation until the cadence point. Harmonically, E supports the entire passage through an extended I-II-V-I cadential progression. Notably, E suggests underlying functional tonality, which remains concealed throughout the whole segment.

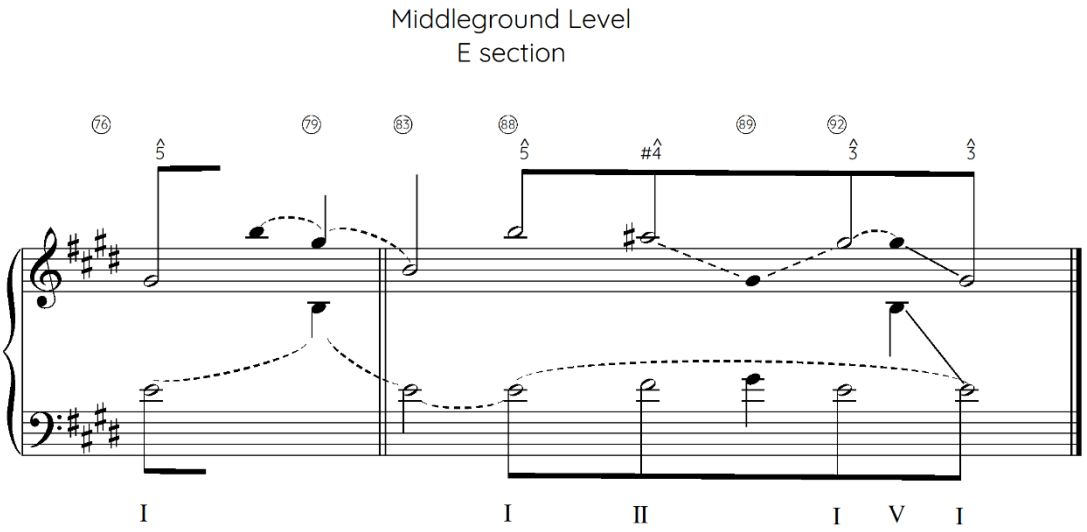

Figure 7: The E harmonic progression of the entire E segment follows I-II-I-V-I while the melodic line progresses through the degree 5ˆ-#4ˆ-3ˆ.

Upon examining the pitch distribution of the entire E section, it is evident that the melodic line prominently features the scale degree 5ˆ-#4ˆ-3ˆ (E-G#-B-A#), as illustrated in Figure 8. The embedded use of E Lydian scale in combination with E major functions as the key generator of the concept of extended tonality in this section. The same progression is repeated at the level of middle-ground, as seen in Figure 7. All these examples demonstrate that in addition to octatonic scale, Brouwer employed an intricated series of diatonic collections in order to extend functional tonality.

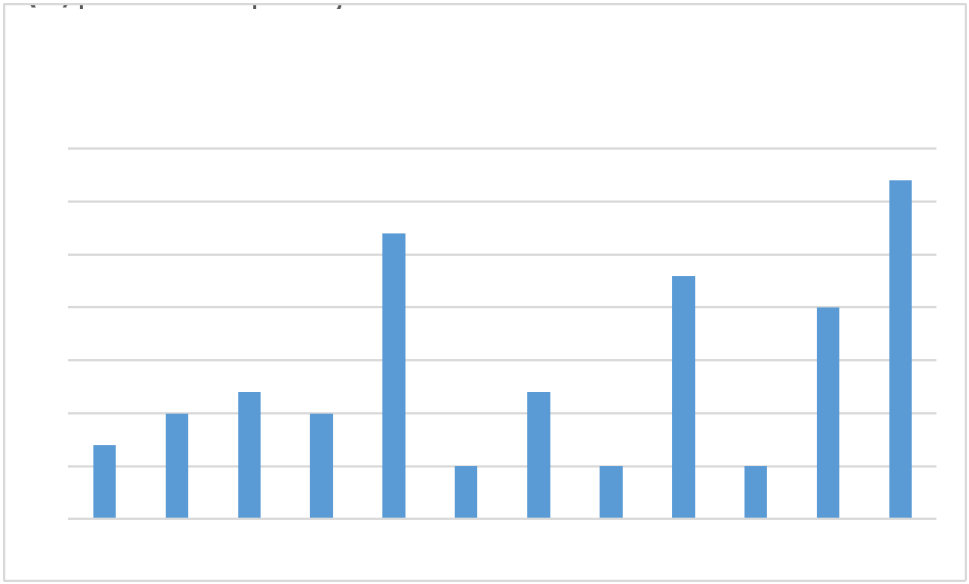

Figure 8: The pitch distribution of the E section highlights the prominence of E, G#, B, and A#.

Conclusion

In summary, this study aimed to investigate Brouwer's final period of guitar music. The theoretical framework of the Recuperacion de la Memoria has been to understand the ways in which pitch collections and their interrelationships were organized. We discovered that the entire section consisted of chord sonorities, octatonic 2-3 A, and fifth-related collections in the key of D, accompanied by connecting passages. Moreover, E section of the movement, which has been evaluated more throughly at both the foreground and middleground via Schenkerian approach, revealed that the roles of collections are also embedded behind the complexity of the foreground. The Schenkerian analysis indicated that the use of functional tonality was concealed throughout the entire section. Overall, our work highlighted the harmonic and melodic implications of the scales in question, as well as their structural similarities and interconnections.

The study showed how the concepts of the extended tonality could offer insights into the structure of Brouwer's fourth period. However, a more comprehensive analysis is necessary in order to understand the inner workings of these schemes. While Schenkerian analysis remains a valuable tool for exploring contemporary music, the coexistence of tonality, atonality, and increasing complexity in modern compositions presents analytical challenges. A singular may not be sufficient to fully interpret such music; therefore, a synthesis of multiple frameworks is essential.

By the twentieth century, musical movements such as tonal, atonal, and twelve-tone music emerged in the classical guitar repertoire, with Leo Brouwer's works exemplifying these trends. This study aimed to explore the application of the extended tonality framework, providing a foundation for future research in this area. Beyond its academic contributions, this article may also serve as a valuable resource for composers in structuring their works.

Keywords: Ivan Wyschnegradsky, Microtonality, Quarter-Tone System, Set Theory.

Aim

The aim of this thesis proposal is to adapt set theory to the 24-TET quarter-tone system and to analyze the vertical structures selected from Ivan Wyschnegradsky's 24 Preludes for Two Pianos in Quarter-Tone System, Op. 22 in the context of set theory.

Material and Method

In this study, set theory, its use in music analysis and how set theory is adapted to the quarter-tone system are mentioned. The vertical structures selected from Ivan Wyschnegradsky's 24 Preludes for Two Pianos in Quarter Tone System, Op. 22 were analyzed in the context of set theory adapted to the quarter tone system.

Findings

In this case, it can be said that 22,88% of the prime forms of the analyzed vertical structures according to the quarter-tone system set theory are the same as the others, 38,98% are included by the others and 38,14% have some pitches in common with the others. Based on this, it can be stated that Ivan Wyschnegradsky uses vertical structures that are structurally and timbally like each other. Although the composer produced works in quarter-tones or other microtonal aesthetics, which were considered far ahead of his time, he followed a similar aesthetic approach to the composers of the period before him. Apart from his understanding of microtonal timbre, Ivan Wyschnegradsky's works are similar to those of his predecessors or composers of his period in many respects.

Figure 2. Similarity chart of the prime forms of the selected vertical structures from 24 Preludes in Quarter Tone System for Two Pianos by Ivan Wyschnegradsky according to the quarter-tone system set theory (Dağtekin, 2024).

The comparison of interval class vectors according to the quarter-tone system set theory in the vertical structures analyzed in this study is important for understanding which intervals Ivan Wyschnegradsky used and how often. The evaluation of these findings is also important for understanding the frequency of the composer's use of 12-TET and 24-TET intervals and interval classes in the piece.

8	113	Interval class 9	Supermajor third Minor fourth Major fifth Subminor sixth
9	101	Interval class 4	Major second Minor seventh
10	98	Interval class 10	Perfect fourth Perfect fifth
11	91	Interval class 12	Augmented fourth Diminished fifth
12	77	Interval class 3	Neutral second Neutral seventh

Figure 5. Ranking of the total usage frequency of the interval classes in the selected vertical structures from 24 Preludes in Quarter Tone System for Two Pianos by Ivan Wyschnegradsky and the intervals included by the interval classes (Dağtekin, 2024).

Looking at the total values of the intervals in the vertical structures analyzed in the piece, it can be said that the intervals in the 12-TET chromatic system are used 780 times, while the intervals in the 24-TET quarter-tone system are used 868 times. Accordingly, the intervals in the 24-TET quarter-tone system are used 88 times more than the intervals in the 12-TET chromatic system in the vertical structures analyzed in the work. Accordingly, it can be stated that Ivan Wyschnegradsky uses 24-TET quarter-tone system intervals more frequently in the vertical structures in the work, although he also includes the intervals in the 12-TET system.

In this context, it can be said that Ivan Wyschnegradsky wanted to create a piece that contains vertical structures built with the interval classes of the quarter-tone system rather than the interval classes of the tampered system in most of the structures he used. Comparing the interval constructions according to the quarter-tone system set theory in the vertical structures analyzed in this study is important for understanding Ivan Wyschnegradsky's aesthetic

perception. For this reason, the following tables show the interval constructions of the selected vertical structures from the work.

It can be said that 6 of the vertical structures analyzed are vertical structures constructed in quarter-tones with series pitches, 33 of them are constructed in quarter-tones with third intervals, 18 of them are constructed in quarter-tones with fourth intervals and 20 of them are vertical structures constructed with mixed intervals. According to the table, it can be said that 2 of the vertical structures analyzed are the vertical structure defined by Ivan Wyschnegradsky, 28 are tone clusters wider than one octave and 11 are tone clusters. Accordingly, the vertical structures in quarter-tones with third intervals were used the most among the analyzed structures, and the vertical structures defined by Ivan Wyschnegradsky were used the least.

From this point of view, although it is understood that Ivan Wyschnegradsky composed the work analyzed in this study with mathematical methods and constructed the structures in its content, it can be said that the composer equally utilized symmetry and asymmetry to position, name and make sense of the structures he created in this system.

By summing up the percentage expressions of the similarity of the prime forms of the vertical structures according to the quarter-tone system set theory and dividing by the number of vertical structures analyzed, it was found that the average similarity rate of the prime forms of the selected vertical structures for this thesis according to the quarter-tone system set theory was 91.87%.

Prelude Number	First Vertical Structure	Second Vertical Structure	Third Vertical Structure	Fourth Vertical Structure	Fifth Vertical Structure

8	%95,6	16	%92,6	24	%80,2

Figure 7. Percentage expressions of the averages of the similarity ratios of the prime forms of the selected vertical structures from Ivan Wyschnegradsky's 24 Preludes in Quarter Tone System for Two Pianos according to the quarter-tone system set theory according to the preludes (Dağtekin, 2024).

As a result of the analysis of the vertical structures in the work according to the quarter-tone system set theory, it can be said that they are generally similar. In this context, it can be stated that although Ivan Wyschnegradsky proceeds from his own aesthetic perception and maintains his point of view throughout the work, he remains under the influence of the Eurocentric music he has been involved in since his student days, and remains faithful to his previous compositional understanding, except for the structures he created with the quarter-tones timbre.

Conclusion

In Ivan Wyschnegradsky's works, most of which are microtonal, it is seen that he is in search of a new timbre and system. Set theory, which is also a mathematical analysis method, was preferred to make sense of the structures and aesthetic approach used in 24 Preludes in Quarter Tone System for Two Pianos and other microtonal works, perhaps the most important of the works created by the composer using highly mathematical methods in this search. Seeking the scope of this study, the simplified forms of the vertical structures in the work written using the accidentals in quarter-tones were reached through set theory.

The importance of the quarter-tones, which is the main system used by the composer in many of his works, emerges here. It is thought that this system will provide the composer with a widening and expansion of the composer's pitch choice and creative palette from the point of view of the Eurocentric buffer system. This situation can also explain the logic of Ivan Wyschnegradsky's writing many of his works in quarter-tones, having a quarter tone piano like composers who lived in different periods and produced works in different genres such as L. van Beethoven, P. I. Tchaikovsky, L. Boulanger, B. Evans, and constructing his works by playing on this piano like other composers.

As perhaps the most important of the conclusions reached in this study, it can be stated that Ivan Wyschnegradsky's works, most of which are written using microtonal materials, constitute an understanding that can be considered as a continuation of the concept of "Emancipation of Dissonance", which was put forward by A. Schoenberg with his atonal approach, and which was likened to the liberation of society and humanity by composers such as C. Ives, D. Ellington and L. Harrison. It is thought that the analysis of the vertical structures in this work will also be instructive in terms of the timbral enrichment of works in genres that include these pitches or that have been written or will be written in other systems. In this context, it can be thought that the structures in the piece written in quarter-tones, which we are trying to analyze, can also be used in the context of liberating / deepening the consonance in works created through different systems. At the same time, this study is expected to inspire not only composers and theoreticians but also improvising musicians in terms of the application of mathematical microtonality and set theory systems and gaining new perspectives.

This study has been shaped by the findings and conclusions obtained in the light of the analysis made with the quarter-tone system set theory, which was created by adapting the set theory to the quarter-tones. It is thought that other microtonal works can be analyzed with a similar approach. It is expected that this study will be a guide for future studies in the context of making sense of the structures and systems used by Ivan Wyschnegradsky and other composers in their microtonal works and will be useful for people who will compose or improvise in microtonal systems.

Ivan Wyschnegradsky, who can be considered as one of the most important composers who made many contributions to microtonal systems and works, created his works with systems and tools that he created entirely on his own, without using folk music or the elements put forward by movements such as spectralism with different tools. The results of the analysis of 24 Preludes in Quarter Tone System for Two Pianos, which stands in a different place in terms of its use of the diatonic chromatic system, are thought to be important in terms of making sense of different musical perspectives, especially the concept of microtonality, both at that time and in the future. It is expected that this study will open new horizons for musicians, composers, theorists and improvisers who want to go beyond the first sixteen improvisers, who are after the meaning, systematization and analysis of different timbres that will be created by the pitches and their combination, and contribute to the search for original ideas and ways of many curious music people who contribute to music by producing new methods and concepts, such as Ivan Wyschnegradsky and other composers who produced microtonal works and systems in the twentieth century.

The concepts of set theory, octave division, diatonic chromaticism, diatonic chromaticism, microtonality and similar systems, which are useful tools offered to composers by mathematics, which is often used as an important tool in the creation of music, can be used to analyze the music of composers such as Ivan Wyschnegradsky, who produced works that simultaneously contain tradition and future understanding of different systems, While guiding the search for the paths of improvisers who shape time through structures and pitches, and contributing to the production of musical structures and works to be created by musical people like Ivan Wyschnegradsky who shape their own musical materials and boundaries, it is thought that will liberate us in terms of timbre, philosophy and aesthetics with the new horizons it opens in the process of maintaining the tradition and shaping the future, and will accompany our wanderings in different musical worlds where our curiosity will always be renewed.

Exploring Perde-Çeşni Transformations in Tanburi Cemil Bey's Nikriz Makam

Burak Kesgin[a]

[a] Istanbul Technical University/Graduate School, Department of Musicology and Music Theory, Music Theory and Composition Programme, Türkiye
kesgin15@itu.edu.tr

Keywords: Analysis, MakamNetz, Nikriz Makam, Perde-Çeşni Transformation, Tanburi Cemil Bey.

Aim

This study aims to analyze four instrumental works composed by Tanburi Cemil Bey, one of the prominent performers of the late Ottoman period, in the *Nikriz makam*, consisting of two *Longa* and two *Zeybek* forms. The objective is to classify the *Perde/Çeşni* transformation principles that Cemil Bey consciously or unconsciously employed while composing these works. Cemil Bey's mastery in performing *taksim*, the improvisatory form of Turkish Music, and his pioneering role in this field are widely recognized and acknowledged by many music researchers. In addition to being a highly influential performer, he composed a total of thirty-four works, including thirteen vocal and twenty-one instrumental compositions. This study will examine the structural elements underlying the variety of *makam* modulations that Cemil Bey introduced within the framework of *Nikriz Makam* while composing his works. Furthermore, the research will analyze the formal structures and *seyir* characteristics of these four pieces to determine the balance between the traditional structure of the *Makam* and Cemil Bey's unique contributions.

Material and Method

The materials examined in this study consist of four works composed by Cemil Bey in *Nikriz makam*: *Nikriz Longa*, *Nikriz Longa 2*, *Nikriz Zeybek*, and *Nikriz Zeybek 2*. The works have been classified and labeled uniquely for this study as "1" and "2" versions. *Nikriz Zeybek 1* is composed in *Aksak usûl* and consists of nineteen measures. *Nikriz Zeybek 2* is also in *Aksak usûl* and comprises eighteen measures. *Nikriz Longa 1* is composed in *Nim Sofyan usûl* with a total of twenty-four measures, structured as two *hane* and a *teslim*. Lastly, *Nikriz Longa 2* is also in *Nim Sofyan usûl* and contains thirty-four measures. While the scores of these works are available in the TRT notation archive, they have been re-notated via MuseScore software for this study due to the necessity of specific annotations. Additionally, certain discrepancies identified between the performance and the archived scores were corrected during this process. The formal structures, *makam seyir* characteristics, and *çeşni* modulations of each piece were analyzed according to the *Perde/Çeşni*transformation model. The transformation points and overlaps were meticulously marked on the scores, providing insights into their musical functions and contexts.

The analytical model is based on the *Perde/Çeşni* transformation model developed by Prof. Dr. Ozan Baysal (Baysal et al. 2024). The model investigates and explains the relationships between two *makam* or *çeşni* structures by focusing on pitch sets, intervallic structures, and pivot *perde*. This analysis model, which is based on Kleonides' concept of modulation, emphasizes the necessity of shared pivots or transformation chains to explain harmonic relationships in modal structures. Accordingly, Cemil Bey's works in *Nikriz makam* have been analyzed through three main transformation types defined within the model: Intraconnected (*Girift) Relationship Transference (Kaydırım),* and *Fixed-Axis Transformations*.

Fixed-Axis transformations occur between different *Perde/Çeşni* structures while maintaining the main or secondary pivot *perde* as constant and are indicated with the abbreviation "P-to-P", "S-to-S" or "S-to-P" in the notations. *transferenrd* typically result from shifting an existing *Perde/Çeşni* structure upwards by perfect fourth or fifth intervals. Finally, *Girift Relationships* are based on the overlap of at least three consecutive *perde* between two *Perde/Çeşni* sets, enabling more fluid and ambiguous modulations. All these transformations are explicitly marked on the scores throughout the analysis.

In our research, we have also used MakamNetz, a web application that aims to model *makam* and *çeşni* structures and their mutual relationships in Turkish Makam Music in the form of a network or map.MakamNetz provides not

just a list of *makam* and *çeşni* but also a map that visualizes the intuitive yet often unsystematically articulated structural relationships between them by considering the transition pathways and connections. However, our analyses revealed that not all connections within the network hold equal significance in practice. For instance, some pathways, although equidistant in the network, are employed at varying frequencies in performance practices. By addressing such structural imbalances, MakamNetz can enable a more accurate modeling of modulations and diversities between *makam*. The *Perde/Çeşni* transformation analyses in this study were conducted entirely through the MakamNetz application (Gül et al., 2024).

Findings

As a result of the analyses, it was found that Cemil Bey utilized *makam* modulations flexibly across all four works. In *Nikriz Longa 1*, besides following the classical *Nikriz makam seyri*, structures outside the conventional descriptions were also employed. Particularly in the development section, *Neva* and *Gerdaniye perde* functioned as secondary pivots, facilitating smoother modulations between *çeşni*.

In *Nikriz Zeybek 1*, the introduction almost fully adheres to the *Rast makam* structure. Some sources even label this piece as *Rast Zeybek*. The *girift* relationships between *Rast/Rast* and *Segâh/Segâh* impart a distinctive character to the piece's *makam* structure. In addition, frequent *S-to-P* transformations towards the final sections provided a strong return to *Nikriz makam*.

In *Nikriz Zeybek 2*, the *S-to-P* transformation principle was consistently applied from the beginning to the end, resulting in a sense of melodic uniformity. Cemil Bey emphasized the main melodic theme across the entire piece. The structure displays the superimposition of *Rast/Nikriz* and *Neva/Buselik çeşni*. Cemil Bey concentrated on two main melodic ideas, shaping the composition around them.

Similarly, *Nikriz Longa 2* primarily employed *S-to-P* transformations. Although this piece displays greater *çeşni* variety, its transformation logic resembles that of *Nikriz Zeybek 2*. At times, this composition also ventures beyond the traditional *makam* framework.

Conclusion

In conclusion, this study enhances the visibility of the transformation principles Cemil Bey employed while structuring his compositions in *Nikriz makam*, supported by visual analyses. Moreover, while identifying these transformations, the research highlights the composer's expertise. Cemil Bey, while adhering to the conventional characteristics of *Nikriz makam*, simultaneously integrates both the stylistic elements of his era and his distinctive musical persona. The study also confirms his skillful and functional use of other *Makam* structures such as *Rast*, *Segâh*, and *Müstear* within his compositions. Overall, this research offers an in-depth analysis both in terms of the under-explored *Nikriz makam* and the compositional features of Cemil Bey's period, once again revealing the *Makam* richness of his works.

The Issue of "Originality" in Arabesk Music: Analysis of Musical Borrowings, Similarities, and Production Practices from Arab music

Yiğit Sarıgül[a]

[a] Istanbul Technical University, Department of Musicology and Music Theory, Turkey
sariguly15@itu.edu.tr

Keywords: Arabesk Music, Originality, Musical Quotation, Arab Music, Copyright.

Aim

The primary aim of this study is to critically examine the issue of "originality" in the context of arabesque music that emerged in Turkey during the 1960s and 1970s, by analyzing the nature of its melodic relations with Arab music through musicological methods. The frequently voiced claim in public discourse that "arabesque music is a copy of Arab music" often relies on reductionist perspectives that lack concrete musicological evidence. This study seeks to identify specific examples that may be considered direct quotations or instances of plagiarism through technical musical analyses; however, it emphasizes that these examples do not represent the entirety of the genre. Arabesque music is not confined solely to Arab musical traditions; rather, it is a multi-layered form that interacts with various musical lineages, including Turkish folk music, Classical Turkish music, and Western music. In this regard, the study not only addresses musical similarities, but also explores the historical, cultural, and industrial contexts in which these melodic transfers took place.

Although Ottoman influence in Egypt weakened by the late 19th century, musical forms such as peşrev and semai and instruments like the tanbur and qanun had already spread across the Arab world. Scholars note that Arab music had been influenced by Turkish and Persian traditions via the Ottoman Empire since the 15th century (Touma, 2003), and despite Egypt's modernization, Ottoman traces persisted (Danielson, 1997; Racy, 1977). This continuity is evident in Umm Kulthum's vocal aesthetics, which emphasize lyrical expression, in contrast to Turkish songs where melodic structures dominate (Danielson, 1997, pp. 111, 161). Additionally, figures like Zekâi Dede, who taught and performed in Egypt, and artists such as Refik Fersan and Münir Nurettin Selçuk, who gave concerts there, reflect sustained musical exchange, making it historically inaccurate to view Arab and Turkish music traditions as disconnected (Rona, 1960, p. 243; Bardakçı, 1995, p. 7; Özcan, 1995, p. 413; Özalp, 2000, p. 224).

Therefore, the question of "originality" in arabesque music cannot be reduced to the mere technical identification of melodic similarities. During the 1960s and 1970s, the institutionalization of composition in Turkey was still in its infancy, and the systematic production of original works had not yet been established. Within this context, turning to melodic material from the Arab world became both an aesthetic and practical choice for local producers. In particular, melodies derived from Egyptian and Syrian sources were often regarded as ordinary components of musical circulation and production during this period (Stokes, 2020, p. 139).

As such, the early examples of arabesque music were shaped less by a pursuit of originality and more by the reworking of existing melodic structures through local lyrics and arrangements. This mode of production reflects not only musical similarities but also the aesthetic norms, industrial conditions, and institutional shortcomings of that era.

Material and Method

This study examines three significant works from the early period of arabesque music: "Gündüzüm Seninle" (1965) by Suat Sayın, "Ağlatan Yıllar" (1972) by Orhan Akdeniz, and "Kullarına Kul Yaratmış" (1979) by Mustafa Sayan. Each of these pieces is analyzed comparatively alongside corresponding works from the Arab repertoire: Mohamed Abdel Wahab's "Bafakkar Fih" (1957), Riyad Al-Sunbati's "Leily Nehary La Ya Habeeby" (1963), and Abdel Wahab's "Fi Youm We Leilah" (1978), respectively.

The methodology of the study is based on transcription-based comparative analysis of melodic structures. Transcriptions of pieces from both traditions were prepared using the same tonal center, and metric structures and tempi were considered in carrying out measure-by-measure comparisons. The analyses focus exclusively on the

introductory sections and metrical instrumental passages of the songs; repeated segments and vocal performances were deliberately excluded.

Additionally, disc and MESAM archives were consulted to obtain recording information, release dates, and production data. Where available, interviews with composers and relevant secondary sources were also incorporated into the study. The goal of this methodological approach is to reveal how melodic borrowings were structurally integrated and to assess the aesthetic considerations that shaped these practices within the production context of the period.

Findings

Released in 1965 under the Grafson label and performed by Ziya Taşkent, Gündüzüm Seninle stands out as an early example of arabesque music composed by Suat Sayın. The melodic similarities it shares with Mohamed Abdel Wahab's 1957 composition Bafakkar Felli Nassini cannot be sufficiently explained as mere "inspiration." In particular, the core melody of the aranağme (instrumental interlude) section is directly adopted as the main theme in Gündüzüm Seninle, with its structural integrity largely preserved. The chorus is also built on a repetition of this theme, indicating that the entire piece is constructed around a single melodic nucleus. This suggests that rather than being a reinterpreted form, the work is based on a direct melodic transfer.

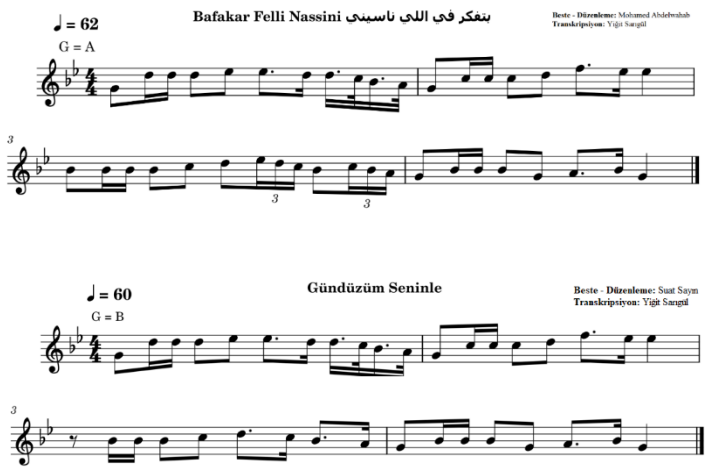

Figure 1. Transcriptions of the songs Gündüzüm Seninle and Bafakar Felli Nassini.

Both compositions are written in 2/4 meter and have very similar tempo markings (approximately 60–62 bpm). This rhythmic parallelism reinforces the notion that the general formal structure of the Turkish piece is largely derived from the Arab original. Aside from a triplet figure at the end of the third measure and in the fourth, no significant rhythmic differences are observed. This minor variation may be considered a matter of performance interpretation, but it does not constitute a meaningful distinction in terms of originality.
